Search for new topological quantum materials is the demand to achieve substantial growth topological phase of matter. In this search process, theoretical prediction is crucial besides the obvious experimental verification. The divination of topological properties in already well-known narrow gap semiconductors is flourishing in quantum material science. We revisited the semiconductor compound in the chalcopyrite series, some of which were potential topological materials. Using this density functional theory-based first-principles calculations, we report a strong topologically nontrivial phase in chalcopyrite ZnGeSb 2, which can act as a model system of strained HgTe. The estimates reveal the non-zero topological invariant (Z 2), Dirac cone crossing in the surface spectral functions with spin-momentum locked spin texture. We also report the tunable topological properties from nontrivial to trivial phases under moderate hydrostatic pressure within *7 GPa. A minor modification of a lattice parameter is enough to achieve this topological phase transition easily accomplished in an experimental lab. We have incorporated the discontinuity in the tetragonal distortion of noncentrosymmetric ZnGeSb 2 to drive the topological quantum phase transition.

MM 14.7   Tue 12:00   SCH A 251

electronic structure of a non-symmorphic kondo lattice system CeAgSb2 — •Sawani Datta[1], Khadiza Ali[2], Rahul Verma[1], Saroj p. Dash[2], Bahadur Singh[1], Arumugam Thamizhavel[1], and Kalobaran Maiti[1] — [1]Tata institute of fundamental research, Mumbai, India — [2]Chalmers university of technology, Goteborg, Sweden

Topological Dirac semimetal with non-symmorphic symmetry (NSS) is one of the most recent discoveries in the field of novel topological quantum materials [1]. The uniqueness of this system is the presence of robust (including spin-orbit coupling) Dirac line nodes with NSS protection. CeAgSb2, a Kondo system, exhibits a large anisotropic resistivity and a complex magnetic ground state at a lower temperature [2]. Employing angle-resolved photoemission spectroscopy (ARPES), we find that CeAgSb2 possesses several non-trivial crossings near the Fermi level protected by the NSS. The ARPES data collected at different photon energies suggest a quasi-2-D behavior which is consistent with the transport results. In addition, we observe energy bands of the surface states in the near-Fermi-level region along with the non-trivial bulk bands that make the electronic structure complex. Our study shows the CeAgSb2 family of materials as a new platform to study the robust non-symmorphic symmetry-protected Dirac semi-metallic systems with high spin-orbit coupling.

An amplitude expansion of magnetic phase field crystal: A continuum model for magnetically driven dislocation networks — •Rainer Backofen, Marco Salvalaglio, and Axel Voigt — Institute of Scientific Computing, TU Dresden

The amplitude expansion of the phase-field-crystal (APFC) model enables a convenient coarse-grained description of crystalline structures. It allows the description of length scales that are orders of magnitude larger than the lattice spacing while retaining microscopic features, such as dislocations. Adaptive finite elements are used to treat the different involved length scales efficiently [1].

Here, an APFC model is presented that captures the basic physics of magnetostructural interactions: magnetostriction and magnetic anisotropy. The free energy of APFC is combined with a continuum field representing local magnetization [2]. The proposed coupling does not increase the partial differential equation to solve compared with the basic APFC model. Still, it is flexible enough to adapt the magnetic anisotropy of the model to basic ferromagnetic materials such as Fe and Ni. Exploiting this model, the influence of external magnetic fields on the evolution of defects and grain boundaries is discussed.

Multi-orbital models within the ghost Gutzwiller approximation — •Carlos Mejuto-Zaera and Michele Fabrizio — SISSA, Trieste, Italy

In the pursuit towards targeted material design leveraging strong electronic correlation, computationally inexpensive yet qualitatively reliable methods play a fundamental role. These approaches should allow for a rapid mapping of phase space, unveiling a first impression of possible phases of matter, which can then be explored in selected regions of parameter space with more accurate yet involved techniques. Recently, the ghost Gutzwiller Approximation (gGA) has been shown to be an interesting candidate for this kind of phenomenological search. Based on a self-consistency condition for the simple one-body reduced density matrix of a discretized impurity model, this method can capture spectral features of both coherent and incoherent nature in the one-body Green's function. In this work we extend its applicability to the multi-orbital regime employing a truncated solver based on selected configuration interaction. This allows for increasing the number of correlated orbitals while keeping the size ratio of bath to impurity constant. We explore the reliability of the gGA for describing the phase diagram of multi-band models, comparing to more sophisticated embedding methods. We shall assess the potential of gGA for modelling of complex materials, possibly in combination with ab-initio methods.

Understanding the success of mGGAs for band gaps. Is it the orbital dependence? — •Péter Kovács, Peter Blaha, and Georg K. H. Madsen — Institute of Materials Chemistry, Technical University of Vienna

Density functional theory has shown remarkable success in predicting various properties of solids, such as lattice parameters and cohesive energies, yet with most functionals it is known to heavily underestimate band gaps. mGGA functionals tend to result in better band gap predictions than LDA or GGAs, but the best results are still achieved at the cost of accuracy for the other properties. Recently using a systematic search in the space of mGGA functionals we were able to find functionals, where this tradeoff is small.[Péter Kovács et al., J. Chem. Phys. 157, 094110 (2022)]

While the failure of LDA and GGA functionals for gaps are often attributed to their lack of the derivative discontinuity, the success of mGGAs can not be explained solely based on their ability to exhibit discontinuous behaviour. On a database of 440 solids, we analyze how two specialized functionals, TASK and our own mGGA23, are able to better predict gaps. We aim to understand what parts of the functional shape is responsible for their success and how these affect their prediction of structural properties, such as lattice parameter. These findings can be used in functional design and also to understand failure cases of already existing functionals.

MM 15: Topical Session: Fundamentals of Fracture – Atomistic Studies of Fracture

Topical Talk   MM 15.1   Tue 10:15   SCH A 216

Multiscale Quantum-Atomistic and Atomistic-Continuum Modelling of Crack Propagation — •James Kermode — Warwick Centre for Predictive Modelling, School of Engineering, University of Warwick, Coventry, United Kingdom

I will review recent progress on the development and application of advanced algorithms to simulate chemomechanical systems where local chemistry and long-range stress are tightly coupled, e.g. at the tip of a propagating crack or the core of a dislocation. I will discuss two general approaches (i): hybrid quantum/classical approaches where bond-breaking is treated at the DFT level embedded within a large-scale classical atomistic model to capture elastic relaxation, including recent applications to tungsten [1] and diamond [2]; (ii) atomistic-to-continuum modelling for crack propagation, either through extracting effective continuum models from large-scale atomistic simulations of fracture [3], or by flexibly embedding an atomistic domain within a continuum model, using a new algorithm to compute bifurcation diagrams for fracture systems [4].

Modelling Fracture in α-Iron via a Numerical-Continuation Scheme — •Lakshmi Shenoy[1], Albert Bartok-Partay[2], and James Kermode[1] — [1]Warwick Centre for Predictive Modelling, School of Engineering, University of Warwick, Coventry CV4 7AL, United Kingdom — [2]Department of Physics, University of Warwick, Coventry CV4 7AL, United Kingdom

I will present results for the stability range of fracture in α-iron mapped using the numerical-continuation flexible boundary scheme (NCFlex) proposed by Buze et. al. [1]. The predictions by two new machine learning interatomic potentials for α-iron [2] - Gaussian approximation potential and atomic cluster expansion - will be compared with those by the classical embedded atom model [3]. From the bifurcation plots produced by NCFlex, the 0K energy barriers to brittle fracture propagation along different crystallographic planes in α-iron will be computed. Using these, a model for the temperature dependence of the brittle-to-ductile transition temperature of α-iron will be proposed, and validated against experimental results. Methods for extending this scheme to finite temperature energy barriers and interaction of the crack tip with point defects will also be discussed.

Revealing Atomistic Fracture in BCC Iron by Active Learning — Lei Zhang[1], Gabor Csanyi[2], Erik van der Giessen[1], and •Francesco Maresca[1] — [1]University of Groningen, Netherlands — [2]University of Cambridge, UK

Fracture is multi-scale process that originates from atomic-scale bond rupture and dislocation activity. A clear understanding of these processes is often lacking, because classical interatomic potentials (IAPs) for Molecular Dynamics simulations yield contradicting results that agree only partially with experiments. This is also due to the limited flexibility of their functional form, which is inadequate

to describe the complex potential energy surface associated with fracture processes. Emerging machine learning (ML) IAPs allow near-quantum accuracy, based on density functional theory (DFT), but are orders of magnitude faster than DFT. In this work, we develop an active learning algorithm that enables the prediction of atomistic fracture mechanisms via the Gaussian Approximation Potential (GAP) approach. An existing DFT database for ferromagnetic bcc iron is first enriched with configurations that are relevant for the fracture process. Next, the active learning approach is applied to four crack systems, in which the maximum predicted per-atom error is reduced to 10 meV. The predicted critical stress intensity factors are compared with theory estimates, and the learning efficiency of the approach is analysed. Our work provides an active learning strategy for improving ML-IAPs for fracture, while revealing for the first time the atomic scale mechanisms that initiate fracture in iron with quantum accuracy.

MM 15.4   Tue 11:15   SCH A 216

Benchmarking of Tungsten Potentials using Blunted Cracks — •Tarakeshwar Lakshmipathy and Erik Bitzek — Department Computational Materials Design, Max-Planck-Institut für Eisenforschung GmbH

Blunted cracks can have radically different fracture behavior compared to their atomically sharp counterparts due to the additional degrees of freedom available to atoms at the crack tip surface. Simulating realistic notch or crack tip radii requires computationally inexpensive atomic interaction potentials. However, empirical potentials are known to show artefacts like the formation of planar faults at the crack tip due to unrealistic minima in their generalized stacking fault energies or fail to reproduce surface reconstructions. Such drawbacks could play an even larger role in blunted crack simulations than in typically studied sharp cracks due to additional surfaces at the crack tip. In this work, the fracture behavior and fracture toughness of some commonly used EAM potentials are benchmarked against density functional theory (DFT) simulations of blunted cracks in tungsten and compared to recently developed modified-EAM (MEAM), atomic cluster expansion (ACE) and bond order potentials (BOP).

MM 15.5   Tue 11:45   SCH A 216

Development of machine learning interatomic potentials for far-from-equilibrium states: a case study of deformation mechanisms in ceramics — •Shuyao Lin[1], Davide Sangiovanni[2], Lars Hultman[2], and Nikola Koutna[1] — [1]Technical University of Vienna, Institute of Materials Science and Technology, A-1060, Vienna, Austria — [2]Linköping University, Department of Physics, SE-58183, Linköping, Sweden

Besides the high chemical stability, the applications of ceramic-based materials into the coating technology require not only high strength but also ductility, a combination of properties necessary for material's resistance to crack growth. The mechanical properties of ceramic materials are dominated by both their movement and interactions. In this talk, we study mechanical response of selected ceramics, including transition metal diborides and nitrides. First, ab initio molecular dynamics simulations (AIMD) are employed to model tensile deformation along main crystallographic directions and under extreme high temperatures with fluid status. Then we develop machine learning interatomic potentials within the moment tensor potential (MTP) framework. The potentials are thor-

oughly tested and validated against AIMD stress-strain curves. With the aid of newly developed potentials, we carry out large-scale simulations during which the ceramics are continuously loaded and can shrink due to Poisson contractions. The observed deformation mechanisms are described and compared to those present in the small-scale training data.

MM 15.6 Tue 12:00 SCH A 216

Atomistic studies of crack tip twin-boundary interactions in lamellar TiAl alloys: Effect of misfit, misorientation and lamella spacing — Anupam Neogi[1,2] and •Rebecca Janisch[1] — [1]ICAMS, Ruhr-University Bochum, Germany — [2]ANSYS Inc., Pune, India

Nano-scale coherent twin boundaries can be an effective way in overcoming the strength-ductility trade-off of metals and their alloys. In this sense also twin boundaries in nano-lamellar lightweight Ti-Al alloys promise a great potential. Furthermore, the existence of three types of these twin boundaries with different misorientation and coherency state at the interface provide an excellent opportunity to study the effect of exactly these parameters in a realistic model system. To this end, we carried out molecular statics simulations to characterize the crack advancement at and across internal true-twins (TTs), rotational boundaries (RBs), and pseudo-twins (PTs) in lamellar γ-TiAl alloys, as well as crack propagation in fully lamellar structures.

It was confirmed that both interface type and spacing affect the fracture toughness and crack growth resistance. Furthermore, the crack tip mechanisms exhibit prominent sensitivity to the crack system and crystallographic directions. For trans-lamellar cracks the tip shows plastic deformation and toughening at all interfaces. The overall fracture initiation toughness in a microstructure of TTs exhibits an increasing trend with decreasing lamellar size down to a critical thickness, below which the fracture toughness drops again. These and more phenomena and their origins will be discussed in the presentation.

MM 15.7 Tue 12:15 SCH A 216

Crack Dislocation Interactions in Tungsten — •Benedikt Eggle-Sievers and Erik Bitzek — Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Straße 1, 40237 Düsseldorf

The fracture toughness of Tungsten at low temperature is critically influenced by its microstructure. Understanding the underlying crack-microstructure interactions is therefore necessary to model and predict failure. In order to gain insight into the interactions of dislocations with the crack-tip, large scale atomistic simulations are carried out. Dislocations of different character and Burgers vector are placed in the vicinity of a strain controlled crack geometry, resulting either in an attraction or repulsion of the dislocation. In the former case interactions can be observed in the course of the simulation, e.g. cross-slipping of screw parts, changes in crack front or crack plane as well as subsequent dislocation emission.

Dependencies on the stress state, the crack system, dislocation type and distance between dislocation and the crack are investigated. The results are discussed with respect to mesoscale and continuum models for crack tip plasticity and fracture toughness.

MM 15.8 Tue 12:30 SCH A 216

Atomistic study of fracture in Laves phases — •Alireza Ghafarollahi and Erik Bitzek — Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Straße 1, Düsseldorf 40237, Germany

Laves phases are intermetallic phases with complex structures that exist in many alloys and have a pronounced impact on their mechanical properties. Although these materials often exhibit superior mechanical properties at high temperatures, their applications as structural materials are limited due to their intrinsic brittleness at ambient temperature. Therefore, understanding the fundamental fracture mechanisms in Laves phases is crucial for tailoring their mechanical properties. Here, with the aid of atomistic simulations, the fracture behavior in C14 and C15 Laves phases is explored using NbCr_2 and MgZn_2 as model systems. In particular, different crack systems are analyzed and the corresponding fracture toughnesses are computed and compared with the Griffith theory.

MM 15.9 Tue 12:45 SCH A 216

Tailoring negative pressure by crystal defects: Crack induced hydride formation in Al alloys — •Ali Tehranchi[1], Poulami Charaborty[1], Marti Lopez Freixes[1], Eunan McEniry[1], Baptiste Gault[1,2], Tilmann Hickel[1,3], and Jörg Neugebauer[1] — [1]Max-Planck-Institut für Eisenforschung GmbH, D-40237 Düsseldorf, Germany — [2]Department of Materials, Imperial College, South Kensington,London, SW7 2AZ, UK — [3]Bundesanstalt für Materialforschung und -prüfung (BAM)

Climate change motivates the search for non-carbon-emitting energy generation and storage solutions. Metal hydrides show promising characteristics for this purpose. To enhance the formation and stability of such often highly volatile hydrides we have consider a novel concept: tailoring and employing the negative pressure of microstructural and structural defects to enhance H solubility and thus hydride formation. Using systematic ab initio and atomistic simulations, we demonstrate that an enhancement in the formation of hydrides at the negatively pressurized crack tip region is feasible by increasing the mechanical tensile load on the specimen. The theoretical predictions have been used to reassess and interpret atom probe tomography experiments for a high-strength 7XXX-aluminium alloy that show a substantial enhancement of hydrogen concentration at structural defects near a stress-corrosion crack tip. Based on these insights we derive strategies for enhancing the capability of metals as H-storage materials.

Spins at Work: Probing Charging and Discharging of Organic Radical Batteries by Electron Paramagnetic Resonance Spectroscopy — •Ilia Kulikov[1], Naitik Panjwani[1], Anatoliy Vereshchagin[2], Domenik Spallek[1], Daniil Lukianov[2], Elena Alexeeva[2], Oleg Levin[1], and Jan Behrends[1] — [1]Berlin Joint EPR Lab, Freie Universität Berlin, Arnimallee 14, D-14195 Berlin — [2]St. Petersburg, 199034, Russian Federation

We report on the development of an operando setup for spectroelectrochemical Electron Paramagnetic Resonance (EPR) measurements on redox conductive polymers for organic radical batteries. [1]

Quantitative EPR experiments performed on electrochemical cells with a TEMPO containing polymer cathode demonstrate a strong decrease in the number of paramagnetic centres upon oxidation. [2] The distinct EPR signatures of the polymer are used to study its degradation upon repeated cycling. A comparison between the EPR and electrochemical data is used to monitor the degradation process.

Low-temperature ex-situ pulse EPR measurements on an oxidized cathode film reveal a spectrum of dilute nitroxide species, which indicates formation of electrochemically inactive islands. These experiments pave the way for studying organic radical battery materials by advanced EPR techniques.

MM 16.2 Tue 10:30 SCH A 215

Revisiting the storage capacity limit of graphite battery anodes: spontaneous lithium overintercalation at ambient pressure — Cristina Grosu[1,2], •Chiara Panosetti[1], Steffen Merz[2], Peter Jakes[2], Sebastian Matera[1], Rüdiger-A. Eichel[2], Josef Granwehr[2], and Christoph Scheurer[1,2] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]IEK-9, FZ Jülich, Germany

The market quest for fast-charging, long-lasting, safe batteries drives the exploration of new energy storage materials, but also promotes fundamental studies of those already widely used–primarily graphite anodes for Li-ion batteries. We focus on the upper intercalation limit in the morphologically quasi-ideal highly oriented pyrolytic graphite, with a LiC_6 stoichiometry corresponding to 100% state of charge. A sample prepared by immersion in liquid Li at ambient pressure, investigated by [7]Li nuclear magnetic resonance (NMR), shows unexpected signatures of superdense intercalation compounds, LiC_{6-x}. These were ruled out for decades, as the highest geometrically accessible composition, LiC_2, can only be prepared under high pressure. We monitored the sample upon calendaric aging and employed DFT calculations to rationalise NMR findings. Computed free energies reveal that non-negligible overintercalation proceeds spontaneously beyond the currently accepted capacity limit. Challenging the widespread notion that any additional intercalation beyond LiC_6 is not possible under ambient conditions, we highlight the implications on performance-crucial phenomena and critically discuss possible quantitative characterization routes[1].

[1] C. Grosu et al., arXiv:2107.11137 (2021)

MM 16.3 Tue 10:45 SCH A 215

Computational investigation of carbon based anode materials for Li- and post-Li ion batteries — •Jafar Azizi[1], Holger Euchner[2], and Axel Gross[1] — [1]Institute of Theoretical Chemistry, Ulm University, 89069 Ulm, Germany — [2]Institute of Physical and Theoretical Chemistry, University of Tübingen, 1572076 Tübingen, Germany

With respect to sodium ion batteries, traditional graphite anodes exhibit a severe limitation due to their inability to intercalate sodium atoms. Hard carbon materials, on the other hand, provide a promising alternative for Na-ion and K-ion batteries with high theoretical capacities and low reaction potentials. The presence of the particular nanostructure of these functionalized carbon-based

materials have been shown to be responsible for these features. The major obstacle for a continued development and improvement is a lack of a functional understanding of the role of these structural features with regard to the intercalation and storage mechanism. To overcome these problems, the intercalation of Li, Na, and K in the presence of distinct defects have been investigated by density functional theory (DFT) calculations. It will be shown how the combination of phonon simulations with electronic band structure calculations allows for a validation of the so-called modified card house model for the alkali metal storage in hard carbon.

MM 16.4   Tue 11:00   SCH A 215

Detailed structural and electrochemical comparison between high potential layered P2-NaMnNi- and doped P2-NaMnNiMg-oxides — •Manuel Dillenz[1], Cornelius Gauckler[2], Mohsen Sotoudeh[1], Holger Euchner[3], Mario Marinaro[2], and Axel Gross[1,4] — [1]Institute of Theoretical Chemistry, Ulm University, Mez-Starck-Haus, Oberberghof 7, 89081 Ulm — [2]ZSW-Zentrum für Sonnenenergie und Wasserstoff-Forschung, Helmholtzstrasse 8, 89081, Ulm, Germany — [3]Institute of Physical and Theoretical Chemistry, Universität Tübingen, Auf der Morgenstelle 15, 72076 Tübingen, Germany — [4]Helmholtz Institute Ulm (HIU) for Electrochemical Energy Storage, Helmholtzstraße 11, 89069 Ulm, Germany

Manganese-based transition metal oxides with a P2 structure are promising cathode materials for sodium ion batteries. Although these materials exhibit high working potential vs Na+/Na and high capacity, they are affected by Na+ ion/vacancy ordering transitions and phase transformations at high voltages, resulting in poor reversibility. Here we present a combined experimental/theoretical approach to investigate the effect of magnesium doping on the layered P2-Na0.67Mn0.75Ni0.25O2 cathode material. The Mg-doped material showed stabilization of the high potential plateau and improved cycle life. Based on our experimental data and periodic density functional theory (DFT) calculations, phase stabilities of the O2, P2, and OP4 phases for the pristine and Mg-doped systems were investigated to elucidate the origin of the "Z"-phase formation in the Mg-doped systems.

MM 16.5   Tue 11:15   SCH A 215

Coarse–Grained Simulation of Dendrite Growth in Lithium Metal Batteries — •Len Kimms, Diddo Diddens, and Andreas Heuer — Institut für physikalische Chemie, Westfälische Wilhelms-Universität Münster, Corrensstraße 28/30, 48149 Münster

In this talk, we will present a simulation study that investigates the formation and growth of dendrites. Due to the increasing demand for portable high–capacity energy storage, there is a renewed interest in Lithium metal batteries (LMBs). In LMBs one electrode is replaced by lithium metal anchored on a current collector. Lithium metal is electrochemically plated on the anode side when charging the battery. Depositing the metal uniformly is a hugely challenging undertaking. The intrinsically high reactivity of lithium metal, electric field effects, and spatial variations of the local composition in the electrolyte all drive dendritic deposition. We employ a versatile coarse–grained model to understand the influence of various electrochemical conditions on the dendrite morphology. The model allows not only the investigation of fundamental driving forces like the electric field and the cation concentration but also the evaluation of more intricate procedures e.g. pulse charging. Different particle types with varying reactivity are implemented, which allows the representation of local passivation. Also, a solid electrolyte interface (SEI) layer can be incorporated either explicitly with a particle layer on the surface or implicitly by modifying the cationic diffusion locally. Here we report results on how to suppress non–uniform deposition by employing charging, microstructured electrode surfaces, and SEI effects.

MM 16.6   Tue 11:45   SCH A 215

Modelling Hard Carbon with High-Dimensional Neural Network Potentials — •Alexander L. M. Knoll[1,2], Jafar Azizi[3], Holger Euchner[4], Axel Gross[3], and Jörg Behler[1,2] — [1]Lehrstuhl für Theoretische Chemie II, Ruhr-Universität Bochum, 44780 Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, 44780 Bochum, Germany — [3]Institut für Theoretische Chemie, Universität Ulm, 89081 Ulm, Germany — [4]Institut für Physikalische und Theoretische Chemie, Eberhard Karls Universität Tübingen, 72076 Tübingen, Germany

Hard carbon (HC) is widely regarded as a promising anode material for lithium and sodium ion batteries. However, this material is notoriously difficult to characterise experimentally, as its properties strongly depend on the carbon precursor and the conditions of preparation. *Ab initio* investigations could help to illuminate its structure, but are severely hampered by its complexity involving large graphitic domains as well as amorphous motifs. To bypass these challenges, we present a high-dimensional neural network potential (HDNNP) for HC that accurately reproduces short-range and dispersion interactions in the system. We show that elaborate structural models can be constructed with this potential using various simulation protocols and demonstrate their validity through comparison to experimental data.

MM 16.7   Tue 12:00   SCH A 215

Computational Studies on the Electrochemical Performance of Doped and Substituted Ti 3 C 2 T x (T = O,OH) MXene — •Mandira Das[1] and Subhradip Ghosh[2] — [1]Indian Institute of Technology Guwahati,Guwahati,Assam,India — [2]Indian Institute of Technology Guwahati,Guwahati,Assam,India

Using Density functional theory (DFT) in conjunction with a solvation model, we have investigated the phenomenon of electrode-electrolyte interaction at the electrode surface and its consequences on the electrochemical properties like the charge storage and total capacitance of doped and substituted functionalized Ti 3 C 2 T x (T = O, OH) supercapacitor electrode. We have studied nitrogen-doped, nitrogen substituted, and molybdenum substituted MXenes in acidic electrolyte H 2 SO 4 solution. By considering nitrogen doping at different sites, we found that the greatest capacitance is obtained for doping at functional sites. Our results agree well with the available experiment. We also found that the enhancement in capacitances due to nitrogen doping is due to amplifications in the pseudo-capacitance. We propose that the primary mechanism leading to the enhanced value of the capacitances due to nitrogen doping is surface redox activity. The performances of substituted systems, on the other hand, are degraded compared to the pristine ones. This suggests that better storage capacities in Ti 3 C 2 T x electrode can be obtained by doping only. We provide insights into the reasons behind contrasting behavior in doped and substituted systems and suggest ways to further improve the capacitances in the doped system.

MM 16.8   Tue 12:15   SCH A 215

Structure-property relationships in functionalized metal organic framework from first-principles high-throughput screening — •Joshua Edzards[1], Holger-Dietrich Sassnick[1] und Caterina Cocchi[1,2] — [1]Institut für Physik, Carl von Ossietzky Universität Oldenburg, 26129 Oldenburg — [2]Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, 12489 Berlin

Metal organic frameworks (MOFs) are novel materials with high potential in many fields of application, ranging from gas storage and catalysis to optoelectronics. MOFs are constituted by metal atoms bound together by linker molecules which can be modified by functional groups. This leads to an enormous variety of MOFs with different structural properties, which can in turn affect their band structures, projected density of states, charge density distribution, etc. In this project, we perform high-throughput first-principles calculations on MOF-5 a well- known member of the MOF family. We scan all possible structures that arise by exchanging the metal ion Zn with alkaline-earth metals, and by functionalizing the linker molecule (1,4-benzodicarboxylate) with Br, CH$_3$, Cl, COOH, NO$_2$, and OH. We investigate the electronic properties of the stable structures and assess how they are influenced by the choice of the metal ion and by the functionalization of the linkers.

Lithium diffusion visualized in Li4+xTi5O12 using optical microscopy (revealing slow-moving phase boundary) — •Yug Joshi, Robert Lawitzki, and Guido Schmitz — Chair of Materials Physics, Institute of Materials Science, University of Stuttgart, Stuttgart, Germany

Lithium titanate (Li4Ti5O12) undergoes a phase transformation from spinel structured (Li4Ti5O12) to rock-salt (Li7Ti5O12). The material has been reported to show sluggish mobility of lithium in fully lithiated and delihiated phases. This challenges the high-rate performance observed in this material. To elucidate this behavior, optical microscopy and the electrochromic character of the material have been used to visualize the phase transformation. The kinetics of lithium transport is observed in a constrained region of sputter-deposited thin-film samples. This enables a study of the lateral transport on the length scales of tens of micrometers. Furthermore, with a thermostatically controlled cell, the Arrhenius-like temperature dependence of lithium diffusivity is revealed. Our quantitative findings demonstrate that indeed the end phases have poor diffusivity. Surprisingly, the phase boundary moves slowly upon lithiation, which has been refuted in prior reports, however, it is confirmed here by the linear growth kinetics of the Li-rich phase in the initial stages of the lithium transport. Interestingly, the partial solubility of lithium in the spinel structured Li4/3+δTi5/3O4 phase increases the diffusivity of lithium drastically. This increase in diffusivity along with the reduction in size of the electrode seems to be compensating the kinetic hindrance induced by the phase boundary.

MM 16.10   Tue 12:45   SCH A 215

Photocatalytic water splitting from Koopmans spectral functionals: The case of *TiO*$_2$ polymorphs — •Marija Stojkovic[1], Edward Linscott[1], and Nicola Marzari[1,2] — [1]Theory and Simulations of Materials (THEOS), and National Centre for Computational Design and Discovery of Novel Materials (MARVEL), École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland — [2]Laboratory for Materials Simulations, Paul Scherrer Institut, 5232 Villigen PSI, Switzerland

Photocatalytic water splitting has drawn considerable attention for renewable energy production. Since the first reported photocatalytic water splitting by titanium dioxide, this material remains one of the most promising photocatalysts,

due to its suitable band gap and band-edge positions. However, estimating both of these properties is a challenging task for standard DFT functionals. Here we show how Koopmans spectral functionals can accurately predict the band structure and level alignment of rutile, anatase and brookite, demonstrating the advantage of orbital-density dependent functionals for predicting the spectral properties of materials.

MM 17: Phase Transformations: Microstructural Transformations

Time: Tuesday 10:15–11:15   Location: SCH A 118

MM 17.1   Tue 10:15   SCH A 118

About the transformation speed of martensitic transformations — •Sebastian Fähler[1], Stefan Schwabe[2], Klara Lünser[1], Daniel Schmidt[3], Kornelius Nielsch[3], and Peter Gaal[3] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Leibniz IFW Dresden, Dresden, Germany — [3]Leibniz-Institut für Kristallzüchtung (IKZ), Berlin, Germany

Structural martensitic transformations enable various applications, which range from high stroke actuation and sensing to energy efficient magnetocaloric refrigeration and thermomagnetic energy harvesting. All these emerging applications benefit from a fast transformation, but up to now the speed limit of martensitic transformations has not been explored. Here, we demonstrate that a martensite to austenite transformation can be completed in under ten nanoseconds. We heat an epitaxial Ni-Mn-Ga film with a laser pulse and use synchrotron diffraction to probe the influence of initial sample temperature and overheating on transformation rate and ratio. We demonstrate that an increase of thermal energy drives this transformation faster. Though the observed speed limit of 2.5×10^{27} $(\text{Js})^{-1}$ per unit cell leaves plenty of room for a further acceleration of applications, our analysis reveals that the practical limit will be the energy required for switching. Our experiments unveil that martensitic transformations obey similar speed limits as in microelectronics, which are expressed by the Margolus-Levitin theorem. [1] S. Schwabe, K. Lünser, D. Schmidt, K. Nielsch, P. Gaal and S. Fähler, Science and Technology of Advanced Materials, 23 (2022) 633

MM 17.2   Tue 10:30   SCH A 118

Solving the 3D puzzle of the martensitic microstructure in epitaxial NiTi films — •Klara Lünser[1,2,3], Andreas Undisz[4,5], Kornelius Nielsch[2,3], and Sebastian Fähler[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Leibniz IFW Dresden, Dresden, Germany — [3]TU Dresden, Dresden, Germany — [4]TU Chemnitz, Chemnitz, Germany — [5]Friedrich-Schiller-Universität Jena, Jena, Germany.

The shape memory effect in the most frequently used shape memory alloy NiTi is driven by a martensitic transformation, resulting in a complex martensitic microstructure with a variety of interfaces. As shape memory properties depend on the microstructure, a detailed understanding is crucial. However, the martensitic microstructure is still puzzling, especially how it is built up in 3 dimensions. The analysis of this puzzle is complicated by grain boundaries present in polycrystalline NiTi. Here, we eliminate the influence of grain boundaries by using epitaxial NiTi films in (111)-orientation as a model system. We analyze the films with electron microscopy to identify clusters and interfaces and compare results to the phenomenological theory of martensite. With this approach, we generate a scale-bridging understanding of the martensitic microstructure. Three kinds of twin boundaries on different length scales are required for the complete, hierarchical microstructure. Integral X-ray measurements confirmed our microstructure model. The results are transferable to NiTi bulk and polycrystalline films,

showing that NiTi epitaxial films are important to extend our understanding of the martensitic microstructure.

MM 17.3   Tue 10:45   SCH A 118

Elucidating the nucleation and growth mechanism of {11-22} twin in titanium — Andriy Ostapovets[1], •Ritu Verma[1,2], and Anna Serra[3] — [1]Institute of Physics of Materials, Czech Academy of Sciences, 616 00 Brno, Žižkova 513/22 Czech Republic — [2]Central European Institute of Technology, Brno University of Technology, Purkyňova 656/123 612 00 Brno, Czech Republic — [3]Universitat Politécnica de Catalunya, Campus Nord, C-2, Jordi Girona, 1-3, 08034 Barcelona, Spain

{11-22} Twin is the predominant twinning mode in hcp metals such as Ti, Zr and Mg under <c> axis compression. We analyze the {11-22} twin nucleation in Ti by reverse α-ω-α phase transformation. The twin nucleated by this mechanism can grow by the migration of the {11-22} twin boundary. This migration is mediated by the gliding of line defects with step and dislocation character, i.e. b3/3 disconnection, along with {11-22} twin boundary. Their structure can be interpreted as a pair of disconnections (bt and bt*) i.e. dissociated core of b3/3 disconnection, which contains ω-phase structure inside. These studies reveal the role of ω- phase in the connection with nucleation and growth mechanism of {11-22} twin boundary. These results clarify the uncertainties with the growth of the {11-22} twins.

MM 17.4   Tue 11:00   SCH A 118

Bicontinuous microstructure formation through peritectic melting — •Zhongyang Li[1], Nina Petersen[1], Lukas Lührs[1], and Jörg Weissmüller[1,2] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology, Hamburg — [2]Institute of Materials Mechanics, Helmholtz-Zentrum Hereon, Geesthacht

Recent research has found that when heated above the peritectic line, the intermetallic compound TiAg decomposes into a separated solid Ti phase and a liquid Ag phase, thereby forming a bicontinuous microstructure. This shows that monolithic networks such as porous Titanium, which has potential application in the field of biomedicine, can be produced with simple heat treatment followed by selective removal of other phases. As a novel dealloying method for bulk materials, the underlying mechanism is still not completely understood. It is also unclear if this method could be used in different alloy systems.

In our research we find a similar microstructural phenomenon for CuSn alloys. With the help of electron microscopy and X-Ray diffraction, formation and evolution processes of the bicontinuous structure of both TiAg and CuSn systems are studied. Research on microstructure evolution can help both, setting up the criteria for searching new alloy systems and optimizing thermal treatment parameters. This enables us to further develop this method for porous metal preparation, and also broaden the application of this method from peritectic dealloying to dealloying at crystal-melt coexistence.

MM 18: Transport in Materials: Metals, Alloys and Oxides

Time: Tuesday 11:30–13:00   Location: SCH A 118

MM 18.1   Tue 11:30   SCH A 118

Understanding diffusion in high entropy alloys from an experiment-ab initio approach — •Xi Zhang[1], Sergiy Divinski[2], and Blazej Grabowski[1] — [1]Institute for Materials Science, University of Stuttgart, D-70569 Stuttgart, Germany — [2]Institute of Materials Physics, University of Münster, 48149 Münster, Germany

Diffusion in high entropy alloys (HEAs), due to the significant chemical complexity and the severe lattice distortion, has many fundamental features that are extremely important for both basic research and industrial development. The most accurate and direct method to study diffusion is the radiotracer technique whereby a number of intriguing phenomena, e.g., ultra-fast, non-/anti-sluggish diffusion, have been observed. To advance the current understanding of the observed phenomena, accurate theoretical analysis is highly required. The key point of the present approach is the combined measurement of diffusivities and interdiffusion profiles on the one hand and a highly accurate DFT-informed assessment of the diffusion mechanisms on the other. In this way, the long-standing mysteries in HEA diffusion, e.g., "sluggish" diffusion, can be compre-

hensively examined and understood. Remarkably, we show by investigating an HCP AlScHfTiZr HEA system that the increasing chemical complexity results in a considerably broadened distribution of the defect formation and migration energies which may enhance the mobility of the defects and thus the diffusion rates. The observed "anti-sluggish" diffusion can be traced back to the lattice distortion as revealed by the DFT calculations.

MM 18.2   Tue 11:45   SCH A 118

Composition dependent thermodynamic factor, Manning factor, and impurity diffusion coefficients estimated by a tracer-interdiffusion couple technique — •Esakkiraja Neelamegan[1], Daniel Gaertner[1], Jasper Berndt[2], Stephan Klemme[2], Aloke Paul[3], Gerhard Wilde[1], and Sergiy V Divinski[1] — [1]Institute of Materials Physics, University of Münster, Münster, Germany — [2]Institut für Mineralogie, University of Münster, Münster, Germany — [3]Department of Materials Engineering, Indian Institute of Science, Bangalore, India

The thermodynamic driving force for the diffusion was never validated experimentally. The newly proposed augmented tracer-interdiffusion couple method

could be adapted to validate the thermodynamic factor. The approach is demonstrated for a model Ni-Fe binary system, especially for the Ni-rich corner. Pure Ni is diffusion-coupled with a Ni-10 at. % Fe diluted alloy at 1000 C for 24h. The interdiffusion coefficients are estimated from the composition profile measured by an Electron Microprobe Analyser. The composition-dependent tracer diffusion coefficients are estimated following the Belova-Murch approach. Diffusion of the Fe55 and Ni63 isotopes under a chemical gradient is followed. The Fe tracer diffusion coefficients are found to be faster than those of Ni in this composition region. Utilizing the Darken-Manning relation, the thermodynamic factor is estimated and compared with that provided by a ThermoCalc software database. As a result, the composition-dependent impurity diffusion coefficients of Co, Cr, and Mn in these alloys are analysed in detail.

MM 18.3   Tue 12:00   SCH A 118
Control of microstructure in binary alloy thin films by means of electromigration — •THOMAS BREDE, REINER KIRCHHEIM, and CYNTHIA A. VOLKERT — Universität Göttingen, Insitut für Materialphysik, Göttingen, Deutschland
Magnetic and electric fields and currents open new and efficient materials processing paths for microstructure optimization than were previously available. For example, it has recently been shown that high DC electric currents can be used to create anisotropic microstructures with elongated ferrite grains in iron-carbon thin films [1]. The elongated grains form in the wake of carbides that migrate due to electromigration induced carbon flux divergences. The underlying mechanisms controlling the microstructural evolution will be presented and will be used to discuss other materials systems that might show this effect and how they could be implemented to achieve precise microstructure control.

MM 18.4   Tue 12:15   SCH A 118
GP-zone formation and growth in rapidly quenched Al-Cu alloys — •DAVID STEIN, JOHANNES BERLIN, TOBIAS STEGMÜLLER, and FERDINAND HAIDER — Universität Augsburg, Institut für Physik, 86159 Augsburg, Germany
Natural aging by the formation of Guinier Preston zones in Al-Cu alloys is only possible in the presence of excess vacancies, quenched in from high temperatures. In collision welded samples of Al and Cu, an unexpected high density of GPII-zones was observed in the TEM. In order to obtain similarly high quenching rates of about 104 K/s, meltspinning was used for alloys with a Cu content from 2-5 wt%. After the quenching process, the samples were analyzed after different natural aging times using Differential Scanning Calometry (DSC) , hardness measurements, resistometry and STEM to obtain information about the unmixing kinetics. Additionally EDX and EBSD were used to characterize the microstructure and chemical homogeneity of the samples.

MM 18.5   Tue 12:30   SCH A 118
Theoretical studies on the oxygen migration through crystalline strontium titanate — •CARMEN FUCHS[1] and TIMO JACOB[1,2,3] — [1]Ulm University, Institute of Electrochemistry, D-89069 Ulm — [2]Helmholtz-Institute-Ulm (HIU), D-89081 Ulm — [3]Karlsruhe Institute of Technology (KIT), D-76131 Karlsruhe
Transition metal oxides with perovskite structure (ABO3) display a range of complex physical phenomena of condensed matter physics, including superconductivity, ferroelectricity, and magnetism. Strontium titanate, SrTiO3 (STO), is the archetypical and most frequently studied representative of perovskite materials. By changing the stoichiometry, major changes in several important properties can be induced including blue light emission,[1] local conductivity,[2] and electron doping.[3] The relationship between the structure and the diffusion behavior of defects in SrTiO3 is studied via DFT calculations using the plane-augmented wave method and the PBE exchange-correlation functional with and without Hubbard U correction. The obtained defect formation energy and activation barriers for oxygen migration through Frenkel- and Schottky-like defects within the crystalline STO structure are discussed and summarized.

MM 18.6   Tue 12:45   SCH A 118
Impact of alloying elements on point defects and diffusion in B2 alloys: an ab initio study — •ADITYA VISHWAKARMA[1], OSAMU WASEDA[1], TILMANN HICKEL[1], NEELAMEGAN ESAKKIRAJA[2], SERGIY DIVINSKI[2], and ALOKE PAUL[3] — [1]Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf, Germany — [2]Institute of Materials Physics, University of Münster, Germany — [3]Department of Materials Engineering, IISc Bangalore, India
Turbine blades in jet engines are vulnerable to many problems due to the harsh application environments. To prevent oxidation and surface degradation, bond coats of B2 NiAl are most widely used. During the operation at high temperatures, however, the Al content in the bond coat is lost by the formation of an Inter Diffusion Zone (IDZ) between the superalloy (turbine blade) and the bond coat. In this report, ab-initio based studies of point defect formation and kinetics are performed, in order to investigate the diffusion mechanisms and the impact of alloying elements on diffusion in B2 NiAl phase. Our results show that isoelectronic substitutions by Pt and Pd decreases the triple defect migration barriers and increases the Ni vacancy concentration in comparison to pure B2 NiAl. Accordingly, the contribution of the triple defect mechanism increases down the periodic table. These results explain the experimentally observed increase of the thickness of IDZ compared to binary B2 NiAl and have, therewith, an impact on the future design of turbine blades.

MM 19: Development of Computational Methods: Simulation Methods − Theory

Time: Tuesday 14:15–15:30   Location: SCH A 251

MM 19.1   Tue 14:15   SCH A 251
Multi-methodological study of temperature trends in Mössbauer effect in beta-Sn — •MARTIN FRIÁK[1], NIKOLAS MASNIČÁK[1], OLDŘICH SCHNEEWEISS[1], PAVLA ROUPCOVÁ[1], ALENA MICHALCOVÁ[2], ŠÁRKA MSALLAMOVÁ[2], and MOJMÍR ŠOB[3,1] — [1]Institute of Physics of Materials, Czech Academy of Science, Brno, CZ — [2]Department of Metals and Corrosion Engineering, University of Chemistry and Technology in Prague, Prague, CZ — [3]Department of Chemistry, Faculty of Science, Masaryk University, Brno, CZ
We have performed a multi-methodological theoretical study of impact of thermal vibrations on the Mössbauer effect in the tetragonal beta-phase of tin. We have seamlessly combined (i) atomic-scale numerical data in the form of mean square displacements of Sn atoms determined by quantum-mechanical calculations, (ii) continuum-level thermodynamic modeling based on the quasi-harmonic approximation and (iii) theoretical analysis of Mössbauer effect resulting in the prediction of temperature dependence of Mössbauer factor. The computed results were compared with our Mössbauer and X-ray experimental data. We show that classical theoretical approaches based on simplistic Debye model of thermal vibrations of solids can be nowadays replaced by exact ab initio calculations of individual thermal vibrations. For details see M. Friák at al., Computational Materials Science 215 (2022) 111780, doi:10.1016/j.commatsci.2022.111780.

MM 19.2   Tue 14:30   SCH A 251
Increasing the Diversity of One-Sided Transition State Searches with Biasing Potentials — •NILS GÖNNHEIMER, KING CHUN LAI, KARSTEN REUTER, and JOHANNES T. MARGRAF — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany

Chemical processes on catalytic surfaces are commonly described in terms of complex networks of chemical reactions. One-sided transition state (TS) searches are a powerful tool for exploring these networks, when not all reactants, products and intermediates are known. To this end, the dimer method is commonly used, since it avoids the computationally demanding calculation of second derivatives. However, a prominent disadvantage of the dimer method is the convergence to the same few TSs even with differently initialised simulations, which raises the possibility of overlooking reaction pathways. Here, we propose a method to overcome this limitation. Specifically, we use a biasing potential to modify the potential energy surface (PES) based on information gathered from previous calculations. This biasing potential is adaptively generated in a series of dimer searches to drive the searching algorithm away from already known TSs. Intuitively, such potentials can be built within the Cartesian space by placing an energy bias at the atomic positions of a found TS. Alternatively, a similarity kernel between the structure and the known TS based on a local environment descriptor can be employed. This ensures that the biasing potential is invariant to permutations between identical atoms, as well as rotations and translations. The performance of both approaches is discussed for adatom diffusion and island formation on the Pd(100) surface.

MM 19.3   Tue 14:45   SCH A 251
How to Speed up First-Principles Based Geometry Optimization with Small Numerical Basis Sets — •ELISABETH KELLER, JOHANNES T. MARGRAF, and KARSTEN REUTER — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany
First-principles based geometry optimizations are often the most expensive part of high-throughput virtual screening studies for functional materials. This is particularly true for large systems, i.e. when studying complex surface reconstruc-

tions or nanoparticles. Here, the computational cost is strongly influenced by the size of the basis set. Large, converged basis sets result in precise equilibrium geometries, yet demand high computational cost and thus limit the simulation scale. Semiemprical methods using minimal basis sets offer a much lower computational cost, but may yield unacceptably large and uncontrolled errors. Furthermore, the availability of adequate parameterizations is rather sparse across the periodic table.

In this presentation, we will discuss the potential of using near-minimal basis sets for accelerating and enabling large-scale geometry optimizations at the DFT level. For this purpose, we studied how the size of the numeric atom-centered orbital (NAO) basis set in FHI-aims impacts the accuracy of bulk geometries. We recover equilibrium geometries at a nearly converged level with a highly compact basis by employing a simple short-ranged pair-potential correction. We show the scheme's ability to treat different systems across the periodic table ranging from small molecules and clusters to large-scale bulk and surface structures.

MM 19.4   Tue 15:00   SCH A 251

Automated Wannierizations — •Junfeng Qiao[1,2], Giovanni Pizzi[1,2,3], and Nicola Marzari[1,2,3] — [1]THEOS, EPFL — [2]NCCR MARVEL — [3]LMS, Paul Scherrer Institut

Maximally localized Wannier functions (MLWFs) are widely used in computational condensed matter physics. The standard approach to construct ML-WFs often requires initial guesses which are based on chemical intuition and some measure of trial and error. Here, we first introduce an algorithm based on "projectability disentanglement" that provides reliably and automatically atom-centered Wannier functions describing both occupied and empty states. Then, we show how to mix these again into target subspaces; e.g., to describe valence and conduction bands separately. We test these algorithms on 200 representative materials (77 insulators), showing that the final MLWFs are very well localized and can accurately interpolate band structures at the meV scale. Such approaches enable automated Wannierizations for both metals and insulators, promoting further applications of MLWFs in physical applications and high-throughput calculations.

MM 19.5   Tue 15:15   SCH A 251

Higher-order finite difference method for accurate calculation of Wannier centers and position matrix elements — •Minsu Ghim[1,2,3], Jae-Mo Lihm[1,2,3], and Cheol-Hwan Park[1,2,3] — [1]Department of Physics and Astronomy, Seoul National University, Seoul 08826, Korea — [2]Center for Correlated Electron Systems, Institute for Basic Science, Seoul 08826, Korea — [3]Center for Theoretical Physics, Seoul National University, Seoul 08826, Korea

An accurate calculation of Wannier function centers and position matrix elements is crucial for calculating many physical quantities such as the electric polarization and optical responses from first-principles Wannier interpolation. Since the Fourier transform of the position operator is the gradient in momentum space, a finite difference technique is used to calculate the position matrix elements for Wannier functions. However, so far, only the first-order finite difference has been considered therein. We present a higher-order finite difference method and demonstrate the advantage of our method over the conventional first-order finite difference method.

MM 20: Topical Session: Fundamentals of Fracture –
Microstructure Impact on Fracture (Experiments)

Time: Tuesday 14:15–15:30   Location: SCH A 216

MM 20.1   Tue 14:15   SCH A 216

Fatigue damage prediction using graph neural networks on microstructure representations — •Ali Riza Durmaz[1,2,3], Akhil Thomas[1,2], Chris Eberl[1,2], and Peter Gumbsch[1,3] — [1]Fraunhofer Institute for Mechanics of Materials IWM, Freiburg im Breisgau, Germany — [2]University of Freiburg, Freiburg im Breisgau, Germany — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany

Crack initiation governs high-cycle fatigue (HCF) life and makes HCF very susceptible to microstructural details. Predicting microscopic cyclic plasticity in polycrystals requires thorough microstructure representations.

In this work, we compare phenomenological crystal plasticity models with graph machine learning models on the task of predicting local cyclic plasticity in ferritic steel (EN1.4003). A workflow is presented which consists of a combined experimental and data post-processing pipeline to establish fatigue damage/crack initiation and short crack propagation data sets efficiently. It evolves around fatigue testing of mesoscale specimens to increase damage detection sensitivity, data fusion through multi-modal registration to address data heterogeneity, and image-based data-driven damage localization. The resulting data fuels both crystal plasticity and graph machine learning efforts. For the latter, the pixel data is transcribed into graph representations of the microstructure before being fed to different graph neural network variants. Interpretability techniques are applied to the machine learning models to learn about driving forces for the formation of extrusions and protrusions in individual grains.

MM 20.2   Tue 14:30   SCH A 216

analysis of plasticity in cyclic compression precracking — •mohamed amine faham, nathalie limodin, jean françois witz, and jérôme hosdez — Univ. Lille, CNRS, Centrale Lille, UMR 9013 - LaMcube - Laboratoire de Mécanique, Multiphysique, Multiéchelle, F-59000 Lille, France

Determining whether a defect will grow or not is of outmost importance particularly for railway axles. In this context, compressive precracking is an interesting procedure to get fatigue crack growth threshold. Using this method, specimens are precracked with both maximum and minimum compressive loads. This study uses fracture mechanics analysis, digital image correlation (DIC) and finite element method (FEM) to assess compressive plastic zone and precrack length ahead of a SENT specimen notch.

The DIC strain field in the direction of loading shows the evolution of the monotonic compressive zone ahead of the notch with increasing load. Other techniques were used to assess the plasticity ahead of the notch and to verify DIC vertical strain field results. One technique consists of projecting (in the least squares sense) the measured DIC displacement fields on Williams' basis. The difference between the DIC vertical displacement field and the analytical one highlights the plasticity in the notch region. A coupled DIC-FEM simulation with boundary conditions issued from DIC displacement fields applied on a numerical model of the specimen with inelastic material behavior was done in order to verify the extent of the compressive plastic zone and to estimate the compressive precrack length.

MM 20.3   Tue 14:45   SCH A 216

Microstructural damage analysis in a DP800 steel subjected to complex strain paths — •Maximilian A. Wollenweber, Luiz R. Guimarães, Nicole Lohrey, Setareh Medghalchi, Talal Al-Samman, and Sandra Korte-Kerzel — RWTH Aachen, Aachen, Germany

During forming processes, initiation and evolution of microstructural damage sites have a strong negative influence on the mechanical properties of the finished product. It is therefore important to investigate the damage behavior during deformation and unravel its relationship with the strain path. The current work investigates the microscopic damage evolution in a dual-phase steel DP800 subjected to different loading scenarios in tension and bending. The aim is to elucidate how the strain path influences the initiation and growth of microstructural damage in order to design more damage-tolerant industrial forming processes. The methods used comprise machine-learning algorithms and in-situ testing in a scanning electron microscope to observe and classify damage sites in the deformed samples. The results show that strain hardening inhibits damage formation, while pre-existing damage sites tend to facilitate further damage formation.

MM 20.4   Tue 15:00   SCH A 216

Three-dimensional characterization of damage sites and strain dependence in dual phase steel — •Setareh Medghalchi[1], Binbin Lin[2], Joscha Kortmann[1], Bai-Xiang Xu[2], Ulrich Kerzel[3], and Sandra Korte-Kerzel[1] — [1]Institute for Physical Metallurgy and Materials Physics, RWTH Aachen University, Aachen, Germany — [2]Mechanics of Functional Materials Division, Institute of Materials Science, Technische Universität Darmstadt, Darmstadt, Germany — [3]Fakultät für Georessourcen und Materialtechnik, RWTH Aachen University, Aachen, Germany

High performance materials like dual phase steels possess a heterogeneous microstructure resulting in the unique interplay between the two phases. High resolution scanning electron microscopy serves as a tool to unravel many of the microscale properties related to the deformation and mechanical properties of these materials. Damage sites in the microstructure serve as the main controlling feature during deformation. There are two fronts to tackle for a deeper understanding of the global damage accumulation: First, bringing high resolution analysis to large scales, and second, moving from two dimensional to three-dimensional characterization. We approach this challenge by employing slice-and-view SEM sectioning in combination with automated convolutional neural networks. With the knowledge of the damage occurring in certain positions with various local conditions, we combine some related parameters to capture not only the trajectory of the damage sites inside the volume of the sample, but also the relative local stress-strain distribution condition.

MM 20.5   Tue 15:15   SCH A 216

Experimental and computational crack growth analysis under in-phase and out-of-phase thermo-mechanical fatigue — •Valery Shlyannikov, Aleksandr Sulamanidze, and Dmitry Kosov — Kazan, Russia

This study presents interpretation and evaluation of non-isothermal experimental crack growth data generated by tests carrying out by stress-controlled in-phase (IP) and out-of-phase (OOP) thermo-mechanical fatigue (TMF) conditions. A crack growth testing method has been developed utilizing inductive heating and direct the crack tip opening displacement (CTOD) techniques for polycrystalline XH73M nickel-based alloy. The crack growth experimental results interpretation is based on finite element analyses of the mechanical stress-strain rate fields at the crack tip and new fracture resistance parameters. To this end, an algorithm for multi-physics numerical calculations was developed and implemented by incorporating Maxwell 3D, Fluent, and the transient structural modules of ANSYS 2021R1, to understand the mechanics of crack tip deformation under thermo-mechanical loading conditions. Fatigue fracture diagrams build in terms of new crack growth parameters have shown that in-phase testing produces accelerated crack growth rates compared with out-of-phase due to increased temperature at peak stress and therefore increased time dependent crack growth.

MM 21: Materials for Storage and Conversion of Energy: Energy Conversion

Time: Tuesday 14:15–15:30   Location: SCH A 215

MM 21.1   Tue 14:15   SCH A 215
Harvesting of low-grade waste heat with shape memory alloys — •Bruno Neumann[1,2] and Sebastian Fähler[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf — [2]Technische Universität Dresden
More than half of all energy converted by humankind is lost in the form of waste heat. Not only does that strongly contribute to the acceleration of global warming, it also leaves an enormous economic potential untouched. However, suitable technologies are limited, since most of this heat is of low temperature ($< 100\,°C$). In the last years, materials and technologies for thermoelectric harvesting and thermomagnetic harvesting have been explored, but a high efficiency of those systems remain a challenge. With our work, we present a thermoelastic harvesting approach for converting the waste heat of a fluid into electricity, utilizing shape memory alloy wires. These wires bring the inherit advantage that their transformation temperatures can be adapted to the required temperature range of the waste heat. Moreover, they provide a very high actuation energy density and are commercially available. In our set-up, we use two mechanically connected arrays of wires to reach a high power density of the system. Our simulation data predicts a thermodynamic efficiency in respect to the Carnot efficiency of 22.7 %, which exceeds current efficiency benchmarks set by thermoelectric materials.

MM 21.2   Tue 14:30   SCH A 215
Atomistic simulations of the Seebeck effect in electrolytes — •Ole Nickel[1], Mathijs Janssen[2], and Robert Meissner[1] — [1]Hamburg University of Technology, Hamburg, Germany — [2]University of Oslo, Oslo, Norway
The Seebeck effect allows electrical energy to be obtained directly from thermal gradients. In electrolytes it is based on an different heat of transport of the ions.

We perform molecular dynamic simulations with different electrolytes between graphene electrodes. We apply an external resistance between the electrodes via a thermopotentiostat, where the thermal fluctuation term is deactivated, effectively resembling an RC-circuit with a time constant of τ=RC.

With this method it is possible to simulate a complete electrochemical cell in open circuit conditions which is charged with a thermal gradient and then discharged at constant temperature. The Seebeck energy is the energy that is dissipated across the external resistance. The goal is to investigate optimal electrolyte parameters to maximize this energy.

MM 21.3   Tue 14:45   SCH A 215
Non-Local DFT calculations towards the discovery of stable water-splitting catalysts — •Akhil S. Nair, Lucas Foppa, Evgeny Moerman, and Matthias Scheffler — The NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft and IRIS-Adlershof of the Humboldt-Universität zu Berlin, Germany
Efficient prediction of the thermodynamic and aqueous stability of materials is essential for leveraging the catalyst discovery for the water splitting reaction. In particular, the oxygen evolution half-reaction is usually carried out using oxide catalysts under harsh potential and pH conditions.[1] This necessitates the application of DFT methods which can predict the oxide stability under experimentally relevant conditions without any *ad hoc* corrections.[2] In this regard, herein, we employ a non-local DFT method using the hybrid HSE functional for calculating the stability of oxide catalysts. Crucially, we scrutinize the effect of the HSE mixing parameter on the formation energies and aqueous stability of oxides and compare to higher-level calculations using coupled-cluster theory for reference systems. Through this approach, we attempt to standardize the application of HSE method for accurate oxide stability prediction which could augment the large-scale catalyst discovery.

MM 21.4   Tue 15:00   SCH A 215
Photocatalytic water splitting from Koopmans spectral functionals: The case of TiO_2 polymorphs — •Marija Stojkovic[1], Edward Linscott[1], and Nicola Marzari[1,2] — [1]Theory and Simulations of Materials (THEOS), and National Centre for Computational Design and Discovery of Novel Materials (MARVEL), École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland — [2]Laboratory for Materials Simulations, Paul Scherrer Institut, 5232 Villigen PSI, Switzerland
Photocatalytic water splitting has drawn considerable attention for renewable energy production. Since the first reported photocatalytic water splitting by titanium dioxide, this material remains one of the most promising photocatalysts, due to its suitable band gap and band-edge positions. However, estimating both of these properties is a challenging task for standard DFT functionals. Here we show how Koopmans spectral functionals can accurately predict the band structure and level alignment of rutile, anatase and brookite, demonstrating the advantage of orbital-density dependent functionals for predicting the spectral properties of materials.

MM 21.5   Tue 15:15   SCH A 215
DFTB Description of the Ground and Excited States Properties of Thiolate Protected Gold Nanoclusters — •Carlos R. Lien-Medrano[1], Arnaud Fihey[2], and Thomas Frauenheim[1] — [1]University of Bremen, Bremen, Germany — [2]University of Rennes, Rennes, France
Gold nanoclusters stand as promising building blocks for solar energy harvesting applications, luminescent materials and catalytic devices. At the frontier between molecular and metallic structures, their large number of electrons prevent the use of *ab intio* quantum mechanic method to rationalize and predict their structure-property relationships, especially when fully coated with organic ligands. Using a semi-empirical DFT-based scheme, namely Tight-Binding Density Functional (DFTB), we demonstrate that is possible to rapidly access the ground (geometry and electronic structure) and excited state (UV-Visible absorption) properties of these nano-objects without sacrificing the qualitative accuracy of its parent DFT, paving the way towards a quantum material design of gold-organic nano-devices.

MM 22: Mechanical Properties and Alloy Design: Porous and Nanostructured Materials

Time: Tuesday 14:15–15:45   Location: SCH A 118

MM 22.1   Tue 14:15   SCH A 118
tailoring mechanical properties of lightweight 1D Nanostructures — Samuel Baltazar[1,2], Javier Rojas[1,2], •Felipe Valencia[2,3], Sebastian Allende[1,2], Rafael Gonzalez[2,4], Eduardo Bringa[5], and Pierre Cocco-Magnard[2] — [1]Physics Department, Universidad de Santiago de Chile, Chile — [2]Center for the development of Nanoscience and Nanotechnology, Universidad de Santiago de Chile, Chile — [3]Engineering Faculty, Universidad Catolica del Maule, Chile — [4]Centro de Nanotecnología Aplicada, Universidad Mayor, Chile — [5]CONICET & Facultad de Ingeniería, Universidad de Mendoza, Argentina
1D Nanostructures such as nanowires (NW) and nanotubes (NT) have gained a lot of attention due to their mechanical and electronic properties. The deformation of NT and NW has been previously studied, finding different fracture mechanisms. Tension and compression deformations show elastic regimes until a sudden stress drop due to the fast generation of dislocations. Synthesis of polycrystalline NW allows the reinforcement of the material's response. We report the mechanical properties are studied for mono and bimetallic systems by means of molecular dynamics simulations. Interatomic potentials were used to model Ni, Fe, and bimetallic NTs and NWs with dimensions similar to the experimental setup. Ni NT shows an asymmetry in the stress response under tension and compression, mediated by twins and stacking-faults dislocations, with no signif-

icant degradation of mechanical properties up to 60% mass reduction than NW, opening the generation of new lightweight and resistant materials.

MM 22.2   Tue 14:30   SCH A 118

Comparing structural response of filled and porous 3D Titanium network structures by application of nanotomography and graph theory — •Stefan A. Berger[1], Markus Ziehmer[1], and Jürgen Markmann[1,2] — [1]Helmholtz Zentrum Hereon — [2]Technische Unoversität Hamburg

Recently, refinements of the classical Gibson-Ashby relation have been invoked to extend its applicability to the description of the mechanical properties of bicontinuous, nanoporous metals. In particular, the network connectivity has been identified as a crucial parameter that needs to be taken under consideration. So far, global parameters like connectivity or genus (density) have been employed, However, these do not uniquely identify the underlying microstructure. This can be achieved by making use of graph theoretical aspects, as demonstrated in Ziehmer et al[1]. In this work, we have investigated the changes in the network structures of porous Titanium and Ti-Mg composites, fabricated by Liquid Metal Dealloying, during compression tests in a x-ray nanotomograph. The reconstructed sample volumes were simplified by skeletonization, the resulting skeletons transferred into a weighted graph representation, and further decomposed into the constituent rings that built the network. This approach allowed for a statistical description of the behavior of the ring elements under load. One major result is that the essential part of deformation is carried by larger rings. [1] M. Ziehmer, E. T. Lilleodden, Acta Materialia 199 (2020).

MM 22.3   Tue 14:45   SCH A 118

Hierarchical-structural effects on mechanical behavior of nanoporous gold in electrochemical environment — •Hansol Jeon[1], Shan Shi[3,1], and Jürgen Markmann[1,2] — [1]Institute of Materials Mechanics, Helmholtz-Zentrum Hereon, 21502 Geesthacht, Germany — [2]Institute of Materials Physics and Technology, Hamburg University of Technology, 21073 Hamburg, Germany — [3]Research Group of Integrated Metallic Nanomaterials Systems, Hamburg University of Technol-ogy, 21073 Hamburg, Germany

Recently, hierarchical nanoporous gold (HNPG) has been emerged with having multiple-level structures. HNPG is more active because of higher surface area than nanoporous gold (NPG) since Au ligaments are supposed to be converted into another porous structure with smaller ligaments and pores. Regarding mechanical behavior, especially with the same solid fraction for both, it has been not directly compared yet whether HNPG would have better me-chanical properties. Here, we investigated the mechanical properties of NPG and HNPG with the same solid fraction by conducting compressive tests at the micro-scale. The NPG and HNPG were prepared from the same precursor alloy Ag85Au15 by dealloying. The pillars were milled by a focused ion beam (FIB), and compressive tests were performed by a nanoindenter with a flat-punch tip. We discussed the difference of dislocation activities and connectivity for NPG and HNPG. Finally, by conducting additional compressive tests in an electrochemical environment, we explored the role of surface state on the mechanical behavior of NPG and HNPG by impos-ing electrode potential.

MM 22.4   Tue 15:00   SCH A 118

Mechanical properties and oxidation performance of nanostructured self-passivating WCrY material — •Jie Chen[1], Andrey Litnovsky[1], Jesus Gonzalez-Julian[1,2], Jan Willem Coenen[1], and Christian Linsmeier[1] — [1]Forschungszentrum Jülich GmbH, Institut für Energie- und Klimaforschung - Plasmaphysik, 52425 Jülich, Germany — [2]Institute of Mineral Engineering, RWTH Aachen University, 52074 Aachen, Germany

Self-passivating W-11.4wt%-0.6wt%Y alloy have been considered as a promising plasma-facing material in fusion power plants. In the present work, bulk material are fabricated via holding at 1300C for 2 minutes in field-assisted sintering. As a result, an average matrix's grain size of 98.9nm and 6.7% surface

area of Cr-rich phase was obtained. Cr-rich phase is formed on the surface of particles during sintering and over 70 at% of Cr is detected by EDX. A hardness HV0.5 of 1287.6 is obtained as a result of small grains while a fraction of Cr-rich phase in the microstructure softens material to some extent. Three point bending tests at temperature up to 1000C are performed to measure fracture toughness and ductile brittle transition temperature. This is done combining with fractography study to investigate the effect of grain size as well as Cr-rich phase on the thermo-mechanical properties. Reduction in grain size down to the order of sub-micrometer range is proven to improve material's anti-oxidation performance in previous study. Oxidation test was performed at 1000C to investigate performance of the microstructure developed. Details of the work are presented in this contribution.

MM 22.5   Tue 15:15   SCH A 118

Study of the oxidation mechanism of Cr_2AlC MAX phase through nanoscale analysis of alumina scale formation — •Anicha Reuban[1,2], Jesus Gonzalez-Julian[1,2], Ivan Povstugar[1], Andrey Litnovsky[1], and Christian Linsmeier[1] — [1]Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — [2]Institute of Mineral Engineering, RWTH Aachen University, 52074 Aachen, Germany

In a Concentrated Solar Power (CSP) plant, the receiver must withstand temperatures >800 °C, be resistant to oxidation by air and/or corrosion by molten salts and maintain its properties over time. MAX phases, which are ternary carbides and nitrides with a unique combination of ceramic and metallic properties, are candidate materials for the receiver. In this work, the oxidation mechanism of the alumina-forming MAX phase Chromium Aluminium Carbide (Cr_2AlC) is studied. The samples are oxidized in a thermogravimetric analyzer (TGA) at 1000 °C and 1200 °C in humid air. The oxide scale is characterized using XRD, FIB-SEM, EDX and STEM. The alpha alumina layer formed consists of needle-like grains on top, with larger grains at the bottom, below which is a layer of chromium carbide. The elemental distribution across grain boundaries and interfaces of various regions of the oxide scale, carbide and bulk material are being analyzed with Atom Probe Tomography (APT), since these are possible pathways for the diffusion of aluminium and oxygen ions to form the oxide layer. The effect of dissolved chromium in the oxide scale and the segregation of impurities such as iron and silicon to interfaces is examined.

MM 22.6   Tue 15:30   SCH A 118

Phase stability of iron and its alloys from first principles dynamical simulations and thermodynamic integration — •Davide Gambino and Björn Alling — Linköping University, Linköping, Sweden

In recent years, thermodynamic integration (TI) based on first principles simulations has been shown to accurately reproduce phase diagrams and is now able to guide the design of functional materials and alloys. For what concerns iron and steels, this methodology is complicated by the presence of magnetic degrees of freedom (DOF) and their interplay with electronic and vibrational DOFs. Here I will show how the phase stability of iron and its alloys can be obtained from first principles employing atomistic spin dynamics - ab initio molecular dynamics (ASD-AIMD) simulations and TI accounting for all DOFs [1].

The free energy difference between bcc and fcc Fe was calculated close to the melting point in the magnetically disordered state, carrying out TI over stress-strain variables along the Bain path, and then propagating it to low temperatures with TI over temperature employing the ASD-AIMD energies. The method captures the $\alpha \to \gamma \to \delta$ transitions, with the latter transition temperature reproduced within 50 K from experiments, and the calculated Gibbs free energy difference being within 5 meV/atom from the CALPHAD estimate over the whole temperature range. The method is then applied to $Fe_{1-x}Mn_x$ alloys for concentrations of $x = 0.05, 0.10$ and for temperatures T ≥ 1400 K and results are compared with the experimental phase diagram.

MM 23.1   Tue 18:15   P2/OG1+2

(ZnO) 42 Nanocluster: A Novel Visibly Active Magic Quantum Dot under First Principle Investigation — •Bijal Mehta and Debesh Roy — Materials and Biophysics Group, Department of Physics, Sardar Vallabhbhai National Institute of Technology, Surat 395007, India.

A systematic density functional investigation on the structural, electronic and optical properties of the growth of (ZnO) 6 cluster unit in the series of (ZnO) 6n for n=1*9 is performed in this report. Different electronic properties of (ZnO) 6n nanoclusters are analyzed in terms of HOMO-LUMO gap (HLG), ionization potential (IP), electron affinity (EA), chemical hardness (η), and electrophilicity index (ω) which all shows a zigzag behavior as the size of (ZnO) 6n clusters increases. The clusters' electronic energy gain (*E) identified an exceptionally sta-

ble *magic* nanocluster, viz. (ZnO) 42. Frontier orbitals analysis results indicate easy electron transfer in (ZnO) 42 nanocluster system. The optical absorption spectra confirm that the magic (ZnO) 42 nanocluster is active in electromagnetic radiation's visible range (λ=406.8 Å). Interestingly, similar optical switching towards the growth of (ZnO) 6 unit is also observed like zig-zag electronic properties. The simulation results of electronic properties as well as the infrared spectra of magic (ZnO) 42 cluster will open up a vista to the experimentalists for its possible synthesis, which in turn will help in the development of the visibly active magic (ZnO) 42 nanocluster with novel applications in the fields of quantum dots or assembled materials.

MM 23.2   Tue 18:15   P2/OG1+2

Investigation of the stability for AlB$_2$-type transition metal diborides from electronic structure — •Nebahat Bulut and Jens Kortus — TU Bergakademie Freiberg, Institute of Theoretical Physics, Germany

Boron has huge chemical bonding diversity (metallic, ionic, and covalent bonds) because it provides fewer valence electrons compared to the number of orbitals it can form. Not surprisingly, intermetallic borides can crystallize in many different crystal symmetries, for example cubic, hexagonal or orthorhombic. The unit cell of the hexagonal AlB$_2$-type has two trigonal prisms in which borons are in the center surrounded by six metal atoms. Interestingly, not all twenty eight transition metals form the AlB$_2$-type crystal structure. The goal of the study is to understand the chemical bonding nature in detail in order to answer why some of these compounds are stable in AlB$_2$-type structure while others are not. We investigate the impact of the d-orbitals of the transition metals on the stability in order to provide a guideline to possible new transition metal diborides. The chemical bonding and charge transfer in these transition metal diborides is investigated by electronic structure calculations based on density functional theory as implemented in Quantum Espresso [1]. The study is focused on the analysis of the electron density together with the electron localization function (ELF) and provide thermodynamic information e.g. formation enthalpies, and mechanical properties.

Trapping and detrapping of excess vacancies during natural ageing in Al-Cu — •Tobias Stegmüller, Johannes Berlin, Andreas Schuss, and Ferdinand Haider — University of Augsburg, Chair for Experimental Physics I, Universitätsstr. 1, 86159 Augsburg

A special feature of Al-Cu alloys is the occurrence of decomposition in supersaturated solid solutions by the formation of Guinier-Preston zones (GPZ) even at ambient temperature, where the equilibrium diffusion coefficient is far too low for any unmixing. A condition for this natural ageing is the existence of excess vacancies which remain in the material after quenching from the homogenisation temperature. As the ageing process proceeds for surprisingly long times (hours or days), the vacancies seem to be stabilised in the material and do not decay to the equilibrium value, which would stop the ageing.

Although there exist theories on the stabilisation of excess vacancies, there is no established and verified model to explain the effect. To illuminate the mechanisms behind the long term formation of GPZ we combine results from TEM and DSC measurements as well as Monte Carlo, molecular static and DFT simulations, which reveal that the GPZ themselves may act as temporal vacancy traps. Values for the trapping energy for vacancies in GPZ and on dislocations are estimated from simulations.

MM 23.4   Tue 18:15   P2/OG1+2

Proof of concept for micro pulling down growth of phase change materials in the example system of NiTi — •Lauritz Schnatmann, Timon Sieweke, and Gabi Schierning — University of Bielefeld

The micro pulling down growth method (mPD) is a common approach to synthesize small crystals for material screening in e.g. high-entropy oxides. Another interesting group of materials are phase change materials namely showing unique structural transitions interplaying with electronic and magnetic contributions. However, the interplay between the different contributions is strongly dependent on the composition of materials. We built up a micro pulling down set up for fast material screening of phase changing materials. We grew a NiTi-shape memory alloy to show the possibility of comparable easy growth of crystals by mPD. Hereby, we verified mPD as a powerful tool for the versatile fabrication of small crystals in the field of phase change materials.

MM 23.5   Tue 18:15   P2/OG1+2

The role of electrons during the martensitic phase transformation in NiTi-based shape memory alloys — •Alexander Kunzmann[1], Jan Frenzel[2], Ulrike Wolff[3], Jeong Woo Han[4], Lars Giebeler[3], David Piorunek[2], Martin Mittendorf[4], Juliane Scheiter[3], Heiko Reith[3], Nicolas Perez[3], Kornelius Nielsch[3,5], Gunther Eggeler[2], and Gabi Schierning[1] — [1]Bielefeld University — [2]Ruhr University Bochum — [3]IFW-Dresden — [4]University of Duisburg-Essen — [5]TU Dresden

The present work provides an experimental contribution to the investigation of the role of conduction electrons in the martensitic phase transition of Nickel-Titanium. This material, which is structurally very well studied due to its shape memory effect, still offers room for further knowledge more than 60 years after its discovery. For this purpose, a series of alloys within the equiatomic NiTi phase was characterized by temperature-resolved transport experiments, thermodynamic characterizations and structural investigations. In addition to the well-known resistivity anomaly, a reduction of the charge carrier density by 90% was measured, which has not been described before for this class of materials. Using a novel approach for structural materials, conclusions could be drawn about the entropy of the electronic system and a correlation with the phase transition temperature could be demonstrated. The obtained data allow an interpretation as the

formation of a charge carrier density wave phase, which explains both the drastic reduction of charge carriers and the large electronic entropy contribution.

MM 23.6   Tue 18:15   P2/OG1+2

developing high-hardness, high-electrical conductivity and gradient structure of bulk Al-2.5Fe alloy by a new severe plastic deformation: high pressure torsion extrusion — •Rui Xu — Institute of Nanotechnology, Karlsruhe Institute of Technology, Germany

The effect of High Pressure Torsion Extrusion (HPTE) on microstructure, hardness and electrical conductivity has been investigated in the bulk Al-2.5Fe alloy. The equivalent strain accumulated in the samples after one pass of HPTE varied in a wide range between 0.9 and 24.8, depending on the processing parameters. HPTE led to the formation of a gradient microstructure in which the grain and Al6Fe intermetallic size decreased by increasing the distance from the central axis of the samples. With increasing the equivalent strain, which is below 5.7, the microhardness and the electrical conductivity simultaneously increased, from 53.7 HV to 87 HV, from 38% IACS to 47% IACS respectively. This can be attributed to the grain size and Al6Fe intermetallic size decreased. When the equivalent strain gradually increased to 24.8, the microhardness continuously increased from 87 Hv to 126 Hv, the electrical conductivity decreased from 47% IACS to 43% IACS. This is contributed to the grain and Al6Fe intermetallic transformed into nanometer size, which significantly increased the microhardness, and some Fe atoms into Al matrix, which decreased the electrical conductivity. The High Pressure Torsion Extrusion process can lead to gradient microstructure and simultaneously increase the microhardness and the electrical conductivity of bulk Al-2.5Fe alloy..

MM 23.7   Tue 18:15   P2/OG1+2

In situ XRD measurements of a Si Li half battery cell — •Leonard Aue, Frederik Stender, Thomas Brede, and Cynthia Volkert — Georg-August-Universität Göttingen, Deutschland

Li-ion batteries have become an indispensable part of modern life. They enable the repeated storage of energy on a medium and small scale, for example in electric vehicles or mobile devices.

In addition to the commonly used graphite, silicon is gaining increasing attention as a suitable anode material due to its higher capacity. However, this capacity decreases rapidly in application and a significant increase of the internal resistance occurs. Both are mainly caused by the large volume changes during lithium uptake and release.

In this work, we investigate the amorphization process that first starts during loading in in-situ XRD measurements of Si-Li composite materials in a half-battery setup. This will give us insight into Si phase changes under direct control of critical parameters such as charge or discharge rates. This knowledge could help to understand and control the phase transformations and thereby improve Si anode performance.

MM 23.8   Tue 18:15   P2/OG1+2

High capacity thin film battery electrodes from lithium titanate — Yijie Tao, •Yug Joshi, and Guido Schmitz — Chair of Materials Physics, Institute of Materials Science, University of Stuttgart, 70569 Stuttgart, Germany

Lithium titanium oxide is becoming an increasingly popular anode material for high-power Li-ion batteries due to their safe operating voltages and high cycle lifetime. The motivation to enhance the specific capacity of Li4Ti5O12 (LTO) is of practical significance. In this work, reactive ion beam sputtering is used to deposit the titanium-based metal oxide thin films. A Li2CO3 modification is introduced by mixing it with LTO and using the composite as a target material. The deposition conditions (i.e., reactive oxygen) and annealing treatment (i.e., under air or vacuum at varying temperatures) are explored to optimize the thin films for the best possible capacity. X-ray diffraction (XRD), X-ray photoelectron (XPS) and electron diffraction (TEM) are used to unravel the chemical and structural nature of the thin films. The films were electrochemically characterized using cyclic voltammetry with a broad potential window, much wider than conventional LTO (i.e., 2.5V to 0.1 V vs Li/Li+, whereas conventional electrode is generally limited to a lower voltage of 1V). The optimised film shows good cyclic stability at a relatively high rate of 1 mV/s and show an astounding maximum capacity of 101.4 μAh*cm-2*μm-1 after 50 cycles. To put this in context, conventional LTO shows theoretically 60.8 μAh*cm-2*μm-1 and 91 μAh*cm-2*μm-1 when cycled down to 1 V and 0.1 V vs Li/Li+, respectively.

MM 23.9   Tue 18:15   P2/OG1+2

high-rate and long-duration Sodium Storage Enabled by Sodiation-Driven Reconfiguration — •Yulian Dong, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Vanadium sulfides, with various crystal structures, such as VS2, V2S3, V3S4, V5S8, and VS4 have attracted increasing attention because they could provide high theoretical specific capacity. Nevertheless, such vanadium-based sulfides frequently suffer significant mechanical pulverization during long-term cycling as a result of volume expansion caused by sodization/desodization, which result

in severe irreversible capacity degradation, poor initial coulombic efficiency, reduced rate capability, and inappreciable cycling stability. Here, we demonstrate a carbon-free 3D micro-nano flower-like VSx heterostructure electrode material that is synthesized by a facile hydrothermal process for SIB applications. The 3D micro-nano flower-like structure can well prevent the accumulation of nanosheets during electrochemical cycles and ensure full contact between the active material and the electrolyte. Therefore, 3D micro-nano flower-like VSx electrode that finally achieves an ultrahigh-rate capacity (613.8 mAh/g at 10 A/g) and an ultra-long cyclability (more than 1500 cycles) by sodiation-driven reconfiguration for sodium ions batteries. This work presents a general approach for preparing super-high specific capacity and rate capacity electrode materials for further improving the SIBs performance.

MM 23.10   Tue 18:15   P2/OG1+2
Detection of Lithium in potential electrode materials — •Patrick Kirscht and Hans Hofsäss — II Physikalisches Institut, Georg August Universität, Göttingen, Deutschland

Nuclear reaction analysis is used to quantify light elements such as lithium in a sample. The advantage of NRA is the isotope specific measurement of elements in a sample. In the current investigations we demonstrate the detection limits and sensitivity of a new setup for the detection of lithium via its nuclear reaction with protons p(7-Li,alpha)alpha with Q=17MeV. For this purpose an external proton beam with 2.5MeV is used. To determine the detection limit, lithium was implanted into silicon and ta-C near the surface by ultra-low energy ion implantation at 100eV. Furthermore, the depth profile and penetration depth were simulated using Imintdyn and SRIM and were compared with the measurements. For the measurement of diffusivity of lithium, the samples were baked at different temperatures. For comparison, MD simulation was performed using LAMMPS. These investigations are the starting point of measurements on graphene and biological materials like wood, which are considered for possible applications as electrode materials in batteries.

MM 23.11   Tue 18:15   P2/OG1+2
High-resolution measurement of displacement field from gold nanoparticules tracking — •Antoine Ollivier, Nicholas Blanchard, Antonio Pereira, Loïc Vanel, and Döme Tanguy — Institut Lumière Matière-UMR 5306, Université Claude Bernard Lyon 1, 6 rue Ada Byron, 69622 Villeurbanne cedex

A new method has been developped to measure displacement field during a tensile test with both high resolution (~ 50 nm) and good precision (~ 1nm). This method has been applied on the reduced activation ferrito-martensitic steel Eurofer97. Gold nanoparticules are created by pulsed-laser induced dewetting of a nanofilm. This technique does not modify the structure of the steel below. Nanoparticules are then observed with a scanning electron microscope during tensile test. Their tracking allows to see displacement field *in situ*. This method is particularly adapted for locating heterogeneities in the displacement field and it could be very useful to understand how fracture appears.

MM 23.12   Tue 18:15   P2/OG1+2
Electronic Properties of Self-assembled 1D Gold Nanoparticle Chains — •Stefan M. Schupp[1], David J. Schupp[2], Emil Schwarz[2], Rebecca Köser[2], Helmut Cölfen[2], and Lukas Schmidt-Mende[1] — [1]Department of Physics, University of Konstanz, Germany — [2]Department of Chemistry, University of Konstanz, Germany

1D nanoparticle (NP) assemblies exhibit unique electronic properties due to their directional charge transport. In addition, the usage of stabilizing ligands enables a further possibility to add new functionalities and tune their conductivities. However, the assembly and characterization of 1D NP chains remains a challenge to this day. Here, we present a study on thiol-induced dipoles on gold (Au) nanoparticle surfaces which result in chain-like assemblies in solution under ambient conditions. Thereby, 1D assemblies of 40 nm Au-NPs with different shapes and thiolated ligands could be achieved. Afterwards, a developed transfer technique allows the electrical characterization of individual 1D NP chains through prefabricated gold electrodes. In this configuration, the temperature-dependent resistance of different NP assemblies is investigated to understand the underlying conduction mechanisms. With the gained knowledge it should be possible to generate 1D Au NP chains with controllable electronic conductivities for future applications.

MM 23.13   Tue 18:15   P2/OG1+2
Local hydrogen absorption in Pd nanoparticles observed with in-situ TEM — •Svetlana Korneychuk[1], Stefan Wagner[1], Georgian Melinte[2], Darius Rohleder[3], Phillipp Vana[3], and Astrid Pundt[1] — [1]Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]King Abdullah University of Science and Technology, Saudi Arabia — [3]Institute of Physical Chemistry Georg-August-University Göttingen, Göttingen, Germany

The mechanism of the hydrogen absorption in metals is of a high interest for many areas of hydrogen technology, such as hydrogen storage, hydrogen detection and catalysis. Palladium is an ideal model system to study hydrogen absorp-

tion in metals due to its extreme affinity to hydrogen. Nanoscale systems, such as nanoparticles and thin films, are of the high interest to hydrogen technology due to their faster interaction with hydrogen. In this work, we investigate the behavior of a model system, Pd nanoparticles, in real time with in-situ H2-gas TEM. With the special gas holder from Protochips it is possible to reach pressures up to 1 atmosphere and study the particles at elevated temperatures within the stability limit of the nanoparticles up to 200°C. We can observe initial stages of hydrogen absorption in Pd nanoparticles and local formation of PdHx at different temperatures and pressures by using EELS. We support our observations with the in-situ strain measurements carried out with nanobeam electron diffraction. Finally, we propose a mechanism of hydrogen absorption in metallic nanoparticles based on the local PdHx formation and strain measures at different loading conditions.

MM 23.14   Tue 18:15   P2/OG1+2
Investigation of the MoS$_2$ crystallization process in thin films — •Annika Korn, Thomas Brede, and Cynthia A. Volkert — Institut für Materialphysik, Göttingen, Germany

Crystalline transition metal dichalcogenide thin films show interesting potential in various application areas (e.g. optoelectronics and data storage). Crystallization of amorphous sputtered thin films is one way to produce large crystalline regions suitable for the application [1]. The aim of this work is to follow the structure of the thin films over the course of crystallization and to characterize them in different intermediate states. In this way, the process and properties of the transition can be studied and better understood. Specifically, various methods (XRD, SEM, EDX, XPS, AFM, TEM) will be used to analyze the microstructures and compositions of the samples. In addition, DSC and TGA will be used to directly measure the crystallization and possible decomposition processes.

[1] Krbal, Milos, et al.: Amorphous-to-Crystal Transition in Quasi-Two-Dimensional MoS2: Implications for 2D Electronic Devices. In: ACS Applied Nano Materials 2021 4 (9), 8834-8844. DOI: 10.1021/acsanm.1c01504

Towards measuring fatigue-generated vacancies in thin copper films using nanoindenter creep tests — •My Nguyen, Thomas Brede, Jan Verhoeven, and Cynthia Volkert — Institute for Materials Physics, Georg-August University of Göttingen

Vacancies can be created in metals during cyclic loading, however, they have been only rarely directly detected. In this study, we develop an experimental set-up to detect fatigue generated vacancies by measuring their contribution to creep deformation. Our methodology involves performing nanoindenter creep tests on thin metal films while they are being fatigued by cyclic loading. The fatigue is realized using delay line structures, with thin copper films on top, on which standing surface acoustic waves are generated. Contributions from thermal drift during the creep tests have been minimized using a continuous stiffness measurement method.

MM 23.16   Tue 18:15   P2/OG1+2
Optical Modulation and Phase Distribution in LiCoO2 upon Li-ion De/Intercalation — Sanaz Banifarsi, •Yug Joshi, Robert Lawitzki, Gábor Csiszár, and Guido Schmitz — Chair of Materials Physics, Institute of Materials Science, University of Stuttgart, 70569 Stuttgart, Germany

The optical modulation of sputter deposited thin-films of LiCoO2 upon de-/lithiation is probed in reflectance geometry. The thin-films of LiCoO2 (LCO) are sputter-coated using ion-beam sputtering, onto mirror-like platinum current collectors. A reversible electrochemical and electrochromic behavior is obtained from the in-operando electrochemical and optical measurements. The optical constants (using ex-situ optical spectroscopy) are obtained by modelling the obtained spectra using Clausius-Mossotti relation. The model parameters reveal a dominant resonant wavelength at 646 nm for the fully intercalated LCO. For the delithiated state, Li0.5CoO2, a much broader and more intense absorption peak is obtained. This broad and intense peak is correlated to the conducting nature of the delithiated state. The obtained complex refractive index (CRI) are justified by prior reported calculations of the density of states. With the evolving CRI, the variation in the imaginary and real part of the dielectric constant is understood by a layered phase propagation. This is due to (i) the faster diffusion between the layers of CoO6 octahedra of the layered structured LCO and, (ii) the alignment of these octahedral planes almost perpendicular to surface of the electrode as a result of the identified growth texture (due to the deposition and the subsequent annealing).

MM 23.17   Tue 18:15   P2/OG1+2
Simulations of two-dimensional amorphous materials based on force fields and ab initio calculations — •Emel Gurbuz and Biplab Sanyal — Uppsala University, Uppsala, Sweden

In recent times, low dimensional crystalline structures and van der Waals(vdW) solids have attracted a lot of attention for their huge potential in device applications.However, the exploration of two-dimensional(2D) amorphous forms is less explored. Here, we present a detailed study of structural, electronic and thermal properties of 2D amorphous graphene(A-Gra), silicene(A-Si) and sil-

icon carbide(A-SiC) by Classical Molecular Dynamics (CMD) simulations for structure generation, stability tests, thermal conductivity and vibrational analysis along with density functional theory (DFT) calculations for the electronic structure.We find that A-Gra is planar and metallic with a thermal conductivity around 55.30 W/Km whereas the monolayer A-Si has a much lower thermal conductivity (2.68 W/Km). Among our studied materials, A-SiC's thermal conductivity is found to be the highest (70.29 W/Km).Vibrational analysis shows that the heat carriers in A-Si and A-SiC are extendons, especially diffusions in the absence of localized vibrational modes. Bilayer and trilayer structures of amorphous structures resulted respectively, in vdW bonding of A-Gra layers; covalent bonding of A-Si layers and weak bonding of SiC layers through only Si atoms. Finally, the observed uneven charge distributions can lead to the designing future electronic devices by tuning the local functionalities of 2D-amorphous structures.

Effect of micro-alloying and structural relaxation on the nanoindentation behavior of Pd-based metallic glasses — •Richard von Destinon, Martin Peterlechner, and Gerhard Wilde — Institut für Materialphysik, Westfälische Wilhelms-Universität Münster, Münster, Germany

Two methods rising in interest to modify the mechanical properties of metallic glasses consist of micro-alloying as well as relaxation. We study the influence of structural relaxation and 1 at.% additions of Fe or Co on the well-researched metallic glass $Pd_{40}Ni_{40}P_{20}$. The relaxation states are created by quenching from temperatures above T_g with different cooling rates. The samples are analyzed using nanoindentation with force ranges up to 1 mN. Correlations between the change in mechanical properties, such as hardness and young's modulus, and the shear deformation behavior through the pop-in distribution are investigated in detail. The results indicate that both, micro-alloying and relaxation increase the hardness of the material significantly, while the pop-in frequency remains insensitive to either.

Orientation-tunable Rod-shaped Liquid Crystal Under Surface Acoustic Wave — •Zhuoqing Li[1], Pai Zhao[1], Patrick Huber[2], and Robert Blick[2] — [1]TU Hamburg Institut für Material- und Röntgenphysik, Hamburg, Germany — [2]Center for Hybrid Nanostructures, University of Hamburg, Hamburg, Germany

Surface acoustic waves (SAW) are widely used in both industry and science, while liquid crystals are unique fluids exhibiting long-rang order and self-organization. In this work, a combination of SAW and rod-shaped nematic liquid crystals will be studied to explore the tunablility of liquid crystal orientations under SAW. Surface acoustic waves are introduced into miniatured solid-state devices on piezoelectric LiNbO3 substrates by interlocking metallic gates called interdigitated transducers (IDT). When a high-frequency sinusoidal signal is applied to the IDT, a mechanical deformation wave will propagate along the surface of the substrate and the induced shear strain will influence the orientation of the nematic liquid crystals on the surface of the substrate. A feature of the nematic phase is that the anisotropic rod-shaped molecules are collectively orientated in preferred directions. Considering the optical anisotropy of rod-shaped liquid crystals, the collective orientation change of liquid crystal molecules under SAW can be analyzed through birefringence measurements. By studying the tunability of the liquid crystal orientation under SAW induced shear component of the wave, we will be able to develop a novel wireless LC-based optical modulator controllable by acoustic stimuli.

MM 23.20   Tue 18:15   P2/OG1+2

Strain-coupled polar textures in ferroelectric nanocylinders — •Svitlana Kondovych[1] and Igor Lukyanchuk[2] — [1]Institute for Theoretical Solid State Physics, IFW Dresden, 01069 Dresden, Germany — [2]Laboratory of Condensed Matter Physics, University of Picardie, 80039 Amiens, France

We consider ferroelectric $PbTiO_3$ nanocylinders of various size hosting strain-coupled polarization vortices. Depending on the cylinder height and radius, the polarization either swirls around the c-oriented cylinder axis (c-vortex) or falls into the state with the a- or b-oriented vortex core (a-vortex). The emergence of vortices occurs due to the competition of elastic and electrostatic interactions and complies with the Arnold theorem for divergenceless vector fields, which exist as two types of topological excitations, either vortices or Hopfions [2]. In $PbTiO_3$ cylinders, we observe the geometry- and temperature-induced vortex axis rotation and corresponding transition between the c- and a-vortex states. The resulting phase diagram, obtained by phase-field modeling in line with analytical calculations, illustrates the variety of polar textures in nanocylinders, applicable for the efficient design of ferroelectric-based device components.

Tuning porous silicon's pore geometry and its influence on laser-excited guided waves — •Marc Thelen[1], Nicolas Bochud[2], Manuel Brinker[1], Claire Prada[3], and Patrick Huber[1,4,5] — [1]MXP, TUHH, Hamburg, Germany — [2]MSME, UPEC, Creteil, France — [3]Institut Langevin, ESPCI Paris, Université PSL, CNRS, Paris, France — [4]CXNS, DESY, Hamburg, Germany — [5]CHyN, UHH, Hamburg, Germany

Nanoporosity in silicon leads to entirely new functionalities of this mainstream semiconductor with a wide range of applications. In a recent study, we investigated the complex mechanics and the influence of the pores' conicity [1]. This provided the basis for predictable applications in robust on-chip devices and evidence that recent breakthroughs in laser ultrasound technology open up entirely new possibilities for non-destructive in-situ mechanical characterization of dry and liquid-functionalized porous materials. The pores' conicity, which is unintentionally generated during the electrochemical synthesis of porous silicon, can be actively influenced by the process parameters and, within certain limits, arbitrary pore profiles can be generated. This is used, for example, in the production of Bragg mirrors. By tuning the pore shape, we are now investigating its influence on guided waves further, with the goal of developing a phononic material.

Unraveling Fluid Phase Behavior in Geometrically Disordered Nanoporous Materials — •Henry R. N. B. Enninful and Rustem Valiullin — Faculty of Physics and Earth Sciences, Felix Bloch Institute for Solid State Physics, Leipzig University, Linnéstraße 5, 04103, Leipzig, Germany.

Mesoporous solids exhibit structural disorder which strongly influence confined fluid properties. This renders quantification of structural disorder and its correlation with physical properties of confined matter a necessary step towards their optimization in practical applications.

In this work, we present advances made in the understanding of correlations between the phase state and geometric disorder in a series of nanoporous solids with variable morphologies. We overview the recently developed statistical theory for phase transitions in a minimalistic model of disordered pore networks represented by the linear chains of pores with statistical disorder. Furthermore, we show that correlating its predictions with various experimental observations, the model gives notable insights into collective phenomena in phase-transition processes in disordered materials and is capable of explaining self-consistently the majority of the experimental results obtained for gas*liquid and solid*liquid equilibria in mesoporous solids. We also show how a newly-introduced interconnectivity parameter of the pore network can be assessed to describe the morphology of porous solids.

MM 23.23   Tue 18:15   P2/OG1+2

Negative Poisson's Ratio in Hierarchical Nanoporous Gold — •Haonan Sun[1,2], Lukas Lührs[2], and Shan Shi[1,3] — [1]Research Group of Integrated Metallic Nanomaterials Systems, Hamburg University of Technology, 21073 Hamburg, Germany — [2]Institute of Materials Physics and Technology, Hamburg University of Technology, 21073 Hamburg, Germany — [3]Institute of Materials Mechanics, Helmholtz-Zentrum Hereon, 21502 Geesthacht, Germany

The recent fabrication of crack-free monolithic hierarchical nested network nanoporous gold enables the investigation on the benefits of hierarchy in the aspect of mechanical properties [1]. It has been demonstrated that hierarchical nanoporous gold (HNPG) can achieve a substantially reduced solid fraction and enhanced specific stiffness and strength compared with non-hierarchical nanoporous gold. However, the role of the hierarchical structure on Poisson's ratio is not explored yet. In this work, we synthesize mm-sized HNPG samples out of a Ag93Au7 master alloy with a dealloying-coarsening-dealloying method. We then explore the elastic and plastic Poisson*s ratios of HNPG by using digital image correlation during compression testsing. Remarkably, we find Poisson*s ratio of HNPG is negative for a given strain regime, which suggests their potential application as auxetic materials. Furthermore, the effect of ligament size at both hierarchy levels on Poisson*s ratio is also investigated. [1] S. Shi, Y. Li, B.-N. Ngo-Dinh, J. Markmann and J. Weissmüller, Scaling behavior of stiffness and strength of hierarchical network nanomaterials, Science 371 (6533), 2021.

Mechanical actuation of nanoporous metal driven by electroactive self-assembled monolayers — •Matts Olga and Mameka Nadiia — Helmholtz-Zentrum Hereon, Geesthacht, Germany

Nanoporous (np) metals fabricated by alloy corrosion are emerging as promising functional materials for (bio-)chemical sensing and actuation. The actuation with np metals exploits the electrocapillary phenomena of metal surfaces, in which surface stress responses to changes of the surface state (e.g. due to adsorption). As the surface stress is coupled with stresses of opposite sigh in the metal bulk [1], its variations manifest themselves through macroscopic movements of the entire solid [2].

Due to high surface area, surface-functionalized np metals offer an ideal platform for highly sensitive sensing and actuation technologies. Here, were report

reversible electroactuation of unimodal and hierarchical np-Au modified with an electroactive ferrocene-terminated self-assembled monolayer (SAM). In our experiment utilizing in situ dilatometry in electrolyte, an electrode potential is imposed on np-Au modulates redox transformations of SAM by oxidation and reduction of the ferrocene moiety. We find pronounced actuation strain variations that accompany the monolayer structural transformations triggered by potential. We discuss an origin of the phenomena in view of surface stress change of gold surfaces functionalized with the redox-active SAM. [1] Weissmüller, Cahn. Acta Mater. 45(5) 1899 (1997). [2] Kramer, et al. Nano Lett. 4(5) 793 (2004).

Importance of symmetry for the collapse of nanowire arrays — •Malte Grunert, Chengzhang Yhang, Huaping Zhao, and Yong Lei — Technische Universität Ilmenau

We present numerical results highlighting the importance of symmetry considerations in the capillary collapse of nanowire arrays. For many of the envisaged applications of nanowire arrays, for example as a novel electrode material in lithium-ion batteries [1], maximizing the aspect ratio of the individual nanowires is one of the main goals. However, collapse occurs for wet-chemical fabrication processes after a critical aspect ratio is exceeded. As the length of the nanowires is increased, the torque resulting from surface tension during the drying step is increased as well, leading to collapse. In literature, only systems consisting of few nanowires are considered [2]. We show using multiphysics FEM simulations that a perfectly symmetric periodic nanowire array does not collapse, as the forces acting on the nanowires exactly cancel out. However, we also show that even slight length variations below the currently achievable experimental precision suffice to break the symmetry enough to load to the collapse of the entire array.

Architecting Nanoscaffolds to Ward Off Agglomeration of Nanowire arrays: Achieving Reliable Length Retention — •Chengzhan Yan, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany.

Nanowire arrays with well-defined arrangements and high aspect ratios are of particular interest for energy storage systems. To this end, one prevailing strategy is to combine ordered porous templates with wet chemical techniques. However, nanowires with high aspect ratios have a more severe tendency to self-agglomerate because of uneven capillary forces, which leads to poor arrangement reliability and degrades the electrochemical performance. Herein, an ultra-thin honeycomb alumina nanoscaffold (HAN) is constructed to ensure the structural stability of nanowire arrays, achieving a four-fold increase in the aspect ratio over the restriction. Within the integrated architecture, each nickel nanowire is individually separated by HAN so that the capillary forces around the nanowire cancel each other out during drying. Moreover, $MnO2$ and polypyrrole are further electrodeposited on these free-standing nanowires to form a vertically aligned core-shell 1D nanostructure arrays as cathodes and anodes for assembling micro-supercapacitors (MSCs). Attributed to the high specific surface area and low charge diffusion resistance, the assembled MSCs attain remarkably improved energy density, rate performance and lifespan.

MM 23.27   Tue 18:15   P2/OG1+2

Porous alumina membranes: how close to perfection? — •Marine Bossert[1], Panayotis Spathis[2], Pierre-Étienne Wolf[2], Laurent Cagnon[2], Isabelle Trimaille[3], and Étienne Rolley[4] — [1]Institut of Materials Physics and Technology, Hamburg University of Technology, Germany — [2]Institut Néel, Grenoble, France — [3]Institut des NanoSciences de Paris, Paris, France — [4]Laboratoire de Physique de l'Ècole Normale Supérieure, Paris, France

Alumina, and to a lesser extent, silicon porous membranes are considered often as model systems made of straight and independent pores, and, as such, porous alumina is used as templates for the synthesis of magnetic or thermoelectric materials [1].

In order to assess to which extent this ideal picture is valid, we have carried out extensive sorption measurements on membranes of different thicknesses, either native or with a pore aperture reduced by Atomic Layer Deposition. For porous silicon membranes, we find constrictions along the pore axis for all samples and interconnections between neighbouring pores when the latter are longer than 2 microns [2]. For alumina membranes, the pores are independent, but conical in shape rather than cylindrical, and rough rather than smooth. Moreover, their average diameter (along their length) is distributed from pore to pore.

We present quantitative estimates of these deviations to ideality, and discuss how to minimize them. [1] Lee and Park Chemical Reviews 2014 114 (15), 7487-7556 [2] Bossert et al, Langmuir 2021 37 (49), 14419-14428

MM 23.28   Tue 18:15   P2/OG1+2

Freezing of water in 3 nm silica nanopores: A molecular dynamics study — •Lars Dammann[1,2], Robert Horst Meissner[2,3], and Patrick Huber[1,2] — [1]Deutsches Elektronen-Synchrotron DESY, Notkestr. 85, Hamburg 22607, Germany — [2]Hamburg University of Technology, Am Schwarzenberg-Campus 1, Hamburg 21073, Germany — [3]Institute of Surface Science, Helmholtz-Zentrum Hereon, Max-Planck-Str. 1, Geesthacht 21502, Germany

The crystallization of water in extreme spatial confinement of nanoporous media plays a pivotal role in many natural and technological processes, ranging from frost heave to modern materials processing. However, the induced interfacial stresses in the porous medium during crystallization, the crystalline structures of nanoconfined water and the lower bounds of pore sizes that still permit phase transitions are subject of scientific discussions. Molecular dynamics simulations might support the investigation of open questions about the phase transitions of water in nanoporous systems. However, liquid to solid phase transitions of bulk water are difficult to simulate since the nucleation process is energetically hindered. In strong confinement the phase transition of water is further frustrated which makes a brute force approach computationally unfeasible. Additionally it is difficult to find collective variables for enhanced sampling techniques without knowledge about the target structure. We present our ongoing investigation on if and how MD simulations about the freezing of water in nanoporous media can be conducted with an exemplary silica nanopore structure of 3 nm pore diameter.

MM 23.29   Tue 18:15   P2/OG1+2

Mechanical properties of bicontinuous Ti networks formed via peritectic melting — •Nina Petersen[1], Zhongyang Li[1], Lukas Lührs[1], and Jörg Weissmüller[1,2] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology, Hamburg — [2]Institute of Materials Mechanics, Helmholtz-Zentrum hereon, Geesthacht

Recent work has shown, that bicontinuous networks can be obtained from TiAg alloys by peritectic melting. These microstructures can then be transformed to open porous networks by selective etching of the Ti or Ag phase. For open porous Ti networks, the ligament size as well as the morphology can be influenced by variation of the melting parameters like temperature and duration of the heat treatment.

In this work, the microstructure of open porous Ti samples was analysed by scanning electron microscopy. The samples were then mechanically tested using continuous compressive loading as well as loading-unloading protocols. The strain was analysed with digital image correlation. The samples exhibit strength values of over 150 MPa that increase with the duration of the heat treatment. This research links the mechanical performance of these Ti networks to the morphological evolution of the microstructures during heat treatment.

MM 23.30   Tue 18:15   P2/OG1+2

Time-resolved EBSD investigation of abnormal grain growth in the aluminum alloy AA5252 — •Karolína Holíková[1], Jules M. Dake[1], Madlen Atzen[1], Thomas Wilhelm[2], Lukas Petrich[2], Orkun Furat[2], Volker Schmidt[2], Baptiste Flipon[3], Marc Bernacki[3], and Carl E. Krill III[1] — [1]Institute of Functional Nanosystems, Ulm University, Germany — [2]Institute of Stochastics, Ulm University, Germany — [3]MINES ParisTech, PSL University, France

Heat treatment causes changes in the microstructure of polycrystalline materials, with growth of the average grain size being a prominent example. The driving force is the reduction in free energy of the system. When the average grain size increases monotonically with time but the grain size distribution remains self-similar, the process is called normal grain growth (NGG). In contrast, abnormal grain growth (AGG) is characterized by the much faster growth of a few grains at the expense of neighbors, resulting in a bimodal size distribution. Analytic models and computer simulations do a good job of describing NGG, but they generally fail at predicting AGG in real systems–owing to insufficient knowledge of the underlying mechanism(s). If one could observe sequential microstructural changes during AGG, then one might gain a deeper understanding of the phenomenon. To that end, we have investigated grain growth in the aluminum alloy AA5252, which is known to manifest AGG. Time-resolved electron backscatter diffraction (EBSD) measurements reveal abnormal microstructural evolution in 2D, from which we extract clues regarding the underlying mechanism for AGG.

MM 23.31   Tue 18:15   P2/OG1+2

Resistometric and dilatometric determination of GP-zone formation and growth — •Fabian Miller, Nikolai Riedmiller, Johannes Berlin, Tobias Stegmüller, and Ferdinand Haider — Universität Augsburg, Institut für Physik, 86135 Augsburg

Aluminium alloys are of crucial importance in today's economy, therefore the deeper understanding of their mechanical and electrical properties is important. These properties can be influenced by precipitate formation. Both resistometry and dilatometry are simple online methods to monitor changes in the microstructure of a metallic alloy. In this work we focused on natural and artificial aging of Al-Cu system with samples containing 2 - 4 wt.% of Cu. Natural

aging depends on quenched in vacancies, so on the quenching conditions. Samples were homogenized at various temperatures and rapidly quenched to ambient temperature. Afterwards measurements with both techniques were conducted during natural and artificial aging. Due to formation of Guinier Preston zones, the resistivity first increases, then slowly decreases, allowing to monitor the unmixing for different temperatures and for different quenching conditions for samples with ternary trace alloying metals than Cu. Dilatometry shows a clear contraction of the samples during GP-zone formation and an expansion, if $\theta^{\prime}$ phase forms.

MM 23.32   Tue 18:15   P2/OG1+2

Circularity: a microstructural clue to the origin of extreme abnormal grain growth in nanocrystalline Pd-Au — •Fabian Andorfer[1], Jules M. Dake[1], Johannes Wild[2], Torben Boll[2], Dorothée Vinga Szabó[2], Stefan Wagner[2], Astrid Pundt[2], and Carl E. Krill III[1] — [1]Institute of Functional Nanosystems, Ulm University — [2]Karlsruhe Institute of Technology KIT

Heat treatment causes polycrystalline materials to manifest either normal or abnormal grain growth. During normal growth, the average grain size increases monotonically, but the grain size distribution remains unimodal. In contrast, when abnormal grain growth occurs, some grains acquire a significant growth advantage compared to the remaining matrix grains, resulting in a bimodal distribution of grain sizes. Inert-gas condensed nanocrystalline Pd-Au alloys undergo an extreme form of such abnormal grain growth: While the grain boundaries separating the abnormal and matrix grains in conventional samples tend to be rather smooth, in nanocrystalline Pd-Au the same boundaries take on rough and highly convoluted shapes - similar to a jagged coastline! In such cases, the measurement and calculation of grain circularity has proven to be a promising tool for classifying the nature of a given grain's abnormality. We have determined the circularity of abnormal grains emerging in nanocrystalline Pd-Au samples, and we have compared the results to values reported in the literature or obtained from simulations. From this information, we hope to gain a deeper understanding of the mechanism(s) responsible for the extreme growth mode observed in nanocrystalline Pd-Au.

MM 23.33   Tue 18:15   P2/OG1+2

Manipulating microstructures by means of magnetic fields — •Thomas Brede[1], Fernando Maccari[2], and Rainer Backofen[3] — [1]Institut für Materialphysik, Universität Göttingen, Deutschland — [2]Institut für Materialwissenschaften, Technische Universität Darmstadt, Darmstadt — [3]Institut für wissenschaftliches Rechnen, Technische Universität Dresden, Dresden

In this project, the isolated influence of strong magnetic fields on the development of the microstructure of ferromagnetic thin films during annealing processes is investigated. For this purpose, thin films out of Iron, Nickel and Cobalt are prepared and characterized, then heat treated in the same heater with and without magnetic field and subsequently characterized. The experiments are accompanied by phase field crystal modeling to separate the different possible influences on the microstructure.

Through the parallel approach of experimental and modeling work, the effect of external magnetic fields on the development of microstructure and grain orientation will be investigated to understand the direct effect of the magnetic field.

Through a deeper understanding of the isolated influence of a magnetic field, additional conclusions should be possible about the influence of induced magnetic fields in the case of sample treatment with high currents.

MM 23.34   Tue 18:15   P2/OG1+2

Anharmonicity of the antiferrodistortive soft mode in barium zirconate $BaZrO_3$ — •Petter Rosander[1], Erik Fransson[1], Cosme Milesi-Brault[2,3,4], Constance Toulouse[2], Frédéric Bourdarot[5], Andrea Piovano[5], Alexei Bossak[6], Mael Guennou[2], and Göran Wahnström[1] — [1]Chalmers University of Technology, Göteborg, Sweden — [2]University of Luxembourg, Belvaux, Luxembourg — [3]Luxembourg Institute of Science and Technology, Belvaux, Luxembourg — [4]Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic — [5]Institut Laue-Langevin, Grenoble, France — [6]European Synchrotron Radiation Facility, Grenoble, France

Few perovskites adopt the ideal cubic phase at low temperatures. However, a promising candidate to, on average, remain cubic, even at 0K, is barium zirconate. The competing phase is a structure with sequentially tilted oxygen octahedra. This distortion is driven by the soft tilt mode at the R-point of the cubic Brillouin zone.

We report data from inelastic neutron scattering (INS) on a single crystal of barium zirconate. This reveals that the tilt mode softens substantially from 9.4 meV at room temperature to 5.6 meV at 2K. Additionally, the INS measurement unveils that the acoustic phonon mode at the same point in the Brillouin zone is almost temperature independent, which is in stark contrast to the tilt mode. The theoretical calculations show that it is critical to account for quantum fluctuations in order to correctly reproduce the experimental temperature dependence.

MM 23.35   Tue 18:15   P2/OG1+2

Terahertz third harmonic generation from a correlated metal — •Gulloo Lal Prajapati[1], Sergey Kovalev[1], Jan-Christoph Deinert[1], Alexey Ponomaryov[1], Atiqa Arshad[1], Gaurav Dubey[2], and Dhanvir Singh Rana[2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Department of Physics, Indian Institute of Science Education and Research Bhopal, Bhopal, India

High harmonic generation, a result of intense nonlinear light-matter interaction, has exciting prospects for probing fundamental ultrafast dynamics in matter and it is the basis for attosecond photonics [1, 2]. Here, we present an experimental study on terahertz (THz) third harmonic generation (THG) on a correlated metal, LaNiO3 which exhibits non-Fermi liquid type of metallic state [3]. We observe an intense THG signal, which is usually not expected in metals, upon pumping it by 0.3 THz pulses with peak fields of about 100 kV/cm. Decreasing temperature or increasing fluence increases the intensity of this THG signal. We speculate the origin of such THG emission could be due to the anharmonic nature of LaNiO3 conduction band caused by electronic correlation or directional nature of Ni-3d orbitals. Further investigations are under way to pinpoint the exact mechanism of the observed THG. Our study paves the way for THz THG emission from strongly correlated systems, and enables tracking of their properties on ultrafast timescales. References: 1. Nature Photon 12, 266, 270 (2018). 2. Invited Talk   MM 24.1   Wed 9:30   SCH A 251

Characterization of hydrogen effect on mechanical properties of metals at different length scales — •Afrooz Barnoush, Prince Baranwal, and Hanan Farhat — Qatar Environment and Energy Research Institute (QEERI), Hamad Bin Khalifa University (HBKU), P.O. Box 34110, Doha, Qatar

Conventional macroscopic mechanical tests cannot resolve the spatiotemporally distributed hydrogen interaction with the metal microstructure under stress and give us enough information to develop predictive models for the hydrogen ef-

fect on mechanical properties. They typically measure an integration of these incidents over time, which manifests in loss of ductility, hence hydrogen embrittlement. Therefore, it is necessary to isolate these incidents and study them separately. To realize it, we develop mechanical testing approaches at different length scales to look at the interaction of hydrogen with different types of defects and how they behave in the presence of hydrogen. This talk will give an overview of the work that has been done in the past 20 years to get an insight into the hydrogen effect on mechanical properties at different length scales.

MM 25: Development of Computational Methods: Crystal Structure and Properties

Time: Wednesday 10:15–11:30   Location: SCH A 251

MM 25.1   Wed 10:15   SCH A 251

A hybrid multiscale phase-field crystal, amplitude phase-field crystal approach - elastic properties and numerical studies — •Maik Punke and Marco Salvalaglio — Technische Universität Dresden, Institut für Wissenschaftliches Rechnen, Bürogebäude Z21, Zellescher Weg 25, 01217 Dresden

The modeling of crystalline materials requires the resolution of microscopic details on large length and time scales to guarantee the description of lattice-

dependent features as well as the dynamics of solidification. The so-called phase-field crystal (PFC) model emerged as a prominent framework to model crystalline systems. Indeed, it describes crystalline materials through a continuous order parameter related to the atomic number density and its dynamic at relatively large (diffusive) time scales. The amplitude expansion of the PFC model (APFC) was developed to further overcome the length scale limitations in the PFC framework. Herein, the continuous density in PFC models is replaced by

the amplitudes of the minimum set of Fourier modes (wave vectors) for a given crystal symmetry.

We propose a multiscale model with local PFC accuracy and APFC length scale limitations. In our hybrid multiscale approach, the PFC and APFC models are coupled through Dirichlet conditions by penalty terms within the spectral framework. We showcase the model capabilities via selected numerical investigations which focus on the energetic and elastic properties of two-dimensional crystals. Furthermore, runtime and accuracy comparisons with the standard PFC and APFC models are made.

MM 25.2   Wed 10:30   SCH A 251

Corrosion evolution in Mg-based alloys: the role of precipitates studied by synchrotron X-ray nanotomography — •Tatiana Akhmetshina[1], Robin E. Schäublin[1], Andrea M. Rich[1], Nicholas W. Phillips[2], and Jörg F. Löffler[1] — [1]Laboratory of Metal Physics and Technology, Department of Materials, ETH Zurich, Switzerland — [2]Paul Scherrer Institute, 5232 Villigen PSI, Switzerland

Magnesium alloys are very promising candidates for light-weight and bioresorbable medical applications. However, being an active metal, magnesium is susceptible to localized corrosion caused by precipitates or solute elements. In this work, we compare the corrosion behaviour of lean Mg-Ca (X0), developed in our laboratory, with the well-known Mg-Y-Nd-Zr (WE43) alloy that is currently deployed as biomedical material. X0 alloys (0.2-0.6 wt.% Ca) offer a combination of high strength and high ductility and can be considered a safe substitute for WE43 in bioresorbable implants. Using the 3D ptychography technique at the cSAXS beamline of the Swiss Light Source, we monitored the corrosion evolution in X0 and WE43. Both exhibit very different precipitates, which can be distinguished by their electron density in X-ray imaging. We found that the rare-earth-rich precipitates in WE43 tend to remain in the corrosion layer, whereas the Ca-rich ones in X0 predominantly dissolve without any pitting effect. The appearance of the corrosion product and the related chemical composition were also quite different. These findings of in-vitro corrosion can help to better understand the in-vivo degradation of Mg-based biomedical devices.

MM 25.3   Wed 10:45   SCH A 251

Amplitude expansion of the phase-field crystal model for complex crystal structures — •Marcello De Donno[1] and Marco Salvalaglio[1,2] — [1]Institute of Scientific Computing, Technische Universität Dresden, 01062 Dresden, Germany — [2]Dresden Center for Computational Materials Science (DCMS), TU Dresden, 01062 Dresden, Germany

The phase field crystal model allows for studying phenomena on atomic length and diffusive time scales. It accounts for elastic and plastic deformation in crystals, including several processes such as crystal growth, dislocation dynamics, and microstructure evolution. The amplitude expansion of the phase field crystal model describes the atomic density by a small set of slowly-oscillating Fourier modes, making it possible to tackle large three-dimensional systems. However, only basic crystal symmetries have been studied so far. We present a general treatment of virtually any lattice symmetry using the amplitude phase field crystal model, incorporating approaches originally proposed for the phase field crystal model which enable the treatment of non-trivial lattices. We discuss the sta-

bility of selected crystal structures, focusing on non-Bravais lattices. As pivotal examples, we show that the proposed approach allows a coarse-grained description of the kagome lattice, exotic square arrangements, and the diamond lattice, hosting dislocations.

Efficient molecular dynamics simulations using fourth-generation neural network potentials — •Emir Kocer[1,2], Andreas Singraber[3], Tsz Wai Ko[1,2], Jonas Finkler[4], Philipp Misof[3], Christoph Dellago[3], and Jörg Behler[1,2] — [1]Lehrstuhl für Theoretische Chemie II, Ruhr-Universität Bochum, Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Bochum, Germany — [3]Institut für Experimentalphysik, Universität Wien, Wien, Austria — [4]Departement Physik, Universität Basel, Basel, Switzerland

Machine learning potentials (MLP) have become a common tool in materials modelling due to their ability to bridge the gap between ab initio and classical molecular dynamics. A limitation of most MLPs, however, is the locality approximation in that only interactions within a cutoff range are considered. This could lead to inaccurate dynamics in systems with relevant long-range interactions. Recently, a fourth-generation of MLPs has emerged that can take also global phenomena like non-local charge transfer into account. An example is the fourth-generation high-dimensional neural network potential (4G-HDNNP), which utilizes a global charge equilibration. In this study, a modified version of 4G-HDNNPs with enhanced efficiency will be presented. The new algorithm has been implemented in the LAMMPS software and tested in large-scale molecular dynamics simulations.

MM 25.5   Wed 11:15   SCH A 251

Sampling-free determination of accurate free energies: A bond lattice mean-field model for central potentials — •Raynol Dsouza[1], Thomas Swinburne[2], Liam Huber[3], and Jörg Neugebauer[1] — [1]Max-Planck-Institut für Eisenforschung GmbH, 40237 Düsseldorf, Germany — [2]CINaM, Campus de Luminy, 13288 Marseille, France — [3]Grey Haven Solutions, Victoria, Canada

The computation of accurate anharmonic free energies at finite temperatures commonly involves the sampling of a large number of configurations. The commonly used (quasi)-harmonic approximation sacrifices physical fidelity by only sampling very few of these configurations. A recent study by the co-authors showed that a mean-field of a lattice of uncorrelated anharmonic first nearest-neighbour bonds can be used to approximate anharmonic free energies of fcc crystals with meV/atom accuracy when paired with a polarized bonding potential [1], thus recapturing an approximation of the anharmonic contributions with minimal computational expense. We extend this approach to central potentials, while maintaining the original constraints of material compatibility and thermodynamic self-consistency of the model. Using a parameterized bonding potential generated from a few T=0 K ab initio calculations [2] for fcc aluminium, we show that the model yields free energies close to meV/atom of those calculated from ab initio thermodynamic integration for a fraction of the computational effort. [1] Swinburne et al., Phys. Rev. B 102, 100101(R) (2020) [2] Glensk et al., Phys. Rev. Lett. 114, 195901 (2015)

MM 26: Interface Controlled Properties and Nanomaterials: Grain Boundaries and Stability, Spectroscopy and Interatomic Potentials

Time: Wednesday 10:15–13:00   Location: SCH A 216

MM 26.1   Wed 10:15   SCH A 216

Grain-boundary segregation effects on bicrystal Cu pillar compression — •Tobias Brink, Mohammed Kamran Bhat, James Best, and Gerhard Dehm — Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Straße 1, 40237 Düsseldorf

It is well known that segregation to grain boundaries (GBs) can modify the mechanical properties of metals, leading for example to improved strength, but also to detrimental effects like embrittlement. Despite this, the nanoscale mechanisms of these changes are currently not fully understood. Here, we present the results of atomistic computer simulations of bicrystalline Cu pillar compression and corresponding micromechanics experiments. The experiments show that Ag segregation to the GB increases the yield stress of the pillars, but only slip traces observed post mortem hint towards the mechanisms. We prepared segregated GB structures with combined molecular dynamics/Monte-Carlo simulations by matching the resulting excess Ag concentration to atom probe tomography results. The virtual nanopillars were cut from this material and varying amounts of dislocation loops were inserted in order to model the pre-existing dislocation networks in the experiment. Switching the atomic types of the segregants between Ag and Cu allowed us to model the exact same pillar and dislocation network with and without segregation, thereby enabling an investigation of the mechanisms underlying the experimentally observed strengthening.

MM 26.2   Wed 10:30   SCH A 216

When grains go wild! Tracing microstructural outcomes back to possible mechanisms for abnormal grain growth — •Carl E. Krill III[1], Elizabeth A. Holm[2], Jules M. Dake[1], Ryan Cohn[2], Karolína Holíková[1], and Fabian Andorfer[1] — [1]Ulm University, Ulm, Germany — [2]Carnegie Mellon University, Pittsburgh, PA, USA

Usually, the coarsening of a polycrystalline material is a civilized affair, with adjacent grains swiping atoms so surreptitiously that relative growth rates remain moderate, and the mutual boundary stays smooth. In some cases, however, certain participants in this competition give free rein to an innate hunger for growth! The result is a subpopulation of large, "abnormal" crystallites embedded in a matrix of much smaller grains, whereby the abnormal/matrix interface can be anywhere from perfectly flat to fractally convoluted. The formation of such a microstructure is the telltale signature of abnormal grain growth (AGG). Although the most prominent feature of AGG is the shape of the abnormal grains, simulations indicate that the mechanism of AGG is encoded to a greater extent in the morphology of the interfaces between abnormal and matrix grains. Based on

this finding, we propose a scheme for inferring the possible mechanism(s) underlying any experimentally observed case of (sufficiently extreme) AGG, and we illustrate our phenomenological method with experimental examples taken from the literature. Surprisingly, in the most clear-cut cases of AGG we have encountered, microstructural outcomes point to boundary-to-boundary mobility variation as the sole governing factor.

MM 26.3 Wed 10:45 SCH A 216

Influence of precipitates during anodization of aluminum alloys studied by TEM at cryogenic temperatures — •LYDIA DAUM, STEFAN OSTENDORP, MARTIN PETERLECHNER, and GERHARD WILDE — Westfälische-Wilhelms-Universität, Münster, Germany

Aluminum alloys with predefined alloying elements are chosen regarding their performance in certain areas of industrial applications due to their hardness, strength and corrosion resistance. Precipitates such as Mg2Si and dispersoids, e.g. enrichments of Mn in EN * AW6xxx alloys hinders the formation of ordered anodic aluminum oxides (AAOs) as achievable using high-purity aluminum samples.

The focus of this work is on correlating the structural and chemical properties of precipitates within AAOs and at the interface to the alloy. Due to geometry and size of the precipitates, transmission electron microscopy (TEM) is performed at selected areas. Measuring the same properties inside an Al 6xxx alloy close to the interface provides information about the contribution of the segregations during anodization. Previous scanning transmission electron microscopy (STEM) studies have shown that cryogenic temperatures can partially reduce the beam damage in electron beam sensitive materials as organics or AAOs [1]. In this study, the sample is also characterized by nanobeam diffraction pattern analysis and electron dispersive X-ray spectroscopy at cryogenic temperatures.

MM 26.4 Wed 11:00 SCH A 216

Disconnection-mediated migration of interfaces: continuum modeling and applications — •MARCO SALVALAGLIO[1], CAIHAO QUI[2], JIAN HAN[2], and DAVID J. SROLOVITZ[3] — [1]Institute of Scientific Computing, TU Dresden, 01062 Dresden, Germany — [2]Department of Materials Science and Engineering, City University of Hong Kong, Hong Kong SAR, China — [3]Department of Mechanical Engineering, The University of Hong Kong, Pokfulam Road, Hong Kong SAR, China

We present a model for the motion of arbitrarily curved interfaces that respects the underlying crystallography of two phases/domains meeting at an interface and is consistent with microscopic mechanisms of interface motion, i.e., migration of disconnection (line defects in the interface with step and dislocation character) [1]. The equation of motion for interface migration under the influence of a wide range of driving forces is discussed with the aid of numerical simulations [1,2]. A diffuse interface framework is also used to handle complex morphology and deliver proof of concept for microstructure evolution [2]. Recent results achieved with this model, concerning grain boundary morphologies, the competition among thermodynamic and kinetic effects, and grain rotation will be illustrated. [1] J. Han et al. Acta Materialia 227, 117178, (2022). [2] M. Salvalaglio et al. Acta Materialia 227, 117463, (2022).

MM 26.5 Wed 11:15 SCH A 216

Simulated mechanical deformations on graphene oxide — •JAVIER ROJAS-NUNEZ[1], SAMUEL BALTAZAR[1], EDUARDO BRINGA[2], and ALEJANDRA GARCIA[3] — [1]Physics Department and CEDENNA, Universidad de Santiago de Chile (USACH), Santiago, Chile — [2]Laboratorio de síntesis y modificación de nanoestructuras y materiales bidimensionales, Centro de Investigación en Materiales Avanzados, Nuevo León, México — [3]CONICET & Facultad de Ingeniería, Universidad de Mendoza, Mendoza, Argentina

The better understanding of nanomaterial properties will be a key factor to tailor and enhance properties of new materials. Graphene oxide in particular can be synthesized with different oxidation levels in order so gain similar properties to its deoxidized counterpart, graphene. Through the molecular dynamic simulations, the atomistic behavior of a tri-layer graphene membrane under mechanical indentation will be studied in this work.

This work will study a highly oxidized graphene oxide tri-layer that will be indented with a repulsive spherical indentator. The modeling of the membrane will generate single layer graphene oxide candidates to pick the lowest energy configuration and later stack this layer over itself. The final tri-layer was used for the indentation simulation, where the young modulus was reproduced with decent similarity to experimental results.

The atomistic analysis of the indentation process suggest an important role of epoxide groups in the mechanical deformation of the membrane.

Atomic cluster expansion for Ag-Pd — •YANYAN LIANG, MATOUS MROVEC, YURY LYSOGORSKIY, and RALF DRAUTZ — ICAMS, Ruhr-Universität Bochum, Germany

Binary alloys of silver and palladium have recently attracted attention due to their importance in catalysis and nanotechnology. However, the binary Ag-Pd system lacks reliable and efficient interatomic potentials that provide an accurate description of structural and thermodynamic properties, in particular for atomistic simulations of nanoparticles. In this work, we present an atomic cluster expansion (ACE) parametrized for binary Ag-Pd. We show that the Ag-Pd ACE potential provides an ab-initio accurate description of elastic, structural and thermodynamic properties of both, elements as well as their compounds. We demonstrate the computational efficiency and the applicability of our ACE for atomistic investigations of complex phenomena in Ag-Pd nanoparticles.

MM 26.7 Wed 12:00 SCH A 216

Spin-orbit interactions in plasmonic crystals probed by site-selective cathodoluminescence spectroscopy — MASOUD TALEB[1], •MOHSEN SAMADI[1], FATEMEH DAVOODI[1], MAXIMILIAN BLACK[1], JANEK BUHL[2], HANNES LÜDER[2], MARTINA GERKEN[2], and NAHID TALEBI[1,3] — [1]Institute of Experimental and Applied Physics, Kiel University, Germany — [2]Integrated Systems and Photonics, Faculty of Engineering, Kiel University, Germany — [3]Kiel, Nano, Surface, and Interface Science, Kiel University, Germany

The study of spin-orbit coupling (SOC) of light is crucial to explore the light-matter interactions in sub-wavelength nanostructures with broken symmetries. Herein, we explore the SOC in a plasmonic crystal, both theoretically and experimentally. Cathodoluminescence (CL) spectroscopy combined with the numerically calculated photonic band structure reveals an energy band splitting that is ascribed to the behavior of light in the plasmonic crystal where the inversion symmetry is locally broken. By shifting the impact position of the electron beam throughout a unit cell of the plasmonic crystal, we show that the emergence of the energy band splitting strongly depends on the excitation position of the surface plasmon (SP) waves on the crystal. Moreover, we exploit angle-resolved CL and dark-field polarimetry to demonstrate polarization-dependent scattering of SP waves interacting with the plasmonic crystal. Our study gives insight into the design of novel plasmonic devices with polarization-dependent directionality of the Bloch plasmons.

MM 26.8 Wed 12:15 SCH A 216

Soft and Hard X-ray Circular Dichroism in Valence-Band and Core-Level Momentum Microscopy — •O. TKACH[1,2], O. FEDCHENKO[1], K. MEDJANIK[1], Y. LYTVYNENKO[1], S. BABENKOV[1], D. VASILYEV[1], Q.L. NGUYEN[3], T.P. VO[4], T.R.F. PEIXOTO[5], A. GLOSKOVSKII[5], C. SCHLUETER[5], M. HOESCH[5], D. KUTNYAKHOV[5], M. SCHOLZ[5], L. WENTHAUS[5], N. WIND[5,6], S. MAROTZKE[5], A. WINKELMANN[7], J. MINAR[4], K. ROSSNAGEL[5,8], H.-J. ELMERS[1], and G. SCHÖNHENSE[1] — [1]Univ. Mainz — [2]SSU, Ukraine — [3]SLAC Nat. Accel. Lab., USA — [4]Univ. West Bohemia, Czech — [5]DESY Hamburg — [6]Univ. Hamburg — [7]AGH Univ., Poland — [8]Univ. Kiel

We introduce full-field mapping of the circular dichroism texture in X-ray momentum microscopy. I(EB,k) energy-momentum space tomography with both soft and hard X-rays at PETRA-III yields CDAD patterns. Kinetic energies of up to >7 keV and a large k-field-of-view enable capturing of structural information via XPD Kikuchi patterns, which show pronounced asymmetries. Patterns at different azimuthal angles exhibit sharp zero lines, when the helicity vector lies in a mirror plane. Similar zero lines also appear in the XPD patterns of core levels, as exemplified for Ge 3p, Si 2p and various W core levels at hv = 6 keV. Calculations using Bloch-wave approach and one-step photoemission show good agreement with experiment. In order to disentangle the contributions of the photoexcitation (intrinsic part) from the Kikuchi process (extrinsic), XPD has been implemented in the Munich SPRKKR package, unifying one-step model of photoemission and multiple scattering theory.

MM 26.9 Wed 12:30 SCH A 216

Direct writing of three-dimensional nano-superconductors — •ELINA ZHAKINA[1], MARKUS KÖNIG[1], SEBASTIAN SEIFERT[1], AMALIO FERNÁNDEZ-PACHECO[2], PAUL SIMON[1], WILDER CARRILLO-CABRERA[1], and CLAIRE DONNELLY[1] — [1]Max-Planck-Institut für Chemische Physik fester Stoffe, Dresden, Germany — [2]Institute of Nanoscience & Materials of Aragón CSIC-University of Zaragoza, Zaragoza, Spain

In recent years, superconductivity and vortex matter in curved 3D nanoarchitectures have become a vibrant research avenue because of the rich physics of the emerging geometry- and topology-induced phenomena [1]. However, the fabrication of such architectures is still challenging. Currently, fabrication techniques of innovative three-dimensional (3D) nano-objects are being developed [2].

Here, we present a new route to fabricating superconducting 3D nanoarchitectures by focused electron-beam-induced-deposition [3] of tungsten, allowing for the realisation of complex 3D superconducting geometries with a critical temperature on the order of 5 K. We observe a geometrical effect of the 3D nanoarchitecture, namely, the angular dependence of the upper-critical magnetic field

that is not possible in bulk superconductors. This method unveils a wide perspective in experimental studies of the dynamics of topological defects in curved 3D nanoarchitectures.

MM 26.10   Wed 12:45   SCH A 216
Influence of a p-n Heterojunction on the Diffusive Transport in Tungsten Trioxide Thin Films — •Jan L. Dornseifer[1,2], Markus S. Friedrich[1,2], and Peter J. Klar[1,2] — [1]Institute of Experimental Physics I, Justus-Liebig-University, Giessen, Germany — [2]Center for Materials Research (ZfM), Justus-Liebig-University, Giessen, Germany

Tungsten trioxide (WO_3) is (typically) an n-type semiconductor and a prominent electrochromic material. It changes its optical properties when charge carriers are inserted. Due to its excellent electrochromic properties, WO_3 is the most commonly used functional material in so called "smart" windows which are a promising technology for significantly lowering the energy consumption for building climatization. Industrially manufactured polycrystalline WO_3 thin films were coated with p-type nickel monoxide (NiO_x) thin films by ion beam sputter deposition. In order to investigate the diffusive transport of hydrogen in WO_3 thin films influenced by a p-n heterojunction, spatially and temporally resolved optical transmission measurements are conducted on NiO_x/WO_3-heterostructures during the potentiostatic coloration of the WO_3 thin films. Spatial and temporal diffusion profiles determined by analyzing these measurements indicate that the lateral propagation of hydrogen in NiO_x coated WO_3 films is accelerated. In addition, an increased transmittance is observed in the colored state. To describe these findings, a model is set up based on an increase in hydrogen concentration inside the WO_3 layer outside the space-charge region formed at the NiO_x/WO_3 interface.

MM 27: Hydrogen in Materials

Time: Wednesday 10:15–13:00   Location: SCH A 215

MM 27.1   Wed 10:15   SCH A 215
Strain-induced twins and martensite: Effects on hydrogen embrittlement of additive manufactured (AM) 316L — •Stefan Wagner[1], Yuanjian Hong[2], Chengshuang Zhou[2], Sabine Schlabach[1,3], Astrid Pundt[1], Lin Zhang[4], and Jinyang Zheng[4] — [1]Karlsruhe Institute of Technology (KIT), Institute for Applied Materials - Materials Science and Engineering (IAM-WK), Karlsruhe, Germany — [2]Institute of Material Forming and Control Engineering, Zhejiang University of Technology, Hangzhou, China — [3]Karlsruhe Nano Micro Facility (KNMFi), KIT-Campus North, Eggenstein-Leopoldshafen, Germany — [4]Institute of Process Equipment, Zhejiang University, Hangzhou, China

Extending the use of hydrogen as a renewable energy carrier 316L is one of the most important structural materials. Additive manufacturing significantly enhances the steels' strength, allowing for weight reduction of construction parts. In this contribution [1] we investigate effects of strain-induced twins and martensite on hydrogen embrittlement of AM316L under tension in the temperature range from 80 K to 300 K. It is revealed that quasi-cleavage of twin boundaries is the major path of material failure. Strain-induced martensite has low impact on the H-embrittlement of AM316L, since it emerges only late in the deformation process.

MM 27.2   Wed 10:30   SCH A 215
Ab-initio insights into hydrogen-carbide interaction in bcc Fe — Saurabh Sagar and •Poulumi Dey — Delft University of Technology, Delft, The Netherlands

Development of advanced high-strength steels is in high demand owing to its wide scale applications. The excellent mechanical properties of these steel grades are attributed to the underlying microstructure which comprises of finely dispersed nano-precipitates. However, one major factor restricting their application is their susceptibility to Hydrogen Embrittlement (HE). Experimental and theoretical work have been carried out to understand if the nano-sized carbides can aid in reducing the susceptibility to HE along with providing strengthening. Within this study, we investigated the effectiveness of finely dispersed nanocarbides (i.e., TiC, NbC and VC) to limit the diffusible hydrogen content in bcc Fe. Our study revealed that the interplay between hydrogen and carbon vacancies, local atomic environment at interface as well as interface geometry can lead to significantly increased hydrogen solubilities. Thus, the trapping at these sites leads to a reduction in concentration of diffusible hydrogen. However, the question remains whether hydrogen can populate the deepest traps (i.e., the carbon vacancies) in the bulk of these carbides. We, thus, extended our study to compute migration barriers of hydrogen across the coherent interface between bcc Fe and TiC, NbC and VC using climbing-image Nudged Elastic Band method. Furthermore, we evaluated whether a chain of interconnected carbon vacancies from the interface to the bulk of the carbides leads to a reduction in the migration barrier of hydrogen.

MM 27.3   Wed 10:45   SCH A 215
Role of diffusible hydrogen on the mechanical behavior of bcc alloys by in situ micromechanics during hydrogen charging — •Maria Jazmin Duarte Correa, Jing Rao, and Gerhard Dehm — Max-Planck-Institut für Eisenforschung, Düsseldorf, Germany

Hydrogen embrittlement represents a major challenge for the use of hydrogen (H) as energy carrier. Understanding individual hydrogen-microstructure interactions by targeting analyses at the nano-/microscale during H exposure is essential to prevent material degradation. We will present nanoindentation and micropillar compression tests during H charging of Fe-Cr alloys (8-20 wt.%Cr) using our novel "back-side" electrochemical H charging approach for nanoindentation related techniques. An enhanced dislocation nucleation is shown consistent with the defactant theory, and a hardening effect while increasing the Cr content and the H entry. The mechanical data is as well analyzed in terms of the diffusion behavior and used to develop a nanohardness-based H diffusion coefficient approach. On the other hand, our unique method allows differentiating between the effects of trapped and mobile H, and performing well controlled measurements with different H levels monitored over time to consider H absorption, diffusion and release through the metal which will be shown using the example of the model alloys mentioned above.

MM 27.4   Wed 11:00   SCH A 215
Hydrogen interstitials in iron oxides using ab-initio calculations — •Ahmed Abdelkawy, Mira Todorova, and Jörg Neugebauer — Max-Planck-Institut für Eisenforschung, Max-Planck-Str.1, 40470 Düsseldorf

The steel making industry is responsible for more than 6% of CO2 emissions. These emissions come from the dependency on carbon and carbon monoxide as reducing agents. Hydrogen, on the other hand, can reduce iron oxides with water released instead. The reduction route from Magnetite to Hematite, then Wüstite, and finally to pure iron requires hydrogen to diffuse into and react with the different solid structures as well as with the multiple solid-solid interfaces. To optimize the reduction process, the mechanistic details of this process requires understanding to the role of hydrogen interstitials in the bulk iron oxides. We therefore computed the diffusion paths of hydrogen through the different iron oxide phases employing density functional theory (DFT) calculations for all three iron oxides - Magnetite, Hematite, and Wüstite. Analyzing the electronic structure of the studied oxides, we examine the reliability of the used exchange correlation functionals and how the electronic structure is affected by the inclusion of hydrogen, both as a neutral and a charged point defect. Finally, we utilize symmetrized plane waves to map the full 3D potential energy surfaces (PESs) for hydrogen interstitials within these iron oxides using a modest number of DFT calculations. Based on these calculations we identify the hydrogen preferential interstitial sites, diffusion barriers, and diffusion paths.

MM 27.5   Wed 11:15   SCH A 215
Influence of impurity atoms on the hydrogen diffusion into ruthenium — •Julian Gebhardt and Daniel Urban — Fraunhofer IWM, 79108 Freiburg

Ruthenium is considered as a promising protection layer to prevent the penetration of small atoms such as hydrogen into the underlying material. However, hydrogen is known to be able to penetrate ruthenium films under certain conditions and it has been hypothesized that impurity atoms, such as Sn, could play a major role in this process, decreasing the barrier of diffusion into the material for incoming hydrogen. We demonstrate that this is not the case for low to medium coverages, i.e., as long as the adsorbed species can be treated individually without significant adsorbate-adsorbate interactions. Within this coverage regime, the hydrogenation is destabilized in the vicinity of impurity atoms, such as X=Mg, P, S, Si, or Zn, due to the strong bonding of the adsorbates with the free ruthenium surface. As a result, the diffusion barriers are not significantly reduced in the vicinity of any of the tested impurity atoms. The most likely and energetically favorable process occurs at a sufficiently large distance to the impurity, with an energy barrier that is almost identical to that of the free surface. Due to the chemical variety of the considered impurity atoms, this finding appears to be general. This means that impurities can be ruled out to enhance hydrogen uptake of ruthenium layers for the considered coverages and other structural properties such as grain boundaries and dislocations should be considered as pathway for the hydrogen penetration.

Metal Hydride Materials for Solid-State Hydrogen Storage Applications: Utilizing the Synergy of Experiment & Theory for Future Materials Design Challenges — Paul Jerabek[1], •Brandon Wood[2], Tae Wook Heo[2], and Claudio Pistidda[1] — [1]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, Geesthacht, Germany — [2]Materials Science Division, Lawrence Livermore National Laboratory (LLNL), Livermore, USA

Metal hydride materials present a safe, efficient and long-term storage option for hydrogen under mild conditions for many stationary and mobile applications and will play an important role in the transition towards an emission-free energy economy.

Deep understanding of (de)hydrogenation thermodynamics and kinetics of such materials is essential to enable targeted design of novel storage materials and optimization of existing compositions tailor-made for specific applications. To obtain the necessary insights, computation and experiment need to work closely together to fully leverage theory-experiment feedback loops.

In this talk, an overview will be given of how experimental activities can be connected with computational multi-scale methodology (from atomistic to mesoscale), as currently performed in the joint efforts by the metal hydride materials research groups at Hereon and LLNL, with the goal being to develop virtuals workflows linking Density Functional Theory methods, thermodynamic modeling and phase-field simulations together with experimental investigations for an integrated description of metal hydride (de)hydrogenation processes.

MM 27.7   Wed 12:00   SCH A 215

Ab Initio Simulations of Laves-phase high-entropy alloys for hydrogen storage — •Yuji Ikeda[1], Kaveh Edalati[2], and Blazej Grabowski[1] — [1]University of Stuttgart, Stuttgart, Germany — [2]Kyushu University, Fukuoka, Japan

High-entropy alloys (HEAs), particularly those in the Laves phases, are promising candidates for hydrogen-storage alloys. Recent experiments have indeed revealed that the equiatomic TiZrCrMnFeNi Laves-phase HEA can work as a hydrogen-storage alloy at room temperature (i.e., without heating) under nearly atmospheric pressure [1,2]. Tuning the compositions of such Laves-phase HEAs should be possible to design hydrogen-storage alloys with more desirable properties. We have demonstrated that ab initio H adsorption energies in $Ti_xZr_{2-x}CrMnFeNi$ become more negative (thus energetically more favorable) on average with increasing the Ti content, consistent with experiments [3]. We will also show how the H adsorption energy depends on the local chemical environment in the Laves-phase HEAs.

Visualizing radiation-induced damage by Hydrogen/Deuterium — •Aparna Saksena, Binhan Sun, Heena Khanchandani, and Baptiste Gault — Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Straβe 1, Düsseldorf 40237, Germany

Atom probe tomography (APT) is now extensively used to measure the local chemistry of materials. APT proceeds by field evaporating a sharp, needle-shaped specimen with a radius * 50 nm, often prepared by focused ion beam (FIB) milling. The interaction of the ion beam at high currents is known to amorphize crystalline materials by changing the lattice and creating vacancies. Therefore, a platinum protective layer and a low-energy ion shower are routinely used to avoid or remove the damaged layer from the specimen. Additionally, for investigating the local chemistry of defects such as interfaces via APT, transmission Kikuchi diffraction (TKD) can be performed during milling steps. The damage resulting from these techniques is considered negligible. Here, we use deuterium charging to probe the damage associated with specimen preparation as vacancies are known to be strong trapping sites for hydrogen/deuterium. We analyzed a medium Mn steel containing austenite (fcc) and ferrite (bcc). APT specimens were charged in a deuterium gas atmosphere, and the distribution of deuterium shows clusters of point defects after Pt deposition, conventional Ga-FIB preparation, and TKD. These deuterium-rich clusters are sequentially minimized by systematically eliminating these preparation-induced damages.

Mechanism-based Lifetime Assessment under the Influence of Hydrogen — •Fabien Ebling[1,2], Heiner Oesterlin[2], Astrid Pundt[1], and Ken Wackermann[2] — [1]Karlsruhe Institute of Technology (KIT) Institute for Applied Materials - Materials Science and Engineering (IAM-WK), Karlsruhe, Germany — [2]Fraunhofer Institute for Mechanics of Materials IWM, Freiburg, Germany

Components see a variety of mechanical and thermal loads during service. Increased damage can occur when used in a hydrogen atmosphere. The experimental investigation of all states is very time-consuming and expensive, especially for testing under hydrogen influence. Mechanism-based lifetime assessments can be used to model crack growth and predict service life. This can significantly reduce the need of experimental investigations for a safe design of components. This work discusses different approaches of modeling hydrogen assisted cracking and presents an adaptation of the ZD parameter according to Heitmann (1983) for the influence of hydrogen at different temperatures.

MM 27.10   Wed 12:45   SCH A 215

Validation of continuum simulations of materials at the mesoscopic level with X-ray and neutron diffraction with a focus on hydrogen storage materials — •Arnab Majumdar[1], Martin Müller[2], and Sebastian Busch[1] — [1]GEMS at MLZ, Helmholtz-Zentrum hereon GmbH, Lichtenbergstr. 1, 85748 Garching, Germany — [2]Institute of Materials Physics, Helmholtz-Zentrum hereon GmbH, Max-Planck-Str. 1, 21502 Geesthacht, Germany

With the advent of new technologies, it has been possible to design new materials through theoretical analysis and simulation. However, these simulations have to be validated by experiments. In this work, we develop a method to validate the structural features in continuum simulations directly on the mesoscopic level with X-ray and neutron scattering experiments. The workflow to compare atomistic computer simulations to scattering patterns is well established: the scattering amplitude of individual atoms is summed, whose positions are obtained from the simulation. This approach fails for larger mesoscopic structures due to the unrealistic computation time required to generate the simulations and scattering pattern on a mesoscopic scale with atomic resolution. We developed a methodology that calculates scattering patterns from a continuum simulation like phase-field modeling, where the material description is continuous instead of a collection of atoms. The approach is validated with simple structures and gradually applied to more complex structures. The long term goal is to use this technique for the simulation of hydrogen storage materials and validation of the simulations with scattering data.

Relation between decoupled α and β relaxation processes and medium-range ordering in $Pd_{40}Ni_{40}P_{20}$ bulk metallic glasses — •Manoel Wilker da Silva Pinto, Mark Stringe, Dražen Radić, Harald Rösner, and Gerhard Wilde — Institut für Materialphysik, Westfälische Wilhelms-Universität Münster, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

Individual annealing treatments at $0.8T_g$ and $0.9T_g$ on $Pd_{40}Ni_{40}P_{20}$ bulk metallic glass samples were performed in a differential scanning calorimeter to either activate mainly β or both α and β relaxation processes. Prior to and after these measurements the samples were heated into the supercooled liquid in order to establish a comparable reference relaxation state.

The medium-range order of the different stages of the amorphous structures were investigated by fluctuation electron microscopy and compared with that of the as-cast state. The results indicate that first, a defined structural reset was achieved when heating into the supercooled liquid; however, with increased strain due reduction of excess volume. Second, the annealing treatment at $0.8T_g$ increases the volume fraction of medium-range order again with annealing time and third, a depletion of the volume fraction is observed after annealing at $0.9T_g$.

MM 28.2   Wed 10:30   SCH A 118

Analysis of the relaxational behavior of PdNiS — •Maximilian Demming[1], Nico Neuber[2], Martin Peterlechner[1], Ralf Busch[2], and Gerhard Wilde[1] — [1]University of Münster, Münster, Germany — [2]Saarland University, Saarbrücken, Germany

In this work we examine a sulfur-containing bulk metallic glass, PdNiS. The impact of sulfur is investigated with a focus on the thermodynamic behavior and the comparison with the well-known PdNiP bulk metallic glass. Several samples from the same initial state were annealed at a certain temperature below Tg for different annealing times in order to adjust distinct relaxation states. After isothermal annealing in a differential scanning calorimeter (DSC), a calorimetric study was carried out to examine the relaxation behavior. Especially the so-called overshoot during heating the samples through the glass transition was

evaluated, since it is one of the most prominent signals which depends on the thermal history of a metallic glass. Additionally, low temperature heat capacity measurements were performed to quantify the so-called boson peak. The boson peak can be related to soft vibrational modes, and thus it is characteristic to the relaxational state of a metallic glass and it is affected by the thermal history of a glass. All methods combined deliver a picture of the relaxational behavior under pre-Tg annealing of this Sulphur-containing metallic glasses.

MM 28.3   Wed 10:45   SCH A 118

Unravelling the origin of the anomalous thermal expansion in Fe-based bulk metallic glasses — •Alexander Firlus[1], Mihai Stoica[1], Gavin Vaughan[2], Stefan Michalik[3], Robin E. Schäublin[1], and Jörg F. Löffler[1] — [1]Laboratory of Metal Physics and Technology, ETH Zurich, 8093 Zurich, Switzerland — [2]European Synchrotron Radiation Facility (ESRF), Grenoble, France — [3]Diamond Light Source Ltd., Didcot, UK

Fe-based bulk metallic glasses (BMGs) are known for their soft-magnetic properties but their magnetic interactions also give rise to an anomalous thermal expansion, called the Invar effect. In the ferromagnetic state, their coefficient of thermal expansion is reduced by a factor of four. This phenomenon has been observed in all ferromagnetic Fe-based BMGs at the macroscopic scale, but due to the lack of long-range order the physics of this effect needs to be described at the atomic scale. Although it is now widely accepted to be of magnetic origin, the contributions of the different atomic species to the Invar effect have been unknown. We studied the atomic-scale thermal expansion of multiple quaternary BMGs by in situ X-ray diffraction. The anomalous thermal expansion is visible in all diffraction patterns and can clearly be associated with the disordered Fe network. Through variations of the minor alloying elements, we elucidated the effect of different atomic species and provide a framework in which their respective influence on the Invar effect can be understood.

MM 28.4   Wed 11:00   SCH A 118

Rejuvenation engineering in metallic glasses by complementary stress and structure modulation — •Daniel Şopu[1,2], Florian Spieckermann[3], Simon Fellner[1], Christoph Gammer[1], and Jürgen Eckert[1,3] — [1]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences, Leoben, Austria — [2]Institut für Materialwissenschaft, Technische Universität Darmstadt, Germany — [3]Department of Materials Science, Chair of Material Physics, Montanuniversität Leoben, Austria

Residual stress engineering is very widely used in the design of new advanced lightweight materials. For metallic glasses the attention has been on structural changes and rejuvenation processes. Here, based on high energy scanning X-ray diffraction strain mapping, transmission electron microscopy (TEM) and microindentation we distinguish between structural and elastic fluctuations, the two key factors for the observed extreme rejuvenation in triaxial compression. TEM characterization shows that structural rejuvenation under room temperature deformation relates to shear-induced softening and dilatation (large volumetric strain). High energy scanning X-ray diffraction strain mapping reveals large elastic fluctuations in metallic glasses after deformation under triaxial compression. Microindentation hardness mapping hints to a competing hardening-softening mechanism after compression and further reveals the complementary effects of stress and structure modulation. Molecular dynamics simulations provide an atomistic understanding of the complex shear band activity in notched metallic glasses and the related fluctuations in the strain/stress heterogeneity.

MM 28.5   Wed 11:15   SCH A 118

Enhancing mechanical properties by introducing surface grooves in metallic glasses — •Xudong Yuan[1], Daniel Şopu[1,2], Kaikai Song[3], and Jürgen Eckert[1,4] — [1]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences, Jahnstraße 12, Leoben A-8700, Austria — [2]Institut für Materialwissenschaft, Fachgebiet Materialmodellierung, Technische Universität Darmstadt, Otto-Berndt-Str.3, Darmstadt D-64287, Germany — [3]School of Mechanical, Electrical and Information Engineering, Shandong University (Weihai), Weihai 264209, China — [4]Department of Materials Science, Chair of Materials Physics, Montanuniversität Leoben, Jahnstraße 12, Leoben A-8700, Austria

The correlation between the mechanical properties and surface defects in metallic glasses (MGs) is investigated by surface ultrasonic bonding experiments and molecular dynamics simulations. The strength together with the compression ductility of Zr65Cu15Ni10Al10 MG can be enhanced by introducing surface grooves. Induced grooves and pre-shear bands (SBs) lead to the formation and interaction of multiple SBs during compression, which consequently enhances ductility. Additionally, the thermal-induced nanocrystallization, together with generated free volume and residual stresses around the grooves contribute to the emergence of hierarchical structure and stress heterogeneity, which delays the propagation of dominant SB and enables the improvement of strength and plasticity of MG.

MM 28.6   Wed 11:45   SCH A 118

Atomic transport in heavy ion irradiated amorphous PdNiP near the glass transition temperature — •Saba Khademorezaian[1], Marilena Tomut[1,2], Maximillian Demming[1], Sergiy Divinski[1], and Gerhard Wilde[1] — [1]Institute of Materials Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster — [2]GSI Helmholtzzentrum für Schwerionenforschung, 64291 Darmstadt, Germany

The influence of ion irradiation on Ag diffusion in Pd40Ni40P20 bulk metallic glass was investigated by the tracer diffusion technique at temperatures below the glass transition. Bulk samples of Pd40Ni40P20 relaxed states were irradiated with 4.8 MeV/u Au, U, and Ca ions at the UNILAC accelerator at GSI Darmstadt. The achieved fluences were in the range of 5e10 to 1e13 ions/cm2. The diffusion rates of 110mAg isotopes after irradiation with heavy ions, Au and U, were found to be monotonously increasing with increasing total fluence. For the light ions, Ca, the diffusion enhancement shows an unexpected non-monotonous, crossover behavior. The results are discussed relating the impacts of irradiation with swift heavy ions on structure modifications and the atomic kinetics in a bulk metallic glass.

MM 28.7   Wed 12:00   SCH A 118

Nanostructural investigations on thin film nanoglasses using different TEM techniques — •Hendrik Voigt[1], Evgeniy Boltynjuk[2], Aaron Rigoni[1], Horst Hahn[2], Harald Rösner[1], and Gerhard Wilde[1] — [1]University of Münster, Institute of Materials Physics, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany — [2]Karlsruhe Institute of Technology, Institute of Nanotechnology, Hermann-von-Helmholtz-Platz 1, 76344 Eggenstein-Leopoldshafen, Germany

Nanoglasses as a relatively new family of amorphous alloys present an attempt to tailor the structure of glasses to improve their properties. The concept of nanoglasses is based on the introduction of glass-glass interfaces into the amorphous material, mimicking the effect that defects have in crystalline matter. Different transmission electron microscopy (TEM) techniques were used to investigate the microstructure of Cu60Zr40 columnar thin film nanoglasses. Nanobeam diffraction pattern (NBDP) analysis and energy dispersive X-ray spectroscopy (EDX) were employed to investigate differences in the excess free volume and chemical composition. NBDP acquired over an extended region of interest were used to perform an angular correlation analysis revealing different symmetry motives compared to a compositionally equivalent homogenous glass. Additionally, time-of-flight secondary ion mass spectroscopy (ToF SIMS) measurements discovered an increase in diffusivity in the nanoglasses. All the results shown here provide clear evidence for the existence of glass-glass interfaces with two structurally different phases present in the nanoglass.

MM 28.8   Wed 12:15   SCH A 118

Properties of Sodium Borosilicate Glasses via Dynamics Simulations with Ultra-Fast Machine-Learning Potentials — •Hendrik Krass[1], Benedikt Ziebarth[2], Wolfgang Mannstadt[2], and Matthias Rupp[3] — [1]University of Konstanz, Konstanz, Germany — [2]Schott AG, Mainz, Germany — [3]Luxembourg Institute of Science and Technology (LIST), Belvaux, Luxembourg

Glasses are of scientific interest and have many industrial applications. However, their investigation and development are limited by the duration and costs of experiments. The computational study of glasses can in principle overcome these limits, but current atomistic glass models are either fast but not accurate enough (classical empirical potentials) or accurate but too slow (ab initio potentials). Machine-learning potentials (MLPs) trained on ab initio reference calculations promise to be both fast and accurate enough.

We investigate the suitability of "ultra-fast potentials" (UFPs) [1]—a class of MLPs that are data-efficient, physically interpretable, sufficiently accurate for applications, can be parametrized automatically, and are as fast as the fastest traditional empirical potentials—to study glasses. For this, we compute structure and properties of interest via dynamics simulations with UFPs and compare them against state-of-the-art models and experimental values for sodium borosilicate glasses, a prototypical glass system.

MM 28.9   Wed 12:30   SCH A 118

An atomic scale inspired phase-field approach to model fracture in amorphous silica — •Gergely Molnar[1], Gaylord Guillonneau[2], Guillaume Kermouche[3], and Etienne Barthel[4] — [1]Univ Lyon, CNRS, INSA Lyon, LaMCoS, UMR5259, 69621 Villeurbanne, France — [2]Univ Lyon, Ecole Centrale de Lyon, CNRS, LTDS, UMR CNRS 5513, 69134 Ecully, France — [3]Mines Saint-Etienne, CNRS, UMR 5307 LGF, Centre SMS, 42023 Saint Etienne, France — [4]ESPCI, CNRS, SIMM, UMR7615, 75231 Paris, France

In the last decade, phase-field models have gained great popularity in fracture simulation. These models regularize the sharp crack using an internal length-scale by diffusing the damage into the material. This work was set out to investigate the competition between homogeneous plastic deformation, shear banding, and brittle failure in amorphous silica. The molecular dynamics inspired finite

element model uses the phase-field approach to model fracture, while a pressure-dependent yield criterion accounts for densification and shear plasticity. The talk presents a proof of concept to model plasticity and crack propagation in micrometer size silica samples.

Band Gap and Formation Energy Inference of Solids using Message Passing Neural Networks — •Tim Bechtel, Daniel Speckhard, and Claudia Draxl — Humboldt-Universität zu Berlin, Physics Department and IRIS Adlershof, Berlin, Germany

Graph-based neural networks and, specifically, message-passing neural networks have shown great promise in predicting physical properties of solids. Here, we target three tasks, formation energy regression, metal- non-metal classification, and band gap regression, using data from the AFLOW materials database [1]. In order to find optimal hyperparameters and model architecture, we perform a neural architecture search on the band gap regression task, using a random search algorithm. The model is based on a message passing neural network with edge updates [2], and provides users with uncertainty estimates via Monte-Carlo dropout. We analyze the domain of applicability of the model, for different space group symmetries, atomic species, and corrections applied to the underlying calculation. While we obtain overall excellent results, the model struggles to accurately predict oxide materials. We find that the uncertainty in different domains reflects the model's predictive performance.

MM 29.2   Wed 12:00   SCH A 251
Predicting electron density using a convolutional neural network — •Jae-Mo Lihm[1,2,3], Wanhee Lee[4], and Cheol-Hwan Park[1,2,3] — [1]Department of Physics and Astronomy, Seoul National University, Seoul, Korea — [2]Center for Correlated Electron Systems, Institute for Basic Science, Seoul, Korea — [3]Center for Theoretical Physics, Seoul National University, Seoul, Korea — [4]Department of Applied Physics, Stanford University, California, USA

Machine-learning methods are being widely applied to computational materials science. Most applications of machine learning in electronic structure calculations focus on learning the total energy and forces, while few works study the prediction of electronic properties. In this work, we develop a machine-learning model for predicting electron density using the convolutional neural network, a standard machine-learning method for image processing. We train the neural network using the electron density calculated from density functional theory. We show that the trained neural network can successfully predict the electron density of systems that were not included in the training set, bypassing the need for the self-consistent density functional theory calculation.

MM 29.3   Wed 12:15   SCH A 251
Chemical ordering and magnetism in CrCoNi Medium Entropy Alloy — •Sheuly Ghosh[1], Vadim Sotskov[2], Alexander Shapeev[2], Jörg Neugebauer[1], and Fritz Körmann[1,3] — [1]Max-Planck-Institut für Eisenforschung GmbH — [2]Skolkovo Institute of Science and Technology — [3]Delft University of Technology

The equiatomic CrCoNi medium entropy alloy is a prototypical multiple-principal element alloy (MPEA), exhibiting many superior mechanical properties. Short-range order (SRO) is known to affect the thermodynamic phase stability as well as mechanical and magnetic properties of MPEA alloys. In CrCoNi also, the presence of SRO and its impact on different aspects has been intensively discussed in various studies. In our recent study, we identified the ground-state ordered structure for this alloy combining *ab initio* calculations and on-lattice machine-learning interatomic potentials. Based on these studies, an ordered $Cr(Ni,Co)_2$ phase ($MoPt_2$-type) was found. In present work, we further discuss the stability of the newly identified ordered structure and compare them with the previously suggested ones, particularly with respect to magnetism, local atomic relaxation energies as well as volume fluctuations.

MM 29.4   Wed 12:30   SCH A 251
Charge-dependent Atomic Cluster Expansion — •Matteo Rinaldi, Anton Bochkarev, Yury Lysogorskiy, Matous Mrovec, and Ralf Drautz — Interdisciplinary Centre for Advanced Materials Simulation, Bochum, Germany

The atomic cluster expansion (ACE) [1,2,3] has proven to be a valuable tool to parametrize complex energy landscapes of pure elements and alloys outperforming popular approaches based on limited body-order descriptions. However, due to the local nature of the many body basis, it is inherently near-sighted. Therefore, long range interactions, such as electrostatics, are ignored in the description. Here, we introduce charge-dependent ACE to be able to tackle the missing electrostatic contributions. This formalism is based on the QEQ charge equilibration scheme from Rappe et al.^[4], where partial charges are obtained by equalizing atomic electronegativities and imposing charge conservation. Moreover, atomic electronegativities and hardness are considered as dependent on the local atomic environment. We demonstrate that our approach yields atomic charges in agreement with those obtained from popular partitioning schemes, such as Mulliken and Hirshfeld, including periodic and non-periodic systems, together with an accurate reproduction of the potential energy landscape. This work opens the possibility to model charge transfer and dielectric response within the increasingly popular ACE framework.

MM 29.5   Wed 12:45   SCH A 251
A machine-learned interatomic potential for silica and mixed silica-silicon systems — •Linus C. Erhard[1], Jochen Rohrer[1], Karsten Albe[1], and Volker L. Deringer[2] — [1]Institute of Materials Science, TU Darmstadt, Darmstadt, Germany — [2]Department of Chemistry, Inorganic Chemistry Laboratory, University of Oxford, Oxford, United Kingdom

The interface between silica and silicon has enormous relevance in various applications, including semiconductors and novel battery materials. However, atomistic modeling of this interface is a challenge due to the different charge states of silicon and the limitations of classical interatomic potentials. To overcome these limitations, we introduce a machine-learning-based interatomic potential based on the non-linear atomic cluster expansion (ACE) for various Si-O phases. This model is based on the previously developed database for silica [1], which was substantially extended by active learning. The new model shows improved performance for high-pressure silica and is also able to describe silica surfaces. Moreover, the use of the ACE formalism enables us to reach more than 100 times longer time or larger length scales compared to the Gaussian approximation potential (GAP). Finally, the potential is able to describe off-stoichiometric mixtures of Si and SiO_2. This capability is used to investigate the nanostructure of silicon monoxide.

Direct observations of grain boundary phase transformations in metallic alloys — •Christian Liebscher — Max-Planck-Institut für Eisenforschung, 40237 Düsseldorf, Germany

Grain boundaries (GBs) play a pivotal role in determining the properties of metallic materials. In most considerations, GBs are seen as a simple 2D defect. However, thermodynamic concepts already proposed 60 years ago showed that GBs can undergo phase transformations, but the search for them has been in vain due to their confined nanoscale nature.

We show that GB phases exist in elemental copper. Atomic resolution scanning transmission electron microscopy is used to unravel multiple coexisting GB structures in the same GB. The intrinsic character and thermodynamic properties of the GB phases and their transitions is investigated by atomistic simulations. We find that the GB phase junction, a line defect that separates different GB phases, is kinetically limiting the transformation and plays a decisive role in the nucleation and arrangement of GB phases within the interface. By heating GBs inside of the electron microscope, we are able to directly observe how GB phases evolve at elevated temperatures with atomic resolution. In the reminder of the talk, we will also discuss the impact of solute segregation on GB transitions in copper and titanium alloys by exploring the local atomic arrangement of solutes within the GB.

MM 31: Data Driven Materials Science: Big Data and Work Flows – Machine Learning

Neural networks trained on synthetically generated crystals can classify space groups of ICSD powder X-ray diffractograms — •HENRIK SCHOPMANS, PATRICK REISER, and PASCAL FRIEDERICH — Institute of Theoretical Informatics, KIT, Karlsruhe, Germany

Machine learning techniques have successfully been used to extract structural information such as the crystal space group from powder X-ray diffraction (XRD) patterns. However, training directly on simulated patterns from databases like the ICSD is problematic due to its limited size, class-inhomogeneity, and bias toward certain structure types. We propose an alternative approach of generating random crystals with random coordinates by using the symmetry operations of each space group. Based on this approach, we present a high-performance distributed python framework to simultaneously generate structures, simulate patterns, and perform online learning. This allows training on millions of unique patterns per hour. For our chosen task of space group classification, we achieve a test accuracy of 77.4% on new ICSD structure types not included in the statistics dataset guiding the random generation. Instead of space group classification, the developed framework can also be used for other common tasks, such as augmentation and mixing of patterns for phase fraction determination. Our results demonstrate, using the domain of X-ray diffraction, how state-of-the-art models trained on large, fully synthetic datasets can be used to guide the analysis of physical experiments.

MM 31.2   Wed 16:00   SCH A 251

Critical Assessment of Uncertainty Estimates of Machine- Learning Potentials — •SHUAIHUA LU[1,2], LUCA M. GHIRINGHELLI[1], CHRISTIAN CARBOGNO[1], and MATTHIAS SCHEFFLER[1] — [1]Novel Ma- terials Discovery at the FHI of the Max-Planck-Gesellschaft and IRIS- Adlershof of the Humboldt-Universität zu Berlin, Berlin, Germany — [2]School of Physics, Southeast University, Nanjing, China

Machine-learning potentials (MLP) trained on first-principles datasets are becoming increasingly popular since they enable the treatment of larger system sizes and longer time scales compared to straight ab initio techniques. A key aspect for the use of these MLPs is to reliably assess the accuracy viz. uncertainty of the predictions, e.g., by training an ensemble of models. Here, we critically examine the robustness of such uncertainty predictions using equivariant message-passing neural networks as an example [1]. We train an ensemble of models on liquid silicon simulated at the gradient-corrected density-functional-theory level and compare the predicted uncertainties with actual errors for various test sets, including liquid silicon at different temperatures and out-of-training-domain data such as solid phases with and without point defects as well as surfaces. These studies reveal that the predicted uncertainties are often overconfident. This is ascribed to the insufficient diversity in the members of the ensemble, as measured via error correlations. [1] S. Batzner et al., Nat. commun. 13, 2453 (2022).

Learning to Spell Materials - Coordinate-free Discovery with Natural Language Processing — •KONSTANTIN JAKOB, KARSTEN REUTER, and JOHANNES T. MARGRAF — Fritz Haber Institute, Berlin, Germany

Over the last decade, computational screening with structure-based machine learning models has led to some advances in the discovery of novel inorganic materials. Unfortunately, the overwhelmingly large space of possible compositions and atomic configurations together with the exceeding rarity of well-suited candidates ultimately poses a limit to the applicability of this approach. In contrast, purely composition-based representations neglect differences in the chemical properties of different crystal polymorphs and thus lack accuracy. A middle ground between full structural and simple compositional representations has been established for organic molecules using string representation such as SMILES. While these have proven highly advantageous for molecular discovery when combined with natural language processing models, analogous representations for the more complex class of inorganic materials are still missing. Bridging this gap, we investigate the performance of recurrent neural networks (RNNs) in predicting crystallographic properties by reading a materials composition element by element. Their striking accuracy suggests that symmetry- or prototype-based string representations could be generated with little computational effort at a large scale. The invertibility of these intermediate representations via restricted structure searches is investigated, paving the way to their application for conditional generative models.

Exploring materials dataspaces by combining supervised and unsupervised machine learning — •ANDREAS LEITHERER[1], ANGELO ZILETTI[1], CHRISTIAN H. LIEBSCHER[2], TIMOFEY FROLOV[3], and LUCA M. GHIRINGHELLI[1,4] — [1]NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft and IRIS-Adlershof of the Humboldt-Universität (HU) zu Berlin — [2]Max-Planck-Institut für Eisen-

forschung — [3]Lawrence Livermore National Laboratory — [4]Physics Department and IRIS-Adlershof of HU zu Berlin

To enable meaningful applications of AI to materials science, much of current efforts is concentrated on the creation of characterized datasets. In this talk, we discuss a rarely addressed topic - the development of automatic tools to explore available materials-science data. In particular, we go beyond purely supervised learning by combining unsupervised analysis with a recently developed crystal-structure recognition method [1]. This neural-network (NN) model automatically learns data representations that contain information on structurally diverse geometries. Using clustering, physically meaningful subgroups can be identified in the NN latent space, which are shown, e.g., to correspond to distinct, experimentally verified grain-boundary phases [2]. Moreover, dimension-reduction analysis allows us to create low-dimensional, interpretable materials charts that visualize complex structural data from both theoretical and experimental origin.

Minimizing data requirements by transfer learning for structure search on organic/inorganic interfaces — •ELIAS FÖSLEITNER, JOHANNES CARTUS, LUKAS HÖRMANN, and OLIVER T. HOFMANN — Institute of Solid State Physics, Graz University of Technology, Graz, Austria

Performing structure search of organic molecules on metallic surfaces requires finding the structure with the lowest energy. However, calculating energies using conventional DFT codes proves to be a time-consuming task since single calculations are expensive and the number of configurations is large. To avoid the calculation of all possible structures, machine learning techniques such as Gaussian process regression have shown to be a useful tool in order to reduce the amount of DFT data needed. In our work we try to further reduce the amount of necessary data by using transfer learning from one substrate to another. To do this we include DFT data from structures of more than one substrate in our training set. In order to calculate the similarities between structures on different substrates we use the SOAP descriptor combined with an alchemical kernel which provides couplings between the different substrate elements. By optimizing these couplings, although molecule-substrate interactions differ notably (e.g. the interfacial charge transfer) between different substrates, we can save up to 50 % of the training data for one substrate A by also using the data of another substrate B. This serves as a stepping stone for the investigation of structures on computationally costly substrates.

Accelerating the Search for High-Performance, Novel Materials with Active Learning — •THOMAS A. R. PURCELL[1], MATTHIAS SCHEFFLER[1,2], LUCA M. GHIRINGHELLI[1,2], and CHRISTIAN CARBOGNO[1] — [1]The NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft and IRIS-Adlershof of the Humboldt-Universität zu Berlin — [2]Physics Department and IRIS-Adlershof at Humboldt Universität zu Berlin, Berlin, Germany.

Active-learning frameworks have the potential to greatly accelerate the search for new materials. By balancing exploitation and exploration, these approaches can efficiently search through materials space and find the regions that are most likely to contain promising candidate materials [1]. Here we present an active learning framework, that uses an ensemble of expressions found by the sure-independence screening and sparsifying operator (SISSO) approach [2,3], and we demonstrate it for the example of discovering new thermal insulators. We statistically process the predictions of independent SISSO models to automatically select the most promising material candidates and then calculate their thermal conductivity κ_L using the *ab initio* Green Kubo method [4]. Using this approach we are able to find multiple new thermal insulators and gain insights into what is driving down their κ_L.

Data-driven magneto-elastic interatomic potentials for discovering novel phases of transition metal alloys — •Mani Lokamani[1], Kushal Ramakrishna[4], Julian Tranchida[3], Svetoslav Nikolov[2], Hossein Tahmasbi[4], Michael Wood[2], and Attila Cangi[4] — [1]HZDR Dresden, Germany — [2]SNL New Mexico, USA — [3]CEA Cadarache, France — [4]CASUS Görlitz, Germany

Structural prediction methods are used for identifying stable and metastable structures in a broad spectrum of materials. The presence of the electron spin degree of freedom in magnetic materials increases the complexity of finding such structures, constraining the analysis to the thermodynamically most relevant structures in a narrow range of temperatures and pressures. We achieve a search over much wider temperature and pressure conditions by utilizing machine-learning interatomic potentials based on the spectral neighbor analysis method within the coupled spin-molecular dynamics framework implemented in LAMMPS. This data-driven methodology enables predicting the properties of magnetic materials on much larger spatial, spin, and temporal domains and is parametrized by first-principles data. Leveraging this methodology, we predict the formation of metastable crystalline structures in transition metal alloys (FeNi, FeMn, FeCr, FeCo, FeGd) at high temperature-pressure conditions and assess their magnetic properties. This enables studying long-range spin structures in novel phases of transition metal alloys and complements the quest for permanent magnets for renewable energy applications that do not depend on rare-earth elements.

FAIR Modelling Recipes for High-Throughput Screening of Metal Hydrides — •Kai Sellschopp[1], Philipp Zschumme[2], Michael Selzer[2], Claudio Pistidda[1], and Paul Jerabek[1] — [1]Institute for Hydrogen Technology,

Helmholtz-Zentrum Hereon, Geesthacht, Germany — [2]IAM - Microstructure Modelling and Simulation, Karlsruhe Institute of Technology, Karlsruhe, Germany

A simple modelling recipe for calculating the hydrogenation enthalpy of metal hydrides with ab-initio methods is presented. It consists of the everyday tasks of a computational materials scientist: relaxing a structure, optimising its volume, and calculating vibrational energies. The corresponding workflow is implemented in the framework of KadiStudio[1], where the scientific process is broken down into simple input-processing-output (IPO) tasks. The approach allows to track the inputs and outputs, to easily re-use the modular tasks in other workflows, and to share the workflow as a simple bash or python script. Therefore, not only the generated research data, but also the workflow itself fully comply with the FAIR data principles. As a first application, the recipe is employed to test how the different ingredients of an ab-initio calculation (e.g. xc-functional) affect the accuracy of predicting hydrogenation enthalpies. This helps to make better choices for studying this class of materials in the future and to judge the uncertainty in existing data. Furthermore, the standardized workflow enables a reliable high-throughput screening of new candidate materials for high-density hydrogen storage at near ambient conditions.

MM 31.10   Wed 18:15   SCH A 251
Take Two: Δ-Machine Learning for Molecular Co-Crystals — •Simon Wengert[1], Gábor Csányi[2], Karsten Reuter[1], and Johannes Theo Margraf[1] — [1]Fritz-Haber Institute, Berlin, Germany — [2]University of Cambridge, Cambridge, United Kingdom

Co-crystals are a highly interesting material class, as varying their components and stoichiometry in principle allows tuning supramolecular assemblies towards desired physical properties. The *in silico* prediction of co-crystal structures represents a daunting task, however, as they span a vast search space and usually feature large unit-cells. This requires theoretical models that are accurate and fast to evaluate, a combination that can in principle be accomplished by modern machine-learned (ML) potentials trained on first-principles data. Crucially, these ML potentials need to account for the description of long-range interactions, which are essential for the stability and structure of molecular crystals. In this contribution, we present a strategy for developing Δ-ML potentials for co-crystals, which use a physical baseline model to describe long-range interactions. The applicability of this approach is demonstrated for co-crystals of variable composition consisting of an active pharmaceutical ingredient and various co-formers. We find that the Δ-ML approach offers a strong and consistent improvement over the density-functional tight binding baseline. Importantly, this even holds true when extrapolating beyond the scope of the training set as demonstrated via molecular dynamics simulations at ambient conditions.

MM 32: Topical Session: Defect Phases I

Time: Wednesday 15:45–18:30   Location: SCH A 216

Topical Talk   MM 32.1   Wed 15:45   SCH A 216
Defect phase diagrams: Concepts, computational approaches and applications — Marvin Poul, Prince Mathews, Ali Tehranchi, Jing Yang, Mira Todorova, Tilmann Hickel, and •Jörg Neugebauer — Max-Planck-Insitut für Eisenforschung GmbH, Düsseldorf, Germany

Extending the well-known concept of bulk phase diagrams to defects allows to predict the thermodynamically stable defect states at any given temperature and bulk composition. Similar to bulk phase diagrams such diagrams allow to identify processing conditions where defect states with particularly desirable stoichiometries, structures and properties form. These diagrams thus provide an exciting new approach in designing materials. Modern atomistic tools based on density functional theory or machine learning potentials can provide all the necessary information to construct such phase diagrams but face severe conceptual and computational challenges: The description of such defects requires thermodynamically open boundary conditions as well as the inclusion of a large number of structural, chemical and electronic degrees of freedom. In the presentation, key concepts of efficiently sampling the large configuration spaces associated with computing defect states and phase diagrams will be discussed. Examples of how this insight can be used to understand and control grain boundary formation, morphology or improved corrosion resistance will be given.

MM 32.2   Wed 16:15   SCH A 216
Fully Automated Calculation of Defect Phase Diagrams — •Marvin Poul, Erik Bitzek, and Joerg Neugebauer — Max-Planck-Institut fuer Eisenforschung, Duesseldorf, Deutschland

Understanding the thermodynamics of segregation at crystal defects is an important part of successful materials engineering.[1] We present an efficient method that constructs finite temperature Defect Phase Diagrams (DPDs) for binary alloys from fully relaxed molecular calculations using machine learning interatomic potentials (MLIP) without user intervention and implemented it as a pyiron[2] workflow. A major challenge that we had to address is the combinatorially growing number of different segregation configurations at any extended defect. The proposed method is able to efficiently tackle hundreds of thousands to millions of configurations and is based on a fast proxy model. This model is based on the ACE descriptors and avoids having to evaluate a full MLIP. This proxy model together with the MAXVOL active learning algorithm allows to pre-screen which configurations to calculate with the underlying MLIP. We apply the workflow on the example of Al and Ca segregation to Mg grain boundaries.

MM 32.3   Wed 16:30   SCH A 216
Effect of chemical changes on the defect structures in lean rare-earth free ternary Mg alloys — •Wassilios Delis[1], Deborah Neuss[2], Marcus Hans[2], Dierk Raabe[3], Sandra Korte-Kerzel[1], and Stefanie Sandlöbes-Haut[1] — [1]Institute for Physical Metallurgy and Materials Physics, RWTH Aachen University, Germany — [2]Materials Chemistry, RWTH Aachen University, Germany — [3]Max-Planck Institut für Eisenforschung, Max-Planck-Straße 1, 40237 Düsseldorf, Germany

Mg is a lightweight structural material with a good specific strength. Unfortunately, it lacks sufficient room temperature formability and therefore a wider commercial use of Mg is hindered. The preferred basal slip and strong basal-type texture were found to be the main reasons for the poor room temperature formability. Alloys containing low amounts of Al and Ca showed a highly increased room temperature ductility. Here, TEM and APT measurements and ab initio calculations showed an increased activity of $<c+a>$ dislocation slip. The effects of the alloying elements are yet not fully understood. Further research has been performed to investigate how the changes in chemistry affect the structure of defects such as boundaries and dislocations.

MM 32.4   Wed 16:45   SCH A 216

High-throughput generation of defect phase diagrams: A case study in grain boundary solute segregation analysis in Ni base alloys — •HAN LIN MAI, TILMANN HICKEL, and JÖRG NEUGEBAUER — Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Straße 1, 40237 Düsseldorf, Germany

Understanding segregation to grain boundaries, and eventually their defect phase diagrams, is critical to enable rational grain boundary engineering for alloys design. Here, we discuss the progress and challenges one may face when generating such a database of defect-solute interactions, in the context of studying of grain boundary segregation of solutes and impurities in Ni GBs. To compute the large number of relevant defect-solute interactions we have performed high-throughput ab initio calculations using efficient and highly automated workflows using pyiron. The study has been performed across a representative set of coincident-site-lattice (CSL) type tilt GBs. Based on the large ab-initio datasets, we extract and analyse the chemical and structural trends observed in the solute segregation behaviour across the periodic table. The features which are most important in evaluating site segregation are presented and discussed.

15 min. break

MM 32.5   Wed 17:15   SCH A 216

Planar defects in intermetallic $Mg_xAl_{2-x}Ca$ Laves phases — •ALI TEHRANCHI[1], TILMANN HICKEL[1,2], and JÖRG NEUGEBAUER[1] — [1]Max-Planck-Institut für Eisenforschung GmbH, D-40237 Düsseldorf, Germany — [2]Bundesanstalt für Materialforschung und -prüfung (BAM)

The intermetallic Laves phases that are present in Mg-based alloys when adding Ca and Al beyond the solubility limit have a beneficial impact on the mechanical properties of these alloys. For example, Laves phases have been observed to enhance the alloy's creep resistance and to extend their application to higher-temperature domains. However, the mechanism of deformation of these phases and their effect on the surrounding matrix is not fully understood. Laves phases not only contain planar defects but also their motifs are observed in planar defects in Mg. In this work, using the concept of defect phase diagrams, we study hcp-like planar defects in the C36 phase and the thermodynamically stable Laves-type planar defects in Mg-based alloys. We show, that while conventional bulk thermodynamic phase diagrams fail to predict the experimentally observed phases the predictions obtained by the defect phase diagrams match well with the experiments. Defect phase diagrams thus provide a powerful tool to predict and interpret the formation of chemically and structurally complex motives at defects as function of experimentally accessible and controllable parameters such as temperature or alloy composition.

MM 32.6   Wed 17:30   SCH A 216

Oxygen vacancy formation energies at grain boundaries in perovskite-type electro-ceramics — •CONG TAO[1], DANIEL MUTTER[1], DANIEL F. URBAN[1,2], and CHRISTIAN ELSÄSSER[1,2] — [1]Fraunhofer IWM, 79108 Freiburg — [2]Freiburg Materials Research Center (FMF), University of Freiburg, 79104 Freiburg

Oxygen vacancy concentrations are assumed to play a major role in the electric-field assisted grain growth of technologically relevant single crystal perovskite phases. The underlying effect on the atomic scale is the redistribution of cationic and anionic point defects between grain boundaries and bulk phases due to different defect formation energies in the structurally different regions, accompanied by the formation of space charge zones. In this study, we present results of classical atomistic calculations of oxygen vacancy formation energy profiles across supercells containing the symmetric tilt grain boundaries $\Sigma 5\,(210)\,[001]$, $\Sigma 5\,(310)\,[001]$, and the asymmetric tilt grain boundary $(430)\,\|\,(100)$. The electro-ceramic perovskite materials $SrTiO_3$, $BaTiO_3$, and $BaZrO_3$ were systematically analyzed. We discuss the dependence of formation energies and resulting concentration profiles on composition and grain boundary type.

MM 32.7   Wed 17:45   SCH A 216

Temperature-dependent impact of antiphase boundaries on properties of Fe_3Al — •MARTIN FRIÁK[1,2], MIROSLAV ČERNÝ[2,3], and MOJMÍR ŠOB[4,1] — [1]Institute of Physics of Materials, Czech Academy of Science, Brno, CZ — [2]Central European Institute of Technology (CEITEC), Brno University of Technology, Brno, CZ — [3]Faculty of Mechanical Engineering, Brno University of Technology, Brno, Czech Republic — [4]Department of Chemistry, Faculty of Science, Masaryk University, Brno, CZ

We have performed a quantum-mechanical study of the influence of antiphase boundaries (APBs) on the temperature dependence of selected materials properties of Fe_3Al. We show that the studied APBs very strongly affect thermal vibrations of Fe_3Al and reduce the width of the band gap in phonon frequencies. Our results also show that the Fe_3Al with APBs exhibits higher volumetric thermal expansion than the defect-free Fe_3Al. The computed free energy of APBs is found to be strongly temperature-dependent. It is lower than the static-lattice temperature-independent APB energy and the reduction is enhanced by increasing temperature (to 76% at T = 700 K). We have also addressed the discrepancy between the experimental bulk modulus and previous theoretical results obtained for the defect-free Fe_3Al. Due to the presence of APBs, the bulk modulus is reduced from the value of 173 GPa, that corresponds to the defect-free Fe_3Al, to 153 GPa, i.e. very close to the experimental value of 147 GPa (at T = 0 K). For details see Intermetallics 151 (2022) 107746, DOI:10.1016/j.intermet.2022.107746.

Topical Talk   MM 32.8   Wed 18:00   SCH A 216

Towards a Rigorous Theory of Grain Boundary Segregation in Polycrystals — •CHRISTOPHER SCHUH — MIT, Department of Materials Science and Engineering, Cambridge, MA USA

Although grain boundary segregation is pervasive across metals and materials, the models used to describe it generally fall short in one of two ways. One class of models is too approximate, using, e.g., a scalar 'average' segregation energy; the other is too detailed, focusing on specific atomic sites in select boundaries. Both approaches fail to capture the complex range of sites in the grain boundary network of polycrystals. This talk will overview a project in our group at MIT that aims to develop a new type of grain boundary segregation theory that bridges this gap: it is designed to be quantitatively accurate at the level of specific grain boundary sites, but simple enough to admit solution with an isotherm that can be analytically represented. The approach is based on the parameterization of segregation spectra: distribution functions of all the key thermodynamic quantities necessary to capture the full physics of segregation in polycrystals. We address the spectra of: segregation sites and their enthalpies, interaction parameters amongst solutes, and vibrational contributions to the segregation free energy. After describing computational methods to determine these spectra, we then address the problem of high-throughput computation of them for many alloy systems using tools of data science.

MM 33: Topical Session: Fundamentals of Fracture – Amorphous Metals

In situ measurement of plasticity accompanying Hydrogen induced cracking — LEONEL STERMANN, LOÏC VANEL, and •DÔME TANGUY — Institut Lumière Matière, UMR5306 Université Lyon 1 - CNRS, Université de Lyon 69622 Villeurbanne cedex, France

Single crack propagation is studied in a Hydrogen embrittled aluminum alloy. Hydrogen is introduced in the system by electrochemical reactions in an acid aqueous medium. After Hydrogen charging, tensile tests are performed in air, on notched samples, with a micro-tensile machine. An optical microscope is used to follow single crack initiation and propagation at a high magnification. Digital Image Correlation gives the displacement field on the surface with a spatial resolution of about 1 micron. It enables the determination of the position of the crack tip and the local velocity at a sub-grain scale. The equivalent Von Mises strain is calculated and gives a precise measure of the local plastic field which

accompanies crack propagation. In addition to the primary plasticity which is emitted from the crack tip or its immediate neighborhood in the form of two intense slip bands,It is systematically found a secondary plastic zone which spreads over several microns ahead of the tip. The characteristics of the plastic zone are measured, together with the velocity and the applied stress intensity factor. In addition, different fracture mechanisms are found on the fracture surface. In particular there are transitions in the fracture mode from intergranular smooth to transgranular parallel to the grain boundary plane. The local fracture mechanisms, in the vicinity of the surface, are linked to the local velocities and plastic deformations.

Liquid metal induced fracture : modelling and supporting experiments — Thierry Auger[1], Antoine Clement[1], Marco Ezequiel[2], •Eva Héripré[1], Ingrid Serre[2], Zehoua Hamouche[1], Julie Bourgon[3], Eric Leroy[3], and Maxime Vallet[4] — [1]PIMM/Arts et Métiers Technology Institute, CNRS, CNAM, 151 Bd de l'hôpital 75013 Paris, France — [2]Univ. Lille, CNRS, INRAE, Centrale Lille, UMR 8207 - UMET - Unité Matériaux et Transformations, F-59000 Lille, France — [3]ICMPE - UMR 7182 2/8, rue Henri Dunant 94320 Thiais, France — [4]MSSMAT, CentraleSupélec, University Paris-Saclay, France

Liquid metal embrittlement of an otherwise ductile material is an environmentally induced fracture phenomenon characterized by potentially high brittle crack propagation rate and deleterious effects on mechanical properties. Its phenomenology is still not well understood, in particular in terms of prediction of sensible couples and about the detailed intergranular fracture mechanisms. Here we will report on the study in the copper systems via both an energetic and QM/MM approaches at the atomic level to predict the sensitivity of model materials to liquid metal embrittlement. The main goal is to try to link micro-testing (flexion in FIB prepared samples or by in-situ TEM) to a sound modelling at the atomistic scale via fracture mechanics type sollicitations. The progress towards predictability of liquid metal embrittlement systems and understanding of fracture mechanisms will be presented along with a vision about their experimental validation.

Microscale fracture behavior of Laves phases in the Mg-Ca-Al ternary alloy system — •Anwesha Kanjilal, Uzair Rehman, James P. Best, and Gerhard Dehm — Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf, Germany

Brittle intermetallic Laves phases often act as preferential sites for defects such as cracks in the Mg-Ca-Al alloys. This study investigates the nano- and microscale fracture behavior of C15 Al2Ca and C14 Mg2Ca Laves phases prepared as single-phase specimens. Spherical nanoindentation was performed at room temperature in grains of varying surface orientation to identify cleavage planes and orientation effects. Post mortem microscopic examination using electron channeling contrast imaging revealed cracks around indents in both Laves phases, and together with electron backscatter diffraction low index crack planes were identified using trace analyses. For C15 phase, further microcantilever bending and micropillar splitting geometries were fabricated using focused ion beam methodology, wherein fracture toughness Kc ~1-2 MPam^0.5 was obtained from in-situ testing. Fast screening methodology based on in-situ scratch and nanoindentation at temperatures from 25 to 500 °C was employed to determine brittle-to-ductile transitions in the Laves phases. The morphology of slip lines and cracks, and decrease in hardness during nanoindentation suggests probable transition ~0.5Tm for C15 phase, while studies on C14 are ongoing.

The authors gratefully acknowledge the financial support of Deutsche Forschungsgemeinschaft (DFG) within project B06 of Collaborative Research Center (SFB) 1394, project number 409476157.

Fracture mechanics concepts in application to functionally graded coatings (FGCs) and FGC structures — •Vera Petrova and Siegfried Schmauder — IMWF, University of Stuttgart, Pfaffenwaldring 32, 70569 Stuttgart, Germany

The problem of thermal fracture of functionally graded thermal barrier coatings on a homogeneous substrate under the influence of thermo-mechanical loadings is analyzed. It is assumed that FGCs contain a pre-existing system of multiple cracks, edge and/or internal. The thermal and mechanical properties, as well as the fracture toughness of the FGC, are modeled by functions based on the rule of mixtures with a power-law coefficient as the gradation parameter. The problem is formulated using the method of singular integral equation, which are solved numerically. The following fracture characteristics are calculated: stress intensity factors, energy release rates, critical stresses and fracture angles. A series of computational experiments is carried out for FGC/homogeneous structures with typical systems of multiple cracks in the FGC at different gradation parameters and for different material combinations. It is known that the fracture resistance of a TBC can be increased by introducing dense vertical cracks in ceramic coatings; this mechanism is due to the shielding effect in these crack systems. These crack systems are studied and discussed. The goal of this study and the investigation based on the model is to find ways to improve the fracture resistance of FGC/homogeneous structures by avoiding certain critical crack systems.

MM 33.5   Wed 16:45   SCH A 215

Nonlinear elastic effect on interacting crack paths in PDMS films — •Loic Vanel[1], Osvanny Ramos[1], Thierry Biben[1], Stéphane Santucci[2], and Anthony Gravouil[3] — [1]ILM - UCBL, Villeurbanne, France — [2]LPENS - ENS Lyon, France — [3]LAMCOS, INSA Lyon, France

The observed repulsive behaviour of two initially collinear cracks growing towards each other and leading to a hook-shaped path questioned recently the validity of the Principle of Local Symmetry within Linear Elastic Fracture Mechan-

ics theory [1]. Theoretical and numerical work has solved this dilemma, providing the precise geometric conditions for the existence of the repulsive phase and revealing a multi-scale behaviour of the repulsive/attractive transition [2].

Nonlinear elastic materials such as elastomers depart from the prediction of linear elasticity for interacting cracks. We performed experiments on PDMS film that indeed show a maximum angle of repulsion not only significantly smaller than the one of linear elasticity, but also smaller than the one observed in polymer films with a plastic process zone. Our FEM simulations on a Mooney-Rivlin material confirm that the nonlinear elastic response of PDMS modifies the crack path, reducing the repulsive strength between the two interacting cracks.

Modelling mechanochemical reactions in epoxy resins under tensile load using hybrid QM/MM/MD approaches — •Christian R. Wick[1], Mattia Livraghi[1], Sampannah Pahi[1], Bariscan Arican[1], David M. Smith[2], and Ana-Sunčana Smith[1] — [1]FAU Erlangen-Nürnberg, PULS Group, Institute for theoretical physics, Erlangen, Germany — [2]Division of Physical Chemistry, IRB, Zagreb, Croatia

Epoxy resins are important thermosetting polymers in our everyday life with a large variety of applications, e.g. as structural materials in airplanes, as coatings, flooring materials or adhesives. With the aim to understand these complex materials at the molecular scale, we investigate the formation and the mechanochemical response of epoxy resins, including the reactions taking place during curing and under tensile load, by means of quantum chemistry and hybrid Molecular Dynamics (MD) simulations. We present a block chemistry based AMBER force field,[1,2] which allows generation of fragment partial charges covering all states of curing and fracture, due to cleavage of molecular bonds. Further, we develop an on-the-fly hybrid QM/MM/MD Ansatz to identify bond rupture events in bulk epoxies to improve our understanding of the mechanochemical behavior of these materials.

Cozzi 53, 20125 Milan, Italy.

Being able to predict the failure of materials based on structural information is a fundamental issue with enormous practical and industrial relevance for the monitoring of devices and components. Thanks to recent advances in deep learning, accurate fracture predictions are becoming possible even for strongly disordered solids, but the sheer number of parameters used in the process renders a physical interpretation of the results impossible. Here we address this issue and use machine learning methods to predict the failure of simulated two-dimensional silica glasses from their initial undeformed structure. We show that our predictions can be transferred to samples with different shapes or sizes than those used in training, as well as to experimental images.

MM 33.8   Wed 17:45   SCH A 215

Using deep neural networks to bridge the gap between statistical fractographic analysis and fracture toughness prediction for polymers — •Guillaume de Luca[1,2], Mohammed Idri[2], and Laurent Ponson[1,2] — [1]Institut Jean le Rond d'Alembert, Sorbonne Universite, CNRS, 4 place Jussieu 75006 Paris, France — [2]Tortoise, 231 rue Saint-Honoré, 75001 Paris, France

We propose to deploy DNNs to bridge the gap between statistical fractography and the toughness K_{Ic} prediction for polymers as well as shed light on the role played by the different structures on their fracture surfaces. We generate the fracture surfaces in laboratory through tensile fracture tests while using DIC (Digital Image Correlation) to locally measure and compute the sought mechanical properties along the crack. An interferometric profilometer extracts the topography from the fracture surfaces, and the resulting height fields are post-treated with tools from statistical fractography to be used as input, while the experimental data are used as labels for the regression problem.

By doing so, we can estimate from a scanned fracture surface a material toughness value $K_{Ic}(x)$ along the crack propagation direction. Furthermore, the advancements in explainable neural networks allow us to go one step further by

making assumptions about what roughness elements present on the fracture surface influence the most the results coming out of the pipeline.

MM 34: Members' Assembly

Welcome to this general meeting of the DPG-SKM division MM! All of you, presenters of MM talks or posters and other interested participants of this conference, are cordially invited to this meeting. The poster prizes will be presented, here. We will come together in a relaxed atmosphere and exchange information regarding MM. The current conference will be discussed and your feedback will be welcome. We will ask for your suggestions for topics for symposia or speakers to be invited for the next conference. Pretzels and drinks will be provided for free. Take this opportunity to tell us your ideas for MM at the next spring meeting and come to this general meeting of MM.

Time: Wednesday 18:45–19:45 Location: SCH A 251

All members of the Metal and Material Physics Division are invited to participate.

Configuration entropy and sample size effect on glass transition temperature — •YANNICK CHAMPION — Univ. Grenoble Alpes, CNRS, Grenoble-INP, SIMaP, 38000 Grenoble, France.
Amorphous materials show an intriguing transition at room temperature between localized and homogeneous deformation. This effect is observed for sample sizes in the micron range for silica glass, tens to hundreds of nm for metallic glasses and less than 20 nm for polymers. It is interpreted as a dependence of the glass transition temperature (Tg) with the sample size. Besides, this has been observed for polymer films and described by an empirical law proposed by Ked-

die and collaborators (Keddie et al, Europhys. Let 1994). A demonstration of this law is proposed from a statistical physics approach and using the potential energy landscape (PEL) description. The work is performed on a Mg-based metallic glass. A configuration entropy is derived from the size distribution of local areas in the PEL favorable to rearrangement. These zones are probed by nano-indentation and assumed to be related to the serrations observed in the deformation curves. The size of the serrations follows a Poisson distribution, indicating that their formation is a rare event. In addition to understanding the effect of size on Tg, the analysis allows the identification of statistical parameters describing the glass structure.

Orisodata: A methodology for grain segementation in atomistic simulations using orientation based iterative self-organizing data analysis — •ARUN PRAKASH — Micro-Mechanics and Multiscale Materials Modeling (M5), TU Bergakademie Freiberg
Atomistic simulations of the molecular statics/dynamics kind have established themselves as a cornerstone in the field of computational materials science. Large scale simulations with tens to hundreds of millions of atoms are regularly used to study the behavior of nano-(poly)crystalline materials. Identifying grains a posteriori in such simulations is a challenging task, particularly for simulations at high temperatures or at large strains. In this work, we propose a methodology for grain segmentation of atomistic configurations using unsupervised machine learning [1]. The proposed algorithm, called OrISODATA, is based on the iterative self-organizing data analysis technique and is modified to work in the orientation space. The algorithm is demonstrated on a 122 grain nanocrystalline thin film sample in both undeformed and deformed states. The Orisodata algorithm is also compared with two other grain segmentation algorithms available in open-source visualization tool Ovito. The results show that the Orisodata algorithm is able to correctly identify deformation twins as well as regions separated by low angle grain boundaries. The intiutive model parameters relate to similar thresholds in experiments, which helps obtain optimal values and facilitates easy interpretation of results.

Comparison of atomic environment descriptors with domain knowledge of the interatomic bond — •MARIANO FORTI, RALF DRAUTZ, and THOMAS HAMMERSCHMIDT — ICAMS, Ruhr Universität Bochum, Universität Straße 150, 44801 Bochum
The study of the relative stability of multicomponent materials and the search for new materials for high performance applications requires extensive samplings of the composition space. This is a demanding task due to the computational effort that is required for the electronic structure calculations. In this work we propose a machine learning approach with descriptors of the local atomic envi-

ronment using different chemistry heuristics based on smooth overlap of atomic positions, recursive solutions of tight-binding Hamiltonians and atomic cluster expansions. We demonstrate that these descriptors, which retain different levels of domain knowledge of structural and electronic properties of the chemical compounds, can be used to predict formation energies with high accuracy even with simple regression algorithms. We apply the methodology to complex crystal structures in binary and ternary intermetallic systems.

MM 36.3 Thu 10:45 SCH A 251
A Machine-Learning Framework to Identify Equivalent Atoms at Real Crystalline Surfaces — •KING CHUN LAI, SEBASTIAN MATERA, CHRISTOPH SCHEURER, and KARSTEN REUTER — Fritz Haber Institute of the Max Planck Society, Berlin, Germany
Functional surfaces and interfaces even of crystalline materials are characterized by breaks of symmetry and long-range order. Yet, even though such a crystalline surface may for instance exhibit numerous vacancies, adatoms, steps, kinks or islands, there are generally still many equivalent atoms, where equivalence refers to an identical or near-identical local environment. There are many equivalent terrace atoms, adatoms, step or kink atoms. In atomic-scale modeling and simulation, identifying these groups of equivalent atoms is a routine task, not least because one would e.g. restrict demanding first-principles calculations like the determination of an adsorption configuration and concomitant adsorption energy to only one site of each equivalence group. Aiming to automatize this routine task, we here present a machine-learning framework to identify all groups of equivalent atoms for any surface or nanoparticle geometry. The initial classification rests on the representation of the local atomic environment through a high-dimensional smooth overlap of atomic positions (SOAP) vector. We then achieve a fuzzy classification by mean-shift clustering within a low-dimensional embedded representation of the SOAP points as obtained by multidimensional scaling (MDS). The performance of this classification framework will be demonstrated with examples of Pd surfaces.

Identifying ordered domains in atom probe tomography using machine learning — •Alaukik Saxena, Navyanth Kusampudi, Shyam Katnagallu, Baptiste Gault, Dierk Raabe, and Christoph Freysoldt — Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf 40237, Germany

Atom probe tomography (APT) is a unique technique that provides 3D elemental distribution with near-atomic resolution for a given material. The spatial resolution of APT is ~1-3 Å in depth and ~3-5 Å in the lateral direction, respectively. Due to the limited spatial resolution, most of the APT data analysis focuses on composition to extract various microstructural features. Here, we aim at identifying additional on-lattice short-range order within an Al-Mg-Li alloy even though the underlying FCC lattice itself is not resolved. We propose a machine learning (ML) methodology to distinguish disordered solid solutions from ordered L12 domains. To encapsulate the local chemistry and noisy structure in APT independent of orientation, we use Smooth Overlap of Atomic Positions (SOAP). To find suitable hyperparameters of the high-dimensional SOAP features, we visualize the data distribution within the latent space of an autoencoder neural network trained on experimental data with a preliminary classification. After the optimization, synthetic data corresponding to FCC and L12 structures is created with APT level spatial noise and then used for training from scratch a dense neural network for order/disorder classification. The trained model is then able to distinguish between ordered and disordered structures in experimental data.

Atomic cluster expansion: training a transferable water interatomic potential from the local atomic environments of ice — •Eslam Ibrahim, Yury Lysogorskiy, Matous Mrovec, and Ralf Drautz — ICAMS, Ruhr Universität Bochum, 44780 Bochum, Germany

We show the predictive power of the atomic cluster expansion (ACE) for modeling challenging systems such as water. We trained ACE on data from ab-initio molecular dynamics simulations (AIMD) of water at 300 K. ACE displays excellent agreement to the first-principles reference data in predicting radial distribution functions and covalent and hydrogen bonding characteristics. However, our investigation confirms that describing properties that require sampling a larger fraction of phase space, for example, self-diffusion or the free energies, requires longer AIMD simulation times at different pressures/densities and temperatures. We then show that ice structures provide a more efficient means of sampling the phase space of water: training ACE to diverse ice phases only describes liquid water in quantitative and qualitative agreement with first principles reference data. This reveals a powerful and efficient strategy for building transferable water interatomic potentials without running expensive AIMD.

MM 36.6 Thu 11:45 SCH A 251
Enhancing molecular dynamics simulations of water in comparison to neutron scattering data with algorithms — •Veronika Reich[1], Luis Carlos Pardo[2], Martin Müller[3], and Sebastian Busch[1] — [1]GEMS at Maier-Leibnitz Zentrum, Helmholtz-Zentrum hereon, 85748 Garching, Germany — [2]Departament de Física Escola d'Enginyeria de Barcelona Est Universitat Politècnica de Catalunya, 08019 Barcelona, Spain — [3]Helmholtz-Zentrum hereon, 21502 Geesthacht, Germany

The structure and dynamics of materials can be studied on the atomic level with neutron and X-ray scattering experiments as well as molecular dynamics (MD) simulations. We connect experimental data with MD simulations to further enhance the simulations and obtain forcefields that are able to reproduce the measured structure and dynamics.

On the example of water, we established a workflow of running MD simulations in the program LAMMPS, calculating X-ray and neutron scattering data with the program Sassena, and comparing the diffractograms and incoherent intermediate scattering functions to already published experimental data.

The agreement between computed scattering curves and experimental data was optimized with algorithms to obtain a set of parameters that can simultaneously reproduce the real nanoscopic structure and dynamics of water probed by the neutron and X-ray scattering experiments.

This scheme is highly adaptable to different MD simulations of various models.

MM 36.7 Thu 12:00 SCH A 251
Stress and Heat Flux via Automatic Differentiation — •Marcel F. Langer[1,2,3], Florian Knoop[3,4], J. Thorben Frank[1,2], Christian Carbogno[3], Matthias Scheffler[3], and Matthias Rupp[3,5] — [1]BIFOLD – Berlin Institute for the Foundations of Learning and Data, Berlin, Germany — [2]Machine Learning Group, Technische Universität Berlin, Germany — [3]The NOMAD Laboratory at the Fritz Haber Institute of the Max Planck Society and Humboldt University, Berlin, Germany — [4]Theoretical Physics Division, Department of Physics, Chemistry and Biology (IFM), Linköping University,

Sweden — [5]Materials Research and Technology Department, Luxembourg Institute of Science and Technology (LIST), Luxembourg

Computationally efficient approximations of the Born-Oppenheimer potential energy surface can be obtained by parametrising an analytical force field based on a set of reference calculations. Inspired by recent developments in machine learning, such potentials can include equivariant semi-local interactions through message-passing mechanisms and rely on automatic differentiation (AD), overcoming the need for manual derivative implementations or finite-difference schemes. We provide a unified framework for using AD in such state-of-the-art potentials, and discuss how AD can be used to efficiently and simply compute the stress tensor and the heat flux. We validate the framework by predicting thermal conductivity for selected semiconductors and insulators with an equivariant machine learning potential [1].

Accurate thermodynamic properties of bcc refractories through Direct Upsamling — •Axel Forslund, Jong Hyun Jung, Prashanth Srinivasan, and Blazej Grabowski — Institute for Materials Science, University of Stuttgart, Pfaffenwaldring 55, 70569 Stuttgart

The outstanding high-temperature properties of the bcc refractory elements make them important in many industrial and scientific applications. Accurate thermodynamic data of unary bcc refractories are a requisite, for example, when used as end members for phase diagrams of high entropy alloys. In this work, we have calculated thermodynamic properties of the four bcc refractory elements V, Ta, Mo and W up to the melting point with full DFT accuracy with the newly developed Direct Upsampling method. We present highly converged Gibbs energy surfaces, from which accurate temperature dependence of heat capacity, thermal expansion coefficient and bulk modulus can be derived. We show their convergence with respect to fitting polynomial order and volume-temperature-grid density. Some group trends are observed, related to the electronic densities of states. In our analysis, we also estimate the contribution from thermal vacancies based on a single high-temperature calculation of the vacancy formation free energy. Further, our results are analysed in terms of homologous temperature for the elements of which a theoretical melting point (connected to the specific exchange correlation functional used) is known. The homologous temperature dependence of the calculated properties show a remarkable agreement with experiments.

MM 36.9 Thu 12:30 SCH A 251
Efficient workflow for treating thermal and zero-point contributions to the formation enthalpies of ionic materials — •Rico Friedrich[1,2,3], Marco Esters[1], Corey Oses[1], Stuart Ki[1], Maxwell J. Brenner[1], David Hicks[1], Michael J. Mehl[1], Cormac Toher[1], and Stefano Curtarolo[1] — [1]Duke University, USA — [2]TU Dresden — [3]Helmholtz-Zentrum Dresden-Rossendorf

The formation enthalpy, quantifying the enthalpy of a compound with respect to its elemental references, is a key parameter for predicting the thermodynamic stability of materials thus enabling data-driven materials design. Although for instance zero-point vibrational and thermal contributions to the formation enthalpy can be quite substantial reaching absolute values of up to ~ 50 meV/atom for ionic systems such as oxides, they are often neglected in *ab initio* workflows.

Here, we first calculate the thermal and zero-point contributions accurately from a quasi-harmonic Debye model. At room temperature, they largely cancel each other due to the different bond stiffness of compound and references reducing the total vibrational contribution to maximally ~ 20 meV/atom [1]. Moreover, the vibrational contributions can be parametrized within the coordination corrected enthalpies (CCE) method completely eliminating the need to compute these terms explicitly. On this basis, using only 0 K *ab initio* data as input, a workflow can be designed providing access to formation enthalpies at different temperatures from the AFLOW-CCE tool [2].

Microstructure-Property Linkages for Effective Elasticity Tensors by Deep Learning — •Bernhard Eidel — TU Freiberg, M5-Micro Mechanics & Multiscale Materials Modeling, Lampadiusstraße 4, 09599 Freiberg

The objective of the present work is to link random heterogeneous, multiphase materials to their elastic macroscale stiffness by 3D convolutional neural networks (CNNs). In an approach of supervised learning the effective elasticity tensors stem from homogenization simulations.

The proposed CNN model is a universal predictor for its extended generalization abilities overcoming bottlenecks in existing studies. It accounts for a large variety of microstructures, for arbitrary phase fractions, for almost arbitrary elastic moduli of the constituent phases, and it predicts the stiffness for periodic boundary conditions (BCs) along with sharp upper and lower bounds for the case of non-periodic matter. The proposed universal CNN model achieves high accuracy in its predictions. For a real, two-phase diamond/SiC coating material the universal CNN is almost as accurate as a CNN exclusively trained for

fixed elastic phase properties of that material. The speedup compared to finite element computations for homogenization is above factor 20 500. The proposed CNN model hence enables fast and accurate stiffness predictions in universal analyses of heterogeneous materials in their linear elastic regime, for details see [1].

Influence of doping atoms on twinning in Ni-Mn-Ga alloy: an ab initio study — •Petr Šesták, Martin Hezcko, and Martin Zelený — Brno University of Technology, Brno, Czechia

Magnetic shape memory alloys (MSMAs) are multifunctional materials which - owing to the tight coupling between their magnetic and ferroelastic order - exhibit interesting phenomena, such as giant magnetoresistance, mag-

netocaloric and elastocaloric effects, and magnetically-induced reorientation (MIR) of martensite. The prototype MSMAs are the Heusler Ni-Mn-Ga based alloys. By combining the large strain and fast response, they may fill the application gap between the shape memory actuators (large strain, slow response) and magnetostrictive/piezo actuators (small strain, fast response). The MSMAs strongly depends on the twinning structure and especially on the twinning stress that is highly dependent on exact alloy composition, as it significantly decreases with increasing content of Mn, which hinders the MIR in Mn-excess alloy.

The recent development in atomistic simulations allows to determine the twinning stress not only from experimental methods but also from theoretical simulations. For example, generalized-planar-fault-energy (GPFE) curves describe the energy pathways associated with twinning as a function of shearing vector. Here, we present results of our calculations to reveal, how doping elements Co, Cu and Fe affects the GPFE curves, and consequently formation and propagation of twins.

MM 37: Topical Session: Defect Phases II

Time: Thursday 10:15–13:00   Location: SCH A 216

Topical Talk   MM 37.1   Thu 10:15   SCH A 216

Structural and chemical atomic complexity of lattice defects – From defect phase diagrams to properties of intermetallics — Martina Freund, Xie Zhuocheng, Lukas Berners, Pei Ling Sun, Stefanie Sandlöbes-Haut, and •Sandra Korte-Kerzel — Institut für Metallkunde und Materialphysik, RWTH Aachen University

Two approaches in materials physics have proven immensely successful in alloy design: First, thermodynamic and kinetic descriptions for tailoring and processing alloys to achieve a desired microstructure. Second, crystal defect manipulation to control strength, formability and corrosion resistance. However, to date, the two concepts remain essentially decoupled. A bridge is needed between these powerful approaches to achieve a single conceptual framework. Considering defects and their thermodynamic state holistically as defect phases, provides a future materials design strategy by jointly treating the thermodynamic stability of both, the local crystalline structure and the distribution of elements at defects.

Here, we will report our work on intermetallics, which are complex already in their underlying crystal structure, to reveal active deformation mechanisms and their dependence on both structure and chemical composition.

MM 37.2   Thu 10:45   SCH A 216

The synthesis and studies of unique oxygen structure on silica-aluminate catalysts — •Linfeng Su[1], Xu Chen[2], Huaping Zhao[1], Zhiyi Lu[2], and Yong Lei[1] — [1]Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — [2]Key Laboratory of Advanced Fuel Cells and Electrolyzers Technology of Zhejiang Province, Ningbo Institute of Materials Technology and Engineering, CAS, Zhejiang, 315201, PR China

To promote the application of silica-aluminate catalysts in catalytic reactions, the unique active oxygen structures on the surface of silica-aluminate were investigated. 4A molecular sieves were prepared with oxygen-rich vacancies of various contents and different chemical environments. Three different types of oxygen vacancies (due to the covalent and coordination bonds of O) on the surface have different mechanisms in catalytic reactions, and the specific structures exhibit the best catalytic activity (87.5% removal rate of pollutants within 6 min in catalytic ozonation). Moreover, silica-aluminate mullite containing abundant neo-oxygen structure (unique bridging oxygen) was successfully prepared at a low preparation temperature. The abundant oxygen structure in silica-aluminate leads to abundant unique bridging oxygen structures with high catalytic activities (81.2% removal rate of pollutants within 15 min under low ozone concentration). The research on the unique oxygen structure of silicate-aluminate provides theoretical guidance for the design and synthesis of catalysts with high catalytic activities for future industrial applications.

MM 37.3   Thu 11:00   SCH A 216

Understanding corrosion phenomena based on surface phase diagrams for Mg alloys in contact with water — •Jing Yang, Mira Todorova, and Jörg Neugebauer — Max-Planck-Insitut für Eisenforschung GmbH, Max-Planck-Strasse 1, D-40237 Düsseldorf, Germany

Defect phases formed at alloy surfaces and interfaces govern their chemical and mechanical behavior. Constructing phase diagrams from ab initio modeling provides valuable information for understanding the microscopic mechanisms of surface and interface processes. In this work, we apply this approach to study the aqueous corrosion of magnesium alloyed with Al and Ca, an important structural material for the automotive and aerospace industries. Constructing defect phase diagrams for the passive film formed on the magnesium surface, we analyze how the Al and Ca alloying atoms evolve during the corrosion process and how they impact the corrosion resistance of the magnesium alloy. In particular,

we resolve the cause of Al enrichment in the passive film, which has been recently observed in experiment. Based on these examples we discuss how defect phase diagrams can help us to better understand microscopic chemical processes under realistic conditions.

MM 37.4   Thu 11:15   SCH A 216

Ab-initio informed CALPHAD modelling of grain boundaries — •Tobias Spitaler[1], Rishi Bodlos[2], Daniel Scheiber[2], and Lorenz Romaner[1] — [1]Montanuniversität Leoben, Department Werkstoffwissenschaft, Leoben, Österreich — [2]Materials Center Leoben Forschung GmbH, Leoben, Österreich

The CALPHAD method is an important tool in material science to calculate phase diagrams and to predict phase stabilities of complex systems. Based on a model of the Gibbs Free energy of the bulk phases as function of composition, pressure and temperature the thermodynamic equilibrium quantities can be calculated with computer programs. In materials grain boundaries play an important role for mechanical properties and grain growth. Alloying elements often tend to segregate from or to the grain boundary, changing the properties of the grain boundary for example by weakening or strengthening the cohesion or by preventing grain boundary movement, which can lead to stabilisation of a nano-crystalline structure.

We therefore devise a formulation of the grain boundary Gibbs Free energy within the compound energy formalism with the goal to obtain the grain boundary state parameters such as composition and grain boundary area. We use DFT calculations to explore energy configurations of grain boundaries and couple them to thermodynamic models to investigate solute segregation and its impact on the grain boundary energy. With these results we can provide grain boundary phase diagrams and address thermodynamic nanocrystalline stability in metallic alloys.

Topical Talk   MM 37.5   Thu 11:45   SCH A 216

Density-based Grain Boundary Phase Diagrams — •Reza Darvishi Kamachali — Federal Institute for Materials Research and Testing (BAM)

Phase diagrams are the roadmaps of material design yet primarily developed and discussed for defect-free bulk phases. Real microstructures, however, also contain large populations of defects, such as grain boundaries, which show their own distinct phase behavior. Recently, CALPHAD-integrated density-based phase diagrams were proposed for studying segregation and phase evolution in grain boundaries. In this method, the connection to available bulk thermodynamic data allows rapid assessment of grain boundary phase behavior. In this talk, density-based phase diagrams of several binary and ternary alloy systems will be discussed, with direct implications for alloy and microstructure design. The significance and integration of elastic energies to the density-based model will be presented. It will be shown that Cu segregation and segregation transition in Al-Cu and Al-Cu-Mg systems can be explained by the presence of solutes' elastic interactions with grain boundaries.

MM 37.6   Thu 12:15   SCH A 216

Learning chemistry dependence of grain boundary segregation energies — •Christoph Dösinger[1], Daniel Scheiber[2], Oleg Peil[2], Vsevolod Razumovskiy[2], and Lorenz Romaner[1] — [1]Montanuniversität Leoben, Department of Materials Science, Leoben, Austria — [2]Materials Center Leoben Forschung GmbH, Leoben, Austria

The grain-boundary segregation energy (E_{seg}) is the central quantity for describing the process of grain-boundary segregation which influences fracture. Usually, to obtain highly accurate values for E_{seg}, density functional theory is

employed, which incurs high computational costs. This makes it impractical to do a thorough study of segregation to multiple grain-boundaries for a range of solutes. To reduce the number of calculations needed for such a complete description, we apply machine learning methods to density functional theory data. By using separate sets of descriptors for the local atomic environment and the solute types, we fit a model based on gaussian process regression. This approach is evaluated on a comprehensive data-set for E_{seg} in tungsten. The tests indicate that the model has the ability to extrapolate to solutes which are not contained in the training data.

MM 37.7   Thu 12:30   SCH A 216

Rationalising the impact of experimental preparation routes on impurity content in Pd nano-aerogels using ab-initio phase diagrams — •Mira Todorova, Su-Hyun Yoo, Poulami Chakraborty, Tilmann Hickel, Se-Ho Kim, Baptiste Gault, and Jörg Neugebauer — Max-Planck-Institut für Eisenforschung, Düsseldorf

Recent advances of experimental techniques with atomic resolution enable us to analyze the structure and composition of samples at the sub-nanometer scale, providing information about contamination with impurities and their distribution. Understanding the factors which govern the ingress, amount and distribution of contaminating elements, opens routes to both improving the sample quality and their utilization in targeted design to achieve a desired functionality. Using an ab-initio based thermodynamic approach and surface phase diagrams we unravel the impact of preparation conditions on experimental observations and materials properties. The power and the performance of these ab-initio based thermodynamic concepts will be highlighted using the example of impurity incorporation during wet-synthesis of nano-aerogels, specifically Na

and K incorporation into grain boundaries [JACS 144, 987 (2022)] and B into the bulk [Adv. Mater. 2203030 (2022)] of Pd nano-aerogels.

MM 37.8   Thu 12:45   SCH A 216

Influence of stoichiometric change on plasticity in the Ca(Al;Mg)2 C15-Laves Phase — •Martina Freund[1], Pei-Ling Sun[1], Carsten Thomas[2], Deborah Neuss[3], Michael Feuerbacher[2], Marcus Hans[3], and Sandra Korte-Kerzel[1] — [1]Institut für Metallkunde und Materialphysik, RWTH Aachen University — [2]Ernst Ruska-Centrum für Mikroskopie und Spektroskopie mit Elektronen und Peter-Grünberg Institut Forschungszentrum Jülich GmbH — [3]Materials Chemistry, RWTH Aachen University

Magnesium is a promising material for light weight applications but is strongly limited because of its low room temperature ductility and low creep resistance. By alloying with Al and Ca dif-ferent Laves phases form, which improve creep strength properties. We did investigations of the stoichiometric C15 Laves phase, finding slip on {111} and {112} planes with the same ac-tivation frequency and approximately same CRSS values. The influence of the stoichiometry regarding the plasticity was analysed using a sample with 6at.-% Mg, by nanoindentation tests, APT and TEM. Hardness and indentation modulus values were in the same range for all indented orientations. Comparing this to the stoichiometric one, the hardness has shown a slight increase around 1 GPa. Changes of plasticity were seen by analysing resulting slip lines. Most activated slip planes were the {112} planes, followed by the {110}. APT was done for both, the stoichiometric and the off-stoichiometric, to evaluate the local chemistry on {112} slip planes. Ultimately, we aim to reveal the connection between the local chemical potential and motion of dislocations on different slip planes.

MM 38: Topical Session: Fundamentals of Fracture – Fracture Experiments

Time: Thursday 10:15–11:15   Location: SCH A 215

Topical Talk   MM 38.1   Thu 10:15   SCH A 215

The Fundamental physics of the onset of frictional motion: How does friction start? — •Jay Fineberg — The Racah Institute of Physics, The Hebrew University, Jerusalem Israel

Recent experiments have demonstrated that rapid rupture fronts, akin to earthquakes, mediate the transition to frictional motion. Moreover, once these dynamic rupture fronts ("laboratory earthquakes") are created, their singular form, dynamics and arrest are well-described by fracture mechanics. Ruptures, however, need to be created within initially rough frictional interfaces, before they are able to propagate. This is the reason that "static friction coefficients" are not well-defined; frictional ruptures can nucleate for a wide range of applied forces. A critical open question is, therefore, how the nucleation of rupture fronts actually takes place. We experimentally demonstrate that rupture front nucleation is prefaced by slow nucleation fronts. These nucleation fronts, which are self-similar, are not described by our current understanding of fracture mechanics. The nucleation fronts emerge from initially rough frictional interfaces at well-defined stress thresholds, evolve at characteristic velocity and time scales governed by stress levels, and propagate within a frictional interface to form the initial rupture from which fracture mechanics take over. These results are of fundamental importance to questions ranging from earthquake nucleation and prediction to processes governing material failure.

MM 38.2   Thu 10:45   SCH A 215

Macro to micro in fracture - shorter is tougher — •Dov Sherman — School of Mechanical Engineering, Tel-Aviv University, Tel-Aviv, Israel

Fracture of brittle solids is ultimately executed by atomistic-scale, discrete, and ultrafast bond-breaking mechanisms along the crack path. Here, we show new fracture behavior and properties of brittle materials not previously explored. It is based on macroscopic fracture cleavage experiments of brittle single-crystal silicon specimens, including cracks energy-speed relationships, and an atomistic-scale semi-empirical model for bond-breaking mechanisms in form of planer kinks along the (curved) crack front. As a result, we identified that the cleavage

energy is not a constant but bounded by the Griffith Barrier and lattice-trapping barrier. Hence, a brittle material can be envisaged as having a pseudo-R-Curve behavior typical of metallic materials. A new and essential fracture mechanism was identified, which we termed *quasi-propagation*, occurring between initiation and propagation. During this mechanism, the sequence of the bond-breaking mechanisms is varying, causing an increase in the macroscale cleavage energy. The range of these changes is dictated by the energy release rate and its first derivative following initiation. The evaluated cleavage energy shows that *shorter is tougher* and hence the material is stronger than that predicted by the Griffith theory.

MM 38.3   Thu 11:00   SCH A 215

How hidden 3D structure within crack fronts reveals energy balance — •Meng Wang and Jay Fineberg — The Racah Institute of Physics, The Hebrew University of Jerusalem, Jerusalem, 91904, Israel

Griffith's energetic criterion, has been pervasively used to measure material resistance to failure and describe the propagation dynamics of simple cracks. When cracks contain secondary structure, full crack fronts must be considered. Secondary structure within a crack front will increase energy dissipation, and it is not, a priori, clear how its presence affects the crack dynamics and contributes to the fracture energy. Here, we study low-speed crack propagation in hydrogels under tensile loading conditions. Such slow cracks are shown to be bistable; either simple or faceted crack states can be generated under identical loading conditions. The selection of either crack state is determined by the form of the initial seed crack. We find that seed cracks containing a small local mode III component generally leads to a single step that propagates along a crack front. In contrast to simple cracks, faceted cracks can no longer be considered as existing in a quasi-2D system. For both simple and faceted cracks, we simultaneously measure the energy flux and local fracture toughness along the crack fronts over velocities. We find that the concept of energy balance must be generalized for 3D systems; faceted cracks obey energy balance, only when we account for the local dynamic dissipation at each point along the crack front. If the local structure is not properly accounted for, energy balance will appear to fail.

MM 39: Phase Transformations: Simulation and Machine Learning

Time: Thursday 11:45–13:15   Location: SCH A 215

MM 39.1   Thu 11:45   SCH A 215

Simultaneous structural and thermal characterisation of Zr-based bulk metallic glasses via synchrotron X-ray diffraction and fast differential scanning calorimetry — •Stefan T. Stanko[1], Jürgen E.K. Schawe[1,2], and Jörg F. Löffler[1] — [1]Laboratory of Metal Physics and Technology, Department of

Materials, ETH Zurich, 8093 Zurich, Switzerland — [2]Mettler-Toledo GmbH, Analytical, 8606 Nänikon, Switzerland

Fast differential scanning calorimetry (FDSC) experiments were performed to measure time-temperature-transformation (TTT) diagrams of Zr-based bulk metallic glasses used for additive manufacturing. The alloys were measured in

powder and bulk form, and multiple crystallisation events upon cooling were observed in both cases. The fast differential scanning calorimeter was modified to allow its integration into a synchrotron X-ray beamline and thus to characterise *in situ* metastable phase transformations. With the *in situ* setup it was possible to simultaneously investigate the structure of the phases involved and their transformation kinetics. The results were correlated with the oxygen content of the alloys, with the aim of optimising the additive manufacturing process of metallic parts.

MM 39.2   Thu 12:00   SCH A 215

Measurement and simulation of cooling times in pump-probe experiments of phase transitions with latent heat — •DANIEL KAZENWADEL, NOEL NEATHERY, and PETER BAUM — Universität Konstanz, Konstanz, Germany

Ultrafast pump-probe experiments are often limited by the need to wait for a sample's back reaction to take place between adjacent laser pulses. Here we investigate by experiments and simulations how the sample geometry influences the cooling rate of VO2, a strongly correlated phase-transition material with substantial latent heat. We measure back reaction times of milliseconds, microseconds and nanoseconds in free-standing thin-films, coated substrates and bulk crystals, respectively. A simple latent heat model reproduces the behavior of all geometries and can therefore be used to predict the speed of the back reaction in other phase-change materials as well.

MM 39.3   Thu 12:15   SCH A 215

Ab initio **thermodynamics and atomistic modeling of NiTi SMA with machine learning interatomic potentials** — •PRASHANTH SRINIVASAN and BLAZEJ GRABOWSKI — Institute for Materials Science, University of Stuttgart, Germany

Equiatomic Nickel-Titanium (NiTi) possesses interesting properties such as pseudoelasticity and shape memory effect that arise from a reversible transformation between the austenite (B2) and the martensite phase (B19$'$). Other competing phases (B19 and B33) make modeling of NiTi challenging. *Ab initio* molecular dynamics (AIMD) calculations have shown that B19$'$ and B2 phases are entropically stabilized (Haskins et. al., 2016), but the calculations were restricted to a single DFT exchange correlational functional (XC). Studying the kinetics of phase transformation using only DFT is also severely expensive.

In this work, we address both challenges. Using a recently developed thermodynamic integration technique (Jung et. al., 2022) aided with machine-learning based moment tensor potentials (MTPs, Shapeev 2016), it is possible to efficiently compute high-temperature thermodynamic phase stability to DFT accuracy. We perform such calculations to analyze three different XCs (GGA, LDA and SCAN). We also perform large-scale molecular dynamics (MD) simulations using the MTPs to study the kinetically-driven phase transformation behavior in each of these cases. Preliminary results show the necessity of having a high k-point density in the underlying DFT calculations. When fitted to such a training set, the MTPs predict highly accurate thermodynamic properties and phase transformation behavior.

MM 39.4   Thu 12:30   SCH A 215

Prediction of quantum paraelectricity and quantum phase transitions using ab initio self-consistent lattice dynamics and machine learning — •QUINTIN MEIER[1], AMBROISE VAN ROEKEGHEM[2], and NATALIO MINGO[2] — [1]Université Grenoble Alpes, CNRS, Institut Neel, 25 Av. des Martyrs, 38042 Grenoble — [2]Université Grenoble Alpes, CEA, LITEN, 17 Rue des Martyrs, 38054 Grenoble, France

Anharmonic interactions of the lattice are essential for understanding the temperature- dependent behavior of many materials. Here we present a method combining DFT and the active learning of interatomic potentials to obtain the necessary sets of forces to calculate the temperature dependent force constants using the quantum self-consistent lattice dynamics formalism [1].A particularly strong anharmonicity has been shown in incipient ferroelectrics like KTaO3. We show that our method can be used to accurately and efficiently compute the strongly anharmonic low temperature behaviour of the soft mode in quantum paraelectric KTaO3, and we study its stability range under pressure and uniaxial strain.

Atomic cluster expansion for modelling of transition metal carbide systems — •MINAAM QAMAR — ICAMS, Ruhr University Bochum, Bochum, Germany

Atomic cluster expansion (ACE) provides an alternative to classical and machine learning potentials by modelling the local environment of an atom with a mathematically complete descriptor. We present an ACE potential for the Mo-C system, which is parametrized over an exhaustive dataset of important phases an defect structures. The resulting ACE is shown to be accurate with respect to the DFT reference data and computationally efficient which allows us to perform large scale finite temperature applications.

MM 39.6   Thu 13:00   SCH A 215

Structure-mapping workflow for the investigation of solid-solid phase transitions — •ARTEM SAMTSEVICH, CHRISTOPH SCHEURER, and KARSTEN REUTER — Fritz Haber Institute of the Max Planck Society, Berlin, Germany

Solid-solid transformations are common in nature and in the aging of functional materials. It is thus crucial to understand the origin of these complex phenomena at the atomistic level. The involved activated processes can be modeled as transitions between basins on a high-dimensional free energy landscape (FES). Using the harmonic approximation to transition state theory (hTST), one can estimate reaction rate constants from the location of saddle points on the FES. The chain-of-states method optimizes presumed pathways between two structural endpoints towards the minimum energy pathway (MEP), yielding transition state estimates. The generation of the initial pathway requires the mapping of atomic structures onto each other, which can be achieved either by purely geometrical methods (mapping of atomic positions and cells) or by the topology-based method, which maps the graphs of interatomic bonds. Both approaches are complementary to each other and generate a diverse set of mappings.

The combination of mapping algorithms with the chain-of-state method has recently been merged into a generalized workflow. We will present applications to phase transitions in high-energy-density and superhard materials [1,2] as well as catalyst aging.

MM 40: Mechanical Properties and Alloy Design

Time: Thursday 15:45–18:30   Location: SCH A 251

MM 40.1   Thu 15:45   SCH A 251

First principles validation of barriers in Ni$_3$Al — •ADAM FISHER[1], THOMAS HUDSON[1], HUAN WU[2], TYLER LONDON[2], and PETER BROMMER[1] — [1]University of Warwick, Coventry, UK — [2]TWI Ltd, Cambridge, UK

Precipitates in Nickel-based superalloys form during heat treatment on a time scale inaccessible to direct Molecular Dynamics simulation, but can be studied using kinetic Monte Carlo (KMC). This requires reliable values for the barrier energies separating distinct configurations over the trajectory of the system. In this study, we validate barriers found with the activation relaxation technique nouveau (ARTn) method in a Ni$_3$Al using a published potential for the atomic interactions against first-principles methods. In a first step, we confirmed that the ARTn barrier energies agree with those determined with the nudged elastic band (NEB) method. As the number of atoms used in those calculations is too great for direct *ab initio* calculations, we then cut the cell size to 255 atoms, thus controlling finite size effects. We then use the plane-wave density functional theory (DFT) code CASTEP and its inbuilt NEB method in the smaller cells. This provides us with a continuous validation chain from first principles to large-scale KMC and allows us to quantify the errors incurred in simulations of precipitate formation and evolution.

MM 40.2   Thu 16:00   SCH A 251

Ab-initio study of partitioning of transition-metal elements in the γ/γ' microstructure of single-crystal superalloys — •ISABEL PIETKA[1], ANDREAS FÖRNER[2], MANUEL KÖBRICH[2], STEFFEN NEUMEIER[2], RALF DRAUTZ[1], and THOMAS HAMMERSCHMIDT[1] — [1]Ruhr-Universität Bochum, Interdisciplinary Centre for Advanced Materials Simulation (ICAMS) — [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Department of Materials Science & Engineering

The outstanding mechanical properties at high temperatures of Ni- and Co-base superalloys are closely tied to the underlying γ/γ' microstructure. Understanding the preferences of alloying elements for the γ matrix or γ' precipitates helps to develop new alloy compositions. In this work, we investigate the partitioning of the 3d, 4d, and 5d transition metals (TMs) in Ni$_3$Al and Co$_3$(Al,W) superalloys. In particular, we determine the preference of the TM elements for the γ or γ' phase by density functional theory calculations. We find clear trends of partitioning across the TM series that are in good agreement with experimental data. Our findings can be rationalized in terms of band filling and atomic size differences by moments analysis from bond order potential theory.

MM 40.3 Thu 16:15 SCH A 251

Towards understanding the yield stress anomaly of Ni₃Al from the energetics of planar defects — •XIANG XU[1,2], XI ZHANG[2], ANDREI RUBAN[3,4], SIEGFRIED SCHMAUDER[1], and BLAZEJ GRABOWSKI[2] — [1]Institute for Materials Testing, Materials Science and Strength of Materials, University of Stuttgart, Germany — [2]Institute for Materials Science, University of Stuttgart, Germany — [3]KTH Royal Institute of Technology, Stockholm, Sweden — [4]Materials Center Leoben Forschung GmbH, Leoben, Austria

The yield stress anomaly of L1₂ intermetallic compounds, especially Ni₃Al, has been investigated for several decades. It is believed that planar defects, e.g., the complex stacking fault and the antiphase boundaries, play an essential role in the dislocation activities during plastic deformation. However, a thorough temperature dependence of the formation energy of these planar defects is still elusive. Facilitated by the state-of-the-art methodology which acquires different thermal mechanisms, especially the magnetic excitations and the full vibrations, the Gibbs energies of the complex stacking fault and the antiphase boundaries of Ni₃Al were calculated within the ab-initio framework up to the melting temperature. The accurate results obtained here are helpful to scrutinize the available experimentally measured data and provide fruitful insights to understand the mechanism behind the yield stress anomaly as well.

MM 40.4 Thu 16:30 SCH A 251

Observation of in-plane oriented Guinier-Preston zones in Al-Cu — •JOHANNES BERLIN, TOBIAS STEGMÜLLER, and FERDINAND HAIDER — Universität Augsburg, Deutschland

Known for a long time, the first metastable precipitates forming in Al-Cu alloys during natural ageing are the so-called Guinier-Preston zones (GPZ), platelets of Cu on {100} planes of only one atomic layer thickness. With the development of aberration corrected (S)TEMs, direct observation and imaging of these platelets was possible, but with the restriction, that only edge view was possible. Using a Cs-probe corrected scanning transmission electron microscopy with HAADF detector (DF-STEM), a single Cu atom in a Al column results in sufficient contrast to the neighbouring columns. In sufficiently thin samples, planar zones then lead to theoretically forbidden reflections of type {110} in the fourier transformed image, since only half of the columns in the GP zone contain a Cu atom. Thus, fourier filtering of such an image with only these forbidden reflections allows to observe GP Zones in a plan-view. The average size, shape and density of the GP-zones was determined for different aging times, and STEM image simulations using the software package DrProbe support this interpretation.

MM 40.5 Thu 16:45 SCH A 251

Dynamical and structural properties of undercooled Cu-Ti melts — •LUCAS KREUZER[1,2], FAN YANG[2], THOMAS HANSEN[3], ANDREAS MEYER[2,3], and WINFRIED PETRY[1] — [1]Heinz Maier-Leibnitz Zentrum (MLZ), Garching, Germany — [2]Institute for Material Physics in Space, German Aerospace Center (DLR), Cologne, Germany — [3]Institute Laue-Langevin (ILL), Grenoble, France

Cu-Ti alloys feature a large, undercooled liquid region and a high glass-forming ability (GFA) and thus, provide the possibility to obtain two component bulk metallic glasses (BMGs). This unusual behavior could be due to the special properties of the liquid Cu-Ti system: a positive excess volume and a negative enthalpy of mixing. However, the relevant atomic mechanisms responsible for such good GFA are still to be explored. Here we discuss the temperature-dependent dynamical and structural properties of Cu-Ti melts, within a compositional range of 24 to 69 at% Ti. Accurate data about viscosity, density, and atomic structure, the Cu-Ti samples was obtained by using have been processed without any container using the electrostatic levitation technique. We found a non-monotonous trend of the viscosity, with the highest values at intermediate Ti contents. Surprisingly, this dynamical trend is not reflected by the macroscopic packing fraction, meaning a high viscosity does not necessarily correlate with a dense packing. However, on the atomic scale, x-ray and neutron diffraction reveal a denser, local packing and a pronounced chemical short-range order. These short-range interactions can explain the high viscosity, while the macroscopic packing fraction is rather governed by long-range interactions.

MM 40.6 Thu 17:15 SCH A 251

Can we measure twinning stress of a high entropy alloy with micromechanics? — •CAMILA AGUIAR TEIXEIRA, SUBIN LEE, and CHRISTOPH KIRCHLECHNER — Institute for Applied Materials, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany

CoCrFeMnNi and CoCrNi high entropy alloys (HEAs) have attracted attention due to their mechanical properties. Extensive mechanical twinning is mainly responsible for their outstanding mechanical response under cryogenic temperatures, e.g. increase in ductility and tensile strength. However, at room temperature dislocation slip is dominant and twinning only observed in highly deformed samples. Although both HEAs have been broadly studied, there is still a lack of in-depth understanding of twinning mechanism and stresses required for its activation, which is crucial for advanced HEAs design. In this work, we aim to

develop protocols to assess the critical resolved shear stress required for twinning by applying in situ micromechanics. Therefore, two points were addressed within the scope of this work: (i) study the transition from full to partial slip using micropillar compression and (ii) observe deformation twinning by shear stress using micro-shear test. Specific grain orientations were chosen through EBSD analyses, for the micropillar single slip orientation with higher Schmid factor for partial slip and for micro-shear [1 1 2] ND and [-1 1 1] TD orientation. Samples were then micromachined by FIB and tested in situ. Post-mortem analysis included SEM imaging, EBSD and (S)TEM to verify if twinning could be observed. The results provided quantitative insights essential for further understanding of the twinning mechanisms.

MM 40.7 Thu 17:30 SCH A 251

Influence of crystal structure on helium-induced tendril formation in an FeCoCrNiV high-entropy alloy — •SVENJA LOHMANN[1], RUSSELL GOODALL[2], GREGOR HLAWACEK[1], RENÉ HÜBNER[1], LE MA[2], and AMY S. GANDY[2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Germany — [2]University of Sheffield, UK

High-entropy alloys (HEAs) are a relatively new class of metal alloys composed of several principal elements, usually at (near) equiatomic ratios. Our goal is to understand how such a multicomponent alloy behaves under irradiation. The FeCoCrNiV HEA exhibits both a face-centred cubic (fcc) and a body-centred tetragonal (bct) phase, thus allowing us to specifically study the influence of crystalline structure at very similar chemical composition. We irradiated both phases with a focussed He beam provided by a helium ion microscope (HIM) at temperatures between room temperature and 500°C. The irradiation fluence was varied between 6×10^{17} ions/cm² and 1×10^{20} ions/cm². High-resolution images of the irradiated areas were taken with the same HIM. Selected irradiated areas were additionally studied by TEM in combination with EDXS. Under irradiation, pores start to be generated in the material with pore sizes differing significantly between the two phases. At higher fluences and above a critical temperature, a tendril structure forms in both phases. We found that the critical temperature depends on the phase and is lower for fcc. TEM images reveal that the tendrils span the whole depth of the irradiated area, and are accompanied by bubbles of various sizes. Scanning TEM-based EDXS of these structures indicates a He-induced change in composition.

MM 40.8 Thu 17:45 SCH A 251

Diffusion and phase stability in a HCP HfScTiZr multicomponent alloy — •MOHAN MURALIKRISHNA GARLAPATI[1], SANDIPAN SEN[1], XI ZHANG[2], SANKARAN S[3], JULIANA SCHELL[4,5], LUKASZ ROGAL[6], GERHARD WILDE[1], GRABOWSKI B[2], and SERGIY V. DIVINSKI[1] — [1]Institute of Materials Physics, University of Muenster, Muenster, Germany — [2]Institute of Materials Science, University of Stuttgart, Stuttgart, Germany — [3]Department of Metallurgical and Materials Engineering, Indian Institute of Technology, Madras, Chennai, India — [4]European Organization for Nuclear Research (CERN), CH-1211 Geneva, Switzerland — [5]Institute for Materials Science and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Essen, Germany — [6]Institute of metallurgy and Materials Science, Polish Academy of Sciences, Krakow, Poland

Phase stability and tracer diffusion in a hexagonal close-packed (HCP) HfScTiZr multicomponent alloy are investigated. The microstructure stability is examined by an in-depth electron microscopy characterization of samples subjected to prolonged heat treatments. It is found that the alloy decomposes into two HCP phases with similar lattice constants. The DFT calculations confirm the possibility of the phase decomposition. The minor and major phases are observed to be enriched with Ti and Sc, respectively. Self-diffusion is measured using the 44Ti, 46Sc, and 89Zr radioactive isotopes. The phase decomposition is found to influence marginally Zr, but significantly Ti and Sc diffusion. The diffusion properties are analyzed in correlation to the microstructure stability and thermodynamic properties of the alloy.

MM 40.9 Thu 18:00 SCH A 251

Solid solution strengthening in single-phase HEAs based on Au-Cu-Ni-Pd-Pt — •SOPHIE DRESCHER[1], JENS FREUDENBERGER[1], SASCHA SEILS[2], ALEXANDER KAUFFMANN[2], and MARTIN HEILMAIER[2] — [1]Leibniz-IFW Dresden, Helmholtzstr. 20, 01099 Dresden, Germany — [2]Karlsruhe Institute of Technology, Institute for Applied Materials, Engelbert-Arnold-Str. 4, 76131 Karlsruhe, Germany

Solid solution strengthening (SSS) is the dominant strengthening mechanism in High entropy alloys (HEAs). In contrast to dilute alloys, SSS of HEAs is yet not well understood. Therefore, it is necessary to develop reliable models to predict their mechanical properties. To verify such models experimental work is needed that illustrates the concentration-dependent solid solution strengthening of different alloys over a large composition range.

The high entropy alloy system Au-Cu-Ni-Pd-Pt is unique as it crystallizes in face-centered cubic crystal structure and is single-phase presumably within the entire concentration range. Hence, it serves a suitable benchmark system to investigate composition-dependent effects on the strength. In this study, it has

been examined whether the model of Varvenne [1] is suitable to predict the SSS in this alloy system. The concentrations of individual elements were varied and the strength and hardness were evaluated. The model of Varvenne is misguiding the development of the strength in a large compositional range. However, the results give insights into the impact of different elements on the strength and can help to further enhance the model.

MM 40.10 Thu 18:15 SCH A 251

Magnetism in nanocrystalline CoMnFeNiGa high entropy alloys: "from micro and bulk to nano" — •Natalia Shkodich[1,2], Varatharaja Nallathambi[1,2], Tatyana Smolyarova[1], Sven Reichenberger[1], and Michael Farle[1] — [1]Faculty of Physics and Center of Nanointegration (CENIDE), University of Duisburg-Essen, Duisburg, 47057 Germany — [2]Max-Planck-Institut für Eisenforschung Max-Planck-Straße 1, 40237 Düsseldorf, Germany

We report the successful fabrication of three types of CoMnFeNiGa high entropy alloys: a) nanoparticles, b) nanocrystalline micron-sized powder, and c) nanocrystalline metallic bulk. Homogeneous micron-sized CoMnFeNiGa HEA powders with a nanocrystalline structure and compositional homogeneity were produced by high energy ball milling (HEBM) for 190 min in Ar at 900/1800 rpm. From these powders we synthesized (a) homogeneous nanocrystalline bulk HEAs by spark plasma sintering (SPS) and (b) HEA nanoparticles - by laser fragmentation in liquids (LFL). The XRD, SEM/EDX, and HR TEM results showed that single fcc phase nanosized grains (~10 nm) are obtained after 190 min of HEBM. These partially transform into a bcc one after SPS at 1073K, while the LFL leads to the formation of nanoparticles with two morphologies, that is spheres and platelets with fcc, bcc and hexagonal structures. Fast annealing up to 1000K of HEBM and LFL HEA particles leads to significant structural and composition changes and increases the saturation magnetization Ms (300K) from 35.4 to 96.1 Am2/kg, and from 37.3 to 49.7 Am2/kg, respectively. We acknowledge financial support from DFG (CRC/TRR 270, project S01).

MM 41: Topical Session: Defect Phases III

Time: Thursday 15:45–18:00   Location: SCH A 216

Topical Talk MM 41.1 Thu 15:45 SCH A 216
Entropy in grain boundary segregation — •Pavel Lejcek — CEITEC, BUT, Brno, Czechia — Institute of Physics, AS CR, Prague Czechia
Experimentally, a linear dependence between the standard entropy and the standard enthalpy of solute segregation at grain boundaries was established which is called *enthalpy-entropy compensation effect*. In this dependence, there exists a region in which the product of temperature and segregation entropy ('entropy term') is larger than the absolute value of the segregation enthalpy, so that the controlling parameter, the Gibbs energy of segregation, is negative. Under this condition the grain boundary segregation is dominated by the entropy, i.e., the phenomenon of the entropy-dominated grain boundary segregation occurs. We show numerous examples of the grain boundaries and solutes in bcc-iron-based alloys exhibiting this phenomenon. In addition, we formulate the idea that a solute can also segregate at the grain boundary (site) that exhibits positive segregation energy/enthalpy (so called *anti-segregation site*) if the entropy term is larger than the segregation enthalpy, so that the Gibbs energy o segregation is negative. In this way, the solute segregation is completely controlled by the entropy term and an entropy-driven grain boundary segregation will exist. We suggest the entropy-driven grain boundary segregation for several model examples in iron-based systems thus serving as indirect evidence of the phenomenon. Finally, the grain boundary configurational entropy is discussed in relation to its volume counterpart and to the segregation variables.

MM 41.2 Thu 16:15 SCH A 216
Impact of precipitation on grain boundary diffusion in microstructure-engineered Ni-Cr-Fe alloy — •Baixue Bian, Mohan Muralikrishna Garlapati, Shabnam Taheriniya, Sandipan Sen, Gerhard Wilde, and Sergiy V. Divinski — Institute of Materials Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster, Gemany
Grain boundary structure-property relationship is studied in a Ni-based Inconel 602CA coarse-grained alloy using a novel correlative tracer diffusion-analytical microscopy approach. Homogenized and intermediate-annealed states are used to engineer the alloy microstructure. Grain boundary diffusion of Ni and Cr is measured in both C- and B-type kinetic regimes. A co-existence of several short-circuit contributions to tracer diffusion is distinguished and correlated to distinct grain boundary precipitation and segregation as revealed by HAADF-STEM combined with EDX measurements. The homogenized state reveals precipitation of Ni-based L12 and Cr23C6 phases which influence significantly diffusion properties. The intermediate annealing promotes a uniform formation of Cr carbides with a minimal/negligible fraction of the L12 phase. The present study demonstrates the correlated structure-kinetic property measurements provide a unique tool to probe the grain boundary precipitation in these industrially used Inconel alloys.

MM 41.3 Thu 16:30 SCH A 216
Orientation relationship and interface inclination in dependence of heat treatment time between Al2Ca and Mg Matrix — •Lukas Berners[1], Zhuocheng Xie[1], Mattis Seehaus[1], Siyuan Zhang[2], and Korte-Kerzel Sandra[1] — [1]IMM, RWTH Aachen — [2]MPIE, Düsseldorf
Mechanical properties of two phase-alloys are highly dependent on the morphology of the second phase as well as the interface character. Analysis of the orientation-relationship between the magnesium matrix and C15 (Al2Ca) Laves phase precipitate is up to now mainly conducted via TEM analysis. However, where defect phases as thermodynamically stable interface configurations are to be identified, a more statistically significant approach is needed. To this end, we use large scale EBSD to reveal prevalent orientation relationships as well as in-

terface character during the transition from hexagonal C36 phase to cubic C15 phase during heat treatment at 500 ˚C and thus unravelling a pathway to the thermodynamically stable interface configuration.

MM 41.4 Thu 16:45 SCH A 216
Non-Arrhenius temperature dependence of grain boundary diffusion in additively manufactured high-entropy CoCrFeMnNi alloy — •Nuri Choi[1], Manoel W. da Siva Pinto[1], Saba Khademorezaian[1], Sangsun Yang[2], Ji Hun Yu[2], Jai Sung Lee[3], Gerhard Wilde[1], and Sergiy V. Divinski[1] — [1]Institute of Material Physics, University of Münster, Münster, Germany — [2]Center for 3D Printing Materials Research, Korea Institute of Materials Science, Changwon, South Korea — [3]Dep. of Mat. Sci. & Chem. Eng., Hanyang University, Ansan, South Korea
Additive manufacturing process induces numerous crystalline defects such as vacancies, dislocations and dislocation networks, non-equilibrium segregation which affect mechanical, kinetic and structural properties of the fabricated materials. Moreover, a non-equilibrium state of grain boundaries has been discovered, too, which is characterized by enhanced rates of grain boundary diffusion at relatively low temperatures [1]. In the present study, grain boundary diffusion of Ni in additively manufactured CoCrFeMnNi high-entropy alloys is measured in an extended temperature interval. A non-monotonous temperature dependence is observed and interpreted in terms of a thermally-activated relaxation of the non-equilibrium state. The grain boundary energy is evaluated from the grain boundary diffusivity data for various heat-treatment conditions and compared to the total energy released during annealing by differential scanning calorimetry. The evolution of microstructure and mechanical properties is discussed, too.

15 min. break

MM 41.5 Thu 17:15 SCH A 216
Unveiling the mechanisms of motion of synchro-Shockley dislocations in Laves phases — •Zhuocheng Xie[1], Dimitri Chauraud[2], Achraf Atila[2,3], Erik Bitzek[2,3], Sandra Korte-Kerzel[1], and Julien Guénolé[4,5] — [1]Institute of Physical Metallurgy and Materials Physics, RWTH Aachen University, 52056 Aachen, Germany — [2]Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Str. 1, 40237 Düsseldorf, Germany — [3]Department of Materials Science and Engineering, Institute I: General Materials Properties, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany — [4]Université de Lorraine, CNRS, Arts et Métiers ParisTech, LEM3, 57070 Metz, France — [5]Labex Damas, Université de Lorraine, 57070 Metz, France
Synchroshear as the dominant basal slip mechanism in Laves phases is accomplished by the glide of synchro-Shockley dislocations. However, the mechanism of synchro-Shockley dislocation motion is still not well understood. In this work, we demonstrate kink propagation as the energetically favorable mechanism for the motion of synchro-Shockley dislocation using atomistic simulations. Vacancy hopping and interstitial shuffling are identified as two key mechanisms of kink propagation. The assistance of vacancy and antisite defects on kink nucleation and propagation are investigated and shown crucial for kink mobility. These findings provide insights into the dependency on temperature and chemical composition of plastic deformation of topologically close-packed phases.

MM 41.6 Thu 17:30 SCH A 216
Defect bulk-boundary correspondence of topological skyrmion phases of matter — •Shuwei Liu[1,2], Likun Shi[1], and Ashley M. Cook[1,2] — [1]Max Planck Institute for the Physics of Complex Systems, — [2]Max Planck Institute for Chemical Physics of Solids

Unpaired Majorana zero-modes are central to topological quantum computation schemes as building blocks of topological qubits, and are therefore under intense experimental and theoretical investigation. Their generalizations to parafermions and Fibonacci anyons are also of great interest, in particular for universal quantum computation schemes. In this work, we find a different generalization of Majorana zero-modes in effectively non-interacting systems, which are zero-energy bound states that exhibit a cross structure, two straight and perpendicular lines in the complex plane, composed of the complex number entries of the zero-mode wavefunction on a lattice, rather than a single straight line formed by complex number entries of the wavefunction on a lattice as in the case of an unpaired Majorana zero-mode. These *cross* zero-modes are realized for topological skyrmion phases under certain open boundary conditions when their characteristic momentum-space spin textures trap topological defects. In the process of characterizing this defect bulk-boundary correspondence, we develop recipes for constructing physically-relevant model Hamiltonians for topological skyrmion phases, efficient methods for computing the skyrmion number, and introduce three-dimensional topological skyrmion phases into the literature.

MM 41.7   Thu 17:45   SCH A 216

Ga Induced Defect Phase Transformations in the Σ7 Mg Grain Boundary — •PRINCE MATHEWS[1], SIYUAN ZHANG[1], CHRISTINA SCHEU[1], TILMANN HICKEL[1,2], and JÖRG NEUGEBAUER[1] — [1]Max-Planck-Institut für Eisenforschung, D-40237 Düsseldorf — [2]Federal Institute for Materials Research and Testing (BAM), D-12489 Berlin, Germany

The design of tailored materials requires to understand not only bulk phases but also the stability of various defect phases. Grain boundaries (GBs) form one class of defects that directly influence the properties of the material. Therefore, GB phase transformations introduced by alloying can alter mechanical performance. In this work, the Σ7 [0001] | 21.78° (sym. plane 12-30) GB in hcp Mg is investigated, for which an A- and a T-type is known. Ab-initio simulations as a function of stress and temperature (using quasi-harmonic approximation) are performed, and show the presence of a phase transformation. Based on the computed Gibbs energies, the defect phase diagram as a function of the Ga chemical potential is determined. To this end, a complete set of Ga configurations at the GB is first screened with an empirical potential, before accurate ab initio calculations are performed for the low-energy configurations. Ga is not only found to trigger a transformation between T and A type, but a systematic transition of the preferred segregation sites is also seen with an increasing number of Ga atoms at the GB. The results qualitatively agree well with experimental results from high-resolution transition electron microscopy (HR-TEM). Physical mechanisms are provided to explain remaining discrepancies.

MM 42: Interface Controlled Properties and Nanomaterials: Nanoporous Materials and Nanolaminates

Time: Thursday 15:45–18:30   Location: SCH A 215

MM 42.1   Thu 15:45   SCH A 215

Nanoporous high entropy alloys – functional nanoscale networks — •LUKAS LÜHRS[1], FRIEDERIKE IHLE[1], and JÖRG WEISSMÜLLER[1,2] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology — [2]Institute of Materials Mechanics, Hybrid Materials Systems, Helmholtz-Zentrum hereon

Both, high entropy alloys as well as nanoporous metals have been the subject of considerable interest in recent years. The former topic explores alloys that are composed of multiple mayor alloying elements yielding countless opportunities for tailor-made material properties, such as outstanding mechanical performance. The latter investigates self-assembled network structures entirely composed of nanoscale elements. Owing to their large surface area to volume ratio, interfaces of nanoporous metals can be manipulated to obtain functional materials that can be used, e.g. as actuators, sensor or structural material with tunable mechanical properties.

In this work we combine both research topics to make monolithic bodies of a nanoporous high entropy alloy (np-HEA) by dealloying, a selective corrosion method, in aqueous media. Structural investigation finds a uniform, bicontinous network with feature sizes in the range of a few tens of nanometer. Moreover, samples of np-HEA exhibit a single phase microstructure with homogenous elemental distribution. Compression tests on macroscopic samples reveal considerable mechanical strength. In electrolyte, functionality is introduced by electrochemical modulation of the electrode potential which enables the generation of significant actuation strains.

MM 42.2   Thu 16:00   SCH A 215

Microstructure and mechanical behavior of hierarchical nanoporous gold-polypyrrole electrochemical actuators — •OLGA MATTS and NADIIA MAMEKA — Helmholtz-Zentrum Hereon, Geesthacht, Germany

Dealloyed nanoporous (np) metals have emerged as promising (electro-)chemical actuators that can compete with conventional actuator materials in terms of large actuation stroke, high strain energy density and low operating voltage [1]. Combining np metals with a conducting polymer polypyrrole (PPy) has been found as an effective way to enhance the actuation strain, mechanical strength and stiffness of np metals [2, 3]. Due to the synergistic effect of the two individual components at the nanoscale, such hybrid structures demonstrate enlarged actuation and tunable elastic modulus amplitudes as well as afford fast response times as compared to PPy alone [1].

In this work, we investigate an effect of structural hierarchy on actuation and elastic properties of *hierarchical* (hc) np-Au/PPy hybrids. We study the behavior in aqueous electrolyte under potential control, exploiting the ability of PPy to change its volume under reversible redox reactions. We reveal pronounced variations in the macroscopic length and Young*s modulus in response to the voltage-induced volume changes of PPy. We correlate this behavior with PPy fractions in pores and discuss the underlying mechanisms of the observations.

Electrosorption-Induced Actuation in Nanoporous Silicon — •MANUEL BRINKER and PATRICK HUBER — Institut für Material- und Röntgenphysik, Technische Universität Hamburg, Denickestraße 15, 21073 Hamburg, Deutschland

Porous silicon provides a scaffold structure to study the confinement related effects of soft matter. We investigate the electro-sorption of electrolyte anions and the electrochemical behaviour of nanoporous silicon in acidic electrolytes. The silicon-electrolyte interface acts as a capacitor which allows the accumulation of electrolyte anions in a chemical double layer by an applied voltage, whose characteristics can be measured by cyclic voltammetry. The surface stresses that are caused to the monolithic porous silicon membrane by such an accumulation lead to a macroscopic strain which can be determined in-situ with a laser beam-bending setup. Comparing nanoporous silicon with a planar silicon surface yields insights on the observed electrocapillarity – in particular with respect to the importance of oxide formation and wall roughness on the single-nanopore scale.[1]

[1] Brinker, M., & Huber, P. (2021). Wafer-Scale Electroactive Nanoporous Silicon: Large and Fully Reversible Electrochemo-Mechanical Actuation in Aqueous Electrolytes. Advanced Materials, 2105923.

MM 42.4   Thu 16:30   SCH A 215

Structural analysis of hierarchical nanoporous gold — •LUKAS RIEDEL[1], JÜRGEN MARKMANN[1,2], JÖRG WEISSMÜLLER[2,1], and SHAN SHI[3,1] — [1]Institute of Materials Mechanics, Helmholtz-Zentrum Hereon, Geesthacht, Germany — [2]Institute of Materials Physics and Technology, Hamburg University of Technology, Hamburg, Germany — [3]Research Group of Integrated Metallic Nanomaterials Systems, Hamburg University of Technology, Hamburg, Germany

Hierarchical nanoporous metals offer the possibility to produce mechanically stable materials with a reduced solid fraction [1], which therefore qualify for lightweight application. Here, hierarchical nanoporous gold is produced from Ag90Au10, following a three-step procedure which consists of first dealloying, coarsening and second dealloying. The ligament size on the upper and the lower hierarchy level can be tuned independently. In addition to scanning electron microscopy (SEM), small- and ultra-small-angle X-ray scattering (SAXS/USAXS) are applied for structural analysis and show consistent results. Descriptive parameters including length scale, specific surface area and pore volume fraction are obtained. From a comparison of the length scale parameters, ligament diameter and mean ligament distance, a conversion factor is yielded. Ultra-small-angle X-ray scattering was found to be suitable for the analysis of structures with a ligament size range of several hundreds of nanometers.

MM 42.5   Thu 16:45   SCH A 215

Self-detachment of nanoporous thin films — •Gideon Henkelmann[1], Diana Waldow[1], Maowen Liu[1,2], Lukas Lührs[1], Yong Li[1,2], and Jörg Weissmüller[1,2] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology, Hamburg, Germany — [2]Institute of Materials Research, Materials Mechanics, Helmholtz-Zentrum Geesthacht, Geesthacht, Germany

Experiment shows thin films of dealloyed nanoporous gold (NPG) spontaneously detaching from massive gold base layers. NPG can also densify near its external surface. This is naturally reproduced by kinetic Monte Carlo (KMC) simulations of dealloying and coarsening and so appears generic for nanoscale network materials evolving by surface diffusion. This talk focuses on how the KMC simulation manages to predict intricate physical phenomena with few and simple assumptions to the kinetics. This contrasts with contemporary popular efforts to fit a multitude of independent energy barriers to quantum mechanical calculations. Simplified kinetics significantly speed up computation, provide clearer understanding of the underlying processes, while still reproducing relevant phenomena. The KMC simulation model is further motivated by thermodynamic principles.

Wetting and Drying Dynamics in Hierarchically Porous Silicon: An In-Situ X-Ray Microscopy Study — •Stella Gries[1,2,3], Laura Gallardo Domínguez[1,2,3], Mark Busch[1,2,3], Mariia Liseanskaia[1,2,3], Juan Sánchez Calzado[1,2,3], Mathis Boderius[1,2,3], Silja Flenner[4], Imke Greving[4], and Patrick Huber[1,2,3] — [1]Institute for Materials and X-Ray Physics, Hamburg University of Technology, Hamburg, Germany — [2]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [3]Center for Hybrid Nanostructures CHyN, University of Hamburg, Hamburg, Germany — [4]Institute of Materials Physics, Helmholtz Zentrum Hereon, Geesthacht, Germany

Hierarchical porosities consist of small, often nano-scaled pores as well as large, macroscopic pores to simultaneously achieve large inner surfaces in combination with optimized mass transport. The investigation of capillary dynamics within optically opaque hierarchically porous membranes necessitates sophisticated microscopy techniques. First hints to unveil the dynamics are obtained from lab-scale experiments, e.g. mass-uptake as a function of time or the mechanical response depending upon wetting and drying in dilatometry. However, these techniques do not spatially resolve on the rising liquid front, which is achieved with transmission X-ray microscopy (TXM). The samples are scanned in radiography (2D) and tomography (3D) to resolve both the static structure and the capillary dynamics. These findings can help to tailor hierarchical porous materials for their designated application and to tune the dynamics depending on the needs.

MM 42.7   Thu 17:30   SCH A 215

Scaling between elasticity and topological genus of nanoporous metals — •Seoyun Sohn[1,2], Claudia Richert[1], Shan Shi[3,1], Jürgen Markmann[1,2], Norbert Huber[1,2], and Jörg Weissmüller[2,1] — [1]Institute of Materials Mechanics, Helmholtz-Zentrum Hereon, Geesthacht, Germany — [2]Institute of Materials Physics and Technology, Hamburg University of Technology, Hamburg, Germany — [3]Research Group of Integrated Metallic Nanomaterials Systems, Hamburg University of Technology, Hamburg, Germany

Nanoporous gold (NPG) made by dealloying has emerged as a model material for random networks and specifically for studies of their mechanics. The mechanical behavior of such open-cell foam structures has been expressed by classical Gibson-Ashby relations. They highlight the solid volume fraction as the most obvious descriptor of strength and stiffness. Yet, recent research acknowledges that Young's modulus, Y, of NPG may significantly depend on additional microstructural descriptors, specifically on the scaled topological genus, g, as a measure of the network's connectivity. It represents the number of connections within a representative volume element of the microstructure. Here, we explore the nature of the dependency of Y on g, and we condense the observations into a scaling law that explicitly involves the scaled genus. Our study inspects and assesses the implications of the existing database, from experiment and simulation, and it adds simulation data for random networks with various

scaled genera. The results suggest a common scaling that is broadly comparable to experimental observations.

MM 42.8   Thu 17:45   SCH A 215

An Improved Kernel-Based NMR Cryoporometry Characterization of Mesoporous Solids — •Henry R. N. B. Enninful and Rustem Valiullin — Faculty of Physics and Earth Sciences, Felix Bloch Institute for Solid State Physics, Leipzig University, Linnéstraße 5, 04103, Leipzig, Germany.

NMR cryoporometry is a pore space characterization technique for industrial and natural materials such as catalysts, gas storage materials, cartilage, bones, rocks and many more. While gaining wide use, the fundamental phenomena underlying solid-liquid phase transitions in geometrically disordered porous materials is still not fully understood. This may lead to inaccurate pore size distributions from the NMR cryoporometry technique.

In this work, we have developed a new approach to NMR cryoporometry. Herein, it takes account of cooperativity effects in pores, the existence of a variable non-frozen layer (NFL) thickness between the frozen core and pore wall and the effect of curvature on thermal fluctuations in pores which hitherto are missing in the current approach. In the first place, we compile a family of transition curves characterizing the phase state in pores with different pore sizes, so called kernels. Thereafter, we apply a general framework for predicting phase equilibria in collection of pores. We demonstrate the new approach by first applying it to ordered porous materials such as MCM-41 and SBA-15. Further more, the technique is used to characterize a highly disordered random porous material where we reproduce all states seen in the material. A more accurate pore size distribution (PSD) is, thus, obtained.

MM 42.9   Thu 18:00   SCH A 215

Interface-related defect annihilation in high entropy amorphous/crystalline nanolaminates under ion irradiation — •Qi Xu[1], Daniel Sopu[1], Xudong Yuan[1], and Jürgen Eckert[1,2] — [1]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences, Jahnstraße 12, Leoben A-8700, Austria — [2]Department of Materials Science, Chair of Materials Physics, Montanuniversität Leoben, Jahnstraße 12, Leoben A-8700, Austria

The main challenge of designing nuclear materials that possess a high irradiation resistance is accumulation of point defects-induced structural damage. The interfaces and grain boundaries play a critical role on the defect generation and annihilation in nanostructured materials. In this work, the irradiation-induced microstructure evolution as well as defect production and recovery in metallic glass (MG) / high entropy alloy (HEA) nanolaminates were investigated by molecular dynamics (MD) simulations. The displacement cascades were simulated for the energies of primary knock-on atoms (PKA) at 5, 10 keV and 15 keV. It was found that, there are more displaced atoms in the thermal spike phase for MG/HEA laminate compared with free-standing MG and HEA. In addition, the interface acts as defect sink and accelerates the recombination and annihilation of interstitial in HEA plate, which leads to more residual vacancies in crystalline plate. Moreover, the residual vacancies diffusion induces the generation of dislocation loops in the HEA plate. Furthermore, the interface acts as a transfer medium that accelerates the crystallization of MG plate during irradiation.

MM 42.10   Thu 18:15   SCH A 215

Anode engineering via ultrathin alumina membrane for next-generation stable sodium metal batteries — •Jiajia Qiu, Changfan Xu, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Sodium metal batteries are recognized as one of the most promising candidates for next-generation batteries, owing to their high theoretical specific capacity and energy density. However, a major bottleneck is the mossy or dendritic growth of Na in the repetitive stripping/plating process with an unstable solid electrolyte interphase (SEI), which limits the Coulombic efficiency and even leads to short circuit risks. In this work, ultrathin alumina membrane (UTAM) is first validated as a functional layer to effectively protect the Na anode for Na-metal batteries. By protecting Na metal with UTAM, the mossy or dendritic growth of Na has been suppressed, resulting in uniform electrodeposition. This highly ordered alumina oxide nanostructure improved electrochemical performance significantly and has the potential to be applied to other metal anodes. The novel design of UTAM protected metal Na anode may bring in new opportunities for next-generation high performance Na metal batteries.

Overview of Invited Talks and Sessions
(Lecture halls CHE 89, CHE 91, GER 37, GER 38, GER 39, WIL A 213,
REC C 213, TRE Phy, TRE Ma, HSZ 01 and HSZ 02; Poster P2/EG)

Plenary Talk

PLV V　　Wed　　8:30– 9:15　　HSZ 01　　**Advances in Ultrafast Electron Microscopy** — •Claus Ropers

Laureate of the Gaede Prize 2023

PRV II　　Wed　　13:15–13:45　　HSZ 01　　**Towards chemical and optical band structure engineering in molecular-based heterostructures** — •Benjamin Stadtmueller

Overview Talks

O 1.1　　Mon　　9:30–10:15　　TRE Phy　　**From surface structure to exciton evolution: a many-body theoretical perspective** — •Sivan Refaely-Abramson

O 27.1　　Tue　　9:30–10:15　　TRE Phy　　**Dive right in! Molecular insights into electrochemical surface science** — •Katrin F. Domke

O 44.1　　Wed　　9:30–10:15　　TRE Phy　　**Spins on Surfaces: A Gateway to the Quantum World** — •Christian R. Ast

O 71.1　　Thu　　9:30–10:15　　TRE Phy　　**Surface dynamics under reaction conditions** — •Edvin Lundgren

O 90.1　　Fri　　9:30–10:15　　TRE Phy　　**Molecular Surfaces With a Twist: Magnetochiral Asymmetries and Topological Self-Assembly** — •Karl-Heinz Ernst

O 98.1　　Fri　　13:15–14:00　　HSZ 03　　**Surfaces go topological – third generation 2D quantum materials** — •Ralph Claessen

Invited Talks of the joint Symposium Ultrafast Excitation Pathways of Quantum Materials (SYUE)
See SYUE for the full program of the symposium.

SYUE 1.1　　Wed　　9:30–10:00　　HSZ 01　　**Dynamics and control in quantum materials using multi-terahertz spectroscopy** — •Richard Averitt

SYUE 1.2　　Wed　　10:00–10:30　　HSZ 01　　**Accessing the nonthermal phonon populations in 2D materials with femtosecond electron diffuse scattering** — •Hélène Seiler, Marios Zacharias, Daniela Zahn, Patrick-Nigel Hildebrandt, Thomas Vasileiadis, Yoav William Windsor, Yingpeng Qi, Christian Carbogno, Claudia Draxl, Ralph Ernstorfer, Fabio Caruso

SYUE 1.3　　Wed　　10:30–11:00　　HSZ 01　　**Exciting potentials – Exploring the realms of ultrafast phase transitions** — •Laurenz Rettig

SYUE 1.4　　Wed　　11:15–11:45　　HSZ 01　　**Sub-cycle multidimensional spectroscopy of strongly correlated materials** — Viktor Valmispild, Evgeny Gorelov, Martin Eckstein, Alexander Lichtenstein, Hideo Aoki, Mikhail Katsnelson, Misha Ivanov, •Olga Smirnova

SYUE 1.5　　Wed　　11:45–12:15　　HSZ 01　　**Witnessing many-body entanglement in light-driven quantum materials** — •Matteo Mitrano, Denitsa Baykusheva, Mona Kalthoff, Damian Hofmann, Martin Claassen, Dante Kennes, Michael Sentef

SYUE 1.6　　Wed　　12:15–12:45　　HSZ 01　　**Optical responses of photoexcited materials: from parametric amplification to photoinduced superconductivity** — •Eugene Demler

Invited Talks of the joint Symposium Physics of van der Waals 2D Heterostructures (SYHS)

See SYHS for the full program of the symposium.

SYHS 1.1	Fri	9:30–10:00	HSZ 01	**Novel moiré excitons and ultrafast optical dynamics in van der Waals 2D heterostructures** — •Steven G. Louie
SYHS 1.2	Fri	10:00–10:30	HSZ 01	**Interaction induced magnetism in 2D semiconductor moiré superlattices** — •Xiaodong Xu
SYHS 1.3	Fri	10:30–11:00	HSZ 01	**Ions in tight places: intercalation and transport of ions in van der Waals heterostructures** — •Irina Grigorieva
SYHS 1.4	Fri	11:15–11:45	HSZ 01	**Spin-orbit proximity in van der Waals heterostructures** — •Felix Casanova
SYHS 1.5	Fri	11:45–12:15	HSZ 01	**Plethora of many-body ground states in magic angle twisted bilayer graphene** — •Dmitri Efetov

Topical Talks of the Focus Session "Frontiers of Electronic-Structure Theory" (joint Session O/HL)

O 9.3	Mon	11:00–11:30	TRE Ma	**Large-scale machine-learning assisted discovery and characterization of materials** — •Miguel Alexandre Lopes Marques
O 17.1	Mon	15:00–15:30	TRE Ma	**Coupled-cluster theory for complex solids made ready** — •Andreas Grüneis
O 35.4	Tue	11:15–11:45	TRE Ma	**Towards low-scaling GW calculations for 2D materials** — •Jan Wilhelm
O 53.2	Wed	10:45–11:15	TRE Ma	**TREX: an integrated HPC software platform for quantum Monte Carlo calculations** — •Claudia Filippi
O 61.5	Wed	16:15–16:45	TRE Ma	**Challenges in modelling correlated electronic matter** — •Roser Valenti
O 79.3	Thu	11:00–11:30	TRE Ma	**New Opportunities for First Principles Simulations of Thousands of Atoms Using Linear Scaling Density Functional Theory** — •Laura Ratcliff

Topical Talks of the Focus Session "Ion Beam Interaction with Surfaces and 2D Materials"

O 5.1	Mon	10:30–11:00	GER 38	**Highly charged, slow and swift ions interacting with surfaces and 2D materials** — •Marika Schleberger
O 5.4	Mon	11:30–12:00	GER 38	**A contactless single-step process for simultaneous nanoscale patterning and cleaning of large-area graphene** — •Tuan Tran
O 13.1	Mon	15:00–15:30	GER 38	**Space weathering of planetary surfaces** — •Peter Wurz
O 31.1	Tue	10:30–11:00	GER 38	**Ultra-low energy ion implantation of two-dimensional materials** — •Hans Hofsäss

Topical Talks of the Focus Session "Scanning Probe Microscopy with Quartz Sensors"

O 45.2	Wed	10:45–11:15	CHE 89	**Single-molecule reactions performed and characterized using atomic force microscopy** — •Leo Gross
O 54.1	Wed	15:00–15:30	CHE 89	**Peering into interfacial water by qPlus-based atomic force microscopy** — •Ying Jiang
O 54.5	Wed	16:15–16:45	CHE 89	**AFM with the qPlus sensor: An indeal tool for oxide surface science** — •Ulrike Diebold
O 87.1	Thu	15:00–15:30	TRE Ma	**Quartz-sensor detection for single-electron tunneling spectroscopy** — •Jascha Repp
O 87.5	Thu	16:15–16:45	TRE Ma	**Application of atomic force microscopy with quartz sensors to quantum states in graphene and related twisted heterostructures** — •Joseph Stroscio
O 97.4	Fri	11:15–11:45	TRE Ma	**Heteroatom-substituted and three-dimensional nanocarbon materials studied with low temperature STM and qPlus AFM** — •Shigeki Kawai

Topical Talks of the Focus Session "Semiconductor Surface Chemistry - from Reaction Mechanisms to Well-Ordered Interfaces"

O 48.1	Wed	10:30–11:00	GER 38	**Surface functionalization of semiconductors: Introducing spectroscopic labels, monolayer control for ultra-shallow doping, and providing surface passivation for atomically-precise processes** — •Andrew Teplyakov
O 48.3	Wed	11:15–11:45	GER 38	**Growth of organic monolayers on Si(111)** — •Martin Franz
O 57.1	Wed	15:00–15:30	GER 38	**Incorporation of arsenic into silicon (001) and germanium (001) for atomic-scale device fabrication.** — •Steven R. Schofield
O 57.3	Wed	15:45–16:15	GER 38	**Semiconductor surface chemistry towards hybrid interfaces with ab initio approaches** — •Ralf Tonner-Zech

Topical Talks of the Focus Session "Ultrafast Dynamics in Nanostructures"

O 75.1	Thu	10:30–11:00	GER 38	**Ultrafast nano-imaging: probing quantum dynamics in space and time** — •Markus Raschke
O 75.5	Thu	11:45–12:15	GER 38	**Lightwave-driven scanning tunneling microscopy and spectroscopy at the atomic scale** — •Vedran Jelic
O 83.1	Thu	15:00–15:30	GER 38	**Imaging ultrafast electron dynamics in isolated nanoparticles** — •Daniela Rupp
O 83.5	Thu	16:15–16:45	GER 38	**Ultrafast coherent manipulation of free electrons via quantum interaction with shaped optical fields** — •Giovanni Maria Vanacore

General Invited Topical Talks

O 7.1	Mon	10:30–11:00	REC C 213	**Superconductivity in atom-by-atom crafted quantum corrals** — •Lucas Schneider
O 10.1	Mon	15:00–15:30	CHE 89	**Photoemission Orbital Tomography: Imaging Molecular Wave Functions in Reciprocal and Real Space** — •F. S. Tautz
O 16.4	Mon	15:45–16:15	TRE Phy	**Microscopic insight into non-equilibrium dynamics through time-resolved x-ray absorption spectroscopy** — •Andrea Eschenlohr
O 33.1	Tue	10:30–11:00	REC C 213	**Fermi liquids, Luttinger integrals, topological invariants ... and magnetic molecules** — •Rok Zitko
O 34.6	Tue	11:45–12:15	TRE Phy	**Photoemission orbital tomography for excitons** — •Peter Puschnig
O 52.4	Wed	11:15–11:45	TRE Phy	**Modeling and Design of Single-Atom Alloy Catalysts** — •Mie Andersen
O 59.1	Wed	15:00–15:30	REC C 213	**Interplay of Inversion Symmetry Breaking and Spin-Orbit Coupling** — •Maximilian Ünzelmann
O 58.3	Wed	15:30–16:00	WIL A317	**Phase-locked photon-electron interaction without a laser** — •Nahid Talebi
O 55.6	Wed	16:15–16:45	CHE 91	**Towards Understanding and Controlling On-Surface Reactions and Self-Assembly Mechanisms** — •Daniel Ebeling
O 80.3	Thu	15:30–16:00	CHE 89	**Topological Plasmonics and Plasmonic Twistronics: Skyrmions, Merons, Quasicrystals, and Sykrmion Bags** — •Harald Giessen
O 86.3	Thu	15:30–16:00	TRE Phy	**Novel concepts to simulate electrified liquid/solid interfaces from first principles** — •Stefan Wippermann

Sessions

O 1.1–1.1	Mon	9:30–10:15	TRE Phy	**Overview Talk Sivan Refaely-Abramson**

Members' Assembly of the Surface Science Division

Thursday   19:00–19:30   HSZ 01

- Report of the Chairman

- Presentation of the Gerhard Ertl Young Investigator Award

- Miscellaneous

Sessions

– Invited Talks, Topical Talks, Contributed Talks, and Posters –

O 1: Overview Talk Sivan Refaely-Abramson

Time: Monday 9:30–10:15   Location: TRE Phy

Invited Talk   O 1.1   Mon 9:30   TRE Phy
From surface structure to exciton evolution: a many-body theoretical perspective — •SIVAN REFAELY-ABRAMSON — Weizmann Institute of Science, Rehovot, Israel
Excited-state processes involving Coulomb-bound electron-hole pairs in functional materials are essential for emerging applications, from energy conversion to quantum information science. The associated exciton creation and relaxation mechanisms are often coupled to optical selection rules, stemming from the underlying material structure. In this talk, I will discuss the relation between exciton evolution and structural modifications in monolayer semiconductors. Two broadly explored examples of such modifications are the introduction of atomic

defects and the composition of layered heterostructures. Both offer controllable design pathways to induce long-lived, low-lying excitons with tunable spatial localization and spin polarization. These structure-sensitive exciton properties can be detected in a variety of experimental scenarios from absorption and luminescence under electric and magnetic fields to angle-resolved photoemission spectroscopy, allowing for a close inspection of the microscopic interaction mechanisms. I will present an overview of a many-body ab initio theoretical approach to capture and predict the involved excitonic phenomena and discuss our recent theory-experiment collaborations to explore these effects and their tunability through defect engineering and interlayer twisting.

O 2: Organic Molecules on Inorganic Substrates I: Electronic, Optical and Other Properties I

Time: Monday 10:30–13:00   Location: CHE 89

O 2.1   Mon 10:30   CHE 89
Hooke's law in a molecular spring: An nc-AFM and STM study of nonahelicene on Ag(110) — •MAX HALBAUER[1], TAKASHI KUMAGAI[2], MARTIN WOLF[1], and AKITOSHI SHIOTARI[1] — [1]Fritz-Haber-Institute of the Max-Planck-Society, Faradayweg 4-6, 14195 Berlin, Germany — [2]Institute for Molecular Science, 38 Nishigo-Naka, Myodaiji, 444-8585 Okazaki, Japan
Helicenes are a class of conjugated aromatic molecules representing macroscopic springs on the molecular scale. However, experimental insights on their mechanical properties remain scarce. This contribution employs scanning tunneling microscopy (STM) and noncontact atomic force microscopy (nc-AFM) measurements (UHV, liq. He) in order to address this issue. Frequency shift-distance traces were acquired on individual nonahelicene molecules and a planar reference molecule (coronene) and converted subsequently to force-distance curves. Model-functions accounting for the elasticity of the molecule were fitted to the data, which yielded the spring-constant - k - for elongation of nonahelicene. This work shows therefore that Hooke's law can be verified on the single-molecule scale by nc-AFM.

O 2.2   Mon 10:45   CHE 89
Complex rotational behavior of ground and excited molecular states — •ANDREAS CHRIST, MARKUS LEISEGANG, PATRICK HÄRTL, and MATTHIAS BODE — Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany
The high sensitivity of molecular rotors to the intricate molecule–substrate interaction leads to a large variety of their rotational behavior [1]. In some cases this interaction can even change for different rotational positions on a molecule's rotation path. We have studied these dependencies for copper-phthalocyanine (CuPc) on Cu(111) by means of low-temperature scanning tunneling microscopy. In agreement with previous results [2,3], we find one ground state oriented along the high-symmetry axes of the substrate and two excited states tilted by $\approx \pm 7°$. A more detailed analysis reveals an exceptionally low threshold of ≈ 20 meV for rotations between these three stable states. Interestingly, the interaction of the molecule with the substrate and therefore the rotation rate varies significantly between the ground and the excited states due to their different molecular bending. Additionally, we find two adsorption positions, which slightly lift the degeneracy between the two excited states.

[3] S. Fremy-Koch *et al.*, Phys. Rev. B **100**, 155427 (2019)

O 2.3   Mon 11:00   CHE 89
Current Driven Unidirectional Rotation of Geländer Molecule — •ŠTĚPÁN MAREK[1], JAN WILHELM[2], RICHARD KORYTÁR[1], and FERDINAND EVERS[2] — [1]Department of Condensed Matter Physics, Faculty of Mathematics and Physics, Charles University, Czech Republic — [2]Condensed Matter Theory Group, Institute of Physics, Faculty of Theoretical Physics, University of Regensburg, Bavaria, Germany
Rotations of molecules driven by current are possible basis for construction of molecular motors. In "Geländer" molecules, the chiral structure was thought to drive the momentum transfer from travelling electrons to the molecule. We construct a simple model, motivated by our DFT based study, to explore the

structure of the current density in such a molecule and identify the regions of the molecule that contribute majority of the angular momentum of the electron current. We also discuss the particularities of our results, especially the conservation of rotation direction under the exchange of electric bias direction. The results are compared with experimental observations.

O 2.4   Mon 11:15   CHE 89
SPM Tip-induced Cleavage of Bridging Groups to Generate Carbon Nanomaterials — •ZILIN RUAN[1], TIM NAUMANN[1], JOHN B. BAUER[2], LUKAS HEUPLICK[1], HOLGER F. BETTINGER[2], and J. MICHAEL GOTTFRIED[1] — [1]Department of Chemistry, Philipps University Marburg, Hans-Meerwein-Straße 4, 35037 Marburg (Germany) — [2]Institut für Organische Chemie, Auf der Morgenstelle 18, 72076 Tübingen(Germany)
The on-surface synthesis of carbon nanomaterials is usually carried out on a metal surface by thermal activation, wherein the reaction selectivity and outcome are influenced by various factors. By contrast, manipulations with a scanning probe microscope (SPM) avoid these obstacles by electrically triggering the chemical transformation of individual molecules via the SPM tip due to electronic excitation or inelastic energy transfer. Here, using tip manipulation, we explore the suitability of the removal of etheno- and diastereomeric 1,2-diol moieties to generate acenes. Compared to other previously used leaving groups such as monoketone, diketone and oxo bridges, the here used bridges have certain advantages in the precursor synthesis, but are more challenging regarding their on-surface removal. Investigation of the various main and side reactions offer a deeper understanding of complex elimination and rearrangement reactions induced by SPM manipulation.

O 2.5   Mon 11:30   CHE 89
Illuminating an individual non-fluorescent molecule — •TZU-CHAO HUNG[1,2], YOKARI GODINEZ LOYOLA[3], MANUEL STEINBRECHER[1], BRIAN KIRALY[1], ALEXANDER A. KHAJETOORIANS[1], NIKOS L. DOLTSINIS[3], CRISTIAN A. STRASSERT[3], and DANIEL WEGNER[1] — [1]Institute for Molecules and Materials, Radboud University, 6525 AJ Nijmegen, The Netherlands — [2]Department of Physics, University of Regensburg, Regensburg, 93040, Germany — [3]Physikalisches Institut and Center for Nanotechnology (CeNTech), Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany
Combining scanning tunneling microscopy, spectroscopy and STM-induced luminescence (STML) allows us to study the optoelectronic properties down to the atomic scale. Generalizing the atomic control and imaging capabilities of STML to phosphorescent or even non-fluorescent molecules can provide a new route to fundamentally understand the photophysical properties of an individual molecule. Nickel phthalocyanine (NiPc) is a non-fluorescent molecule. Light emission from the ligand-centered excited state known as Q-band is quenched due to fast relaxation into the nonradiative metal-centered excited state. Hence, the transition energy of the Q-band can only be determined by absorption spectroscopy. Here, we propose an alternative approach to activate radiative decay of the Q-band of NiPc by utilizing STML in combination with control of the local environment and discuss the involved excitation and relaxation pathways. We compare our results with optical spectroscopy and ab initio calculations and discuss the involved excitation and relaxation pathways.

O 2.6 Mon 11:45 CHE 89

STM-induced luminescence from single graphene nanoribbons — •SONG JIANG[1], TOMÁŠ NEUMAN[1,2], ALEX BOEGLIN[1], FABRICE SCHEURER[1], and GUILLAUME SCHULL[1] — [1]Université de Strasbourg, CNRS, IPCMS, UMR 7504, F-67000 Strasbourg, France — [2]Institut des Sciences Moléculaires d'Orsay (ISMO), UMR 8214, CNRS, Université Paris-Saclay, 91405 Orsay Cedex, France

Graphene nanoribbons (GNRs) have emerged as promising candidates for high-performance nanoelectronic devices due to their tunable energy band gaps resulting from lateral quantum confinement and edge effects. The recent development of on-surface synthesis has achieved various types of atomically precise GNRs, revealing fascinating electronic, magnetic, and mechanical properties. Their optical properties, on the other hand, remain largely unexplored. The intrinsic luminescence properties of atomically precise GNR remains remain to be addressed at single molecule level. Here, excitonic emission from atomically precise GNRs synthesized on a metal surface is probed using a scanning tunneling microscopy (STM) approach. A STM-based strategy to transfer the GNRs to a partially insulating surface is used to prevent light emission quenching of the ribbons by the metal substrate. Sub-nanometer resolved STM-induced fluorescence spectra reveal emission from localized dark excitons build upon the topological end states of the GNRs accompanying with a series of vibronic peaks. Our study provides a novel path to investigate the interplay between excitons, vibrons and topology in atomically precise graphene nanostructures.

O 2.7 Mon 12:00 CHE 89

Substrate induced magnetic alignment and magnetization dynamics of dimetallofullerene single-molecule magnets — •TOBIAS BIRK[1], FABIAN PASCHKE[2], VIVIEN ENENKEL[1], FUPIN LIU[3], JAN DREISER[4], VLADYSLAV ROMANKOV[4], STANISLAV M. AVDOSHENKO[3], ALEXEY A. POPOV[3], and MIKHAIL FONIN[1] — [1]Department of physics, University of Konstanz, 78457 Konstanz, Germany — [2]IBM Research Europe, 8803 Rüschlikon, Switzerland — [3]IFW Dresden, 01069 Dresden, Germany — [4]SLS, PSI, 5232 Villigen, Switzerland

Since several years, lanthanide based single-molecule magnets (SMMs) are in focus of a broad research community due to their record high blocking temperatures above 77 K [1]. However, surface supported SMMs lag behind in terms of blocking temperatures and relaxation times due to molecule-substrate interactions. Yet, for the surface-supported lanthanide dimetallofullerene SMMs blocking temperatures of up to 28 K and long relaxation times were reported [2]. Here, we study the effect of coupling to a metallic substrate on the electronic and magnetic properties of $Dy_2@C_{80}CH_2Ph$ and compare those to our results for the graphene substrate [3, 4]. A combination of scanning tunneling microscopy, -spectroscopy and X-ray absorption spectroscopy provides a detailed insight into the local electronic properties as well as magnetization dynamics of the studied SMMs.

O 2.8 Mon 12:15 CHE 89

Enantiospecific adsorption on a ferromagnetic surface at the single-molecule scale — •M.R. SAFARI[1], F. MATTHES[1], K-H. ERNST[2], D.E. BÜRGLER[1], and C.M. SCHNEIDER[1] — [1]Peter Grünberg Institut (PGI-6), Forschungszentrum Jülich,52425 Jülich, Germany — [2]Molecular Surface Science Group, Empa, Swiss Federal Laboratories for Materials Science and Technology, 8600, Dübendorf, Switzerland

The recently discovered effect of chirality-induced spin selectivity (CISS) not only enables spin-selective electron transport in organic molecules [1], but also offers a novel approach to chiral separation by exploiting the CISS-induced enantiospecific interaction of chiral molecules with perpendicularly magnetized substrates [2]. Using low-temperature spin-polarized scanning tunneling microscopy, we have investigated the enantiospecific adsorption of heptahelicene molecules on ferromagnetic Co bilayer islands [3,4]. High-resolution and spin-polarized STM images enable direct determination of the enantiomeric adsorption ratio R on oppositely magnetized Co islands. Statistical analysis of 748 molecules on 110 islands yields $R = 0.69 \pm 0.05$, which we attribute to different enantiospecific adsorption energies. The well-defined structural, electronic, and magnetic properties of the molecule-substrate systems make our results readily amenable to theoretical modeling that will hopefully shed light on the microscopic origin of enantiospecific adsorption on ferromagnetic surfaces. Safari et al., arXiv:2211.12976 (2022)

O 2.9 Mon 12:30 CHE 89

Clars goblet based J1 & J2 alternative heisenberg spin half chain — •LIN YANG — TU Dresden, Dresden, Germany

Spin-1/2 alternating-exchange Heisenberg chain has been intensively pursued for decades not only for understanding its underlying many-body physics but also for its great potential of realizing quantum computing and information. The existing candalites are limited in effective spin arrays embeded in three dimensional crystals, where the quasi-one dimensional spin system is inevitably affected by the cross talk between arrays and the spin-phonon coupling. Here, paradigmatic alternating-exchanging Heisenberg chains with spin-1/2 are realized in a designer graphene system using on-surface synthesis. The couplings: J1 = 38 meV, J2 = 23meV are determined by inelastic tunneling spectra, which is strong enough to support practical quantum operation.

O 2.10 Mon 12:45 CHE 89

CoPc on Ag(100): getting the most out of PEEM images — •THORSTEN WAGNER[1], GRAZYNA ANTCZAK[2], MICHAEL GYÖRÖK[1], ANNA VOLOKITINA[1], FELIX MARSCHNER[1], AGATA SABIK[2], FRANCISZEK GOŁEK[2], and PETER ZEPPENFELD[1] — [1]Johannes Kepler University, Institute of Experimental Physics, Surface Science Division, 4040 Linz, Austria — [2]University of Wrocław, Institute of Experimental Physics, 50-204 Wrocław, Poland

We use photoelectron emission microscopy (PEEM) and the Anderson method to study in situ the thin-film growth of cobalt-phthalocyanine (CoPc) on Ag(100) surfaces. Based on the Fowler-DuBridge theory, we were able to correlate the evolution of the mean electron yield acquired with PEEM for coverages up to two molecular layers of CoPc to the global work function changes measured with the Anderson method. For coverages above two monolayers, the transients measured with the Anderson method and those obtained with PEEM show different trends allowing us to determine the inelastic mean free path of the low-energy electrons while passing through the third layer of CoPc.[1] Already before (and during) the condensation of solid phases (2D islands or 3D crystallites), there is a dilute 2D gas phase consisting of individual molecules diffusing across the surface or clusters, which can not be resolved with PEEM. Therefore, we discuss, how image features below and above the resolution limit of a PEEM affect the mean electron yield and the (normalized) standard deviation.[2]

O 3: Metal Substrates: Adsorption and Reaction of Small Molecules I

Time: Monday 10:30–12:15   Location: CHE 91

O 3.1 Mon 10:30 CHE 91

A Nanocar and rotor in a molecule — •KWAN HO AU-YEUNG[1], SUCHETANA SARKAR[1], TIM KÜHNE[1], OUMAIMA AIBOUDI[2], DMITRY A. RYNDYK[3,4], ROBERTO ROBLES[5,6], NICOLAS LORENTE[5,6], FRANZISKA LISSEL[2], CHRISTIAN JOACHIM[7], and FRANCESCA MORESCO[1] — [1]Center for Advancing Electronics Dresden, TU Dresden, 01062 Dresden, Germany — [2]Leibniz-Institut für Polymerforschung Dresden e.V., 01069 Dresden, Germany, and Faculty of Chemistry and Food Chemistry, TU Dresden, 01062 Dresden, Germany — [3]Institute for Materials Science, TU Dresden, 01062 Dresden, Germany — [4]Theoretical Chemistry, TU Dresden, 01062 Dresden, Germany — [5]Centro de Física de Materiales CFM/MPC (CSIC-UPV/EHU), 20018 Donostia-San Sebastián, Spain — [6]Donostia international physics center, 20018 Donostia-San Sebastian, Spain — [7]GNS & MANA Satellite, CEMES, CNRS, 29 rue J. Marvig, 31055 Toulouse, France

Depending on its adsorption conformation on the Au(111) surface, a zwitterionic single molecule machine works in two different ways under STM voltage pulses: It is a unidirectional single molecule-rotor while anchoring on the surface; It is a fast-drivable molecule-vehicle (nanocar) while physisorbed. By tuning the molecular coverage, the conformation of the molecule can be selected as a rotor or a nanocar. The movement triggered by inelastic tunneling excitation is investigated under the same experimental conditions for the unidirectional rotation of the rotor and the directed movement of the nanocar.

O 3.2 Mon 10:45 CHE 91

Controlling the Switching of Azobenzene Derivatives on Graphite-Air Interface — •THIRUVANCHERIL G. GOPAKUMAR[1], KHUSHBOO YADAV[1], HARIOM BIRLA[1], SHOWKAT H. MIR[2], THOMAS HALBRITTER[3], ALEXANDER HECKEL[3], and JAYANT K. SINGH[2] — [1]Department of Chemistry, Indian Institute of Technology Kanpur, Kanpur 208016, India — [2]Department of Chemical Engineering, Indian Institute of Technology Kanpur, Kanpur 208016, India — [3]Institute for Organic Chemistry and Chemical Biology, Goethe-University Frankfurt, Max-von-Laue-Str. 9, 60438 Frankfurt, Germany

The trans isomer of azobenzene (AB) and its derivatives is the most abundant under equilibrium-thermodynamical conditions and is known to switch between

its trans and cis states when triggered by light and electrons/holes on graphite.[1] In this work, we show that AB derivatives are switching between two cis states (cis, cis') when electrons/holes induced switching is performed on a cis dominant non-equilibrium initial condition at HOPG-air interface. The switching efficiency in the cis adlayer is several folds higher than that in the trans adlayer. This is related to the low switching barrier for cis-cis' switching compared to that of trans-cis switching as revealed by density functional theory (DFT) calculations.[2]

O 3.3   Mon 11:00   CHE 91

STM-induced ring closure of vinylheptafulvene molecular dipole switches on Au(111) — •Suchetana Sarkar[1], Kwan Ho Au-Yeung[1], Tim Kuehne[1], Oumaima Aiboudi[2], Dmitry A. Ryndyk[3,4], Thomas Heine[4], Franziska Lissel[2,4], and Francesca Moresco[1] — [1]Center for Advancing Electronics Dresden, TU Dresden, 01062 Dresden, Germany — [2]Leibniz Institute of Polymer Research, 01069 Dresden, Germany — [3]Institute for Materials Science, TU Dresden, 01062 Dresden, Germany — [4]Faculty of Chemistry and Food Chemistry, TU Dresden, 01062 Dresden Germany

Dihydroazulene/vinylheptafulvene pairs are known as molecular dipole switches that undergo a ringopening/- closure reaction by UV irradiation or thermal excitation. We show that the ring-closure reaction of a single vinylheptafulvene adsorbed on the Au(111) surface can be induced by voltage pulses from the tip of a scanning tunneling microscope. This cyclization is accompanied by the elimination of HCN, as confirmed by simulations. Post the ring closure reaction, lateral movement induced via voltage pulses from the STM tip shows a different response. This behaviour is discussed by comparing the dipole moment and the charge distribution of the open and closed forms on the surface.

O 3.4   Mon 11:15   CHE 91

Surface segregation of PdAu(111) in reactive gas environments from ab initio thermodynamics — •Olga V Vinogradova, Vanessa J Bukas, and Karsten Reuter — Fritz Haber Institute of the Max Planck Society, Berlin, Germany

Catalytic properties of alloys are largely determined by the specific chemical composition at the surface. Differences in composition between surface and bulk regions depend intricately on both the parent metals and surrounding gas-phase environment. While a non-reactive environment is expected to induce surface segregation of the more noble alloy component, a reactive environment such as oxygen often favors the more active component at the surface. Using ab initio thermodynamics, here we explore the structure and composition of the PdAu(111) alloy surface in oxygen, nitrogen, and carbon containing environments. An exhaustive, yet systematic, search of the available phase-space shows the segregation profile in an oxygen atmosphere to follow the anticipated picture described above. Unlike oxygen, however, carbon at low coverages burrows deeper into the alloy substrate without first the adsorbate-induced segregation of Pd at the surface. A nitrogen environment induces an intermediate behavior to oxygen and carbon where the nitrogen atoms first favor either surface or subsurface sites depending on the detailed metallic composition profile.

O 3.5   Mon 11:30   CHE 91

Atomistic investigations on the effect of vibrational excitation on O_2 adsorption on Pt surfaces — •Simon Homann, Björn Kirchhoff, and Timo Jacob — Institute of Electrochemistry, Ulm University, D-89081 Ulm

Platinum is considered an excellent model system for surface studies and is also an important heterogeneous catalyst. Combined with non-thermal plasmas, many studies found an improvement in turn-over frequency compared to thermal catalysis with the non-excited gas phase. One possible contender towards an explanation of this is the interaction of the vibrationally excited molecules in the plasma with the metal surface. As a first proof of concept, we present in this study Born-Oppenheimer molecular dynamics simulations of vibrationally excited Oxygen on low-indexed Platinum surfaces using a reactive force field (ReaxFF). The vibrational density of states simulated this way is in agreement with typical results obtained, e.g. from kinetic modeling of the plasma afterglow. The higher vibrational energy leads to an altered adsorption behavior in terms of dissociation and preferred adsorption positions, as well as changes in surface morphology.

O 3.6   Mon 11:45   CHE 91

Fluctuating nature of CO adlayer structures on metal surfaces — •Sung Sakong and Axel Gross — Ulm University, Ulm, Germany

The dynamics of atomic and molecular adlayers on surfaces is an critical issue in heterogeneous catalysis and electrocatalysis as it determines how reaction partners can meet on the catalyst surfaces. The adlayer formation influences the performance of catalysts and the structure of the electric double layer. Recently, video scanning tunneling microscope (V-STM) experiments have demonstrated the influence of the CO adlayer dynamics on oxygen diffusion on Ru(0001) [1,2] and the dynamical nature of a CO monolayer on Pt(111) [3]. We will present microscopic pictures of CO adlayer fluctuations on Ru(0001) and Pt(111) based on density functional theory (DFT) calculations and kinetic Monte Carlo (kMC) simulations. The calculations demonstrate how local disorder can lower the adsorption energy of a CO adlayer. We will particularly demonstrate the importance of the so-called door opening mechanism for oxygen diffusion on a CO-covered surface [1,2] and the dynamical nature of CO adlayers [3] by comparing DFT-based simulations with V-STM experiments.

O 3.7   Mon 12:00   CHE 91

Self-assembly and dehydrogenation reactions of borazine on Ag(111) — •Tobias Weiss[1], Aleksandr Baklanov[1], Georg S. Michelitsch[2], Martin Schwarz[1], Manuela Garnica[1], Karsten Reuter[3], and Willi Auwärter[1] — [1]Physics Department E20, Technical University of Munich, Germany — [2]Laboratoire des Solides Irradiés, École Polytechnique, France — [3]Chair of Theoretical Chemistry, Technical University of Munich, Germany

Borazine ($B_3N_3H_6$), is a prominent precursor for the growth of hexagonal boron nitride (hBN) on metal supports [1]. With monolayer hBN playing an important role in the field of 2D-materials, borazine adsorption, assembly and decomposition on surfaces is a topic of interest. Space-averaging studies revealed flat or tilted adsorption geometries on different substrates depending on their catalytic activity [2,3].

Here, we provide unprecedented real-space insight into adsorbed borazine molecules and their on-surface chemistry in ultra-high vacuum. This scanning tunneling microscopy investigation of the self-assembly of borazine on Ag(111) reveals a highly regular, porous hexagonal phase or a dense packed structure, depending on exposure. Furthermore, tip-induced dehydrogenation reactions of single molecules result in a tilted adsorption geometry. Complementary density functional theory calculations were performed to comprehensively characterize potential reaction products and adsorption configurations.

O 4: Tribology: Surfaces and Nanostructures

Time: Monday 10:30–12:30   Location: GER 37

O 4.1   Mon 10:30   GER 37

High throughput first-principle prediction of interfacial adhesion energies in metal-on-metal contacts — Paolo Restuccia, •Margherita Marsili, and Maria Clelia Righi — Department of Physics and Astronomy, University of Bologna, 40127 Bologna, Italy

Adhesion energy ultimately dictates the mechanical behavior and failure of interfaces. As natural and artificial solid interfaces are ubiquitous, it represents a key quantity in a variety of fields, from geology to nanotechnology. An ab-initio determination of adhesion energies is crucial because the specific atomistic details of the interface primarily determine the strength of adhesion, but, especially for heterogeneous interface is challenging, as computations can be very expensive. We performed the high-throughput DFT determination of the adhesion energy of around a hundred metallic heterostructures, ranging from transition to noble metals [1]. We identified general trends confirming that adhesion energies can be reasonably well inferred from the knowledge of the surface energies of the two interface constituents. Finally, by using a machine learning approach, we obtained a simple analytical expression for predicting the adhesion energy from the intrinsic properties of the two heterostructure constituents alone, which can prove useful for avoiding expensive supercell calculations. These results are part of the SLIDE project funded by the European Research Council under the Horizon 2020 research and innovation program (Grant agreement No. 865633). [1] P. Nanoscale Friction across the First Order Charge Density Wave Phase Transition of 1T-TaS$_2$ — Wen Wang[1], •Dirk Dietzel[2], and Andrè Schirmeisen[2] — [1]School of Mechanical Engineering, Southwest Jiaotong University, Chengdu, China — [2]Institute of Applied Physics, Justus Liebig University Giessen, Giessen, Germany

In material science, analyzing phase transitions is a fundamental way to understand material properties and their changes on the atomic level. At the same time, phase transition materials are intriguing model systems for nanotribology, where well-defined transformations can occur if a specific control parameter, like e. g. temperature, changes. On one hand, varying friction between tip and sample can be linked to the specific properties of different phases. On the other hand, during the phase transition localized mechanical probing of the surface can allow for a direct coupling to the reorganization of the material as was recently demonstrated for the case of 1T-TaS$_2$ [1]. However, previous experiments did not allow for an in-depth analysis of the influence of crucial parameters like sliding velocity and normal force on the process of local nucleation. This was now done by friction force microscopy on 1T-TaS2 for different stationary temperatures across the charge density wave phase transitions. Our results corroborate an anticipated mechanism, where the AFM-tip gradually induces local transformations of the material close to the spinodal point in a thermally activated and shear assisted process until the surface is fully 'harvested'.

O 4.3 Mon 11:00 GER 37

Kinetic nanoscale friction on van der Waals heterostructures — •BARTOSZ SZCZEFANOWICZ[1], ZHAO LIU[1], JOAO MARCELO J. LOPES[2], ANTONY GEORGE[3], ZIYANG GAN[3], ANDREY TURCHANIN[3], ALEXANDER ROTHSTEIN[4], CHRISTOPH STAMPFER[4], and ROLAND BENNEWITZ[1] — [1]INM - Leibniz Institute for New Materials, Saarbrücken, Germany — [2]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany — [3]Friedrich Schiller University Jena, Institute of Physical Chemistry, Jena, Germany — [4]JARA-FIT and 2nd Institute of Physics A, RWTH Aachen University, 52074 Aachen, Germany

2D materials exhibit exceptional tribological properties due to their weak normal-to-plane interactions. Friction Force Microscopy (FFM) demonstrated that the microscopic processes underlying friction can be tuned by application of high contact pressure [1] or by combining different 2D materials into van der Waals heterostructures [2].

Samples of MoSe$_2$/hBN and graphene/hBN were prepared by the exfoliation technique. Sample of MoS$_2$/graphene was produced by thermal decomposition of SiC(0001), followed by direct growth of MoS$_2$ by Chemical Vapor Deposition (CVD). Friction forces were measured on those heterostructures in FFM experiments in ultrahigh vacuum as function of normal load and electric bias. We will discuss the results in terms of atomic potential corrugation, bending rigidity of 2D heterostructures, and bias-induced electrostatic attraction.

Temperature Dependent Wear Effects on the Nanometer Scale — •JENNIFER KONRAD, DIRK DIETZEL, and ANDRE SCHIRMEISEN — Institute of Applied Physics, Justus-Liebig University Giessen, 35392 Giessen, Germany

On the nanoscale, the temperature dependence of friction as observed by friction force microscopy is a well-known phenomenon that can often be described by the thermally activated Prandtl Tomlinson Model. Similarly, nanoscale wear is also often anticipated as a thermally activated and shear assisted process, which results in a temperature dependence, where the overall wear rate increases with temperature [1]. However, this behavior can change when the effects of interfacial bond formation and breaking have to be taken into consideration. Surprisingly, lower temperatures can then result in higher wear rates as will be demonstrated by temperature dependent wear experiments performed for different interfaces involving silica and diamond surfaces. This behavior can phenomenologically be explained by considering shear assisted bond formation, which leads to a higher number of interfacial bonds formed at lower temperatures [2]. By straining this larger number of bonds during scanning an increased wear rate at low temperatures is then caused, even if the energy barrier for bond breaking is lower than for the removal of adjacent surface atoms.

O 4.5 Mon 11:30 GER 37

Rewritable friction on Nitrogen-doped graphene moiré superstructures — •SHUYU HUANG[1,2], ANTOINE HINAUT[2], YIMING SONG[2], SEBASTIAN SCHERB[2], GEMA GNAVARRO[2], THILO GLATZEL[2], YUNFEI CHEN[1], and ERNST MEYER[2] — [1]Jiangsu Key Laboratory for Design and Manufacture of Micro-Nano Biomedical Instruments, School of Mechanical Engineering, Southeast University, Nanjing 211189, China — [2]Department of Physics, University of Basel, Klingelbergstrasse 82, 4056 Basel, Switzerland

Graphene, as typical atomically-thin solid lubricant with potential applications in micro- and nano-electromechanical systems (MEMS/NEMS), has been ex-

tensively investigated on its nanotribological properties. In the present work, we compare the frictional properties between pristine graphene and modified graphene, showing that atomic-scale friction can be significantly altered by Nitrogen doping-induced modification, then it can be recovered after tip rubbing. Specifically, C60 nano-flakes are deposited as a mask on graphene/Ir (111) surface by thermal evaporation. The sample is then exposed to a nitrogen radical flux produced by a remote RF plasma source. After thermal annealing, to desorb C60 molecules, both nano-patterned modified graphene and pristine graphene, located below former C60 islands, surface is obtained simultaneously. By the means of high-resolution ultrahigh vacuum atomic force microscopy, the topography of surface with two different regions are characterized and discussed in non-contact mode and friction force variation is measured in contact mode.

O 4.6 Mon 11:45 GER 37

Atomic friction over bonds: Impact of the chemical neighbourhood — •LUKAS HÖRMANN[1], JOHANNES J. CARTUS[1], ALFRED J. WEYMOUTH[2], and OLIVER T. HOFMANN[1] — [1]Institute of Solid State Physics, Graz University of Technology, Graz, Austria — [2]Universität Regensburg, Regensburg, Germany

Friction causes a significant amount of energy loss in any moving mechanical device. Given the trend toward the miniaturisation of devices, studies of the fundamental mechanisms governing friction at the atomic scale become ever more important. At this scale, friction is governed by electronic and phononic excitations as well as by the potential energy surface (PES) at the interface.

We computationally investigate these mechanisms on the example of a CO-tip of a lateral force microscope oscillating above a PTCDA monolayer on Cu(111). Our investigation combines ab-initio electronic structure methods with machine-learning algorithms to predict highly accurate PESs and to estimate frictional energy dissipation. We gauge the dependence of frictional energy dissipation on the local chemical environment, i.e. the location of the CO-tip above the surface during the friction measurement. Moreover, we investigate how the oscillation direction and the stiffness of the CO-tip affect friction. Hereby we study the role of quantum-mechanical interactions by comparing our results to friction estimates based on a Lennard-Jones potential as well as experimental measurements. Finally, we investigate frictional energy dissipation channels by studying how the movement of the CO-tip may be damped as a result of electronic friction.

O 4.7 Mon 12:00 GER 37

Quantum-mechanically enhanced water flow in sub-nanometer carbon nanotubes — •ALBERTO AMBROSETTI, GIORGIO PALERMO, and PIER LUIGI SILVESTRELLI — Dipartimento di Fisica e Astronomia, Università degli Studi di Padova, via Marzolo 8, 35131, Padova, Italy

Water-flow in carbon nanotubes (CNT's) starkly contradicts classical fluid mechanics, with permeabilities that can exceed no-slip Haagen-Poiseuille predictions by two to five orders of magnitude. Semi-classical molecular dynamics accounts for enhanced flow-rates, that are attributed to curvature-dependent lattice mismatch. However, the steeper permeability-enhancement observed experimentally at nm-size radii remains poorly understood, and suggests emergence of puzzling non-classical mechanisms. Here we address water-CNT friction from a quantum-mechanical perspective, in terms of water-energy loss upon phonon excitation. We find that combined weak water-phonon coupling and selection rules hinder water-CNT scattering, providing effective protection to water super flow, whereas comparison with a semiclassical theory evidences a friction increase that can exceed the quantum-mechanical prediction by more than two orders of magnitude. Quasi-frictionless flow up to sub-nm CNT's opens new pathways towards minimally-invasive trans-membrane cellular injections, single-water fluidics and efficient water filtration.

O 4.8 Mon 12:15 GER 37

Screw-like beetle joints and their tribological features — •CORNELIA F. PICHLER[1], RICHARD THELEN[1], THOMAS VAN DE KAMP[2], and HENDRIK HÖLSCHER[1] — [1]Institute of Microstructure Technology (IMT), Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Institute for Photon Science and Synchrotron Radiation (IPS), Karlsruhe Institute of Technology, Karlsruhe, Germany

Understanding and finally mimicking lubricants in the joints of various insects promises environmentally friendly alternatives for mineral-oil-based lubricants. The compactness of the insect joints and the tiny quantities of their respective lubricants make it challenging to analyze their frictional properties. In my work, I characterize lubricants directly in dissected screw-like beetle joints by lateral force measurements with the atomic force microscope (AFM). This approach gives insight into the frictional properties of the lubricant in its natural form as well as the functional structure found in the joints. In addition to lubricant films, we also observe microstructures which suggest that beetles advance frictional properties of their joints by a sophisticated combination of surface structure and lubrication.

O 5: Focus Session: Ion Beam Interaction with Surfaces and 2D Materials I

Ion beam techniques are an important tool in surface science and nanotechnology in terms of surface composition analysis as well as tailoring of surface properties. Recent important developments took place using ultra-low energy ion implantation to introduce foreign atoms into 2D material lattices or triggering self-organization mechanisms to form large-scale ordered crystalline surface structures. This focus session brings international specialists in the connecting fields of ion physics and surface science together to discuss recent progress to our fundamental understanding of ion-surface interactions as well as pathways towards new applications for emerging material classes.

Organizer: Richard Arthur Wilhelm (TU Wien)

Topical Talk   O 5.1   Mon 10:30   GER 38

Highly charged, slow and swift ions interacting with surfaces and 2D materials — •MARIKA SCHLEBERGER — Fakultät für Physik, Universität Duisburg-Essen and CENIDE

Ion beams are a proven, versatile, and efficient tool for material modification and in particular for defect engineering. An ion stores its energy in the form of kinetic (E_{kin}) and so-called potential energy (E_{pot}), the latter corresponding to the energy required to create its respective charge state. At low velocities, the energy deposition is based on elastic collisions leading to linear sputtering cascades or collision peaks in the volume of the material, and ultimately to the emission of atoms. At higher kinetic energy, electronic excitations and ionizations are dominant. The release of potential energy again occurs via electronic processes that can also lead to the emission of atoms from the target material. By adjusting these two parameters, E_{pot} and E_{kin}, one can in principle fine-tune the nature of the interaction and thus the corresponding material changes. However, the basic mechanisms of defect formation through electronic excitation have not yet been clarified. We have introduced 2D materials as target material for the study of ion-solid-interactions. Due to their well-defined thickness, the flexible preparation and last but not least the wide range of available materials, they are an ideal target material for our task. We have studied the interaction of ions of different types with surfaces and 2D materials and I will present key results.

Model for Nanopore Formation in Two-Dimensional Materials by Impact of Highly Charged Ions — •A. S. GROSSEK, A. NIGGAS, R. A. WILHELM, F. AUMAYR, and C. LEMELL — TU Wien

Experiments of highly charged ions (HCI) on 2D-materials have shown that HCIs extract numerous electrons from the 2D target. This interaction has shown to lead to nanopore formation in materials such as monolayer MoS_2 while single layer graphene remains structurally intact. One hypothesis proposed for the cause of nanostructuring of these materials is charge build up by hole charges in the target, which -depending on material charge conductivity- may sustain sufficiently long in order to lead to structural damage of the target atoms. We study this hypothesis of nanostructuring by HCI impact on 2D-materials via molecular dynamics simulations. The charge transfer from target to HCI is well described by the classical-over-the-barrier model, of which a simplified version is implemented into the simulation. Charge conduction in the target is modelled by charge hopping with a hopping time t_h between lattice sites. Our 2D lattice is simulated by a Stillinger-Weber potential with parameters fitted to reproduce graphene. We study different materials by respectively adjusting the hopping time t_h (conductivity) of the graphene lattice in the simulation. After the simulation kinetic and potential energies of the individual target atoms are evaluated to determine if a pore has formed. Our simulation is able to qualitatively reproduce experimental results showing pore formation efficiencies and pore sizes to be dependent on initial HCI charge state and conductivity of the material.

O 5.3   Mon 11:15   GER 38

Charge-state-enhanced ion sputtering of metallic gold nano islands — •GABRIEL L. SZABO[1], BENEDYKT R. JANY[2], HELMUT MUCKENHUBER[1], ANNA NIGGAS[1], MARKUS LEHNER[1], ARKADIUSZ JANAS[2], PAUL S. SZABO[3], ANTONY GEORGE[4], ZIYANG GAN[4], ANDREY TURCHANIN[4], FRANCISZEK KROK[2], and RICHARD A. WILHELM[1] — [1]TU Wien, Institute of Applied Phyiscs, 1040 Vienna, Austria, EU — [2]Jagiellonian University, Institute of Physics, 30-348 Kraków, Poland, EU — [3]University of California, Space Sciences Laboratory, Berkeley 94720, USA — [4]Friedrich Schiller University Jena, Institute of Physical Chemistry, 07743 Jena, Germany, EU

Irradiation of certain targets with slow highly charged ions (HCIs) can trigger phase transitions or nano-structure formation. The main driving force for these processes is the electronic excitation of the target's electronic sub-system in close proximity of the impact triggered by the ion neutralization. Subsequent electron-phonon coupling mediates lattice heating of the target. So far charge state dependent erosion of metallic surfaces was not unambiguously shown. The potential energy stored in the HCI dissipates quickly before a transfer to the target's atomic lattice can take place. By reducing the size of the target down to the nanometer regime, geometric confinement might prevent free electrons of the target to dis-

sipate the electronic excitations on the fs time-scale. In this work we irradiated gold nano islands with Xe^{q+} (q=1,18,25,32,40) with a constant kinetic energy of 180 keV, which results in an erosion of the islands that is strongly enhanced by the potential energy deposition.

Topical Talk   O 5.4   Mon 11:30   GER 38

A contactless single-step process for simultaneous nanoscale patterning and cleaning of large-area graphene — •TUAN TRAN — Department of Physics and Astronomy, Uppsala University, Sweden

In this talk, we will present a contactless single-step process for structuring self-supporting graphene with customizable patterns and over large areas. Using energetic ions passing through a suspended mask with through-hole nanopatterns, we can deterministically structure the graphene with a minimum feature size down to 15 nm, comparable to what can be achieved with focused ion beam techniques. Our process, however, instead uses a broad parallel beam with no stringent requirement on the beam focusing, and hence enables a contactless approach. Neither, any chemicals and coating layers are necessary, substantially reducing the amount of contamination which might otherwise occur using other lithographic methods. In addition to the structuring capability, we found that the method can simultaneously render the graphene cleaner. The areas surrounding the direct ion impacts are significantly cleaned from the initial contamination which commonly are remnants from the transferring process of the graphene. We will explain the mechanism leading to such cleaning effect. Finally, selective area electron diffraction were used for detailed characterization of the graphene lattice after ion irradiation with and without the mask at different doses and temperatures. These diffraction data are necessary for understanding the creation and annihilation of defects and the possible role of the contamination on self-healing and stabilization of the graphene lattice.

O 5.5   Mon 12:00   GER 38

chemical etching of 2D materials — •MITISHA JAIN, SILVAN KRETSCHMER, and ARKADY KRASHENINNIKOV — Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, 01328 Dresden, Germany

Transmission electron microscopes are used for imaging 2D materials to the resolution of single atoms. On the other hand, the imaged material gets damaged (modified by the beam) quite easily. Hence, the information about the damage done by the beam are important for proper imaging. Different channels of damage construction such as knock-on, ionization (excitation), chemical etching (e.g. adatoms) have been determined. In this study, the knock-on threshold energies for graphene (C), h-BN (B and N) and MoS2 (S) materials in the presence of adsorbed adatoms (H, C, N, O) on the surface are calculated in the framework of spin-polarized density functional theory. From the preliminary results, we found that when an adatom is adsorbed, the threshold energies are reduced by 2-3 eV compared to pristine systems. Further, we consider the additional effect of electronic excitation on the threshold energies in combination with adsorbed adatoms. The displacement cross-section under the electron beam are assessed employing the McKinley-Feshbach formalism allowing to compare different channels of damage creation.

O 5.6   Mon 12:15   GER 38

Influence of the swift heavy ions' charge state on pore creation in single-layer MoS_2 — •YOSSARIAN LIEBSCH[1], LUKAS MADAUSS[1], HENNING LEBIUS[2], ABDENACER BENYAGOUB[2], CLARA GRYGIEL[2], RADIA RAHALI[2], RAJENDRA SINGH[3], JANI KOTAKOSKI[3], and MARIKA SCHLEBERGER[1] — [1]University Duisburg-Essen, Duisburg, Germany — [2]CIMAP/GANIL, Caen, France — [3]University Vienna, Vienna, Austria

The initial charge state of a swift heavy ion is usually of no special interest when discussing the interaction of the ion with a bulk target. This is due to the potential energy being small in comparison to the kinetic energy of the ion and due to the equilibrium charge the ion accumulates within a few nanometers after it enters the material. However, in single-layer materials the travelling distance is less than the typical distance needed to establish the equilibrium charge state. Hence, we try to investigate the influence of the charge state of the ions on the defect formation in MoS_2. This is done by irradiating single-layers with swift

heavy ions of different charge states. For this experiment we chose 6.6 MeV/u Xe ions with charge states ranging from +41 to +48. Evaluation of the effect on the material is done by analyzing the pore radii and creation efficiencies with STEM-HAADF. With this experiment we aim to shed light onto the fundamental processes and interactions between ultra thin materials and swift heavy ions as well as quantifying the influence of the charge state on the stopping power in single-layered materials.

O 5.7   Mon 12:30   GER 38

Spectroscopic and microscopic analysis of ion-induced modifications in 2D materials — •Carolin Frank[1], Lucia Skopinski[1], Lars Breuer[1], Jennifer Schmeink[1], Lukas Kalkhoff[1], Stephan Sleziona[1], Ulrich Hagemann[2], and Marika Schleberger[1] — [1]University of Duisburg-Essen, Faculty of Physics and CENIDE, 47057 Duisburg, Germany — [2]University of Duisburg-Essen, CENIDE, ICAN, 47057 Duisburg, Germany

In this contribution we present results concerning modifications induced by xenon- and gold-ions in two-dimensional molybdenum disulfide exfoliated on gold including Raman spectroscopy, X-ray photoelectron spectroscopy and friction force microscopy. Irradiations at the target station HICS, located at the University of Duisburg-Essen, as well as at the target stations MSS@CRYRING and M1-Branch, both located at the GSI Helmholtzzentrum für Schwerionenforschung, were implemented with slow, highly charged ions as well as with swift heavy ions, which differ from each other regarding their charge state and their kinetic energy.

A focus will be given to the impact of both the kinetic and potential energy of the ions on modifications of the molybdenum disulfide and also on the size of ion-induced defects. Based on the results of friction force microscopy it is shown for the first time that the impact of the potential energy of the swift ions

regarding generation of defects in 2D materials is significantly larger than the impact of the kinetic energy. Additionally, results regarding interaction between the gold substrate and the molybdenum disulfide will be discussed.

O 5.8   Mon 12:45   GER 38

Manipulation of the electrical and memory properties of MoS_2 field-effect transistors by highly charged ion irradiation — •Stephan Sleziona[1], Aniello Pelella[2], Enver Faella[2], Osamah Kharsah[1], Lucia Skopinski[1], André Maas[1], Yossarian Liebsch[1], Antonio Di Bartolomeo[2], and Marika Schleberger[1] — [1]Fakultät für Physik and Cenide, Universität Duisburg-Essen, Lotharstraße 1, 47057 Duisburg — [2]Physics Department, University of Salerno, 84084 Fisciano, Salerno, Italy

Molybdenum disulfide (MoS_2) is a semiconductor that develops a direct bandgap of 1,8 eV when its thickness is reduced to the monolayer limit and is therefore a suitable 2D material for applications in opto-electronic devices. MoS_2 field-effect transistors (FET) in particular exhibit a hysteresis in their transfer characteristics, which can be utilized to realize a 2D memory device. This hysteresis is generally attributed to adsorbates or defects either in the MoS_2 lattice or in the underlying substrate. We fabricated MoS_2 FETs on SiO_2/Si substrates and irradiated these devices with Xe^{28+} ions at a kinetic energy of 180 keV to deliberately introduce defects and modify their electrical and hysteretic properties. We evaluate different electrical properties before and after the irradiation and find clear influences of the irradiation e.g., on the conductivity and charge carrier mobility of the devices. Significantly reduced n-doping and a well-developed hysteresis can be measured after irradiation. We utilize this hysteresis to demonstrate the use of the MoS_2 FET as a memory device, which has remarkably longer relaxation times ($\approx$ minutes) compared to previous works.

A Newly Developed IRAS System to Investigate Adsorbates on Metal-Oxide Single Crystal Surfaces — •David Rath, Jiri Pavelec, Ulrike Diebold, Michael Schmid, and Gareth S. Parkinson — Institute of Applied Physics, TU Wien, Austria

The IRAS system GRISU (GRazing incident Infrared absorption Spectroscopy Unit) was developed to investigate adsorbates on metal oxide single crystals in the research field of single-atom catalysis [1]. It combines the commercially available FTIR spectrometer Bruker Vertex 80v with an UHV chamber [2]. The compact design requires only one CF150 port for the main optical components, features five mirrors for beam guidance placed in HV and UHV environment and optimises the system's performance, flexibility, and usability. The result is a small controllable focal-spot diameter (max. 3 mm) on the sample, motorised optical components, and an aperture limiting the incidence angle range (variable, 49° to 85°) on the sample. Based on ray tracing results and preliminary intensity measurements, the system shows up to 10× higher intensities compared to a commercial system with two parabolic mirrors with a focal length of 250 mm. First IR spectra measured with the recently installed IRAS measurement system will be shown.

O 6.2   Mon 10:45   GER 39

Insights on the Liquid/vacuum interface of ionic liquids by ARXPS and UHV Pendant Drop — Ulrike Paap, •Afra Gezmis, Florian Maier, and Hans-Peter Steinrück — Friedrich-Alexander Universität, Erlangen, Germany

Ionic liquids (ILs) are characterized by a low melting point and a low vapor pressure. Many ILs exhibit high gas solubility along a high chemical and thermal stability. Such properties are beneficial in many areas such as gas absorbents, refrigerants, lubricants, antistatics and surfactants. The low vapor pressure of ILs opens the possibility to investigate them under ultra-high vacuum (UHV) conditions. In this context, angle-resolved X-ray photoelectron spectroscopy (ARXPS) has already proven to be a particularly powerful tool. We now combine information on the surface composition derived from ARXPS and measurements of the surface tension performed under ultraclean conditions with our new pendant drop setup, which operates in UHV. Our results allow for a deeper understanding of enrichment and molecular orientation processes at the outermost surface of these systems on the microscopic and the macroscopic scale. This work was supported by the Collaborative Research Center (CRC) 1452: Catalysis at Liquid Interfaces.

O 6.3   Mon 11:00   GER 39

Kintetic In Situ Synthesis (KISS) technique of large-area 2D materials exfoliation — •Antonija Grubisic-Cabo[1,2], Matteo Michiardi[3], Charlotte E. Sanders[4], Marco Bianchi[5], Davide Curcio[5], Dibya Phyual[2], Magnus H. Berntsen[2], Qinda Guo[2], and Maciej Dendzik[2] — [1]University of Groningen, Netherlands — [2]KTH, Sweden — [3]University of British Columbia, Canada — [4]Central Laser Facility, UK — [5]Aarhus University, Denmark

Two-dimensional (2D) materials provide an extremely rich platform to investigate novel quantum phenomena and to design nanostructures with desired functionalities. Some of the key techniques employed in studies of 2D materials, such as photoemission spectroscopy, have stringent requirements for the quality, sample size and cleanliness of the surface. Fulfilling these conditions using a standard mechanical exfoliation in a glove box is often problematic. Here, we present a novel method for in situ exfoliation of 2D materials performed directly in ultra-high vacuum, which yields large flakes of excellent crystallinity and purity. In our experiments, multiple semicondicting and metallic transition metal dichalcogenides were exfoliated onto Au, Ag and Ge substrates, showing the versatility of the technique, and characterised by angle resolved photoemission spectroscopy. Importantly, the proposed method is straightforward, simple, and does not require any specialised equipment. This technique is ideally suited for the electronic structure research of air-sensitive 2D materials since the sample preparation process happens entirely in ultra-high vacuum.

O 6.4   Mon 11:15   GER 39

Two new methods for the analysis of TPD data — •Michael Schmid, Gareth S. Parkinson, and Ulrike Diebold — Institute of Applied Physics, TU Wien, Austria

Temperature programmed desorption (TPD) is the most common experimental technique for obtaining the binding energies of adsorbates. TPD data are usually analyzed using the Polanyi–Wigner equation; this is far from straightforward. We present two new methods, based on equilibrium thermodynamics, bypassing the use of the Polanyi–Wigner equation or transition state theory: In the case of all adsorption sites being equivalent, the adsorption energy can be directly calculated from the desorption temperature, the width of the TPD peak, the sticking probability (at the desorption temperature), and thermodynamic data [1]. This "magic formula" is remarkably robust; in many cases even wrong assumptions about the desorption order or the presence of a distribution of adsorption energies lead to negligible errors. In more complex cases, with a distribution of adsorption energies, we show that TPD spectra are approximately given by a convolution integral. We present a method (and computer program) for TPD inversion, i.e, the determination of the energy distribution from a single TPD spectrum at saturation coverage [1]. Although this method is derived for the case of non-interacting adsorbates, we argue that it is a good approximation in cases of short-range repulsion and it can also reveal (though not quantitatively

analyze) the presence of attractive interactions between adsorbates.

O 6.5   Mon 11:30   GER 39

Surface-Sensitive Spectroscopy from First Principles — •Yair Litman[1,2], Jinggang Lan[3], Kuo-Yang Chiang[2], Venkat Kapil[1], Yuki Nagata[2], and David Wilkins[4] — [1]University of Cambridge, Cambridge, United Kingdom — [2]MPI for Polymer Research, Mainz, Germany — [3]Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland — [4]Queen's University Belfast, Belfast, United Kingdom

Our current understanding of the structure and dynamics of aqueous interfaces at the molecular level has grown substantially in the last decades due to an increasing synergy between experimental measurements and atomistic simulations. However, the latter are either based on empirical force field models, which are neither suitable to describe bond breaking and formation nor systems with complex electronic structure, or on *ab initio* calculations which due to their computational cost cannot be statistically converged. In this work, we overcome all these limitations by combining high-dimensional neural network potentials with symmetry-adapted Gaussian process regression [1] to simulate the sum-frequency generation (SFG)[2] spectra of the water-air interface with *ab initio* accuracy. We obtain a good agreement with last-generation experiments and show how these models can in principle be improved systematically towards exact results. Overall, the machinery presented in this work paves the way for the modelling of surface-sensitive spectroscopy of complex interfaces. [1] V. Deringer, *et al.*, Chem. Rev. **16**, 121 (2021) [2] A. Morita, J. Hynes, J. Phys. Chem. B **106**, 673 (2002).

O 6.6   Mon 11:45   GER 39

Artificial Neural Network based Interatomic Potentials to Describe Laser-Excited Materials — •Bernd Bauerhenne, Pascal Plettenberg, and Martin E. Garcia — Universität Kassel, Heinrich-Plett-Straße 40, 34132 Kassel, Germany

Femtosecond laser pulses create a transient state with hot electrons at temperature Te and cold ions, in which ultrafast nonthermal effects occur. Later, the decay of this state due to electron-phonon interactions gives rise to ultrafast effects of more thermal character. Quantum mechanical methods like Te-dependent density functional theory (DFT) allow a precise description of the non-thermal state with hot electrons. However, simulations of laser material interactions at surfaces on experimentally relevant sizes require to take a huge amount of atoms into account, which is only possible by the usage of interatomic potentials. Most known interatomic potentials are determined assuming that electrons are in their ground state and cannot describe nonthermal effects initiated by bond-softening or hardening. In order to take ultrafast thermal and non-thermal effects on the same theoretical level, Te-dependent interatomic potentials are needed. Here, we present an Te-dependent interatomic potential based, for the first time, on an artificial neural network. We studied silicon and show that the phonon band structure, the cohesive energy curves for several crystal structures, the electronic specific heat, atomic forces and cohesive energies are described in excellent agreement with DFT calculations for a wide range of Te. In addition, we simulated the laser-induced annealing of surface defects on a thin silicon film.

Real-time TD-DFTB full periodic implementation for solids and low-dimensional materials — •Carlos R. Lien-Medrano[1], Franco P. Bonafé[2], Cristián G. Sánchez[3], and Thomas Fraeunheim[1] — [1]University of Bremen, Bremen, Germany — [2]MPSD, Hamburg, Germany — [3]University of Cuyo, Mendoza, Argentina

The current implementation of the real-time TD-DFTB dynamics for molecules and finite systems in the DFTB+ package[1] is based on the length gauge of the electric field. Here we show a proof-of-concept implementation of the vector potential in the velocity gauge of the electric field that in principle would allow us to extend the real-time dynamics to any periodic direction, making the new implementation suitable for the study of photo-induced dynamics processes in bulk, low-dimensional materials and surfaces. Instead of the dipole moment, the observable of choice is the frequency dependent conductivity which can be obtained from the Fourier transform of the autocorrelation function of the electric current density averaged over a unit cell. The conductivity provides access to the dielectric constant of the system allowing the calculation of optical properties.

Structure discovery in AFM imaging of ice — •Fabio Priante[1], Ye Tian[2], Dong Guan[2], Chen Xu[1], Shuning Cai[1], Niko Oinonen[1], Peter Liljeroth[1], Ying Jiang[2], and Adam Foster[1,3] — [1]Department of Applied Physics, Aalto University, Helsinki FI-00076, Finland — [2]International Center for Quantum Materials, Peking University, Beijing, 100871, China — [3]WPI Nano Life Science Institute (WPI-Nano LSI), Kanazawa University

The interaction of water with surfaces is crucially important in a wide range of natural and technological settings. Using high-resolution AFM and STM, several studies have demonstrated the presence of water pentamers, hexamers, heptamers (and of their combinations) on a variety of metallic surfaces. However, in all these situations, the observed structures were completely flat, providing a relatively straightforward path to interpretation. To address more complex cases, while simultaneously alleviating the interpretation effort, we develop an automated workflow centered around a convolutional neural network (to extract atomic positions) and a neural network potential (to rapidly sort candidate structures with high accuracy). We test our workflow on several high-resolution AFM measurements of water clusters on Cu(111), whose understanding is challenging due to both their highly 3D configuration and to their large size. For each of them, we propose an underlying atomic structure, finally comparing the experimental images with simulated AFM from Density Functional Theory. These results provide new insights into the early phases of ice formation, which is a ubiquitous phenomenon ranging from biology to astrophysics.

O 6.9   Mon 12:30   GER 39

Designing Covalent Organic Frameworks Through Active Machine Learning — •Yuxuan Yao[1,2], Christian Kunkel[3], Karsten Reuter[3], and Harald Oberhofer[2] — [1]Chair for Theoretical Chemistry, Technische Universität München — [2]Chair for Theoretical Physics VII, University of Bayreuth — [3]Fritz-Haber-Institut der Max-Planck-Gesellschaft

Covalent organic frameworks (COFs) are a class of materials, that are formed by molecular building blocks (BBs) connected with covalent bonds. They have found application in many fields such as catalysis, or optoelectronics. It is well known that their design space is far too large to sample one by one because numerous available BBs. We modify an earlier active machine learning (AML) approach that explores the massive available BBs space through the use of surrogate models for charge injection and transport descriptors. In this method, the Gaussian Process Regression(GPR) and AML are combined to train the molecular space. This way we ensure that only promising molecules that are very different from already explored ones have their descriptors evaluated by Density Functional based Tight Binding (DFTB) calculations. Specifically, we modify molecular generation rules in order to produce three-fold rotationally symmetric candidates molecules for use in hexagonal COFs. In the future this approach can be generalized for any other symmetries, to potentially even allow for 3-dimensional network generation. We gauge the performance of our AML by evaluating the success ratio, which is the ratio of promising candidates to all generated molecules.

Machine-learning-backed evolutionary search for SrTiO$_3$(110) surface reconstructions — •Ralf Wanzenböck, Florian Buchner, Jesús Carrete, and Georg K. H. Madsen — Institute of Materials Chemistry, TU Wien, Vienna, Austria

To determine the atomic structure of surface reconstructions, structural models derived from domain knowledge and intuition have historically been essential. Evolutionary algorithms combined with density functional theory have proven to be powerful tools for such structure searches if one accepts the prohibitive cost that comes with a thorough exploration of a potential energy surface. We train a neural-network force field (NNFF) as a surrogate model to drive the exploration of the rich phase diagram of TiO$_x$ overlayers on SrTiO$_3$(110) utilizing the covariance matrix adaptation evolution strategy (CMA-ES). We verify the transferability of the NNFF by performing CMA-ES runs on SrTiO$_3$(110) 3×1, 4×1 and 5×1 with a model trained solely on 4×1 data. With the speedup afforded by the surrogate model we were able to perform exhaustive sets of exploratory runs to identify known and new low-energy reconstructions and match different symmetries found in experimental data. [R. Wanzenböck et al., Digital Discovery, 2022, 1, 703-710.]

O 7: Spins on Surfaces at the Atomic Scale I

Topical Talk   O 7.1   Mon 10:30   REC C 213
Superconductivity in atom-by-atom crafted quantum corrals — •Lucas
Schneider[1], Khai That Ton[1], Ioannis Ioannidis[2,3], Jannis Neuhaus-
Steinmetz[1], Thore Posske[2,3], Roland Wiesendanger[1], and Jens Wiebe[1]
— [1]Department of Physics, University of Hamburg, D-20355 Hamburg, Ger-
many — [2]I. Institute for Theoretical Physics, University of Hamburg, D-20355
Hamburg, Germany — [3]Centre for Ultrafast Imaging, Luruper Chaussee 149,
D-22761 Hamburg, Germany

Gapless materials in electronic contact with superconductors acquire proximity-
induced superconductivity in a region near the interface. Here, we investigate
the most miniature example of this so-called proximity effect on only a single
quantum level of a surface state confined in a quantum corral on a supercon-
ducting substrate, built atom-by-atom using a scanning tunneling microscope.
Whenever an eigenmode of the corral is pitched close to the Fermi energy by
adjusting the corral's size, a pair of particle-hole symmetric states is found to
enter the superconductor's gap. By comparison to a resonant level model of a
spin-degenerate localized state coupled to a superconducting bath, we identify
the in-gap states as scattering resonances theoretically predicted 50 years ago by
K. Machida and F. Shibata, which had so far eluded detection. We further show
that the observed anticrossings of the in-gap states indicate proximity-induced
pairing in the quantum corral's eigenmodes. In a final step, we study how indi-
vidual magnetic adatoms interact with the corral's eigenmodes.

**Tailoring Yu-Shiba-Rusinov bands in a Kagome lattice by molecular self-
assembly** — •Laetitia Farinacci, Gael Reecht, Nils Bogdanoff, Ben-
jamin W. Heinrich, Felix von Oppen, and Katharina J. Franke — Freie
Universitaet Berlin, Germany

Coupling of magnetic bound states in superconductors (so-called Yu-Shiba-
Rusinov or YSR states) leads to fascinating phenomena; such as the formation
of topological states. Bottom up approaches allow for a precise characterization
of the coupling parameters, shedding light onto the formation of YSR bands and
their properties. Most studies so far rely on atom manipulation, which is time
demanding and typically limits the size of the systems to below a hundred sites.

Here, we show that self-assembly of Fe-porphine-chloride (FePCl) molecules
on Pb(111) can be controlled by varying the sample temperature during and af-
ter molecular deposition. In particular, we show that we can obtain islands in
which the FeP molecules arrange in a Kagome lattice or in its precursors. This
way, we can, on the one hand, characterize the YSR hybridization with molecu-
lar precision and, on the other hand, study the long-range band formation across
2D islands.

Atom-by-Atom Study of Spin Lattices on a Superconducting Rashba Material
— •Khai That Ton, Lucas Schneider, Jens Wiebe, and Roland Wiesendan-
ger — Department of Physics - University of Hamburg, Hamburg, Germany

In the research field of topological superconductivity, Rashba-spin-orbit-
coupling is believed to be a stabilizing parameter for topological phases, increas-
ing the size of the topological gap.

One well-known category of materials with large spin-orbit coupling are
Bismuth-based surface alloys, which have been extensively studied by surface-
sensitive methods like angle-resolved photoemission and scanning tunneling
spectrosopy [1,2,3,4]. However, studies of such materials proximitized by su-
perconducting substrates are lacking so far. In this work, we grew Bismuth-
based surface alloys on thin films proximitized by elementary superconducting
substrates, adsorbed transition metal atoms, and then built dimers, chains and
small two-dimensional lattices of these atoms via STM-tip based atom manip-
ulation. We will present a scanning tunneling spectroscopy investigation of the
low-energy electronic structure of these different spin lattices.

O 7.4   Mon 11:30   REC C 213
Symmetry-dependent coupling in Yu-Shiba-Rusinov dimers — •Lisa
Rütten[1], Eva Liebhaber[1], Harald Schmid[1], Gaël Reecht[1], Kai
Rossnagel[2,3], Felix von Oppen[1], and Katharina Franke[1] — [1]Fachbereich
Physik, Freie Universität Berlin, 14195 Berlin, Germany — [2]Institut für Ex-
perimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel,
24118 Kiel, Germany — [3]Ruprecht Haensel Laboratory, Deutsches Elektronen-
Synchrotron DESY, 22607 Hamburg, Germany

Unpaired adatom spins on superconductors interact with the Cooper pairs of
the substrate and cause Yu-Shiba-Rusinov (YSR) states inside the superconduct-
ing gap. These can be probed by scanning tunneling spectroscopy at the single-

atom scale. On superconducting van der Waals materials, the YSR wave func-
tions of magnetic impurities can extend over several nanometers. This provides a
wide range of adatom spacings over which their interaction is sufficiently strong
to be potentially observed as a splitting in the tunneling spectra. Additionally,
the YSR wave functions inherit their symmetry from the substrate. Depending
on the symmetry and spacing in YSR dimers, the spins may interact differently
via RKKY and Dzyaloshinskii-Moriya interactions. This manifests in splittings
and/or shifts of the YSR states.

Here, we manipulate Fe atoms on superconducting $2H$-NbSe$_2$ using the tip of
a scanning tunneling microscope and build dimers with different symmetries.
Depending on the orientation of the dimers with respect to the crystal symmetry
of the substrate we find YSR hybridization but also more complex effects caused
by spin interactions.

O 7.5   Mon 11:45   REC C 213
**Magnetic impurity states proposed as thermometer for superconduct-
ing quasiparticle temperatures** — •Ciprian Padurariu[1], Sujoy Karan[2],
Haonan Huang[2], Björn Kubala[1,3], Christian R. Ast[2], and Joachim
Ankerhold[1] — [1]Institute for Complex Quantum Systems and IQST, Ulm
University, Ulm, Germany — [2]Max-Planck-Institut für Festkörperforschung,
Stuttgart, Germany — [3]Institute of Quantum Technologies, German Aerospace
Center (DLR), Ulm, Germany

The occupation of the quasiparticle continuum in a superconductor is of critical
importance for the functionality of Josephson junction-based quantum devices.
While significant progress has been made recently, the detection and trapping
of quasiparticles remains a significant challenge. This talk will describe the de-
sign of a thermometer that detects the presence and effective temperature of su-
perconducting quasiparticles. The device consists of a mK-STM functionalized
with a single Yu-Shiba-Rusinov (YSR) state inside the gap. Transport between
the tip and a clean superconducting substrate shows Zeeman-split peaks in the
differential conductance associated to the YSR state [1]. The current is sensi-
tive to quasiparticles above the gap. We show, based on a simple rate equation
model, how the control of the magnetic field, as well as the voltage bias, allows
the operation of the junction as a thermometer for the effective temperature of
quasiparticles.

Magnetic phase diagram of a YSR-molecule — •Niels P.E. van Mullekom[1],
Benjamin Verlhac[1], Werner M.J. van Weerdenburg[1], Hermann
Osterhage[1], Manuel Steinbrecher[1], Katharina J. Franke[1], and Alexan-
der A. Khajetoorians[1] — [1]Institute for Molecules and Materials, Radboud
University Nijmegen, the Netherlands — [2]Fachbereich Physik, Freie Universität
Berlin, Germany.

Yu-Shiba-Rusinov (YSR) states arise from the exchange coupling between a local
spin and a superconductor, and are strongly linked to Kondo screening. Under-
standing the interplay of this exchange interaction with other energy scales, as
well as the role of higher spin degrees of freedom, requires magnetic field depen-
dent characterization. To date, most studies of YSR states have been limited to
bulk superconductors, which easily quench in the presence of modest magnetic
fields.

Here, using high resolution milliKelvin scanning tunneling microscopy and
spectroscopy, we characterize the magnetic phase diagram of a molecule on the
surface of a thin film superconductor. We see nontrivial changes in the YSR ex-
citations, that go beyond the trends that are expected in a spin 1/2 picture. We
relate these changes to the various properties of the molecule, including the role
of multiple channels and magnetic anisotropy. We additionally propose a model
to understand the various changes in the excitation. These results provide an in-
depth and detailed approach to understand the role of high spin systems in the
presence of Kondo and YSR states.

Controlling the Spin States of iron porphyrin on Au(111) — •Xiangzhi Meng[1], Jenny Möller[2], Masoud Mansouri[3,4], Daniel Sánchez-Portal[3,4], Aran Garcia-Lekue[3,5], Alexander Weismann[1], Chao Li[1], Rainer Herges[2], and Richard Berndt[1] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität, 24098 Kiel, Germany — [2]Otto-Diels-Institut für Organische Chemie, Christian-Albrechts-Universität, 24098 Kiel, Germany — [3]Donostia International Physics Center (DIPC), 20018 Donostia-San Sebastián, Spain — [4]Centro de Física de Materiales CSIC-UPV/EHU, 20018 Donostia-San Sebastián, Spain; — [5]Ikerbasque, Basque Foundation for Science, 48013 Bilbao, Spain

Spin-flip excitations of FeTBrPP molecules on Au(111) are investigated with a low-temperature scanning tunnelling microscope under ultrahigh vacuum condition. The molecules show two distinct adsorption configurations that exhibit different magnetic anisotropy energies. Density functional theory calculations show that the different structures and excitation energies reflect unlike occupations of the Fe 3d levels. We demonstrate that the magnetic anisotropy energy can be well controlled by adjusting the adsorption site, the orientation, or the tip-molecule distance.

O 7.9   Mon 12:45   REC C 213

Mapping magnetism with a molecule — •Alex Fétida[1], Michelangelo Romeo[1], Olivier Bengone[1], Marie-Laure Bocquet[2], Nicolas Lorente[3], and Laurent Limot[1] — [1]Université de Strasbourg, CNRS, IPCMS, UMR 7504, 67000 Strasbourg, France — [2]PASTEUR, Ecole Normale Supérieure, PSL University, Sorbonnes Université, CNRS, 24 Rue Lhomond, 75005 Paris, France — [3]Centro de Fisica de Materiales (CFM MPC) CSIC-EHU, 20018 San Sebastián, Spain

The decoration of metal probe-tips by a molecule intentionally picked up from a surface has proven to be a powerful method to improve the measurement capabilities of a scanning tunneling microscope (STM). The success of this approach opens the prospect of introducing spin sensitivity through the tip functionalization by a magnetic molecule. We show here that a metallocene-terminated tip can probe surface magnetism through the inelastic component of the tunneling current, which provides an electrical access to the metallocene spin states. When the tip is 100 picometers away from point contact, the exchange interaction between the tip and a magnetic sample changes the metallocene spin states. This detection scheme can then be used to independently measure the sample exchange field and spin polarization with atomic-scale resolution with knowledge of spin orientation as we show on ultra-thin cobalt layers.

Coulomb-correlated few-electron states from a laser-driven Schottky emitter — •Rudolf Haindl[1,2], Armin Feist[1,2], Till Domröse[1,2], Marcel Möller[1,2], Sergey V. Yalunin[1,2], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen — [2]4th Physical Institute, University of Göttingen

Observing correlation phenomena for free electrons requires a highly confined emission source, readily available by femtosecond photoemission from nanotips [1,2], and can in principle be studied using the supreme beam control provided by electron microscopes [3]. However, ensemble-averaged detection usually prevents studying multi-particle correlations in free-electron beams.

In this work, we use event-based electron microscopy to characterize laser-triggered few-electron pulses generated at a Schottky field emitter [4]. We find surprisingly strong energy correlations of about 2 eV in the two- and three-electron states hinting at a correlated emission process. Furthermore, state-sorted beam caustics show characteristic transverse pair distributions, as well as an increase and a longitudinal shift of the source.

Inducing strong few-electron Coulomb correlations facilitates non-Poissonian electron pulse statistics, promising applications in free-electron quantum optics.

Impact of layer thickness on the anisotropic carrier dynamics of a laser-excited Fe$_n$/(MgO)$_m$(001) heterostructure from real-time TDDFT — •Elaheh Shomali, Markus Ernst Gruner, and Rossitza Pentcheva — Department of Physics and Center for Nanointegration, CENIDE, University of Duisburg-Essen, Germany

The carrier dynamics of Fe$_n$/(MgO)$_m$(001) metal/insulator heterostructures has been investigated from first-principles as a function of the Fe and MgO layer thickness (n=1,3,5 and m=3,5,7), excitation energy and polarization direction. The imaginary part of the dielectric tensor calculated within the random phase approximation (RPA) shows for all structures a similar metallic-like behavior in the in-plane component, $\epsilon_{xx}(\omega)$, whereas for $\epsilon_{zz}(\omega)$ the initially low response below the MgO band gap for Fe$_1$/(MgO)$_3$(001) increases substantially with the number of Fe layers. Electronic excitations calculated in the framework of RT-TDDFT confirm the concerted excitation mechanism previously proposed for Fe$_1$/(MgO)$_3$(001) also for the larger systems, which involves two simultaneous excitations via interface states [1]: one from occupied states of the metal to the conduction band of the insulator and simultaneously, another from the valence band of MgO into Fe states above the Fermi level. This mechanism allows for an effective bidirectional relocation of excitations between the metallic and insulating subsystems even for photon energies below the MgO gap. Funding by DFG via SFB 1242, project C02 is gratefully acknowledged. [1] E. Shomali, M. E. Gruner, and R. Pentcheva, Phys. Rev. B **105**, 245103 (2022).

Relaxation and transport dynamics of laser-excited electrons — •Markus Heckschen[1], Yasin Beyazit[1], Florian Kühne[1], Elaheh Shomali[1], Markus Gruner[1], Rossitza Pentcheva[1], Ping Zhou[1], Detlef Diesing[2], Axel

Lorke[1], Uwe Bovensiepen[1], and Björn Sothmann[1] — [1]Faculty of Physics and Center for Nanointegration (CENIDE), University of Duisburg-Essen, Lotharstraße 1, 47057 Duisburg, Germany — [2]Faculty of Chemistry, University of Duisburg-Essen, Universitätsstraße 5, 45141 Essen, Germany

Scattering of electronic excitations after laser excitation is of key importance to understand transport and relaxation effects. A recent back-pump front-probe two-photon-photoemission experiment in Fe/Au samples measured the electron distribution as a function time and energy [1]. The time at which the maxima of the electron distribution occur as a function of Au-layer thickness provides information on velocity, transport regime and relaxation processes. Here, we present a trajectory-based simulation approach to describe the energy relaxation and the transport through the sample in the ballistic regime. Our results agree qualitatively with the experiment and provide new insight into ultrafast electron dynamics.

Capturing non-thermal electrons: To what extend can a temperature-based model compete with a kinetic description? — •Markus Uehlein, Sebastian T. Weber, and Baerbel Rethfeld — Department of Physics and Research Center OPTIMAS, RPTU, Kaiserslautern, Germany

The development and usage of laser systems in research allows to study the dynamics of laser-excited electrons in metals on sub-picosecond timescales. Kinetic models can trace non-equilibrium distributions in great detail for instance by using full Boltzmann collision integrals [1]. Due to the excitation of non-thermal electrons, this dynamics cannot be described with purely temperature-based models. However, there are a number of extensions of the well known two-temperature model to trace the non-thermal electrons in a numerically simplified way.

We aim to clarify, whether an extended TTM (first published in Refs. [2, 3], improved in Ref. [4]) can describe this electronic non-equilibrium dynamics by comparing it to the kinetic description. In particular, we compare the spectral particle dynamics to a time-resolved two-photon photoemission measurement [5].

Radio-frequency controlled electron pulses for time-resolved LEED — •Dennis Epp[1], Benjamin Schröder[1], Marcel Möller[1], and Claus Ropers[1,2] — [1]Max-Planck-Institut für Multidisziplinäre Naturwissenschaften — [2]Georg-August-Universität Göttingen

In this contribution, we demonstrate temporal compression of low-energy electron pulses using rf-fields. Specifically, we combine a millimetre-sized electron gun [1] with a rf-cavity driven by a sinusoidal wave. A phase-locked loop synthesizer controls the timing between the incident electron pulses and the sinusoidal signal. By electron energy filtering, we measured an initial energy spread of ∆E*1.5 eV for the uncompressed pulses with mean kinetic energies in the range of 50 eV to 100 eV [2]. In perspective, ULEED with sub-ps resolution

will allow for the observation of the impact of electron-phonon coupling and coherent vibrational motion on the efficiencies of surface phase transitions and the resulting changes in materials functionality. [1] Vogelgesang, et al., Nature Physics 14,184-190 (2018). [2] Epp et al., in preparation

O 8.6　Mon 11:45　TRE Phy

High-harmonic generation in topological insulator surface states using wave-packet approaches — •Vanessa Junk[1], Wolfgang Hogger[1], Alexander Riedel[1], Cosimo Gorini[2], and Klaus Richter[1] — [1]Institute for theoretical physics, University of Regensburg, Germany — [2]Université Paris-Saclay, CEA, CNRS, SPEC, 91191, Gif-sur-Yvette, France

The interaction of matter with strong-field light gives rise to highly non-linear electron dynamics within the material. The electric field of the light accelerates electrons through the band structure and drives non-perturbative transitions, leading to strongly anharmonic electron velocities and the emission of high-order harmonics.

Here, we want to study these electron dynamics for the surface states of topological insulators by solving the time-dependent Schrödinger equation for wave packets. That the separation of bulk and surface high harmonics is experimentally possible has been demonstrated recently [1]. Furthermore, an alternating polarization rotation between odd and even order harmonics was found and attributed to the hexagonal warping present in Bi_2Te_3 surface states. Using effective Dirac models and taking into account effects of the Fermi sea, we can reproduce these experimental features with our wave-packet approach.

O 8.7　Mon 12:00　TRE Phy

Subcycle surface-bulk coupling in a topological insulator — •Suguru Ito[1], Michael Schüler[2], Manuel Meierhofer[3], Josef Freudenstein[3], Dmytro Afanasiev[3], Jens Güdde[1], Michael Sentef[4], Rupert Huber[3], and Ulrich Höfer[1] — [1]Philipps-Universität Marburg, Germany — [2]Paul Scherrer Institute, Switzerland — [3]Universität Regensburg, Germany — [4]Max Planck Institute for the Structure and Dynamics of Matter, Germany

Intense lightwaves at terahertz frequencies can drive currents in electronic bands as well as non-perturbative excitations across the band gap, whose interplay leads to strong-field phenomena such as high-harmonic generation. Angle-resolved photoemission spectroscopy (ARPES) with subcycle time resolution allows us to observe such lightwave-driven processes in momentum space.

Here, we will present our investigation of subcycle coupling between the topological surface state (TSS) and the bulk conduction band (BCB) in Bi_2Te_3, where the TSS is well seperated from the bulk along the $\bar{\Gamma}$-$\bar{K}$ direction. Under exposure of a strong 25-THz lightwave, however, transient replicas of the equilibrium TSS, Floquet-Bloch states, are formed. Their hybridization with the BCB enables an efficient population transfer into the BCB. In contrast, TSS and BCB are less separated along $\bar{\Gamma}$-$\bar{M}$, where already an intraband current can induce an efficient subcycle population transfer. Both distinct mechanisms are readily seen in our

experiment. The dynamical Floquet-bulk coupling is confirmed by our full quantum calculations and provides a momentum-resolved view of non-perturbative interband excitations.

O 8.8　Mon 12:15　TRE Phy

Ultrafast electron dynamics in a topological crystalline insulator — •Magnus Berntsen[1], Yuzhu Fan[1], Antonija Grubisic-Cabo[1,2], Maciej Dendzik[1], Qinda Guo[1], Cong Li[1], Yang Wang[1], Wanyu Chen[1], Dibya Phuyal[1], Jonas Weissenrieder[1], and Oscar Tjernberg[1] — [1]Department of Applied Physics, KTH Royal Institute of Technology, Sweden — [2]University of Groningen, Nether- lands

Topological crystalline insulators is a class of materials that possesses helical Dirac-like electronic surface states whose existence is protected by crystal symmetries. This intricate coupling of topology and crystal structure makes it particularly interesting to study the transient electronic structure in these materials induced by an optical excitation since an accompanying symmetry-breaking lattice deformation could lead to a break-down of the topological phase on an ultrafast time scale. Here, we have studied the ultrafast electron dynamics in the archetypal topological crystalline insulator (Pb,Sn)Se by time- and angle-resolved photoemission spectroscopy. The electronic excitation occurs mainly along a preferential direction in momentum space determined by the polarization of the pump pulse and the excitation spectrum displays multiple time scales suggestive of the existence of multiple relaxation channels. Supported by time-resolved diffraction data acquired by ultrafast electron microscopy, we discuss our findings both in the light of the specific electronic structure of the surface states as well as the potential influence of lattice dynamics on the decay of the electronic excitation.

Field-induced ultrafast modulation of Rashba coupling in ferroelectric α-GeTe(111) — Geoffroy Kremer[1,2], Julian Maklar[3], Laurent Nicolaï[4], •Chris W. Nicholson[1,3,5], Changming Yue[1], Caio Silva[3], Philipp Werner[1], J. Hugo Dil[6,7], Juraj Krempaský[6], Gunther Springholz[8], Ralph Ernstorfer[3,9], Jan Minár[4], Laurenz Rettig[3], and Claude Monney[1] — [1]Université de Fribourg, Switzerland — [2]Université de Lorraine, France — [3]Fritz Haber Institute of the Max Planck Society, Germany — [4]University of West Bohemia, Czech Republic — [5]SPECS Surface Nano Analysis GmbH, Germany — [6]Paul Scherrer Institut, Switzerland — [7]EPFL, Lausanne, Switzerland — [8]Johannes Kepler Universität, Austria — [9]TU Berlin, Germany

Rashba materials provide an ideal playground for spin-to-charge conversion in prototype devices. I will present our recent time- and angle-resolved photoemission spectroscopy and momentum microscopy results on α-GeTe(111). This is a non-centrosymmetric ferroelectric (FE) semiconductor displaying a giant FE distortion below 700 K, which hosts spin-polarized states that are promising for a new type of highly efficient non-volatile memory device based on switchable polarization. We find a transient modification of the bulk Rashba splitting corresponding to an enhancement of the FE lattice distortion. This enhanced response results from a transient surface photovoltage which induces a delayed displacive excitation of a phonon along the FE distortion direction [1].

O 9: Focus Session: Frontiers of Electronic-Structure Theory I (joint session O/HL)

Electronic-structure calculations, based on density-functional theory (DFT) and methodology beyond, are getting increasingly involved as they face the following challenges: First, investigations of modern materials typically require large unit cells, owing to complex crystal structures, mixed compositions, internal interfaces, etc. Second, at the same time, they often require advanced methods, including hybrid functionals of DFT, Green-function techniques from many-body perturbation theory (MBPT), high-level wavefunction-based methods like coupled-cluster (CC) theory, or quantum Monte-Carlo simulations. All these methods should ideally be implemented in scientific software that is running efficiently on modern supercomputers. With both methodology and computer architectures exhibiting increasing complexity, collaborative development and shared tools, including ready-to-use libraries and codes, are becoming indispensable. This interdisciplinary symposium covers recent progress in the broad area of electronic-structure methods and highly-sophisticated tools that enable the entire community to explore most exciting materials from different perspectives to either predict peculiar features or get insight into measured counterparts.

Testing the hell out of DFT codes with virtual oxides — Emanuele Bosoni[1], •Stefaan Cottenier[2], and Giovanni Pizzi[3] — [1]ICMAB-CSIC, Spain — [2]Ghent University, Belgium — [3]EPFL, Switzerland

If you use DFT to predict a property of a crystal, how confident can you be that the prediction is computed in a bug-free way? And if your DFT-code uses pseudopotentials, can you trust that the pseudopotential does not modify your predictions? Answering such questions has been the goal of a study a few years ago,

in which 71 unary crystals were examined in exactly the same way by 40 different DFT methods and codes [DOI 10.1126/science.aad3000]. In a next step, a consortium of 41 scientists (*) has done a similar exercise for a much larger pool of crystals: all elements of the periodic table up to Z=96, each in 10 different crystal structures, 6 of them being (virtual) oxides that sample a range of chemical bond types and 4 being unary crystals that sample low to high coordination environments. In this presentation, we will discuss the reasons to choose these crystals, the different quality criteria by which results can be compared, we will demonstrate how this exercise leads to more precise and more trustworthy pseudopotential libraries, and we will show how this data set is shared with the community in order to foster better-tested codes and pseudopotentials for all.

(*) Unfortunately the size of this abstract does not allow to mention them all.

High-throughput absorption spectra obtained by beyond-DFT workflows — •Fabian Peschel, Alexander Buccheri, and Claudia Draxl — Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany
Fully converging *ab initio* calculations can be a challenging task, in particular when it comes to excited states, which require multiple ground-state calculations for different physical quantities. In this work, we aim at computing highly precise absorption spectra by employing the Bethe-Salpeter equation of many-body perturbation theory, as implemented in the all-electron full-potential package exciting [1,2]. To obtain benchmark data for a wide range of material classes, we have developed workflows where Python tools automatically create input files, start calculations, and evaluate results. For each material, all relevant input parameters, such as the number of k-points for the Brillouin-zone sampling, basis-set basis cutoff and the number of unoccupied states, are varied until the targeted convergence criteria are reached. With the help of a workflow manager, the calculations can be executed in a high-throughput fashion on a high-performance computing cluster. We demonstrate our approach with core-level spectra of elemental and binary solids, and provide an in-depth analysis of the obtained data. This work is carried out in the framework of the NOMAD Center of Excellence [3] and the CRC FONDA [4].

Large-scale machine-learning assisted discovery and characterization of materials — •Miguel Alexandre Lopes Marques — Institut für Physik Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany
In this talk we discuss our recent attempts to discover, characterize, and understand inorganic compounds using ab initio approaches accelerated by machine learning. We start by motivating why the search for new materials is nowadays one of the most pressing technological problems. Then we summarize our recent work in using crystal-graph attention neural networks for the prediction of materials properties. To train these networks, we curated a dataset of over 2 million density-functional calculations with consistent calculation parameters. Combining the data and the newly developed networks we have already scanned more than two thousand prototypes spanning a space of more than one billion materials and identified tens of thousands of theoretically stable compounds. We then discuss how simple, interpretable machine learning approaches can be used to understand complex material properties, such as the transition temperature of superconductors. Finally, we speculate which role machine learning will have in the future of materials science.

Predicting the electronic structure at any length scale with machine learning — •Attila Cangi — Helmholtz-Zentrum Dresden-Rossendorf, Görlitz, Germany
The properties of electrons in matter are of fundamental importance. They give rise to virtually all molecular and material properties and determine the physics at play in objects ranging from semiconductor devices to the interior of giant gas planets. Calculations rely primarily on density functional theory (DFT), which has become the principal method for predicting the electronic structure of matter. While DFT calculations have proven to be very useful, their computational scaling limits them to small systems. We have developed a scalable machine learning framework for predicting the electronic structure on any length scale [1,2,3]. It shows up to three orders of magnitude speedup on systems where DFT is tractable and, more importantly, enables predictions on scales where DFT calculations are infeasible. Our work demonstrates how machine learning circumvents a long-standing computational bottleneck and advances science to frontiers intractable with any current solutions.

O 9.5   Mon 12:00   TRE Ma
Demonstrating temperature transferability of neural network models replacing modern density functional theory — •Lenz Fiedler and Attila Cangi — Helmholtz-Zentrum Dresden-Rossendorf / CASUS
Due to its balance between accuracy and computational cost, Density Functional Theory (DFT) is one of the most important computational methods within materials science and chemistry. However, current research efforts such as the modeling of matter under extreme conditions demand the application of DFT to larger length scales as well as higher temperatures. Such investigations are currently prohibited due to the computational scaling of DFT.

We have recently introduced a machine-learning workflow that replaces modern DFT calculations [1,2,3]. This workflow uses neural networks to predict the electronic structure locally. We show that by employing such an approach, models can be trained to predict the electronic structure of matter across temperature ranges. This paves the way for large-scale simulations of thermodynamically sampled observables relevant to modeling technologically important phenomena such as radiation damage in fusion reactor walls.

Pure non-local machine-learned density functional theory for electron correlation — •Johannes T. Margraf — Fritz-Haber-Institut der MPG, Berlin, Germany
Density-functional theory (DFT) is a rigorous and (in principle) exact framework for the description of the ground state properties of atoms, molecules and solids based on their electron density. While computationally efficient density-functional approximations (DFAs) have become essential tools in computational chemistry, their (semi-)local treatment of electron correlation has a number of well-known pathologies, e.g. related to electron self-interaction. Here, we present a type of machine-learning (ML) based DFA (termed Kernel Density Functional Approximation, KDFA) that is pure, non-local and transferable, and can be efficiently trained with fully quantitative reference methods. The functionals retain the mean-field computational cost of common DFAs and are shown to be applicable to non-covalent, ionic and covalent interactions, as well as across different system sizes.

O 9.7   Mon 12:30   TRE Ma
Predicting the response of the electron density to electric field using machine learning — •Alan Lewis and Mariana Rossi — MPI for Structure and Dynamics of Materials, Hamburg, Germany
The response of the electron density of a molecule or material to a homogeneous electric field defines its dielectric constant, along with its Raman and sum-frequency spectrum. We present a local and transferable machine learning approach capable of predicting the density response of molecules and periodic system on the same footing. This uses a very similar framework to that of the SALTED method recently introduced by these authors,[1,2] requiring only a small modification to the $\lambda-$SOAP descriptors used to represent the atomic environments. This allows us to predict the density response of liquid water to a field applied in each Cartesian direction from a single machine learning model. The tensorial dielectric constant can then be derived from this predicted density response, dramatically reducing the computational cost of calculating these properties relative to the standard approach of using density functional perturbation theory. We discuss the transferability of the model to different phases, and demonstrate the extrapolative power of this approach.

Analysis of Batching Methods in Graph Neural Network Models for Materials Science — •Daniel Speckhard, Tim Bechtel, Jonathan Godwin, and Claudia Draxl — Humboldt-Universität zu Berlin, Physics Department and IRIS Adlershof, Berlin, Germany
Graph neural network (GNN) based models have shown promising results for materials science [1]. These models often contain millions of parameters, and like other big-data based models, require only a portion of the entire training dataset to be fed as a mini-batch to update model parameters. The effect of batching on the computational requirements of training and model performance has been thoroughly explored for neural networks [2] but not yet for GNNs. We explore two different types of mini-batching methods for graph based models, static batching and dynamic batching. We use the Jraph library built on JAX to perform our experiments where we compare the two batching processes for two data-sets, the QM9 dataset of small molecules and the AFLOW materials database [3]. We show that dynamic batching offers significant improvements in terms of computational requirements for training. We also present results on

the effect of the batch size and batching method on model performance.

Photoemission Orbital Tomography: Imaging Molecular Wave Functions in Reciprocal and Real Space — •F. S. Tautz — Quantum Nanoscience, Peter Grünberg Institute (PGI-3), Forschungszentrum Jülich, Germany

The photoemission orbital tomography (POT) technique, a variant of angle-resolved photoemission spectroscopy, has been very useful in the characterization of the electronic properties of molecular films. It is a combined experimental and theoretical approach that is based on the interpretation of the photoelectron angular distribution in terms of a one-electron initial state. This includes the unambiguous assignment of emissions to specific molecular orbitals, their reconstruction to real space orbitals in two and three dimensions, the deconvolution of complex spectra into individual orbital contributions beyond the limits of energy resolution, the extraction of detailed geometric information such as molecular orientations, twists and bends, the precise description of the charge balance and transfer at interface, and the detection of momentum-selective hybridization with the substrate, to name only a few examples. In its simplest form, POT relies on the plane-wave approximation for the final state. While this works surprisingly well in many cases, this approximation does have its limitations, most notably for small molecules and with respect to the photon-energy dependence of the photoemission intensity. Regarding the latter, a straightforward extension of the plane wave final state leads to a much-improved description while preserving the simple and intuitive connection between the photoelectron distribution and the initial state.

Structural Reorientation of Organic Molecules on Surfaces by Alkali Metal Doping — •Ralf Hemm[1], Ka-Man Yu[1], Steffen-Rambert Rothenberg[1], Sergey Soubatch[2], Christian Kumpf[2], Martin Aeschlimann[1], and Benjamin Stadtmüller[1,3] — [1]RPTU Kaiserslautern-Landau, Erwin-Schrödinger-Str. 46, 67663 Kaiserslautern, Germany — [2]Peter Grünberg Institut, Forschungszentrum Jülich, 52425 Jülich, Germany — [3]Johannes-Gutenberg-Universität Mainz, Staudingerweg 7, 55128 Mainz, Germany

Organic semiconductors are promising materials for the fabrication of next-generation organic-based electronic devices. The electron properties of the organic thin film can be tuned by alkali metal doping and the consequent charge transfer. Here, we study the influence of Cs doping on the structural and electronic properties of the model system PTCDA/Ag(111). Using momentum microscopy, we can simultaneously access changes in occupation of the molecular orbitals and determine modifications of the azimuthal orientation of the PTCDA molecules upon Cs doping. We can identify two structural Cs-PTCDA phases depending on the Cs concentration with either one or two Cs atoms per PTCDA. With increasing Cs concentration, we observe a gradual structural reorientation of the molecules that is accompanied by a modification of the population of the molecular states. Both cases are different from the pristine case. The structural reorientation of the PTCDA molecules can be attributed to the electrostatic interactions between the partially ionized Cs atoms and the negatively polarized oxygen end groups of PTCDA.

O 10.3   Mon 15:45   CHE 89
Tip-enhanced Raman Spectroscopy of a charged molecule — •Rodrigo Cezar de Campos Ferreira[1], Jiří Doležal[1,2], Amandeep Sagwal[1,2], Sofia Canola[1], and Martin Švec[1,3] — [1]Institute of Physics,Czech Academy of Sciences; Czech Republic — [2]Faculty of Mathematics and Physics, Charles University; Czech Republic — [3]Institute of Organic and Inorganic Chemistry, Czech Academy of Sciences; Czech Republic

The Tip-enhanced Raman spectroscopy (TERS) technique has been proven to unveil fundamental features of single molecules at the nanoscale level via near-field spectroscopy [1,2]. The confined light in the STM junction can be used as a probe to obtain an essential understanding of molecular structure and electronic properties. Here, the LT-STM-controlled TERS technique was performed and verified for the perylene tetracarboxylic dianhydride (PTCDA), which was measured the Raman fingerprint for a single molecule on Ag(111) and on insulating NaCl/Ag(111) from different excitation sources. Moreover, the precise control of geometry and charge state of the molecule in the system [3] can be observed together with the Raman fingerprint and revealed an abrupt change in the spectra. We correlate them to the presence of Kondo signature and discuss the implication for other systems.

Charge-induced symmetry breaking in the adsorption configuration of C60 layers on h-BN/Ni(111) — •Max Bommert, Roland Widmer, Néstor Diez, Bruno Schuler, and Oliver Gröning — Empa * Swiss Federal Laboratories for Materials Science and Technology, 8600 Dübendorf, Switzerland

Hexagonal Boron Nitride (h-BN) and Nickel's (111) surface share a nearly perfectly matching lattice constant. Consequently, monolayer h-BN can be grown commensurately on Ni(111) without exhibiting a Moiré superstructure like on many other h-BN/transition metal systems. Nevertheless, upon adsorption at room temperature and scanning tunneling microscopy (STM) imaging at 5K, we observe a complex, geometrically frustrated adsorption pattern for sub-monolayer C60 coverages. The fullerenes form large molecular islands with a distinct striped pattern that we can identify as C60 adsorbed in different orientations. We use scanning tunneling spectroscopy (STS) to resolve the lowest unoccupied molecular orbitals (LUMO) of the C60. Tip-induced manipulation of single molecules affects the LUMO energy of neighboring molecules. Based on our STS investigations, we propose a significant charge transfer from the substrate to specific C60 and the associated electrostatic repulsion to be a driving force in forming the stripe pattern. We rationalize the latter by Monte Carlo simulations of the C60 lattice, considering the various contributions to the intermolecular and molecule-substrate interactions. Our results deepen the understanding of molecular adsorption and charge transfer processes, which are crucial for developing organic-inorganic hybrid devices.

O 10.5   Mon 16:15   CHE 89
Nickel(II) Porphyrins versus Nickel(II) Corroles on Different Metal Surfaces: Oxidation-State Tuning of Nickel Tetrapyrrole Complexes — •Jan Herritsch[1], Jan-Niclas Luy[1,2], Ralf Tonner-Zech[1,2], and J. Michael Gottfried[1] — [1]Fachbereich Chemie, Philipps-Universität Marburg, Germany — [2]Wilhelm-Ostwald-Institut, Leipzig, Germany

Using the example of Ni tetrapyrrole complexes, we demonstrate how the oxidation state of the central atom and the molecule-substrate interaction can be influenced by a modification of the ligand. In particular, the effect of the ring size is addressed by comparing porphyrins with corroles. The latter represent a smaller macrocycle and provide a tighter coordination environment for the metal center. In addition, Ni(II) corroles have an unusual electronic structure with an unpaired electron located at the π-electron system of the ligand. Here, we focus on the interactions of Ni(II) porphyrins and corroles with different metal surfaces (Au(111), Ag(111), Cu(111)). Depending on the used substrate, the Ni(II) porphyrin is subject to an interfacial charge transfer resulting in the reduction of the Ni atom as was shown by XPS. However, due to its unique properties Ni(II) corroles exhibit a different behavior at the metal/organic interface. While the corrole's Ni(II) state remains unchanged even on the reactive Cu(111) surface, the ligand is subject to a charge transfer by accepting electron density from the substrate. This charge transfer could be traced with experimental valence spectra (UPS), which were evaluated with the help of quantum chemical calculations (DFT).

O 10.6   Mon 16:30   CHE 89
Electronic Properties of N-Heterotriangulene Derivatives adsorbed on Au(111) — •Jakob Steidel[1], Ina Michalsky[2], Milan Kivala[2], and Petra Tegeder[1] — [1]Institute of Physical Chemistry, Heidelberg University, Im Neuenheimer Feld 253, 69120 Heidelberg — [2]Institute of Organic Chemistry, Heidelberg University, Im Neuenheimer Feld 270, 69120 Heidelberg

A large number of opto-electronic devices based on organic compounds utilize donor-acceptor-systems (D-A-systems), for example as the emitting layer in organic light emitting diodes or for charge separation in organic photovoltaics. Triphenylamine and its derivatives are a class of donors in D-A-systems with a high potential for applications in devices.

Introducing an etheno-bridge in the planar triphenylamine derivative indolo[3,2,1-jk]carbazole (N-heterotriangulene-550, N-HTA-550) closes an antiaromatic ring with seven members in the resulting N-heterotriangulene-557 (N-HTA-557). This significantly changes the electronic structure while retaining the molecular geometry as well as the steric demands. By oxidation of N-HTA-557 and a subsequent condensation reaction with quinoxaline-2,3-diamine an intramolecular D-A-system is created.

In the present contribution we study the electronic properties of N-HTA-550 and its derivatives on a Au(111) surface using two-photon photoemission spectroscopy.

Influence of N-introduction in pentacene on the electronic structure
— •MOHSEN AJDARI[1], MARVIN HOFFMANN[2], FELIX LANDWEHR[1], OLENA
TVERSKOY[3], UWE H. F. BUNZ[3], ANDREAS DREUW[2], and PETRA TEGEDER[1]
— [1]Physikalisch-Chemisches Institut — [2]Interdisziplinäres Zentrum für Wissenschaftliches Rechnen — [3]Organisch-Chemisches Institut, Universität Heidelberg

Organic electron-transporting (n-channel) semiconductors such as N-heteropolycyclic aromatic compounds are of great interest for use in a variety of (opto)electronic applications.

In this study, vibrational and electronic high-resolution electron energy loss spectroscopy (HREELS) in combination with quantum-chemical calculations are utilized to investigate the influence of N- introduction on the adsorption geometry and electronic structure of two pentacene derivatives, namely 6,13-diazapentacene (DAP) and 6,7,12,13-tetraazapentacene (TAP) on Au(111).

Our findings indicate that in comparison to parent pentacene (PEN), introduction of nitrogen atoms in the aromatic backbone of its aza derivatives leads to a narrowing of the optical gap ($S_0 \rightarrow S_1$ transition) from 2.1 eV for PEN to 2.0 eV for DAP and to 1.6 eV for TAP as well as an increase in the first triplet state energy from 0.9 eV for PEN and DAP to 1.2 eV in TAP. Additionally, In the series PEN, DAP, and TAP, the α-band ($S_0 \rightarrow S_2$ transition) gains significantly in intensity due to individual effects of the introduced nitrogen atoms on the orbital energies.

O 10.8   Mon 17:00   CHE 89

Electrostatic design of the internal surfaces of porous organic materials —
•EGBERT ZOJER — Institute of Solid State Physics, NAWI Graz, Graz University of Technology, Austria

Collective electrostatic effects are ubiquitous at surfaces and interfaces involving organic materials. [1] Thus, they, for example, allow tuning the electronic properties of interfaces employing monolayers of molecules with embedded dipoles [2]. This raises the question, whether controlled assemblies of dipoles couldn't also be used to control the properties of the inner surfaces of porous structures. This question is addressed for the prototypical case of layered covalent organic frameworks that are stacked in a way that 1D channels are formed. Employing state-of-the-art quantum-mechanical simulations, it is shown that by changing the polarity of the functional groups covering the surfaces of these pores, the electrostatic energy in the pores can be changed by more than one eV in a comparably straightforward manner. As this energy crucially determines the interaction between the host material and adsorbates within the pores, the proposed strategy holds the promise of revolutionizing various fields of application of such materials, e.g., as battery electrodes, in catalysis, and in excited-state charge separation processes.

Screening Non-alternant π-Electron Systems for Metal-Organic Interfaces: Interplay between Topology, Aromaticity, and Adsorption Behavior —
•JAKOB SCHRAMM and RALF TONNER-ZECH — Universität Leipzig, Deutschland

Metal-organic interfaces play an important role in organic electronics. Topology, aromaticity, and interface properties are closely connected here as previously shown by experimental and theoretical studies of isomer pairs of alternant and non-alternant adsorbates. While non-alternant azulene and azupyrene chemisorb on Cu(111), the alternant isomers naphthalene and pyrene physisorb.[1,2] This promises to be a general trend and can be exploited for interface design.

Here, we report data based on periodic DFT calculations for a set of 11 non-alternant molecules in comparison to analogous alternant molecules. Influence of topology on atomic and electronic structure, especially aromaticity, was analyzed based on molecular gas phase calculations. Interface properties were then derived using slab approaches at the example of Cu(111). We report on the interplay of topology and adsorption structure, adsorption energy, and charge transfer.

Machine-Learning Driven Global Optimization of Surface Adsorbate Geometries — •HYUNWOOK JUNG, LENA SAUERLAND, SINA STOCKER, KARSTEN REUTER, and JOHANNES T. MARGRAF — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany

The adsorption energies of molecular adsorbates on catalyst surfaces are key descriptors in computational catalysis research. For the relatively large reaction intermediates frequently encountered, e.g., in syngas conversion, a multitude of possible binding motifs leads to complex potential energy surfaces (PES), however. This implies that finding the optimal structure is a difficult global optimization problem, which leads to significant uncertainty about the stability of many intermediates. To tackle this issue, we present a global optimization protocol for surface adsorbate geometries which trains a surrogate machine learning potential on-the-fly. The approach is applicable to arbitrary surface models and adsorbates and minimizes both human intervention and the number of required DFT calculations by iteratively updating the training set with configurations explored by the algorithm. We demonstrate the efficiency of this approach for a diverse set of adsorbates on the Rh(111) and (211) surfaces.

O 11.2   Mon 15:15   CHE 91

The effect of ultrathin ionic liquid films on the adsorption dynamics of 1,3-butadiene and 1-butene on Pt(111) studied by molecular beam techniques — •LEONHARD WINTER, CYNTHIA CAROLINA FERNÁNDEZ, AFRA GEZMIS, TIMO TALWAR, STEPHEN MASSICOT, FLORIAN MAIER, and HANS-PETER STEINRÜCK — Lehrstuhl für Physikalische Chemie II, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstr. 3, 91058 Erlangen

Ionic Liquids (ILs) are low temperature melting salts. In "Solid Catalyst with Ionic Liquid Layer (SCILL)" systems, IL thin films are used to coat the catalytically active metal and thereby enhance the selectivity of the catalyst; this approach is beneficial, e.g., in the industrially important hydrogenation of 1,3-butadiene to butenes, since further hydrogenation to *n*-butane must be suppressed. We used a supersonic molecular beam to investigate the adsorption dynamics of this reaction in a UHV SCILL model system. Along the method of King and Wells we measured sticking coefficients of 1,3-butadiene and 1-butene on Pt(111) coated with ultrathin layers of the IL 1,3-dimethylimidazolium bis[(trifluoromethyl)sulfonyl]imide ([C_1C_1Im][Tf_2N]). At 180 K, the sticking coefficients decrease non-linearly with increasing IL coverage. We explain the deviation from a simple site-blocking model with trapping into a mobile precursor state of the hydrocarbon molecules that arrive on top of IL islands. This deviation is less pronounced for films prepared at 250 K, which we attribute to larger IL island sizes.

Supported by the DFG through SFB 1452 CLINT.

O 11.3   Mon 15:30   CHE 91

On-surface synthesis of porphyrinoid monomers and dimers — •HONGXIANG XU[1], RITAM CHAKRABORTY[2], BIAO YANG[1], JOACHIM REICHERT[1], ABHISHEK K. ADAK[2], SHOBHANA NARASIMHAN[2], JOHANNES V. BARTH[1], and ANTHOULA C. PAPAGEORGIOU[1,3] — [1]Technical University of Munich, Germany — [2]Jawaharlal Nehru Centre for Advanced Scientific Research, India — [3]National and Kapodistrian University of Athens, Greece

Porphyrinoid molecules can incorporate a wide array of the elements of the periodic table in a chemical pocket. By engineering their coordination pocket one can tune the functional properties for catalysis, spintronics, electronics and sensors. Here we use a common natural pigment, indigo, with Fe atoms on Au(111). By a series of thermally activated reaction steps including selective C-H activation, we obtain a novel metallated porphyrinoid species with high yield. By McMurry-type coupling on the same surface, this porphyrinoid species fuses into dimers. The reaction products are identified by a combination of scanning tunnelling microscopy, bond resolving atomic force microscopy and density functional theory investigations. Our studies expand the available chemistry for on-surface synthesis of macrocyclic tetrapyrroles [1] and contribute to versatile metal-organic nanostructures with smaller coordination pockets, which are challenging to obtain via solution chemistry.

Fischer-Tropsch synthesis on magnetite (111) surface — •HESHMAT NOEI[1], ROBERT GLEISSNER[1], MICHAEL WAGSTAFFE[1], CHRISTOPHER GOODWIN[2], MARKUS SOLDEMO[2], MIKHAIL SHIPILIN[2], PATRICK LÖMKER[2], CHRISTOPH SCHLUETER[3], PETER AMANN[2], and ANDREAS STIERLE[1] — [1]Centre for X-ray and Nano Science CXNS, Deutsches Elektronen-Synchrotron DESY, Notkestraße 85, 22607 Hamburg, Germany — [2]Stockholm Universitet, Department of Physics, Roslagstullsbacken 21, 10691 Stockholm, Sweden — [3]Deutsches Elektronen-Synchrotron DESY, Notkestraße 85, 22607 Hamburg, Germany

Magnetite (Fe_3O_4) is an important and diverse transition metal oxide with applications in catalysis, data storage and biomedical imaging. In this contribution, we demonstrate an operando Fischer-Tropsch synthesis with a focus on product detection on the magnetite (111) surface and clarify the reaction mechanism and intermediates applying state of the art ambient pressure XPS with ability to measure photoemission spectra 76 at above 1 bar using hard X-ray at PETRA III beamline at DESY in Hamburg and clarify the mechanism of FT synthesis by monitoring reaction products operando on single crystal Fe_3O_4. We show then the dominant product from FT synthesis is a methoxy species and short chain alkanes under our reaction conditions (500 mbar, 400°C) and that no aldehydes and ketones are formed during reaction.

O 11.5   Mon 16:00   CHE 91

On-Surface CO_2 Capturing by Electron-Rich Phosphines: Comparison of the Assembly on Ag(100) and on the NaBr(100) Double Layer — •Vladimir Lykov[1], Florenz Buss[2], Fabian Dielmann[3], and Karina Morgenstern[1] — [1]Ruhr-Universität Bochum, Germany — [2]Institut für Anorganische und Analytische Chemie, Westfälische Wilhelms-Universität Münster, Germany — [3]Institute of General, Inorganic and Theoretical Chemistry, University of Innsbruck, Center for Chemistry and Biomedicine, Innsbruck, Austria

Electron-rich phosphines exhibit exceptional electron donor properties and form zwitterionic Lewis base adducts with small inert molecules, for instance, carbon dioxide (CO_2) and sulfur dioxide (SO_2) [1]. The main focus of this project is understanding the influence of geometrical confinement on the capturing of CO_2 by electron-rich phosphines. The effect of geometrical confinement is studied with a surface science approach. For this purpose, we use a low-temperature (7 K) scanning tunneling microscope (STM). To understand the influence of the metal surface on carbon dioxide capture, we compare the molecules adsorbed on Ag(100) to those on NaBr(100) double layer, supported by Ag(100). The subsequent deposition of carbon dioxide and electron-rich phosphines confirmed the affinity of CO_2 to these phosphines. The influence of the two surfaces on the product assembly will be discussed in this presentation.

O 11.6   Mon 16:15   CHE 91

On-surface synthesis of enetriynes — Nan Cao[1,2], •Biao Yang[1], Alexander Riss[1], Johanna Rosen[2], Jonas Björk[2], and Johannes V. Barth[1] — [1]Physics Department E20, Technical University of Munich, Garching, Germany — [2]Department of Physics, Chemistry and Biology, IFM, Linköping University, Linköping, Sweden

Belonging to the enyne family, enetriynes comprise a distinct electron-rich all-carbon bonding scheme. However, the lack of convenient synthesis protocols limits the associated application potential within, e.g., biochemistry and materials science. Herein we introduce a pathway for highly selective enetriyne formation via tetramerization of terminal alkynes on a Ag(100) surface. Taking advantage of a directing hydroxyl group, we steer molecular assembly and reaction processes. Induced by O2 exposure the terminal alkyne moieties deprotonate and organometallic bis-acetylide dimer arrays evolve. Upon subsequent thermal annealing tetrameric enetriyne-bridged compounds are generated in high yield, readily self-assembling into regular networks. We combine high-resolution scanning probe microscopy, X-ray photoelectron spectroscopy and density functional theory calculations to examine the structural features, bonding characteristics and the underlying reaction mechanism. Our study provides an integrated strategy to precisely fabricated functional enetriyne species, providing access to a distinct class of highly conjugated π-system compounds.

Cold plasma deoxidation of copper and iron surfaces — •Viktor Udachin[1], Sebastian Dahle[2], and Wolfgang Maus-Friedrichs[1] — [1]Clausthal University of Technology, Clausthal-Zellerfeld, Germany — [2]University of Ljubljana, Ljubljana, Slovenia

The removal of native oxides, which are present on metals in ambient atmosphere, is an important step in many industrial applications. Cold plasma meth-

ods, like dielectric barrier discharge (DBD) plasmas, have gained attention due to the high deoxidation efficiencies and relative simplicity of the setups. Several groups have indicated a reduction of copper oxygen layers using DBD hydrogen-containing plasmas, but no detailed information about reduction kinetics and limitations on different metal systems is available. In this study, we investigated the deoxidation effect of a DBD plasma in Ar/H_2 and Ar/SiH_4 atmospheres on natively oxidized Cu and Fe surfaces at 1000 hPa. We observed deoxidation effect on Cu already at 25 °C in both atmospheres. In contrast, reduction of iron oxide was obtained only at the surface temperature of 200 °C, showing an increase in the efficiency of the plasma-induced thermal treatment in comparison to thermal one. The chemical state of the samples and the kinetics of the reduction of oxides were studied via X-ray photoelectron spectroscopy (XPS). The morphology was characterized with the atomic force microscopy (AFM). By using optical emission spectroscopy (OES), the reactive species within the implemented DBD plasmas were described. Funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) - Project-ID 394563137 - SFB 1368

Multiscale modeling and simulation of texture effects on the corrosion of stainless steel in aqueous media — •Vahid Jamebozorgi[1,2], Karsten Rasim[3], and Christian Schröder[1,2] — [1]Bielefeld Institute for Applied Materials Research, Bielefeld University of Applied Sciences, 33619 Bielefeld, Germany — [2]Faculty of Physics, Bielefeld University, 33615 Bielefeld, Germany — [3]Miele & Cie. KG, Center for Materials (CFM), Carl-Miele-Straße 29, 33332 Gütersloh

Texture plays a crucial role in physical processes and properties of condensed matter as it is broadly highlighted in the literature. In this work we describe a robust methodology to investigate texture effects which does not suffer from common limitations of quantum based computational approaches in time and space but also can provide the same accuracy as atomistic calculations with orders of magnitude less computational costs. Our methodology is based on the finite element method (FEM) and utilizes 3D digital representations of multi grain microstructures. We demonstrate the efficiency of our approach by studying pitting corrosion in stainless steel. As reflected in literature the irregular geometry of pit expansion through pitting corrosion is mostly caused by texture. We found that the texture significantly affects the pitting corrosion rate and consequently causes various irregular pit growth patterns in granular microstructures. These results are consistent with our DFT and reactive force field molecular dynamics simulations which validates our suggested approach.

O 11.9   Mon 17:00   CHE 91

The role of aromaticity in the cyclization and polymerization of alkyne-substituted porphyrins on Au(111) — •Nan Cao[1], Jonas Björk[2], Eduardo Corral-Rascon[1], Zhi Chen[3,4], Mario Ruben[3], Mathias O. Senge[5], Johannes V. Barth[1], and Alexander Riss[1] — [1]Technical University of Munich, Germany — [2]Linköping University, Sweden — [3]Karlsruhe Institute of Technology, Germany — [4]Shenzhen University, China — [5]Institute for Advanced Study, TUM, Germany

Aromaticity is one of the most practical and versatile concepts for the assessment of the reactivity of organic molecules. However, in on-surface chemistry - where the interaction with the substrate can significantly alter the electronic and geometric structure of the adsorbates - the role of aromaticity is not understood. Here we investigate how aromaticity affects the reactivity of alkyne-substituted porphyrin molecules in cyclization and coupling reactions on a Au(111) surface.[1] We examine and quantify the regioselectivity of the reactions by scanning tunneling microscopy and bond-resolved atomic force microscopy at the single-molecule level. Our experiments show a substantially lower reactivity of carbon atoms that are stabilized by the aromatic diaza[18]annulene pathway of free-base porphyrins. The results are corroborated by density functional theory calculations, revealing a direct correlation between aromaticity and thermodynamic stability of the reaction products. These insights will help to design and understand reactions in on-surface chemistry and heterogeneous catalysis. 1. https://doi.org/10.21203/rs.3.rs-1271465/v1

Performance boundaries of piezoelectric friction-inertia walkers due to the choice of contact materials — •Felix Huber, Susanne Baumann, and Sebastian Loth — University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany

High precision positioners are an important tool to realize and automate cutting edge experiments. Piezoelectric friction-inertia walkers enable high accuracy movement on the millimeter scale with nanometer resolution, which makes them essential to realize scanning probe microscopes. The working principle of

these nanopositioners makes use of the friction-inertia principle [1]. Therefore, the choice of materials for the contact surfaces defines the performance limits and the reproducibility of stepwise motion. We use optical interferometry to determine the key performance parameters of a linear piezoelectric friction-inertia walker and test combinations of metallic and ceramic contact surface materials to improve the capabilities and reliability of high precision positioner devices.

Surface tension measurement of microdroplets using AFM — •Pranav Sudersan[1], Mohammad Hormozi[2], Maren Müller[1], Shuai Li[1], Hans-Jürgen Butt[1], and Michael Kappl[1] — [1]Max Planck Institute for Polymer Research, Mainz, Germany — [2]Technical University of Darmstadt, Darmstadt, Germany

Surface tension is a physical property which is central to our understanding of wetting phenomena. One could easily measure liquid surface tension using commercially available tensiometers. However, these tensiometers are designed for bulk liquid volumes of the order of millilitres. In order to perform similar measurements on extremely small sample volumes in the range of femtoliters, Atomic Force Microscopy (AFM) is a promising tool. It was previously reported that by fabricating a special 'nanoneedle' shaped cantilever probe, a Wilhelmy-like experiment can be performed with an AFM. In our study, we carried out measurements on microscopic droplets with the AFM, but instead using standard pyramidal cantilever tips. The AFM tips were coated with a hydrophilic polymer brush, which reduced its contact angle hysteresis. Numerical simulations of a liquid drop interacting with a pyramidal geometry were used to calculate surface tension from the experimentally measured force. Our method eliminates the need for specially fabricated 'nanoneedle' tips, thus reducing complexity and cost of measurement, making it more suitable for widespread application.

O 12.3 Mon 15:30 GER 37

Modification of Fluid-FM Cantilevers for Studying Local Electrochemistry at Solid | Liquid Interfaces — •Matin Karimnia[1] and Timo Jacob[1,2,3] — [1]Institute of Electrochemistry, Ulm University, Ulm, Germany — [2]Helmholtz-Institute-Ulm (HIU), Ulm, Germany — [3]Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany

Local electrochemical measurements at the solid | liquid interface are of particular interest to gain deeper insights into the structure-activity relationship for electrochemical systems. Atomic force microscopy (AFM), can be effectively used for *in situ* monitoring of electrochemical processes, including adsorption, and metal deposition[1−4]. For a better resolution of local phenomena, in this work, we present the use of Fluid-FM. Here the cantilever has a hollow microfluidic channel, allowing for probing electrochemical processes in the vicinity of the tip. This can be achieved by modifying the Fluid-FM cantilever to serve as a counter electrode in the electrochemical cell formed by the tip and the investigated substrate. The feasibility of the approach is demonstrated using a Au surface in contact with a diluted H_2SO_4 electrolyte. The influence of parameters such as the ratio between the surface area of the working electrode and counter electrode, as well as the volume of the electrolyte on the electrochemical performance is discussed.

O 12.4 Mon 15:45 GER 37

Analysis of DNA-origami-based calibration standard for AFM using artificial intelligence — •Ziba Akbarian[1,2], Tim Johannes Seifert[1], Birka Lalkens[2], Ingo Busch[3], Harald Bosse[3], and Uta Schlickum[1,2] — [1]Technische Universität Braunschweig, Braunschweig, Germany — [2]Laboratory for Emerging Nanometrology (LENA), Braunschweig, Germany — [3]Physikalisch Technische Bundesanstalt, Braunschweig, Germany

In this investigation, we focus on a nanoscale-standard reference system for calibrating atomic force microscopes utilizing DNA origami. To introduce measurable protrusions on the DNA origami nanostructure, markers at well-defined positions have been attached. To analyze the nanostructures as accurately as possible, we propose the use of artificial intelligence (AI) based image analysis techniques. Commonly, evaluation of the obtained data from atomic force microscopes is performed manually and includes preparatory steps to visualize images before analysis. As a result, the data analysis process requires a lot of time and always introduces not-avoidable errors. We present an AI-based measurement procedure using the YOLOv5 object detection and a semantic segmentation network trained on synthetic data to crop origami structures and pixelwise locate markers, respectively. This way, we can achieve a relative calibration accuracy in the range of 1% with an automatic data evaluation tool.

O 12.5 Mon 16:00 GER 37

Interplay between magnetic and electrostatic forces when imaging complex current carrying stripline geometries with Magnetic Force Microscopy — Denis Goman, Dhavalkumar Mungpara, and •Alexander Schwarz — Institute of Nanostructure and Solid State Physics, University of Hamburg, Jungiusstr. 11, 20355 Hamburg

Current carrying strip-lines have been oftentimes used to calibrate the sensitivity of magnetic tips to perform quantitative magnetic force microscopy, because for this system the Oersted field can be calculated analytically. In these investigations possible electrostatic contribution to the measured signal have been usually ignored.

Our research focuses on more complex strip-line arrangements with meander and spiral geometries, which are part of a magnetometer. Current dependent magnetic force microscopy (MFM) images clearly show that the measured signal possesses a large electrostatic contribution, which, in a peculiar fashion, depends on the tip location. We find that electrostatic contributions stem from three sources: (i) the contact potential difference between strip-line and substrate material, (ii) the potential drop along the strip-line and (iii) an edge effect related to the finite size of the tip apex. This knowledge helps to disentangle magnetostatic and electrostatic contributions even for rather complex strip-line geometries.

O 12.6 Mon 16:15 GER 37

Influence of Surfaces Charges and Trap States in KPFM Measurements of Doping Concentration — •Thilo Glatzel, Urs Gysin, and Ernst Meyer — University of Basel, Department of Physics, Klingelbergstr. 82, 4056 Basel, Switzerland

Kelvin Probe Force Microscopy is a scanning probe method for imaging the surface potential by atomic force microscopy. The surface potential is one of the most important surface properties and is correlated to e.g. the work function, surface dipoles, localized surface charges, and structural properties. It gives detailed information on the electrical properties and can be combined with optical and electrical excitation mechanisms providing additional properties like surface band bending and charge carrier mobilities. We will introduce the main concept and will briefly describe the major methods of operation. Based on the analysis of a Si super-junction device structures dopant profiling and the concept of surface photovoltage measurements will be introduced. The influence of local charge accumulation and trap states on these devices will be presented and the effect on the measured contact potential values will be discussed.

O 12.7 Mon 16:30 GER 37

Development of SNOM combining plasmonic picocavities with noncontact AFM — •Akitoshi Shiotari[1], Jun Nishida[2], Adnan Hammud[1], Martin Wolf[1], Takashi Kumagai[2], and Melanie Müller[1] — [1]Fritz-Haber Institute of the Max-Planck Society, Berlin, Germany — [2]Institute for Molecular Science, Okazaki, Japan

Scattering-type scanning near-field optical microscopy (s-SNOM) is a powerful tool to visualize the nanoscale optical response of sample surfaces. However, the resolution of conventional s-SNOM is usually limited by thermal instabilities of the tip-apex structure and the weak light intensities scattered from small volumes. On the other hand, it has been shown recently that light can be confined to the atomic scale using plasmonic picocavities. Here we demonstrate the development of plasmonic s-SNOM based on noncontact atomic force microscopy (nc-AFM) under the low-temperature and ultrahigh-vacuum conditions. A quartz tuning fork sensor with a Ag tip sharpened by focused ion beam milling enables precise control of the subnanometer tip-sample gap under illumination with visible laser light. The extremely high field enhancement and localization of light in the picocavity enhances the scattered light intensity and allows to image the optical response of samples at 1 nm resolution. The combination of ncAFM with plasmonic picocavities has high potential for atomic resolution optical imaging of various materials, including insulators.

O 12.8 Mon 16:45 GER 37

Polarization-sensitive scanning near-field optical microscopy — •Felix G. Kaps[1,2], Susanne C. Kehr[1,2], and Lukas M. Eng[1,2] — [1]Technische Universität Dresden, Germany — [2]Würzburg-Dresden Cluster of Excellence - EXE 2147 (ct.qmat), Dresden, Germany

Scanning near-field optical microscopy (SNOM) enables nanoscopic optical surface characterization at visible, infrared, and THz wavelengths [1], with applications to various research fields e.g. 2D materials, semiconductors, and in biology [2]. Here, typically the pure out-of-plane field components are considered. For resonant samples however, near-field excitation of all vectorial components becomes possible [3], enabling the full polarization analysis at the nanometer length scale.

In the work presented here, we examine the polarization-dependent near-field response of both non-resonantly (Au) and resonantly (SiC) excited samples at around 10.6 μm. By varying the incident linear polarization direction from s- to p-polarization, we are able to capture differently scattered near-field contributions, showing up in characteristic lobe-shaped polarization signatures. These results are confirmed by theoretical simulations, where we combine the analytic dipole model [5] and the Jones matrix formalism. Comparing the experiment with our simulations, we are able to disentangle the near-field's vectorial contributions via spectral and polarization analysis.

Topical Talk   O 13.1   Mon 15:00   GER 38
Space weathering of planetary surfaces — •Peter Wurz — Physics Institute, University of Bern, Bern, Switzerland

The surfaces of planetary objects in interplanetary space are subjected to external agents modifying their chemical and mineralogical composition and causing removal of material from these surfaces into interplanetary space. These external agents are the flow of ions and electrons from the Sun (the solar wind), currents of magnetospheric systems, energetic particles from outer space, impacting micro-meteorites, and photons from the Sun. In particular, the ion precipitation on these surfaces is of high interest. The removal of surface material, e.g., the ion-induced sputtering, contributes atoms to the interplanetary particle population, which eventually end up as ions in the interplanetary plasma flow. The changes in composition of the surface are also of interest because they affect the spectroscopic appearance of these surfaces. Since most of the planetary objects are only studied via telescopic observations, relating the spectroscopic appearance of the space-weathered surface to the underlying material is of high importance.

                                    O 13.2   Mon 15:30   GER 38
Quantifying the erosion of the lunar surface due to solar wind sputtering — •Johannes Brötzner[1], Herbert Biber[1], Noah Jäggi[2], Paul Stefan Szabo[3], Daniel Primetzhofer[4], André Galli[2], Peter Wurz[2], and Friedrich Aumayr[1] — [1]TU Wien, Institute of Applied Physics, Vienna, Austria — [2]University of Bern, Physics Institute, Bern, Switzerland — [3]University of California, Space Sciences Laboratory, Berkeley, USA — [4]Uppsala University, Department of Physics and Astronomy, Uppsala, Sweden

Without a protective atmosphere nor its own magnetic field, the lunar surface is subjected to bombardment by the solar wind, a stream of mostly H^+ and He^{2+} ions originating from the Sun. Combined with other effects, this leads to the ejection of material and subsequently the formation of a tenuous gas layer around the Moon, the exosphere. Understanding its formation and coupling to surface properties could potentially enhance our knowledge of not only the Moon, but also other rocky bodies in the solar system.

Previous attempts at modelling the creation of an exosphere used sputter yield values of limited validity for the sputtering contribution to this process – data for relevant minerals were simply not available. While in the past few years, investigations using adequate analogue materials has progressed, we present both experimental and numerical results for the irradiation of H^+ and He^+ ions on samples prepared from actual lunar material, gathered during the Apollo 16 mission in 1972.

                                    O 13.3   Mon 15:45   GER 38
Sputtering from Sinusoidal Surfaces: Monte Carlo Simulations and Comparison to Analytical Results — •Gerhard Hobler[1] and R Mark Bradley[2] — [1]Institute of Solid-State Electronics, TU Wien, AUSTRIA — [2]Departments of Physics and Mathematics, Colorado State University, Fort Collins, CO 80523, USA

Sputtered surfaces are virtually never planar at the nanoscale, and so there has been longstanding interest in the spatially averaged sputter yield $\bar{Y}$ that results when a broad ion beam is incident on a surface with a nontrivial morphology. Considering the simple case of sinusoidal surfaces, the aim of the present study is (i) to investigate the contributions of redeposition and secondary sputtering to $\bar{Y}$, and (ii) to test a recently developed theory [1] that predicts $\bar{Y}$ for small amplitudes from the angular dependent sputter yield of a flat surface. For the simulations we use the Monte Carlo binary collision code IMSIL [2]. Apart from expected results on redeposition and sputtering by reflected ions, we also find that sputtering by recoils that are sputtered and then strike the surface may compensate for a sizable amount of redeposition. The simulations confirm the theory's prediction that $\bar{Y}$ may either increase or decrease with amplitude depending on the incidence angle. They also confirm the theory's prediction that redeposition scales with the square of the amplitude over the wavelength, and are generally in excellent quantitative agreement with theory.

MeV-SIMS: mass spectrometry with ultra-fast projectiles — •Lars Breuer[1], Tobias Heckhoff[1], David Theuner[1], Frieder Koch[2], and Andreas Wucher[1] — [1]Universität Duisburg-Essen — [2]GSI Helmholtzzentrum für Schwerionenforschung

While secondary ion mass spectrometry has become a standard tool in surface analysis, it still offers multiple challenges. While ionization probabilities are usually fairly low and may be altered by the chemical environment of the target surface, fragmentation of molecules introduces even more experimental challenges. Therefore, better understanding of the underlying processes and methodology improvement is an ongoing topic of research. Here, we present strategies developed to shed light on the fundamental processes in sputtering of different materials from metals and insulators to organic samples by tuning the contribution of nuclear and electronic sputtering. For that purpose, a time-of-flight spectrometer has been coupled to the M-Branch of the UNILAC at GSI in Darmstadt, using swift heavy ions as projectiles. By laser post-ionization not only secondary ions are accessible but their neutral counterparts as well to enable us to gain insight into sputtering and ionization under extreme conditions.

                                    O 13.5   Mon 16:15   GER 38
A new material science target station for swift and highly charged ions at CRYRING@ESR — •Kevin Vomschee[1], Michael Wagner[2], Nils Ulrich[2,3], Frieder Koch[2], Sadra Kour[1], André Maas[1], Christina Trautmann[2,3], Marika Schleberger[1], and Lars Breuer[1] — [1]Univ. Duisburg-Essen — [2]GSI Helmholtzzentrum für Schwerionenforschung — [3]Technische Univ. Darmstadt

This contribution describes the new target station MSS@CRYRING ("Material Science Station at CRYRING") operated at GSI. The new setup at the storage ring CRYRING allows the irradiation of samples with highly charged ions up to completely stripped uranium (U^{92+}) with full control over the kinetic energy of the projectile between keV and GeV. This allows the investigation of the specific effect of the kinetic and potential energy. The latter is dissipated in a very shallow volume upon impact while at high kinetic energies the entire bulk material is irradiated.

We report on results from the first beam times using the extracted beam at the new target station. For testing the setup, polymer films were irradiated with $^{107}Ag^{47+}$ at a kinetic energy of 5.9 MeV/u. Applying track etching techniques the number of ions per cm^2 was analyzed using scanning electron microscopy. Comparing these results with the number of ions extracted from the storage ring as deduced from a DC-transformer and a Schottky detector gives an ion transmission of 53.7 % and a maximum flux of $3 \cdot 10^7$ cm^{-2} per pulse.

                                    O 13.6   Mon 16:30   GER 38
Compact Electron Beam Ion Source — •Daniel Thima[1], Matthias Werl[1], Gabriel Lukas Szabo[1], Paul-Friedmar Laux[2], Mike Schmidt[2], Günter Zschornack[2], and Richard Arthur Wilhelm[1] — [1]TU Wien, Institute of Applied Physics, Vienna, Austria — [2]D.I.S Germany GmbH, Dresden, Germany

In many modern fields of research, such as plasma and atomic physics, material science or astrophysics, highly charged ions play an important role. Research with highly charged ions relies strongly on stable ion sources, providing long-term operation with the low output currents in standard devices. Typically, these devices are heavy, stationary machines such as electron cyclotron resonance ion sources or electron beam ion sources (EBIS), sometimes even relying on cryogenic magnetic systems.

Gaining portability by downsizing an EBIS has been pursued recently by a commercial supplier. With only 30 cm in length and using in-vacuum mounted magnets, the resulting prototype EBIS fits onto almost any ultra high vacuum chamber, needing only a single CF40 port. An included Wien filter allows separation of produced ions based on their charge state and mass.

We are currently characterising this compact EBIS in our laboratory, focusing on ion output current. Here, we present our setup and the results of first measurements.

                                    O 13.7   Mon 16:45   GER 38
On the path to ion based pump-probe experiment: generating picosecond keV Ne$^+$ ion pulses from a cooled supersonic gas beam — •Lukas Kalkhoff, Marika Schleberger, Klaus Sokolowski-Tinten, Andreas Wucher, Alexander Golombek, and Lars Breuer — University Duisburg-Essen, Duisburg, Germany

The dynamics triggered by the impact of an ion onto a solid surface has been explored mainly by theoretical modeling or computer simulation to date. Results indicate that the microscopic non-equilibrium relaxation processes triggered by the interaction of the ion with the solid occur on a (sub-)picosecond time scale. A suitable experimental approach to these dynamics therefore requires a pump-probe method with an appropriate time resolution. Our experiments have successfully used laser photoionization of a supersonic beam of cooled noble gas atoms at $T_{atoms} \simeq 4$ K in combination with a Wiley-MacLaren ion buncher. The measured distribution of the arrival time of individual Ne$^+$ ions impinging on the surface of a fast microchannel plate with a kinetic energy of 4 keV gives a full width at half maximum of the ion pulse of $t_{ion} = 130$ ps. A more detailed analysis shows that this pulse width is only an upper limit related to the detection limit of the electronics. The true pulse width results from extrapolation of our data and is $t_{ion} = 18 \pm 4$ ps. This opens the door to pump-probe experiments with keV ions with a time-resolution in the picosecond range.

Generation of pulsed ions using ultrafast electrons — Marius Constantin Chirita Mihaila, Gabriel Lukas Szabo, Alexander Sagar Grossek, and •Richard Arthur Wilhelm — TU Wien, Institute of Applied Physics, 1040 Vienna, Austria

Ultrafast physics is a very active research field where high temporal and spatial resolution provides unprecedented structural information in material science.

Here, we describe the development of a new technique that allows the creation of pulsed ions using ultrafast electrons. The general technique of using picosecond ion pulses to study novel time-resolved processes in materials will be hugely impactful and aims at investigating ultrafast phenomena that are intractable with pump-probe measurements using pulsed electrons and lasers. However, the use of pulsed ions has been limited by the complexity of achieving short pulse lengths at the sample plane.

The experimental setup features a Ti: Sapphire laser that triggers femtosecond electron pulses from a low-workfunction cathode. The pulsed electrons then propagate through a miniaturized ion source and generate pulsed ions. Current challenges of preserving a short ion pulse length upon transport to the sample plane and prospects of pump-probe measurements with ultrafast ions are discussed.

Tailoring Stone-Wales transitions in Ti_2O_3 honeycombs with alkaline earth metals — •Martin Haller, Stefan Förster, and Wolf Widdra — Martin-Luther-Universität Halle-Wittenberg, Institute of Physics, Von-Danckelmann-Platz 3, 06120 Halle, Germany

In 2013 the first 2D oxide quasicrystal (OQC) has been discovered in thin Ba-Ti-O films [1]. It shows a twelvefold diffraction pattern that is incompatible with lattice periodicity. In real space it can be described by squares, triangles and rhombus tiles. Just recently, the atomic structure has been solved [2,3]. The essence are Ti_nO_n ring structures with n = 4, 7 and 10. These evolve by Stone-Wales transitions from a pure honeycomb network [4]. The transformations are stabilized by alkaline earth metal ions and their associated dipole and can be controlled by the alkaline earth metal coverage. Here we investigate the basic steps of individual Stone-Wales transformations with LEED and STM for ultra-low coverages deposited onto a Ti_2O_3 honeycomb on a close-packed metal surface. The transformations to ring structures with n = 4, 5 and 7 are monitored and related to the formation of square and triangle tilings.

Formation of an extended quantum dot array driven and auto protected by an atom thick h-BN layer — •Joel Deyerling[1], Ignacio Piquero-Zulaica[1], Mustafa A. Ashoush[2], Knud Seufert[1], Mohammad A. Kher-Elden[2], Zakaria M. Abd El-Fattah[2], and Willi Auwärter[1] — [1]Physics Department E20, Technical University of Munich, James-Franck-Straße 1, D-85748 Garching, Germany — [2]Physics Department, Faculty of Science, Al-Azhar University, Nasr City, Cairo E-11884, Egypt

Fabricating nanoarchitectures to confine two dimensional nearly free electrons on crystalline surfaces by tip manipulation with a scanning tunneling microscope (STM) or by applying supramolecular chemistry principles yields diverse artificial electronic structures. These electronic states are prone to scattering by adsorbates making them extremely susceptible to the environment. Nonetheless, little attention has been given to their protection, e.g., by an inert overlayer.

Here, we show that a quasi-hexagonal CuS nanoporous network can be formed at the h-BN/Cu(111) interface by thermally-induced sulfur segregation from the Cu(111) bulk. The growth and structure is characterized by STM and X-ray photoemission spectroscopy. We demonstrate by employing STM and scanning tunneling spectroscopy that within the pores of the network the surface state of Cu(111) as well as the image potential states of h-BN/Cu(111) are confined, effectively creating arrays of quantum dots with well-defined sizes that are covered by an inert h-BN overlayer.

First-principles investigation of doped borophene quantum dots as donor materials for solar cell applications — •Rachana Yogi, Vaishali Roondhe, and Alok Shukla — Department of Physics, Indian Institute of Technology Bombay, Mumbai 400076, India

Because of fast-depleting fossil fuel reserves, there is an urgent need for harvesting alternative sources of energy. We present a first-principles atomistic study of borophene quantum dots (BQDs) B35 and B36 for their possible utilization in solar-cells. The pristine-BQDs are doped by C, N, and O atoms, and find that they have bowl-like structures in the ground state. The electronic and optical properties of pristine-BQDs, and doped-BQDs are investigated. The chemical potentials of several of these BQDs are slightly higher than that of popular solar-cell acceptor system PC71BM, they will act as electron donors in a PC71BM-based solar-cell. The calculated values of the open-circuit voltage corresponding to PC71BM and BQD-based device indicate efficient electron injection from the BQDs to PC71BM. O-doped B36-QD and B35-QD have the highest value of short-circuit current density attributed to their reduced HOMO-LUMO gap and high HOMO energy levels as compared to all other considered doped systems further enhancing the photoelectric properties. The power conversion efficiency of doped-BQDs exhibits significant improvement. The efficiency of O-doped B36-QD is maximum due to its high electron injection rate in PC71BM. Present calculations show that adding a foreign atom in BQD makes it a suitable candidate for high-performance solar-cells.

O 14.4   Mon 15:45   GER 39

Electrospray Depositions of a Spin-Crossover Active Iron(II) [2×2] Grid Complex on Ag(111) with Different Landing Energies — •Dennis Meier[1], Benedikt Schoof[1], Joachim Reichert[1], Nithin Surayadevara[2], Andreas Walz[1], Annette Huettig[1], Hartmut Schlichting[1], Mario Ruben[2], Anthoula C. Papageorgiou[1,3], and Johannes V. Barth[1] — [1]Technical University of Munich, Germany — [2]Karlsruhe Institute of Technology, Germany — [3]National and Kapodistrian University of Athens, Greece

Chiral spin-crossover (SCO) complexes are intriguing building blocks for innovative magneto-optical nanoarchitectures.[1] Such an Fe(II) [2×2] grid complex was deposited in ultra-high vacuum with electrospray controlled ion beam deposition (ES-CIBD)[2] on Ag(111) and investigated by scanning tunnelling microscopy. Low landing energy (< 3 eV/z) resulted in clusters and single molecules. Higher landing energies (> 3 eV/z) led to coordination bond cleavage and a rich variety of self-assembled surface networks forming from the grid fragments. Applying established on-surface synthesis methodology employing the possible constituents of these networks (ligands and Fe atoms) reproduced only a part of them. It is thus proposed that ES-CIBD provides an unexpected route to novel on-surface coordination network synthesis.

Giant confinement of surface electrons in a two-dimensional metal-organic porous network — •Lu Lyu[1], Tobias Eul[1], Wei Yao[1], Zakaria M. Abd El-Fattah[2], Mostafa Ashoush[2], Ignacio Piquero-Zulaica[3], Johannes V. Barth[3], Martin Aeschlimann[1], and Benjamin Stadtmüller[1,4] — [1]Department of Physics, University of Kaiserslautern, Germany. — [2]Physics Department, Faculty of Science, Al-Azhar University, Egypt. — [3]Physics Department E20, Technical University of Munich, Germany — [4]Institute of Physics, Johannes Gutenberg University Mainz, Germany.

Two-dimensional metal-organic porous networks (2D-MOPNs) are highly flexible nano-architectures for exploring the quantum confinement of surface electrons on noble metals. So far, 2D-MOPNs have been predominantly studied for the confinement of occupied Shockley-type surface states (SS). In contrast, the confinement of excited surface states, such as image potential states (IPSs), remains elusive. In this work, we apply two-photon photoemission to investigate the band dispersion of the first image-potential state (n = 1 IPS) in a Cu-T4PT nanoporous network on Cu(111). We find the formation of a Bloch-like band structure with a substantially increased effective band mass of the IPS (> 150 %). In contrast, the effective band mass of the SS remains almost unchanged (< 3%). This band renormalization of the IPS can be attributed to the spatial distribution of its charge density perpendicular to the surface, which reveals the highest density at the vertical adsorption position of the T4PT backbone. This coincidence is responsible for the giant confinement.

Modification of Single-Layer Organometallic Networks: from Ag-Bridged to Cu-Bridged Alkynyl Metal-Alkynyl Linkages on Ag(111) Surfaces — •Wenchao Zhao, Felix Haag, Ignacio Piquero-Zulaica, Yi-Qi Zhang, Francesco Allegretti, Biao Yang, and Johannes V Barth — Physics Department E20, Technical University of Munich, 85748 Garching, Germany

The metal-exchange reaction, is of importance for the advanced preparation of functional metal-organic frameworks for various applications[1]. Notably,

building two-dimensional organometallic networks (OMNs), can provide versatile nanoarchitectures for potential application in nanodevice[2,3]. Although various OMNs have been constructed with molecular building blocks by abstracting surface metal atoms, the degree of success is often individual and substrate-dependent. Thus metal-exchange reactions hold promise for multiple production by modification and functionalization of OMN templates. Here, we demonstrate the modification of a single-layer OMN by metal-exchange reaction. By introducing external Cu atoms into the alkynyl-Ag OMN[3], we successfully synthesized in situ a highly ordered alkynyl-Cu OMN on a Ag(111) surface. While maintaining a similar lattice periodicity and pore morphology, it possesses higher thermal stability, guaranteeing higher robustness for possible applications. Reference. 1. M.-M. Structure Formation in Ceramic Thin Films with Hybrid Molecular Dynamics — •NYDIA ROXANA VARELA ROSALES and MICHAEL ENGEL — Institute for Multiscale Simulation, University of Erlangen-Nürnberg, Cauerstraße 3, 91058 Erlangen, Germany

How can we model and predict ceramic thin films? Highest accuracy is achieved with ab-initio quantum mechanical methods. But these methods are not suitable for large systems including their phase transformations. Atomistic modeling with molecular dynamics and Monte Carlo simulations reaches large system sizes but require sophisticated tailored interaction potentials. Here, we develop and apply a coarse-grained simulation method for structure formation in thin films. Our method considers the chemical bond network of the ceramics explicitly to simplify the complexity of the simulation and to reach high simulation speeds and large system sizes. Of particular interest are (quasi-)crystalline ceramic thin films recently discovered in experiments of (Ba/Sr)-Ti-O perovskites. Solely by considering the extrinsic topology of the tiles and utilizing a harmonic interaction potential, we reproduce the appearance of approximants of the dodecagonal quasicrystals, which was also predicted by ab-initio simulations. Our work highlights the role of bond network topology in understanding complex thin film structures without a need for reliance on quantum simulation methods.

O 14.8 Mon 16:45 GER 39

A Holistic Characterisation of Bi Thin Films on Au(111) — •PABLO VEZZONI VICENTE[1], TOBIAS WEISS[1], MARC GONZALEZ-CUIXART[4], DENNIS MEIER[1], BENEDIKT KLEIN[2], DAVID DUNCAN[2], EZEQUIEL TOSI[3], PAOLO LACOVIG[3], SILVANO LIZZIT[3], JOHANNES BARTH[1], PETER FEULNER[1], and FRANCESCO ALLEGRETTI[1] — [1]Physics Department E20, Technische Universität München, Germany — [2]I09 beamline, Diamond Light Source, United Kingdom — [3]3SuperESCA beamline, Elettra Synchrotron, Italy — [4]4IMDEA Nanociencia, Spain

We present a comprehensive analysis of the long-range ordered, coverage-dependent phases of Bi epitaxially grown on a Au(111) surface in UHV, from the sub-monolayer ($\sqrt{37} \times \sqrt{37}$)$R25.3°$ Kagome lattice up to few-layer Bi(110) thin films. Particular focus is devoted to the sub-monolayer, high-coverage ($p \times \sqrt{3}$) phase, paving the way to its use as a buffer layer for epitaxial growth with tunable geometry and low electronic interaction.

Our work clarifies and expands the current literature reports, specifically on the complex ($p \times \sqrt{3}$) phase. The wide range of analysis techniques used, including Low-Energy Electron Diffraction (LEED), Photo-Electron Spectroscopy (XPS, UPS), Temperature Programmed Desorption (TPD), Scanning Tunneling Microscopy and Spectroscopy (STM, STS), and X-ray Standing Waves (XSW), yields an unprecedented understanding of the system's structural and electronic properties.

O 14.9 Mon 17:00 GER 39

Analytical electron microscopy of nanostructured vanadium dioxide — •VLASTIMIL KŘÁPEK[1], JAN KRPENSKÝ[1,2], MICHAL HORÁK[1], KATARÍNA ROVENSKÁ[1], PETER KEPIČ[1], TOMÁŠ ŠIKOLA[1], FILIP LIGMAJER[1], and ANDREA KONEČNÁ[1] — [1]Brno University of Technology, Czechia — [2]CIC nanoGUNE, San Sebastián, Spain

Vanadium dioxide (VO_2) is a phase-changing material exhibiting temperature-induced metal-insulator transition (MIT) around 340 K. A rather low transition temperature makes VO_2 a suitable material for active nanophotonics, e.g., switchable optical metasurfaces. Such applications require nanostructuring of VO_2 thin films. Here we study the possibility to employ focused ion beam (FIB) milling for the nanofabrication and its impact on the properties of resulting nanostructures.

Taking the VO_2 thin film with experimentally verified MIT, we utilized FIB milling with Ga ions to fabricate V-shaped lamella of the thickness between 0 and 250 nm, which was subsequently transferred onto a heating chip for transmission electron microscopy and analyzed with analytical electron microscopy: high-resolution imaging, energy-dispersive X-ray spectroscopy, and temperature-dependent electron energy loss spectroscopy. We observed a porous character of the pristine material, a coexistence of several crystal structures, negligible contamination with Ga ions, and a variation of stoichiometry with the thickness of the lamella, with the thinnest parts composed of VO and V_2O_3.

O 14.10 Mon 17:15 GER 39

Tuning Nanoporous Au Film Formation via High Voltage Electrolysis — •EVELYN ARTMANN[1], LUKAS FORSCHNER[1], KONSTANTIN M. SCHÜTTLER[2], MOHAMMAD AL-SHAKRAN[1], TIMO JACOB[1], and ALBERT K. ENGSTFELD[1] — [1]Institute of Electrochemistry, University of Ulm, Germany — [2]Institute of Surface Chemistry and Catalysis, University of Ulm, Germany

Nanoporous Au (NPG) films have different properties compared to the bulk material, which opens up new areas of application, such as (electro)catalysis. Usually, NPG films are prepared by dealloying. One disadvantage of this method is that residues of the precursor alloy guest metal can remain in the resulting NPG film, which can have a decisive influence on the electrocatalytic activity of the NPG film.

In this work we report on the preparation of NPG films by high voltage electrolysis (Chem. Phys. Chem., 22 (2021) 2429). In this process, a Au oxide film is first formed on the Au substrate by applying a high positive voltage (between 100 and 540 V), which can subsequently be reduced to NPG. The Au oxide as well as NPG films were characterized by electrochemical methods, as well as (cross-section) SEM and XPS measurements.

Possibilities to selectively modify the resulting NPG films by tuning experimental parameters such as the applied voltage, and electrolyte temperature during HV electrolysis, or the electrolysis time, were systematically investigated. The influence of the reduction method (electrochemical or by H2O2) on the final film structure is discussed.

O 14.11 Mon 17:30 GER 39

Evolution of the Si-Au alloy: from the gold (110) substrate to silicon nanoribbons — •EKATERINA TIKHODEEVA[1], MARÍA E DÁVILA[2], PAOLA DE PADOVA[3], GAY LE LAY[4], MARINA BAIDAKOVA[5], EVGENIYA LOBANOVA[5], JAIME SANCHEZ-BARRIGA[6], DMITRII SMIRNOV[6], and MANUEL IZQUIERDO[1] — [1]European XFEL, Schenefeld, Germany — [2]CSIC, Madrid, Spain — [3]Consiglio Nazionale delle Ricerche, Rome, Italy — [4]Aix-Marseille Université, Marseille, France — [5]Saint Petersburg, Russia — [6]Helmholtz-Zentrum Berlin, Berlin, Germany

The development of the Si-Au alloy was investigated on the path from the gold single crystal surface to silicon nanoribbons (SiNR). Si sub-monolayers were deposited on the missing row reconstructed Au(110) substrate. At various stages of evaporation, low-energy electron diffraction (LEED) patterns were recorded to refine the surface geometry. The arrangement of the Si atoms has been correlated with the missing row orientation. The recovery of the Au(1x1) reconstruction, as well as the gradual transition from surface alloy to SiNRs were explored. In parallel with LEED, photoelectron spectroscopy was used to clarify the atom distribution. The profiles of the Au 4f and Si 2p core levels were deconvoluted and analyzed at all stages of Si deposition. The appearance of a new low kinetic energy component was noticed in the Au 4f spectra. It is related to the Si-Au bond and indicates a strong interaction between them. The Si core levels exhibit up to three components corresponding to the different chemical environments.

Electron-spin resonance atomic force microscopy — •LISANNE SELLIES, RAFFAEL SPACHTHOLZ, PHILIPP SCHEUERER, and JASCHA REPP — University of Regensburg, Regensburg, Germany

Recently, we combined the high energy resolution of electron spin resonance (ESR) with the spatial resolution offered by atomic force microscopy (AFM). This ESR-AFM technique relies on driving electron spin transitions between the

non-equilibrium triplet state levels of a single molecule. Since these triplet states typically have different lifetimes, driving such transitions modifies the overall triplet lifetime [1,2], which can be detected by an electronic pump-probe scheme [3].

ESR-AFM allows to measure ESR signals with a sub-nanoelectronvolt energy resolution, as we demonstrated for pentacene on thick NaCl films. Thereby, molecules only differing in their isotopic configuration can be distinguished.

Moreover, due to the minimally invasive nature of the ESR-AFM technique, the electron spins of pentacene can be coherently manipulated over tens of microseconds. After introducing ESR-AFM, recent results obtained by this technique will be presented.

Coherent spin dynamics in a single atom hyperfine system — •Lukas Veldman, Laëtitia Farinacci, Evert Stolte, Mark Canavan, and Sander Otte — TU Delft, Delft, The Netherlands

The combination of electron spin resonance (ESR) with scanning tunneling microscopy (STM) has opened up the possibility to investigate the interaction between electrons and nuclei in individual atoms on a surface [1]. Recently, we showed that for TiH atoms on MgO the hyperfine interaction is highly anisotropic and contains information on the groundstate orbital of the atom [2]. In this work, we go to the low field regime where electron and nuclear states hybridize. We use DC voltage pulses [3] to spin pump both the electron and the nuclear spin [4]. We measure the coherent oscillations of the electron spin driven by the hyperfine interaction. These measurements open the door to controlled spin manipulation of nuclear spins in single atoms.

Quantum coherence of single atomic S = 1/2 spins on ultra-thin insulating layers — Hong Bui[1,2], We-Hyo Seo[1,2], Yu Wang[1,2], Andreas Heinrich[1,2], and •Soo-Hyon Phark[1,2] — [1]Center for Quantum Nanoscience, Institute for Basic Science, Seoul 03760, Korea — [2]Department of Physics, Ewha Womans Universtiy, Seoul 03760, Korea

A scanning tunneling microscope (STM), when combined with electron spin resonance (ESR), provides a solid-state platform of atomic scale spin qubit. However, its quantum coherence is considerably limited by couplings with metallic substrate and tunneling electrons. Here we report a study on the quantum coherence of single Ti atomic spins (S = 1/2) on two- (2ML) and three- (3ML) monolayer-thick MgO on Ag(100) using pulsed-ESR equipped in a STM at 0.4 K. We were able to drive the coherent rotations of the spin on the 3ML-MgO with a Rabi rate (Ω) up to 100 MHz, which is an order faster than that on the 2ML-MgO. Coherence time (T2) from Hahn-echo measurement revealed the role of the tunneling electrons, resetting the state of a Ti spin with a probability of 0.15/electron, which is the same for Ti spins on both 2ML- and 3ML-MgO. Of more interesting is the zero current T2 of 2 microsec on 3ML-MgO, about 5 times longer than that on 2ML-MgO, emphasizing the importance of decoupling the spin from the metallic substrate as well as tunneling electrons. Such considerable improvements in Ω and T2 are promising for high fidelity quantum gate operations to a Ti spin qubit, further brightening a way to raise the on-surface spin qubits on a stage of the quantum-coherent applications.

Certifying entanglement of spins on surfaces using ESR-STM — •Yelko del Castillo[1,2] and Joaquín Fernández-Rossier[1] — [1]International Iberian Nanotechnology Laboratory (INL), Av. Mestre José Veiga, 4715-330 Braga, Portugal — [2]Centro de Física das Universidades do Minho e do Porto, Universidade do Minho, Campus de Gualtar, 4710-057 Braga, Portugal

We propose a protocol to certify the presence of entanglement in artificial on-surface atomic and molecular spin arrays using electron spin resonance carried by scanning tunnel microscopes (ESR-STM). We first generalize the theorem that relates global spin susceptibility as an entanglement witness to the case of anisotropic Zeeman interactions, relevant for surfaces. We then propose a method to measure the spin susceptibilities of surface-spin arrays combining ESR-STM with atomic manipulation. Our calculations show that entanglement can be certified in antiferromagnetically coupled spin chains using state of the art spectral resolution of ESR-STM magnetometry.

Ultrafast dynamics of magnetic adatoms on MgO — •Lukas Arnhold[1], Daria Sostina[2], Nicolaj Betz[1], Susanne Baumann[1], Philip Willke[2], and Sebastian Loth[1] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — [2]Karlsruhe Institute of Technologies, Physikalisches Institut, Karlsruhe, Germany

The utilization of single magnetic atoms as qubits requires detailed understanding of their energy levels and the associated time-scales, ideally also those of excited states. Ever since coherent driving of a single spin in the junction of a scanning tunneling microscope has been shown [1], the technique of ESR-STM has been established and used for example to perform qubit operations, as well as, to address multiple qubits [2]. Besides the technique of electron spin resonance, quantum stochastic resonance measurements offer new insights into a system's

energy transition cycles, or in other words, it's associated time-scales [3]. Applying this measurement scheme onto ESR active adatoms on a MgO substrate, gives access to additional manipulation pathways and allows for further understanding and mastery of coherent spin manipulation.

All-electrical driving and probing dressed states of a single spin on surface — •Hong Bui Thi[1,2], Christoph Wolf[1,3], Yu Wang[1,3], Masahiro Haze[1,4], Yi Chen[1,3], Yujeong Bae[1,2], Andreas Heinrich[1,2], and Soo-Hyon Phark[1,3] — [1]Center for Quantum Nanoscience, Institute for Basic Science (IBS), Seoul 03760, Korea — [2]Department of Physics, Ewha Womans University, Seoul 03760, Korea — [3]Ewha Womans University, Seoul 03760, Korea — [4]The Institute for Solid State Physics, University of Tokyo, Kashiwa 277-8581, Japan

We demonstrate the creation of dressed states of a single electron spin localized on a surface by using a resonant radio-frequency field in a scanning tunneling microscope. Owing to the unique sub-nm probe-sample geometry field strengths as high as   1 GV/m can be achieved at a bias of the radio-frequency field below 100 mV. Magnetic resonance of a single spin in such a cavity is a direct consequence of coupling between the atomic dipole moment and driving electric field, resulting in the dressing of the atomic states. The read-out of these dressed states is facilitated in an all-electrical fashion by a weakly coupled probe spin. Our work highlights the strength of the atomic-scale geometry inherent to the scanning tunneling microscope in terms of the creation and control of dressed states, which are known to provide decoherence-free subspaces critical to the creation of long-lived quantum states.

Surface spins as quantum bits - a simulation perspective — Jose Reina Gálvez[1], Nicolas Lorente[2], and •Christoph Wolf[1] — [1]Center for Quantum Nanoscience, Institute for Basic Science, Seoul, South Korea — [2]Materials Physics Center, San Sebastian, Spain

Spins localized at or close to a clean surface have emerged as systems of interest in quantum nanoscience. They can be tailored to a desired spin state, manipulated to form structures with designed interactions and as of recent have been used to implement basic quantum logic operations - a control-NOT gate - in a scanning tunneling microscope (STM). In this work we want to explore quantum coherent phenomena of surface spins from a computational perspective. Since surface spins interact rather strongly with the environment, we performed open quantum systems calculations. First, we will show how electron-electron double resonance can be understood by solving the time-dependent Schrodinger equation under continuous and pulsed radio-frequency driving. Using the same prototypical system of two coupled electron spins we also show how the AC Stark effect manifests itself as Autler-Townes doublets and Mollow triplets. To go one step further, we use our recently developed approach to explicitly calculate the current present in the STM experiment using the non-equilibrium Green's functions formalism. These simulations show how the current plays a dual role in these systems by driving quantum transitions but also limiting quantum coherence. Our simulations outline realistic expectations for quantum coherent surface spin systems and their prospective applications.

O 15.8   Mon 16:45   REC C 213

A non equilibrium Green's Function formalism applied to STM/ESR experiments — •Jose Reina-Galvez[1], Nicolas Lorente[2], and Christoph Wolf[1] — [1]Center for Quantum nanoscience, Seoul, South Korea — [2]Centro de Fisica de Materiales, San Sebastian, Spain

The demonstration of reproducible single-atom and single-molecule electron spin resonance (ESR) in a STM junction opened new possibilities in the analysis of surface science at the atomic scale. Recent experiments have demonstrated quantum-coherent Rabi oscillations and even the implementation of a quantum logic operation: a CNOT gate.

Here, we want to focus on the theory we developed to reproduce some relevant results in the field. Our theoretical framework uses open quantum systems formalism in combination with non equilibrium Green's Function technique. It consists of a quantum impurity connected to a polarized STM tip and an isolated surface, both considered as fermionic baths. The time dependent bias voltage used in the experiments is introduced in the hopping terms. These hoppings are driving the electron transitions from the baths to the quantum impurity which uses a modified Anderson impurity model with localized electronic states, a Coulomb repulsion term and a Zeeman term.

Our model is general, allowing to connect an arbitrary number of localized spins with the transport spin. We will demonstrate how driving the system on resonance modifies the population and the calculated true current through the many-body impurity which can be directly compared to the experiment.

Microscopic theory of spin-relaxation of a single Fe adatom coupled to substrate vibrations — •Haritz Garai-Marin[1,2], Manuel dos Santos Dias[3,4,5], Samir Lounis[3,4], Julen Ibañez-Azpiroz[6,7], and Asier Eiguren[1,2,8] — [1]Physics Department, University of the Basque Country UPV/EHU, Bilbao, Spain — [2]Donostia International Physics Center, Donostia, Spain — [3]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich & JARA, Jülich, Germany — [4]Faculty of Physics, University of Duisburg-Essen & CENIDE, Duisburg, Germany — [5]Scientific Computing Department, STFC Daresbury Laboratory, Warrington, United Kingdom — [6]Centro de Física de Materiales CSIC-UPV/EHU, Donostia, Spain — [7]IKERBASQUE Basque Foundation for Science, Bilbao, Spain — [8]EHU Quantum Center, University of the Basque Country UPV/EHU

Understanding the spin-relaxation mechanism of single adatoms is an essential step towards creating atomic magnetic memory bits or quantum bits. Here we present a theory to study the role of electron-phonon coupling by combining *ab-initio* electronic and vibrational properties with the multiplet many-body nature of atomic states. Our calculations reproduce the millisecond spin lifetime measured on Fe adatoms on MgO/Ag(100), which demonstrates that the essential features of the spin-phonon coupling are successfully captured. We show a clear fingerprint for experimentally detecting a localized spin-phonon excitation and we show how the atomic interaction with the environment should be tuned in order to enhance the magnetic stability.

O 15.10　Mon 17:15　REC C 213

Electron spin resonance of individual magnetic molecules on surfaces — •Wantong Huang[1], Máté Stark[1], Paul Greule[1], Daria Sostina[2], David Collomb[1], Christoph Sürgers[1], Wolfgang Wernsdorfer[1], and Philip Willke[1] — [1]Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Institute of Quantum Materials and Technologies (IQMT), Karlsruhe Institute of Technology, Karlsruhe, Germany

Single molecular magnets which consist of one central metal ion surrounded by ligands are promising building blocks for nanoscale spintronics and future quantum devices. The recent development of scanning tunnelling microscopy (STM) combined with electron spin resonance (ESR) constitutes here a powerful technique to image and coherently control individual molecular spins on surfaces [Zhang et. al, Nat. Chem. 14, 59 (2022); Willke, ACS Nano, 15, 11, 17959 (2021)]. Here, we explore the magnetic properties and spin dynamics of iron phthalocyanine (FePc) molecules adsorbed on magnesium oxide (MgO) grown on Ag(100). We investigate the magnetic properties of different FePc by scanning tunneling spectroscopy and ESR-STM. Such molecular magnetic structures provide a versatile platform to study complex magnetic interactions and atomic-scale spin dynamics.

Orbital and spin excitations of hydrogenated titanium modulated by electric field — •Daria Sostina[1], Lukas Arnhold[2], Nicolaj Betz[2], Susanne Baumann[2], Philip Willke[3], Wolfgang Wernsdorfer[3], and Sebastian Loth[2] — [1]Institute of Quantum Materials and Technologies (IQMT), Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — [3]Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany

The goal for coherent control of individual spins on surfaces has prompted the development of new local probe techniques such as a combination of electron spin resonance (ESR) with scanning tunneling spectroscopy (STM). Yet, the excitation mechanism of ESR in STM is not conclusively determined. [Baumann et.al, Science 350, 6259, 2015, Ferron et. al, Phys. Rev. Research 1, 033185 (2019)]. Here we study a higher order orbital excitation of hydrogenated titanium complexes positioned on the oxygen site of the MgO surface. We observe a strong dependence of its excitation energy on the electric field generated by the STM tip. At the same time an ESR transition on that TiH exhibits a shift with the DC bias voltage applied to the junction which was attributed to a change in g-factor of the complex [Kot et. al, arXiv 2209.10969, 2022]. The ability to tune orbital and spin excitations by means of electric fields gives further insight on new pathways for electrical control of single spins centers on surfaces.

Lanthanide atoms on MgO(100)/Ag(100) as Candidate for Single-Atom-Qubits — Stefano Reale[1,2,3], Aparajita Singha[1,2,4], Safa L. Ahmed[1,2], Denis Krylov[1,2], Luciano Colazzo[1,2], Christoph Wolf[1,2], Carlo S. Casari[3], Alessandro Barla[5], Edgar Fernandez[6], Francois Patthery[6], Marina Pivetta[6], Stefano Rusponi[6], Harald Brune[6], and •Fabio Donati[1,2] — [1]Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS), Republic of Korea — [2]Department of Physics, Ewha Womans University, Republic of Korea — [3]Department of Energy, Politecnico di Milano, Italy — [4]Max Planck Institute for Solid State Research, Germany — [5]Istituto di Struttura della Materia (ISM), Consiglio Nazionale delle Ricerche (CNR), Italy — [6]Institute of Physics, Ecole Polytechnique Federale de Lausanne, Switzerland

Lanthanide atoms on surfaces are an exceptional platform for atomic-scale magnetic information storage [Science 352, 318 (2016)]. However, their potential as qubits is yet unexplored. Here we combine x-ray absorption spectroscopy and scanning tunneling microscopy (STM) with density functional theory and multiplet calculations to estimate the performance of Er and Tm on MgO(100)/Ag(100) as spin qubit candidates. For both atoms, we infer a magnetic ground state that is suitable for quantum coherent operations. By adapting the piezoelectric model of electron spin resonance (ESR)-STM [Science Advances 6, eabc5511 (2020)] to the case of lanthanide atoms, we predict a detectable signal and a higher Rabi rate compared to the systems studied up to date [S. Reale et al., accepted in Phys. Rev. B].

Time Resolved Photoemission Study of the Charge Transfer Dynamics in Rutile $TiO_2(110)$ for CO Photooxidation to CO_2 — •Helena Gleissner[1,2,3], Michael Wagstaffe[2], Lukas Wenthaus[4], Simon Chung[2], Steffen Palutke[4], Siarhei Dziarzhytski[4], Dmytro Kutnyakhov[4], Michael Heber[4], Günter Brenner[4], Harald Redlin[4], Heshmat Noei[1,2], and Andreas Stierle[1,2,3] — [1]The Hamburg Centre for Ultrafast Imaging, Hamburg, Germany — [2]Center for X-ray and Nano Science (CXNS), Deutsches Elektronen-Synchrotron (DESY), Hamburg, Germany — [3]Fachbereich Physik Universität Hamburg, Hamburg, Germany — [4]Deutsches Elektronen-Synchrotron (DESY), Hamburg, Germany

In a pump-probe experiment at the free electron laser in Hamburg (FLASH) we gained insight into the ultrafast charge transfer on rutile $TiO_2(110)$ during CO oxidation to CO_2. Pumped with a 770 nm optical laser and probed with 643 eV FEL soft x-rays we monitored the changes in the O 1s and Ti 2p core levels on a picosecond timescale using time-resolved photoemission spectroscopy.

We find that oxygen gets activated and reacts with CO to CO_2 in 0.2 ps up to 1 ps after the laser excitation. A complementary study found that the CO oxidation on anatase $TiO_2(101)$ takes place between 1.2 and 2.8 ps after irradiation with an ultrashort laser pulse.[1]

O 16.2　Mon 15:15　TRE Phy

Transient Absorption Spectroscopy of NiO — •Mahendra Kabbinahithlu[1], Tobias Lojewski[1], Sergey Kovalenko[2], Heiko Wende[1], Uwe Bovensiepen[1], Julia Stähler[2], and Andrea Eschenlohr[1] — [1]Universität Duisburg-Essen, Fakultät für Physik und Center for Nanointegration (CENIDE), Lotharstraße 1, 47057 Duisburg, Germany — [2]Humboldt-Universität zu Berlin, Institut für Chemie, Brook-Taylor-Straße 2, 12489 Berlin, Germany

In nickel oxide (NiO), a correlated transition-metal oxide, the strong electron-electron repulsion splits the d-bands into an occupied lower Hubbard band (LHB) and an unoccupied upper Hubbard band (UHB). The presence of additional oxygen p-bands at the adjacent sites and their interaction with the Hubbard bands leads to complex properties governed by the Hubbard potential (U) and the charge transfer (p $\leftrightarrow$ LHB) gap Δ. NiO is a charge-transfer insulator with the p-bands located between the LHB and the UHB ($\Delta < U$). We present excited state dynamics in NiO thin films via time-resolved optical spectroscopy. NiO is pumped above the band gap with 4.8 eV photons and the transient absorption spectrum is probed using a time-delayed supercontinuum. The time-resolved absorption spectrum, shows within the first 500 fs positive pump-induced changes at 2.2 eV and 3.2 eV which are separated from substrate contributions. We also see a strong negative change around 4.3 eV. The positive changes from in-gap states decay on a time scale of 100 fs, while the negative change represents the bleached ground state which recovers within 6 ps, potentially by interaction with phonons.

O 16.3   Mon 15:30   TRE Phy

Photoinduced dynamics of flat bands in the kagome metal CoSn by TR-ARPES — •Denny Puntel[1], Wibke Bronsch[2], Manuel Tuniz[1], Mingu Kang[3], Paul Neves[3], Shiang Fang[3], Efthimios Kaxiras[4,5], Joseph G. Checkelsky[3], Riccardo Comin[3], Fulvio Parmigiani[1,2], and Federico Cilento[2] — [1]Dipartimento di Fisica, Università degli Studi di Trieste, Trieste (Italy) — [2]Elettra - Sincrotrone Trieste S.C.p.A., Trieste (Italy) — [3]Department of Physics, Massachusetts Institute of Technology, Cambridge, MA, USA — [4]Department of Physics, Harvard University, Cambridge, MA, USA — [5]John A. Paulson School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, USA

In kagome systems, the geometry of the lattice localises the electrons in real space, enhancing the correlations and giving rise to flat bands. In CoSn two flat bands with nontrivial topological character lie below the Fermi level [1]. In order to study the response of the localisation mechanism to impulsive excitation, we performed the first time- and angle-resolved photoelectron spectroscopy study on CoSn. At temporal overlap we observe an increase in the electronic temperature, along with a shift and broadening of the flat bands by few meV. A smaller broadening of the flat band persists for the whole duration of the investigated time delay range (about 6 ps). A possible explanation for this broadening is the partial disruption of the real-space electron localisation, because of the increased mobility of the carriers due to the energy injected by the infrared pump pulse.

Microscopic insight into non-equilibrium dynamics through time-resolved x-ray absorption spectroscopy — •Andrea Eschenlohr — Faculty of Physics and CENIDE, University Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany

Time-resolved x-ray absorption spectroscopy provides access to element- and chemically sensitive information on the femto- to picosecond timescales of the elementary microscopic processes involving charge, spin and lattice dynamics in solids via optical pump, x-ray probe experiments. Recently implemented specialized x-ray optics at the SCS instrument of European XFEL allow for a simultaneous acquisition of the ground state and optically excited x-ray spectra as well as a reference signal for normalization of the data to the incident x-ray intensity, and thus provide excellent data quality in combination with kHz repetition rates [1]. We employ this scheme to analyze the temporal evolution of the electronic structure of ferromagnetic Ni after optical excitation and distinguish transient broadening and energy shifts in the absorption spectra, which we show to be caused by electron repopulation and correlation-induced modifications of the electronic structure, respectively. Crucially, an ab initio theoretical description requires taking the local Coulomb interaction into account, revealing the temporal interplay between electron correlations and ultrafast spin-dependent charge dynamics [2].

Direct observation of light-induced ultrafast currents in black phosphorus — •Maciej Dendzik[1,2], Andrea Marini[3], Samuel Beaulieu[2], Shuo Dong[2], Tommaso Pincelli[2], Julian Maklar[2], R. Patrick Xian[2], Enrico Perfetto[3,4], Martin Wolf[2], Gianluca Stefanucci[4,5], Ralph Ernstorfer[2], and Laurenz Rettig[2] — [1]KTH Royal Institute of Technology, Stockholm, Sweden — [2]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [3]CNR-ISM, Rome, Italy — [4]Tor Vergata University of Rome, Rome, Italy — [5]INFN, Rome, Italy

Understanding intricate details of light-matter interaction on the femtosecond timescale is at the heart of modern photonics and optoelectronics. However, fundamental coupling between charge carriers response and corresponding induced electromagnetic fields upon an ultrafast optical excitation remain largely unexplored in many quantum materials. Here, we present an experimental time- and momentum-resolved photoemission study of black phosphorus (BP) combined with state-of-the-art simulations of ultrafast carrier dynamics and induced fields. We find dramatically different electron dynamics following excitation by light polarized along the zigzag and armchair directions which we associate with a difference in initial population momentum distributions. Remarkably, we observe a sub-picosecond population imbalance of excited carriers with opposite momenta, which correspond to the generation of transient in-plane currents. The results provide a comprehensive picture of the ultrafast carrier dynamics in BP and pave the way for novel applications in optoelectronics or quantum computing.

Band-resolved relaxation of laser-excited gold. — •Tobias Held[1], Pascal D. Ndione[1], Sebastian T. Weber[1], Dirk O. Gericke[2], and Baerbel Rethfeld[1] — [1]RPTU, Kaiserslautern, Germany — [2]CFSA, University of Warwick, Coventry, UK

Irradiation of gold with visible light may excite d-band electrons into the free sp-electron states. This process increases the energy content of the electron system and induces an occupational nonequilibrium. Since the particle exchange is significantly slower than the energy transfer between the electron subsystems, the nonequilibrium band occupation persists long after a temperature can be well defined. Subsequently, density equilibration and the electron-phonon relaxation need to be considered consistently. In Ref. [1], we have simulated the non-equilibrium band occupation with electron density-resolved rate equations and coupled them with a two-temperature model to include the energy transfer from the electrons to the lattice. The results are sensitive to the electron-phonon coupling parameter applied.

Here, we investigate the electron-phonon coupling strength in more detail. We describe the interaction of the d- and sp-electrons with the lattice by complete Boltzmann collision integrals and show that the extracted electron-phonon coupling parameters strongly depend on the band occupation. Consequently, we incorporate this aspect into the simulation by assigning different temperatures to these bands and couple them separately to the phonons.

Multi-directional energy transfer across hybrid plasmonic-excitonic interface — •Tommaso Pincelli[1], Thomas Vasileiadis[1], Shuo Dong[1], Samuel Beaulieu[1], Maciej Dendzik[1], Daniela Zahn[1], Sang-Eun Lee[1], Hélène Seiler[1], Yinpeng Qi[1], Rui Patrick Xian[1], Julian Maklar[1], Emerson Coy[2], Niclas S. Mueller[3], Yu Okamura[3], Stephanie Reich[3], Martin Wolf[1], Laurenz Rettig[1], and Ralph Ernstorfer[1] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]NanoBioMedical Centre, Adam Mickiewicz University, Poznan, Poland — [3]Freie Universität Berlin, Berlin, Germany

Hybrid plasmonic devices involve a nanostructured metal supporting localized surface plasmons to amplify light-matter interaction, and a non-plasmonic material to functionalize charge excitations. We combine the use of time and angle-resolved photoemission spectroscopy and femtosecond electron diffraction to investigate charge carrier and phonon dynamics in such a system: epitaxial Au nanoislands on bulk WSe_2. The Au nanostructures show delayed electronic temperature increase and cause a shortening of the Σ-exciton lifetime. Lattice heating is accelerated in WSe_2 and delayed in Au. Our results resolve a multi-directional energy exchange on timescales shorter than the electronic thermalization of the nanometal, driven by a non-linear plasmon-exciton interaction. Non-radiative exciton recombination, electron-phonon coupling, and diffusive charge-transfer determine the subsequent energy backflow.

O 16.8   Mon 17:00   TRE Phy

Electronic hybridization and ultrafast dynamics in Terrylene/WS$_2$ heterostructure. — •Samuel Palato[1], Boubacar Tanda Bonkano[1], Sergey Kovalenko[1], Michele Guerrini[1], Caterina Cocci[2], and Julia Stähler[1] — [1]Humboldt Universität zu Berlin, DE — [2]Carl von Ossietzky Universität Oldenburg, DE

Hybrid organic-inorganic heterostructures offer the possibility of optoelectronic materials with tailored properties. We report on electronic coupling and charge carrier injection in heterostructures formed of terrylene (T) and monolayer WS_2 investigated using steady-state and femtosecond optical spectroscopy.

Terrylene molecules in solution show a typical Frank-Condon transition to a singlet state with a lifetime of 3.7 ns. TD-DFT calculations indicate a transition dipole moment along the long axis of the molecule. In contrast, the spectrum of the T film is complex and implies strong H-aggregation. We assign the dynamics to thermal reorganization of the molecules in the film, giving rise to changes in the magnitude and sign of charge-transfer coupling.

The response of the T/WS_2 hybrid indicates direct hybridization of higher-lying exciton states. Upon excitation of T/WS_2, the transient response is similar to that of WS_2; it suggests direct injection of charge carriers from the organic to the inorganic layer.

The presence of hybrid states and the evidence of direct injection underlines the potential of hybrid organic-inorganic materials with tailored optoelectronic properties.

O 16.9   Mon 17:15   TRE Phy

Ultrafast electron dynamics at D$_2$O/Na$^+$/Cu(111) interfaces — •Florian Kühne[1], Jayita Patwari[1,2], Ping Zhou[1], Karina Morgenstern[2], and Uwe Bovensiepen[1] — [1]Faculty of Physics and Center for Nanointegration (CENIDE), University of Duisburg-Essen — [2]Department of Chemistry and Biochemistry, Ruhr-University Bochum

Ion-solvent interactions and electron transfer across the ion-metal hybrid interfaces are of fundamental interest because of their widespread application in energy storage and energy conversion. We aim to understand the effect of solvation on the elementary processes involved in electrochemical applications by developing a microscopic insight into the hybrid interfaces in presence of a solvent. Electron transfer across such interfaces and the consequent relaxation dynamics are the key microscopic steps behind all these applications which occur on femtosecond time scales. Thus, to experimentally analyze the underly-

ing elementary dynamics, we use femtosecond time-resolved two-photon photoelectron spectroscopy (*tr*-2PPE). We discuss the influence of the solvent at the $D_2O/Na^+/Cu(111)$ interface. We conclude on the local structure - dynamics relation as a function of D_2O coverage from the measured energy transfer rate determined by the transient energy shift of the Na 3s resonance on Cu(111). We analyze furthermore the screening of the excited electron in this resonance by the solvent based on the relaxation time variation with D_2O coverage.

Coupled-cluster theory for complex solids made ready — •Andreas Grüneis — TU Wien, Institute for Theoretical Physics, Wiedner Hauptstraße 8-10/136, 1040 Vienna, Austria
This talk will review recent progress in applying periodic coupled-cluster theory, which has the potential to achieve a systematically improvable level of accuracy, to solids and surfaces. We will discuss novel techniques that reduce the computational cost by accelerating the convergence of calculated properties towards the complete basis set as well as the thermodynamic limit. The newly developed techniques have been implemented in the free and open source simulation software Cc4s that is interfaced to a growing number of widely-used electronic structure theory codes. These developments have enabled an increasing number of ab initio studies and allowed for assessing the level of accuracy of coupled-cluster theory by comparing to experimental findings as well as quantum Monte Carlo results. The presented applications will cover a wide range of materials science problems including the study of phase diagrams, molecule-surface interactions and properties of defects.

Speedup of structural optimisations using hybrid functionals: Case studies for energy materials — •Daniel Fritsch — Weierstrass Institute for Applied Analysis and Stochastics, Mohrenstr. 39, 10117 Berlin, Germany — Helmholtz-Zentrum Berlin für Materialien und Energie, Hahn-Meitner-Platz 1, Berlin, 14109, Germany
First-principles calculations based on density functional theory have been established as de facto standard for computational materials investigations. Depending on the size of the unit cell, for every material of interest a suitable choice for the unknown exchange and correlation functional has to be made; taking not only into account the desired accuracy, but also the available computational resources.

In recent years, a promising combination of two approaches emerged, starting from a structural relaxation based on a simpler (semi)local functional, supplemented by a single shot hybrid functional calculation. Here, we propose a new method for combining different levels of exchange and correlation functional for structural relaxations.

In a first benchmarking step, this new method will be applied to various sets of promising energy materials, where full hybrid functional calculations are available, with a main focus on the performance of this new approach on the structural properties and the required computational resources. In a second step, this new approach will be applied to materials, which up-to-now have not been accessible to hybrid functional calculations due to the required computational resources. All the presented results on the structural, electronic, and optical properties will be critically discussed alongside experimental findings.

O 17.3 Mon 15:45 TRE Ma
All-Electron Large-Scale Hybrid Density Functional Simulations — Florian Merz[1], Andreas Marek[2], •Sebastian Kokott[3], Christian Carbogno[3], Yi Yao[3], Mariana Rossi[4], Markus Rampp[2], Matthias Scheffler[3], and Volker Blum[5] — [1]Lenovo HPC Innovation Center, Stuttgart — [2]Max Planck Computing and Data Facility, Garching — [3]The NOMAD Laboratory at the FHI-MPG and IRIS-Adlershof HU, Berlin — [4]MPI for the Structure and Dynamics of Matter, Hamburg — [5]Duke University, North Carolina, USA
The localized resolution-of-identity approach [1] enables $O(N)$ hybrid density functional simulations and, thus, the computation of accurate electronic properties of large scale atomistic models in the range of ten thousands of atoms in *FHI-aims* [2]. In this range, parallelization and memory requirements of the exact exchange part, and the evaluation of the Hartree potential, remain challenging. The solution of the generalized eigenvalue problem with direct eigensolvers like ELPA [3] naturally becomes a bottleneck due to $O(N^3)$ scaling. In this work, we present recent algorithmic advances for the exact exchange part and the evaluation of the Hartree potential, as well as optimizations of the ELPA library. We systematically perform benchmark tests on CPU and GPU-accelerated architectures covering inorganic solids, large molecules, and organic crystals with up to 50,000 atoms.

A Koopman's compliant exchange correlation potential for semiconductors — •Michael Lorke[1], Peter Deak[2], and Thomas Frauenheim[2] — [1]Institute for Theoretical Physics, University of Bremen, Otto-Hahn-Allee 1, Bremen, 28359, Germany — [2]BCCMS, University of Bremen, Germany
Density functional theory is the workhorse of theoretical materials investigations. Due to the shortcoming of (semi-)local exchange correlation potentials, hybrid functionals have been established for practical calculations to describe surfaces, molecular adsorption, and defects. These functionals operate by mixing between semi-local and Hartree-Fock exchange semi-emprically. However, their parameters have to be optimized for every material separately. To treat materials with a more physics driven approach and without the need of parameter optimization is possible with many-body approaches like GW, but at an immense increase in computational costs and without the access to total energies and hence geometry optimization. We propose a novel exchange correlation potential[1] for semiconductor materials, that is based on physical properties of the underlying microscopic screening. We demonstrate that it reproduces the low temperature band gap of several materials. Moreover it respects the required linearity condition of the total energy with the fractional occupation number, as expressed by the generalized Koopman*s theorem. We also show that this novel functional can be used as a kernel in linear response TDDFT to reproduce excitonic effects in optical spectra [1] Physical Review B 102 (23), 235168 (2020)

O 17.5 Mon 16:30 TRE Ma
Accurate and efficient treatment of spin-orbit coupling via second variation employing local orbital basis functions — •Hannah Kleine[1], Andris Gulans[2], Sven Lubeck[1], Cecilia Vona[1], and Claudia Draxl[1] — [1]Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin — [2]Department of Physics, University of Latvia
Spin-orbit-coupling (SOC) effects can significantly change the properties of materials containing heavy elements, mostly by introducing shifts and splittings in the band structure. Including SOC effects in density-functional-theory (DFT) calculations can be challenging. In the linearized augmented planewaves plus local orbitals (LAPW+LO) method, SOC is treated as a perturbation and solved by a second variational (SV) scheme where eigenvectors of the scalar-relativistic Kohn-Sham Hamiltonian are used as basis functions for the SO-coupled problem. For certain materials, especially those with strong SOC effects, many SV basis functions are required which leads to high computational costs. By adding LOs to the SV basis, we are able to drastically reduce the basis-set size and thus the computational cost. We implement this approach in the all-electron full-potential computer package exciting [1] and combine it with the use of relativistic LOs to achieve high accuracy results for a variety of different materials.

Exact sum-rule approach to polarizability and asymptotic van der Waals functionals – derivation of exact benchmarks — •Alberto Ambrosetti[1], John Dobson[2], Matteo Ricci[1], and Pier Luigi Silvestrelli[1] — [1]Dipartimento di Fisica e Astronomia, Università degli Studi di Padova, via Marzolo 8, 35131, Padova, Italy — [2]Nanoscale Science and Technology Centre, Griffith University, Nathan, Queensland 4111, Australia
Using a sum-rule approach we develop an exact theoretical framework for polarizability and asymptotic van der Waals correlation energy functionals of isolated objects[1]. The functionals require only monomer groundstate properties as input. Functional evaluation proceeds via solution of a single position-space differential equation, without the usual summations over excited states or frequency integrations. Explicit functional forms are reported for reference physical systems, including atomic hydrogen and single electrons subject to harmonic confinement, and immersed in a spherical-well potential. Direct comparison with the popular Vydrov-van Voorhis density functional shows that this performs best when density decay occurs at atomic scales. The adopted sum-rule approach implies general validity of our theory, enabling exact benchmarking of van der Waals density functionals, and direct inspection of the subtle long-range correlation effects that constitute a major challenge for approximate (semi-)local density functionals.

Interacting electrons and bosons in the doubly screened $G\widetilde{W}$ approximation — •Yaroslav Pavlyukh — Department of Theoretical Physics, Wroclaw University of Science and Technology

In Ref. [1] we built on the Generalized Kadanoff-Baym Ansatz for electrons and bosons to map a broad class of nonequilibrium Green's function theories onto a coupled system of ordinary differential equations with linear time-scaling. Available methods to treat e-e correlations include GW [2], T-matrix and Faddeev, while e-b correlations are described by Ehrenfest and second-order diagrams in the e-b coupling [3].

In this work we present a substantial advance in the treatment of correlations, requiring no extra computational cost and preserving all conserving properties. Specifically, we include the effects of dynamical screening due to *both* e-e and e-b interactions ($G\widetilde{W}$ approximation). The $G\widetilde{W}$ extension opens the door to a wealth of phenomena ranging from carrier relaxation and exciton recombination to molecular charge migration and transfer in optical or plasmonic cavities.

CVD growth of 2D transition metal dichalcogenides for electronics and optoelectronics — •Seung Heon Han[1], Ziyang Gan[1], Emad Najafidehaghani[1], Julian Picker[1], Christof Neumann[1], Uwe Hübner[2], Antony George[1], and Andrey Turchanin[1] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena, Jena, Germany — [2]Leibniz Institute of Photonic Technology (IPHT), Jena, Germany

Two-dimensional (2D) transition metal dichalcogenides (TMDs) are of great interest for fundamental science and technology due to their exceptional electronic and photonic properties. Chemical vapor deposition (CVD) is a viable method for scalable growth of high-quality monolayer TMDs on various substrates and with tailored properties. Here, we present some of our recent research results on the CVD growth of 2D TMDs including monolayer single-crystal TMDs, atomically sharp TMD1-TMD2 lateral heterostructure, and TMD1-TMD2 lateral heterostructure alloys. Moreover, we demonstrate various exciting applications of these monolayers in field-effect transistors, high-performance photodetectors and memtransistors.

O 18.2   Mon 18:00   P2/EG

Assembly of van der Waals heterostructures with ultra-clean surfaces for surface science techniques — Keda Jin[1], Tobias Wichmann[1], Felix Lüpke[1], Tomáš Samuely[2], Oleksander Onufrienko[2], F. Stefan Tautz[1], Markus Ternes[1], and •Jose Martinez-Castro[1] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Centre of Low Temperature Physics, Faculty of Science, P. J. Safarik University & Institute of Experimental Physics, Slovak Academy of Sciences, Kosice, Slovakia

Van der Waals heterostructures have become an excellent platform to study emerging physical phenomena that are the result of synergistic proximity effects. Until recently, surface science techniques such as ARPES or STM have been excluded from the study of such heterostructures because of their high sensitivity to surface contamination and the fact that they are sensitive to the top-most layer and thus, not being able to use, boron nitride as the encapsulating layer. Here, we report a novel technique for the assembly of van der Waals heterostructures that do not require encapsulation nor melting of polymers, allowing the study of air-sensitive materials surface. By performing low temperature STM, we demonstrate no surface degradation, achieving atomic resolution as well as detecting a perfectly formed superconducting gap in NbSe2.

Growth and characterization of transition metal dichalcogenides on Au(111) grown by chemical vapor deposition — •Julian Picker[1], Felix Otto[2], Ziyang Gan[1], Maximilian Schaal[2], Marco Gruenewald[2], Christof Neumann[1], Antony George[1], Roman Forker[2], Torsten Fritz[2], and Andrey Turchanin[1] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena, Lessingstraße 10, 07743 Jena, Germany — [2]Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

Transition metal dichalcogenides (TMDs) are layered two-dimensional (2D) materials which have attracted significant attention in recent years. Especially, the exciting properties of their monolayers such as the strong, direct bandgap photoluminescence make them promising for novel electronic and optoelectronic applications. Here, we demonstrate the *ex-vacuo* growth of different TMD monolayers on Au(111) by chemical vapor deposition (CVD). Afterwards, the samples were analyzed in ultra-high vacuum (UHV) with the help of surface sensitive methods, including (low-temperature) scanning tunneling microscopy and spectroscopy (STM/STS), low-energy electron diffraction (LEED), as well as X-ray and angle-resolved ultraviolet photoelectron spectroscopy (XPS/ARPES). While we confirm the formation of high-quality TMDs, we also accessed the structural and electronic properties of these samples down to the atomic scale. In particular, the focus is on the interaction of the TMDs and Au(111) as Au is the most widely used electrical contact material for TMD devices.

O 18.5   Mon 18:00   P2/EG

Unoccupied electronic states of the CDW material 1T-TiSe$_2$ — •Patrick Geers, Marcel Holtmann, and Markus Donath — Universität Münster, Wilhelm-Klemm-Str. 10, 48149 Münster

We present angle-resolved inverse-photoemission (IPE) measurements of the unoccupied electronic structure of the transition metal dichalcogenide 1T-TiSe$_2$. The spectra along the $\overline{\Gamma}\,\overline{M}$ and $\overline{\Gamma}\,\overline{K}$ high symmetry directions are dominated by the Ti-$3d$ bands with rather flat $E(\mathbf{k}_\parallel)$ dispersion. The two energetically separated subgroups e_g and t_{2g} are clearly resolved in the spectra. We observe two e_g bands as expected, while the spectral features of the t_{2g} group are too broad to identify the three predicted states individually. In addition, an image-potential surface state with its free-electron-like dispersion is observed below the vacuum energy. We compare our experimental $E(\mathbf{k}_\parallel)$ results with a theoretical 3D band-structure by estimating the $\mathbf{k}_\perp$-component of the electron wavevector within the nearly-free-electron approximation. Furthermore, we observe temperature-dependent changes in our IPE data that are attributed to the charge density wave phase transition. Interestingly, only bands of t_{2g} symmetry show energy shifts, proving the orbital selectivity of bands involved in the phase transition [1].

Electronic structure of benzene on MoS2 — •Jan-Phillip Topmöller and Michael Rohlfing — Institute of solid state theory, Münster, Germany

TMDCs show great potential in terms of their applicability in optical electronics. Due to their large surface, molecules can easily bind to the TMDC, which might affect its electronic properties. We investigate benzene as such a molecule because it is a small, prototypical one.

We use DFT (LDA, GGA) and DFT-D3 to determine the most stable adsorption position of benzene on MoS2. Subsequently, we use many body perturbation theory to calculate the electronic structure of the adsorbate system and its individual components (MoS2 and the benzene molecule). For example, we find that the HOMO-LUMO of the benzene molecule decreases from 10.5eV by 2.07eV when considering the screening of the monolayer.

O 18.7   Mon 18:00   P2/EG

Evolution of Band structure in 2D transition metal dichalcogenides alloy $Mo_xW_{1-x}Se_2$ — •Sarath Sasi[1], Laurent Nicolaï[1], Lucie Nedvědová[1], Rostislav Medlín[1], Michal Procházka[1], Marie Netrvalová[1], Sunil Wilfred Dsouza[1], Christine Richter[2,3], Karol Hricovini[2,3], and Ján Minár[1] — [1]New Technologies Research Centre, University of West Bohemia, Pilsen, Czech Republic — [2]LPMS, CY Cergy Paris Université, Neuville-sur-Oise, France — [3]Université Paris-Saclay, CEA, CNRS, LIDYL, Gif-sur-Yvette, France

Among two-dimensional (2D) materials that emerged in the research scenario after the discovery of graphene, transition metal dichalcogenides (TMDCs) with the general formula MX_2 (M=Mo, W; X=S, Se, Te) attract huge interest as a potential candidate for electronic and optoelectronic applications. There are many artificial methods to engineer the bandgap and spin-polarized bands, such as chemical doping, external electric field etc. Here we are studying the band structure of $Mo_xW_{1-x}Se_2$ single crystals alloy with various stoichiometric ratio x in comparison with WSe_2. The structural characterisation of samples was analysed using Low energy electron diffraction, Raman Spectroscopy and Scanning Electron Microscopy with Energy Dispersive X-Ray Analysis, X-ray photoemission spectroscopy(XPS). Angle-Resolved Photoemission Spectroscopy (ARPES) was used to investigate the electronic band structure of the samples. We evaluated the band dispersion and observed the bands' splitting at the K point. Thus we are evaluating a potential way for band engineering in TMDCs.

O 18.8   Mon 18:00   P2/EG

Tuning the electronic structure of MoS2: how self-intercalation affects screening, interactions and strain — •Borna Pielić[1,2], Matko Muzevic[3], Dino Novko[2], Jiaqi Cai[1], Alice Bremerich[1], Robin Ohmann[1], Marko Kralj[2], Iva Srut Rakic[2], and Carsten Busse[1] — [1]Department Physik, Universitat Siegen, Siegen, Germany — [2]Institute of Physics, Zagreb, Croatia — [3]Department of Physics, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia

Growth of quasi-freestanding 2D materials on van der Waals (vdW) typed substrates can be accompanied by intercalation in order to modify their intrinsic properties. In this work, we epitaxially grow MoS2 monolayer islands on graphene on Ir(111) using two different procedures: (i) two-step molecular beam epitaxy (MBE) growth which results in S intercalation between graphene and Ir(111), and (ii) single-step MBE growth resulting in Mo intercalation. Scanning tunneling microscopy (STM) measurements reveal significant difference in MoS2 islands morphology, and suggests that S intercalation weakens the interaction in the MoS2/graphene stack, while Mo intercalation strengthens it. More importantly, our scanning tunneling spectroscopy (STS) measurements show notable non-rigid shifts of electronic states. The numerical calculations reveal a strong correlation between substrate screening, strain and binding energy, that are in line with experiment. We suggest that this elegant and non-invasive technique could in general be used for altering vdW, electron-electron and electron-phonon interactions in 2D materials.

O 18.9   Mon 18:00   P2/EG

Designing a symmetry-correct minimal model for $2H$-WSe$_2$ — •Max Xylander[1,2], Philipp Eck[1,2], Simon Moser[2,3], Lukasz Plucinski[4], and Giorgio Sangiovanni[1,2] — [1]ITPA, Universität Würzburg, Germany — [2]Würzburg-Dresden Cluster of Excellence, ct.qmat — [3]EP4, Universität Würzburg, Germany — [4]PGI-6, Peter Grünberg Institut Jülich, Germany

Transition metal dichalcogenides (TMDCs) have been studied for their structure-dependent valley physics. Due to inversion symmetry breaking in combination with strong SOC originating from the transition metal d-shell, these materials posess momentum-dependent spin splitting. Recently, the interest in TMDCs has been further stimulated by twisted moiré lattices, where the emerging flat bands have been associated to chiral representations in twisted bilayer graphene.

Here we present a study on the chiral wavefunctions in $2H$-WSe$_2$ based on *ab initio* calculations and minimal modeling. Especially, we will focus on an analysis of the irreducible representations, which allow us to design a minimal d-orbital tight-binding Hamiltonian with SOC and inversion symmetry breaking terms. For the validation of the model, we plan further experimental studies with circularly polarized light angle-resolved photoemission.

O 19: Poster: Ultrafast Electron Dynamics at Surface and Interfaces I

O 19.1   Mon 18:00   P2/EG

Ultrafast transport and energy relaxation of hot electrons on tmdc/au/fe/mgo(001) investigated by time resolved photoelectron spectroscopy — •Florian Kühne[1], Jesumony Jayabalan[1], Ping Zhou[1], Detlef Diesing[2], Stephan Sleziona[1], Marika Schleberger[1], and Uwe Bovensiepen[1] — [1]Faculty of Physics and Center for Nanointegration, University of Duisburg-Essen — [2]Faculty of Chemistry, University of Duisburg-Essen

Optically excited electrons are of particular interest in solid state physics because analysis of their dynamics allows an understanding of the microscopic interactions. Excited charge carriers in metals and semiconductors relax on a femto- to picosecond timescale due to electron-electron and electron-phonon scattering. Using a back-side pump geometry in time-resolved photoelectron spectroscopy (PES), see Kühne *et al.*, PRR **4**, 033239(2022), and Beyazit *et al.*, PRL **125**, 076803(2020), we demonstrated the analysis of hot electron transport through metallic heterostructures Au/Fe/MgO(001). By pumping the Fe side by femtosecond laser pulses, hot electrons are excited in the Fe layer and injected into the Au layer. They subsequently propagate to the surface, where they are probed by PES. This work aims to employ these heterostructures as electrodes for photo-excited electrons which are injected into transition metal dichalcogenides. Thereby we aim at an analysis of scattering and propagation of electrons through 2D material layers discerning local and non-local effects. Funding by the DFG through Project No. 278162697 - SFB1242 is gratefully acknowledged.

T-ReX: a facility for time-resolved optical and angle-resolved photoemission spectroscopies — •Wibke Bronsch[1], Denny Puntel[2], Manuel Tuniz[2], Fulvio Parmigiani[1,2], and Federico Cilento[1] — [1]Elettra-Sincrotrone Trieste, Trieste, Italy — [2]Università degli Studi di Trieste, Trieste, Italy

The T-ReX laboratory at FERMI, Elettra-Sincrotrone Trieste, is a user facility for ultrafast table-top time-resolved spectroscopies [1-3]. Our facility comprises a number of time-resolved optical spectroscopy (TR-OS) setups and an endstation for time- and angle-resolved photoemission spectroscopy (tr-ARPES). The latter is connected to diverse table-top laser sources, allowing for probe energies ranging from 6 to 30 eV. In order to show how the complementarity of these setups can be beneficial for gaining more comprehensive insights on a sample system, we will present our recent experiments on the charge-density-wave materials VTe2 and VSe2, shedding light on phonon dynamics and electronic structures of the samples under investigation.

Excited state photoemission momentum maps from time-dependent density functional theory — •Melvin Hodžić, Christian S. Kern, Andreas Windischbacher, and Peter Puschnig — Institute of Physics, NAWI Graz, University of Graz, Austria

Angle-resolved photoemission spectroscopy is a powerful experimental technique to reveal the electronic structure of thin films and interfaces. In particular, constant binding energy angular distributions, so called momentum maps, have been shown to be related to the Fourier transform of the electron-emitting initial state molecular orbital, thereby bridging experiment and theory in photoemission orbital tomography (POT). The extension of POT to optically excited states has, of late, been demonstrated via a femtosecond pump-probe setup, paving the way for tracing the momentum distribution of electrons on ultrafast time scales. However, linking the measured momentum maps to the spatial structure of the exciton wave functions has yet to be achieved. We propose a simple procedure which involves a coherent sum of the ground-state Kohn-Sham orbitals that construct the exciton wave function. Here, we validate this approach by solving Casida's equation for a series of organic molecules in the gas phase leading to optical absorption spectra and exciton compositions. With the gained information, momentum maps obtained via linear-response TDDFT are cross-checked by directly simulating angle-resolved photoemission spectra within the framework of real-time TDDFT. To this end, we record the flux of the emitted electrons through a detector surface.

O 19.4   Mon 18:00   P2/EG

Ultrafast all-optical manipulation of the charge-density-wave in VTe2 — •Manuel Tuniz[1], Wibke Bronsch[2], Denny Puntel[1], Davide Soranzio[3], Davide Bidoggia[1], Steven Johnson[3], Maria Peressi[1], Fulvio Parmigiani[1,2], and Federico Cilento[2] — [1]Dipartimento di Fisica, Università degli Studi di Trieste, Italy — [2]Elettra - Sincrotrone Trieste S.C.p.A., Italy — [3]Institute for Quantum Electronics, ETH Zurich, 8093 Zurich, Switzerland

By means of broadband time-resolved optical spectroscopy (TR-OS) we investigated the ultrafast reflectivity changes caused by collective and single particle excitations in the charge-density wave (CDW) system VTe2. This material has been recently subject of investigation since the modifications in its electronic structure triggered by the CDW formation are strongly orbital-dependent and

may give rise to a topological change in specific bands [1]. In our contribution, we show by means of TR-OS measurements the possibility to optically excite the amplitude mode (AM) of the CDW phase and therefore couple to the CDW condensate [2]. Moreover, through double pump experiments, we show the possibility to control the intensity and the phase of the amplitude mode of the system.

Modification of the ultrafast charge carrier dynamics in a molecule/TMDC heterostructure — •SEBASTIAN HEDWIG[1], MATTHIAS RÜB[1], BENITO ARNOLDI[1], KAI ROSSNAGEL[3,4], BENJAMIN STADTMÜLLER[1,2], and MARTIN AESCHLIMANN[1] — [1]Department of Physics, University of Kaiserslautern and Research Center OPTIMAS, 67663 Kaiserslautern, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany — [3]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24118 Kiel, Germany — [4]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany

Tailoring the properties of layered van der Waals materials is one of the most intriguing challenges in the field of 2D materials. While for transition metal dichalcogenides (TMDCs) this is mainly achieved by the formation of heterostructures with other 2D materials, our approach is to functionalize the properties of TMDCs by the adsorption of molecular films. Here we present our recent fs-time-resolved optical-pump XUV-probe ARPES experiments on a C_{60}/TiSe$_2$ heterostructure. TiSe$_2$ was selected since it can host a charge density wave phase at low sample temperature that can be melted by fs pulses [1]. We find a clear modification of the optically induced phase transition dynamics from the CDW into the semi-metallic phase. This observation is discussed in the light of interactions and the interfacial charge carrier dynamics at the C_{60}/TiSe$_2$ interface.

O 19.6　Mon 18:00　P2/EG

Analysis of Nonlocal Correlations in $1T$-TaS$_2$ Driven Out of Equilibrium — •JESUMONY JAYABALAN[1], FLORIAN K. DIEKMANN[2], PING ZHOU[1], KAI ROSSNAGEL[2], and UWE BOVENSIEPEN[1] — [1]Fakultät für Physik, Universität Duisburg-Essen, Germany — [2]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, Germany

Driving correlated materials out of equilibrium on ultrafast time scales can provide information about the correlation phenomena and their complex free energy landscapes. Time- and angle-resolved photoemission spectroscopy provided access to the ultrafast dynamics of Doublons [Ligges et al., PRL 120, 166401 (2018)] and concluded on presence of empty and doubly occupied sites at few tens of femtosecond timescales which match calculated spectra with 5% static hole doping. Thus the doublon decay was concluded to be mediated in $1T$-TaS$_2$ by the presence of holes. We propose experiments aimed at a doping dependent relaxation dynamics measurements that would reveal the role of screening and charge excitations on such photo-induced states. Two different approaches will be used for doping: 1) $1T$-TaS$_2$ crystals are grown by Ta substitution to induce a less than half filled band and hole doping and 2) surface doping by adsorption of alkali adsorbates on the cleaved $1T$-TaS$_2$ surface. Such doping depending studies at the timescale of the charge density wave amplitude mode potentially allow to examine the role of strong correlations in the coupled electron-lattice dynamics of $1T$-TaS$_2$ as well as possibilities to control two-dimensional correlated surfaces via photo excitation of the substrate.

O 19.7　Mon 18:00　P2/EG

Disentangling HOMO and LUMO excitation in momentum space by means of time-resolved photoemission orbital tomography — ALEXA ADAMKIEWICZ[1], MIRIAM RATHS[2], •MARCEL THEILEN[1], MONJA STETTNER[2],

SABINE WENZEL[2], MARK HUTTER[2], SERGEY SOUBATCH[2], CHRISTIAN KUMPF[2], FRANCOIS C. BOCQUET[2], ROBERT WALLAUER[1], F. STEFAN TAUTZ[2], and ULRICH HÖFER[1] — [1]Philipps-University Marburg, Germany — [2]Peter Grünberg Institute (PGI-3), Jülich Research Centre, Germany

Time-resolved photoemission orbital tomography allows to trace electron dynamics in momentum space by measuring the angle-resolved photoemission intensity on an ultrafast timescale. For molecule-metal interfaces it proved to be a powerful technique to investigate the population dynamics of molecular states [1]. Here, we find for a well-ordered monolayer of CuPc on Cu(001)-2O a delay-dependent change in the momentum pattern of the molecular LUMO. In addition, we show how the temporal evolution of the momentum distribution can be systematically disentangled from contributions of the projected HOMO by varying the pump photon energy and polarization. By aligning the polarization of the pump pulse along the molecular axis of CuPc molecules, we are able to selectively excite molecules of a specific orientation. The temporal evolution of the excitation and decay from the LUMO can be well described by solving the optical Bloch equations for a three-level system.

O 19.8　Mon 18:00　P2/EG

Spin- and valley-dependent charge carrier dynamics in a WSe$_2$ bulk crystal — •GREGOR ZINKE[1], SEBASTIAN HEDWIG[1], BENITO ARNOLDI[1], MARTIN AESCHLIMANN[1], and BENJAMIN STADTMÜLLER[1,2] — [1]Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, 67663 Kaiserslautern, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany

The intriguing spin functionalities of transition metal dichalcogenides such as WSe$_2$ are rooted in the spin- and valley-degrees of freedom. These are responsible for the particular spin-texture of TMDCs as well as the helicity- and valley-dependent light absorption. However, despite the clear understanding of the initial spin-and valley-dependent light-matter interaction, a clear picture of the spin-dependent intra- and intervalley scattering of electrons and holes is still elusive. Here, we focus on the ultrafast carrier dynamics in a bulk crystal of WSe$_2$. Using spin-, time- and angle-resolved photoemission with XUV-radiation, we simultaneously image the temporal evolution of the excited carriers in the conduction band as well as the corresponding hole dynamics within the valence band on a fs timescale. The spin-polarization of the initially excited carriers is controlled by the helicity of the optical excitation. We will show clear changes of the spin-polarization of the excited electrons after intra-band scattering from the K- to the Σ-point, and discuss these results in regards to the influence of electron-electron and electron-phonon scattering for the spin-polarized electron population in the conduction band.

Ultrafast dynamics of CT excitons in 2d heterostructures investigated with SHG imaging microscopy — •MARLEEN AXT, JONAS E. ZIMMERMANN, GERSON METTE, and ULRICH HÖFER — Fachbereich Physik, Philipps-Universität Marburg, Germany

The exciton dynamics in vertically stacked TMDC heterostructures can be modified by variation of the twist angle between the two layers. Using time-resolved second hamornic (SH) imaging microscopy we observe the ultrafast formation of charge transfer (CT) excitons in micrometer-sized MoS$_2$/WSe$_2$ heterostructures with different stacking angles. We make use of the strong anisotropy of the nonlinear SH response to selectively probe the carrier dynamics in individual layers of the system. For misaligned layers with a stacking angle of 16° the formation of CT excitons takes place within 85 fs after resonant excitation of the WSe$_2$ A excition. In contrast, an alignment close to 2H stacking (52°) leads to an enhanced electronic coupling between the layers resulting in a much faster CT exciton formation time of only 12 fs. Moreover, different formation and relaxation pathways are identified depending on the pump-photon energy.

Aging behavior in a self-induced spin glass — LORENA NIGGLI, •JULIAN H. STRIK, ANAND KAMLAPURE, MIKHAIL I. KATSNELSON, DANIEL WEGNER, and ALEXANDER A. KHAJETOORIANS — Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands

Elemental neodymium has been shown to be a so-called self-induced spin glass, which, unlike conventional spin glasses, shows glassy behavior solely from frustrated magnetic interactions and in the absence of disorder [1]. Additionally, in contrast to most conventional spin glasses, neodymium has a disorder to order transition. As the temperature increases it goes from the self-induced spin glass phase to a multi-Q long range ordered phase resulting from competing long-

range interactions on different length scales [2]. This disorder to order transition might have profound effects on the metastable states and aging dynamics in the low temperature phase. In this study, we use spin-polarized scanning tunneling microscopy combined with varying external magnetic fields to investigate the aging dynamics in the spin glass phase, and quantify this in terms of the various local spin-spin correlations (Q-states) observed. These observations may have interesting implications on the aging behavior in self-induced spin glasses, which might differ from conventional spin glasses.

Tuning the frequency response of stochastically switching orbital states of Fe and Co atoms on black phosphorus — •Kira Junghans, Hermann Osterhage, Werner M. J. van Weerdenburg, Niels P. E. van Mullekom, Ruben Christianen, Eduardo J. Domínguez Vázquez, Hilbert J. Kappen, and Alexander A. Khajetoorians — Radboud University, Nijmegen, The Netherlands

The concept of the atomic Boltzmann machine (BM) is based on the recently discovered idea of orbital memory [1,2]. Orbital memory is characterised by two stable valency configurations [2,3]. By applying a bias voltage to a scanning tunneling microscopy (STM) tip above a threshold, stochastic switching between the states can be induced. The favorability of the individual states depends strongly on the applied bias voltage.

Unlike coupled spins under exchange, leading to bistability, coupled atoms that exhibit orbital memory show multi-stability in their stochastic dynamics. This multi-well energy landscape serves as a basis for the BM and realizing multiple time scales.

Here, we show that single Fe and Co atoms respond frequency and amplitude dependent to an AC component of the applied bias. In addition, we present how the stochastic behavior of coupled atoms in the multi-well regime respond to a harmonic drive voltage.

Development of a gate-tunable graphene substrate for spins on surfaces — •Paul Greule[1], Máté Stark[1], Wantong Huang[1], David Collomb[1], Daria Sostina[2], Christoph Sürgers[1], Wolfgang Wernsdorfer[1], and Philip Willke[1] — [1]Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Institute of Quantum Materials and Technologies (IQMT), Karlsruhe Institute of Technology, Karlsruhe, Germany

Single spins on surfaces constitute a promising architecture for future quantum technologies as quantum sensors and possible qubits for quantum information processing. The recent combination of electron spin resonance (ESR) and scanning tunneling microscopy (STM) emerges as a new technique to coherently manipulate spin states on a single atom level [Y. Chen et al., Adv. Mater. 2022, 2107534]. Nevertheless, this architecture does not provide yet any method to continuously tune the coupling between single electron spins. Here, we want to introduce graphene field-effect transistors as a new substrate for ESR-STM on single molecules. Gated graphene devices enable tuning of the charge carrier density of the substrate as already shown by means of scanning tunneling spectroscopy (STS) [Y. Zhang et al., Nature Phys. 5, 722-726 (2009)]. This constitutes a promising way to manipulate the substrate-mediated exchange coupling between single spin centers. We present the development of gated graphene devices for STM using single layer graphene. Moreover, we characterize the samples with in-situ transport measurements and show first topographic and spectroscopic STM measurements.

O 20.4　Mon 18:00　P2/EG

Magnetic phase diagram of a YSR-molecule — •Benjamin A. Verlhac[1], Niels van Mullekom[1], Werner M.J. van Weerdenburg[1], Hermann Osterhage[1], Manuel Steinbrecher[1], Katharina J. Franke[2], and Alexander A. Khajetoorians[1] — [1]Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands — [2]Fachbereich Physik, Freie Universität Berlin, Germany

Yu-Shiba-Rusinov (YSR) states arise from the exchange coupling between a local spin and a superconductor. However, characterizing this exchange interaction, related to Kondo screening, requires a study in magnetic field to understand its interplay with other energy scales, as well as the role of higher spin degrees of freedom. To date, most studies of YSR states have been limited to bulk superconductors, which easily quench in the presence of modest magnetic fields. Here, using high resolution milliKelvin scanning tunneling microscopy and spectroscopy, we characterize the magnetic phase diagram of a molecule on the surface of a thin film superconductor. We observe non-trivial changes in the YSR excitations in applied magnetic field, that cannot be described by the prototypical spin 1/2 model. These variations occur while the superconducting gap remains robust. We relate the changes to the various properties of the molecule, including the role of multiple channels and magnetic anisotropy. We additionally propose a model to understand the various behaviors in the excitation. These results provide an in-depth and detailed approach to understand the role of high spin systems in the presence of Kondo and YSR states.

Electronic Structure of Chromium(II)-Bromide Islands on Niobium Diselenide — •Xianzhe Zeng[1], Haonan Huang[1], Sujoy Karan[1], Klaus Kern[1,2], and Christian Ast[1] — [1]Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany — [2]Institut de Physique, Ecole Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland

Chromium(II) bromide is an inorganic two-dimensional (2D) van der Waals material. With molecular-beam epitaxy (MBE), superconducting islands can be formed after evaporating chromium(II) bromide onto a niobium diselenide substrate. Measurements have been conducted on the islands and at the edge of the islands with low-temperature scanning tunneling microscopy and spectroscopy. At the edge of the islands, a subgap peak could be identified from the dI/dV spectrum, suggesting the existence of an in-gap state. Our discovery is the first observation in the chromium(II) bromide-niobium diselenide heterostructure system, providing an interesting comparison with the reported Majorana zero energy mode at the edge of chromium(III) bromide islands growing on the same substrate.

Josephson diode effect due to single magnetic atoms — Martina Trahms[1], Larissa Melischek[2], Jacob F. Steiner[2], •Bharti Mahendru[1], Idan Tamir[1], Nils Bogdanoff[1], Olof Peters[1], Gaël Reecht[1], Clemens B. Winkelmann[3], Felix von Oppen[2], and Katharina J. Franke[1] — [1]Fachbereich Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany — [2]Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany — [3]Université Grenoble Alpes, CNRS, Institut Neél, 25 Avenue des Martyrs, 38042 Grenoble, France

Properties of Cooper-pair tunneling through a Josephson junction can be described by the phase difference between two superconductors. In a current-biased Josephson junction, the phase dynamics can be accessed via switching and retrapping currents. Here, we investigate Josephson junctions formed by a superconducting Pb tip and a Pb surface in a scanning tunneling microscope. While pristine Pb-Pb junctions are hysteretic but symmetric in the biasing direction, we observe asymmetric retrapping currents in the presence of single magnetic atoms placed in the junction. The behavior thus mimics diode properties in the retrapping current. We model the phase dynamics of these junctions by an extended resistively and capacitively shunted Josephson junction (RCSJ). We find the asymmetric retrapping current originates in a non-ohmic dissipative channel due to the particle-hole-symmetry-broken Yu-Shiba-Rusinov (YSR) states. By investigating different magnetic adatoms on different Pb surfaces, we carve out a general relation of asymmetric YSR states and asymmetric retrapping currents.

Organometallic sandwich complexes as model spin 1/2 impurities on superconductors — •Adithya Sadanandan[1], Lukas Arnhold[1], Nicolaj Betz[1], Andrea L Sorrentino[2], Giulia Serrano[2], Roberta Sessoli[2], Susanne Baumann[1], and Sebastian Loth[1] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — [2]University of Florence, Department of Chemistry 'Ugo Schiff', INSTM Research Unit, Florence, Italy

Self-assembled layers of organometallic sandwich complexes containing transition metal atoms enable selective control of the spin delocalization and hybridization of the molecules with the electron bath of surfaces [1,2]. We study small self-assembled rafts of [CpTi(cot)] sandwich complexes on epitaxial Pb islands on Si(111). [CpTi(cot)] features a single electron in the d orbitals and long coherence times in solution [2] making it an interesting candidate for molecular qubits and a well-defined spin 1/2 system. Using low temperature scanning tunnelling microscopy (STM) we find weakly bound Yu-Shiba-Rusinov states (YSR) in the superconducting gap and a crossover between Kondo screening and spin excitations when superconductivity is quenched by a magnetic field. The simple level structure of [CpTi(cot)] makes it possible to model this system with an Anderson impurity model [3] and deduce the dynamics of the YSR states.

O 20.8　Mon 18:00　P2/EG

Electrospray deposition for STM sample preparation in UHV — •Caroline Hommel, Lukas Spree, Dasom Choi, Luciano Colazzo, and Andreas Heinrich — Center for Quantum Nanoscience, 52 Ewhayeodae-gil, Daehyeon-dong, 03760 Seoul, South Korea

Lanthanide single molecule magnets are promising materials for future spintronics applications, such as ultrahigh density memory devices. Using several methods, we have succeeded in synthesizing different double-decker phthalocyanine complexes (M-Pc$_2$; M = Y, Er, Tb) and depositing them on a metal substrate in ultra-high vacuum (UHV) for scanning tunneling microscopy (STM) analysis. Due to their flat geometry they are very well suited for surface deposition. Based on the very well-known chemical properties of the phthalocyanine ligands, it is possible to functionalize them for various purposes. M-Pc$_2$ form ordered structures on the surface, which could be further enhanced by long chain alkane groups on the phthalocyanine ligands. However, such large organic molecules cannot be sublimated without fragmentation. Using electro spray deposition (ESD), thin films of thermally unstable molecules can be deposited directly in UHV. Various parameters, such as pressure, time, and solvent

play a role in this process. The influence of the parameters on the deposition will be investigated for M-Pc$_2$ molecules and their chemical derivatives.

O 20.9 Mon 18:00 P2/EG

Scanning tunneling spectroscopy of a spin-crossover complex on a superconductor — •Marten Treichel[1], Florian Gutzeit[2], Jan Homberg[1], Rainer Herges[2], Richard Berndt[1], and Alexander Weismann[1] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, Kiel, Germany — [2]Otto-Diels-Institut für Organische Chemie, Christian-Albrechts-Universität zu Kiel, Kiel, Germany

A spin-crossover complex based on Ni-porphyrin is studied on superconducting Pb(100) using scanning tunneling spectroscopy at 0.3 K. A pronounced molecule-induced surface faceting is found with molecular chains located at multiple substrate steps. The step orientations deviate from the high-symmetry directions of the substrate and appear to be imposed by molecular interactions. Monatomic substrate steps remain undecorated. Conductance spectra reveal spin-flip excitations with clear spatial variations. The data suggest that neighbor molecules are rotated by 90° with respect to each other. We find that an $S = 1$ quantum spin model with the hard axis tilted away from the surface normal reproduces spectra measured in magnetic fields up to 9 T.

O 20.10 Mon 18:00 P2/EG

Strong exchange interaction between open-shell nanographenes and TbAu2 — •Nicolò Bassi[1], Feifei Xiang[1], Jan Wilhelm[2], Roman Fasel[1], and Pascal Ruffieux[1] — [1]Empa-Swiss Federal Laboratories for Materials Science and Technology, Dübendorf, Switzerland — [2]Institute of Theoretical Physics, University of Regensburg, Regensburg, Germany

Rare-earth intermetallic compounds belong to a family of novel substrates, which is becoming a promising platform to control properties of nanomaterials via specific surface-adsorbates interactions. Different combinations, including GdAu2(1), LaAu2(2) and TbAu2(3),have been so far studied. They are all characterized by a ordered hexagonal superstructure with similar lattice constants. Here, we investigate various open-shell nanographenes on TbAu2 alloy by means

of STM and STS combined supported by ab inito simulation. For on surface synthesized 7-AGNRs, we find that the predicted spin properties of the end states are indeed conserved on TbAu2. Here, 7-AGNRs are uncharged and the occupied and unoccupied end states have a spin polarization-induced energy splitting of 1.4 eV. In addition, we investigated phenalenyl, the smallest open-shell molecule with spin S = 1/2, at monolayer coverage. Low bias spectroscopy reveals a splitting of the peak of more than 20 mV, which we assign to the exchange interaction between the molecular spin and Tb atoms of the surface layer. These results open new perspectives for studying different open-shell molecules on a magnetic substrate.1 ACS Nano 4, (2010). 2 Phys. Rev. B 88, 125405 (2013). 3 J. Phys. Chem. Lett. 11, (2020).

O 20.11 Mon 18:00 P2/EG

Observation of in-gap states on 4f-shell magnet-superconductor hybrid system — •Yu Wang, Felix Friedrich, Artem Odobesko, and Matthias Bode — Physikalisches Institut, Experimentelle Physik II, Universitaet Wuerzburg, Am Hubland, D-97074 Würzburg, Germany

Magnetic impurities assembled on s-wave superconductor are the prototypical system for the realization of MZMs at the chain ends. Particularly the magnet-superconductor hybrid system of one-dimensional magnetic chains on superconductors has been well demonstrated theoretically and experimentally. Nowadays, various 3d-shell transition metals (Cr, Mn, Fe, Co, Ni) on clean Nb (110) have been studied [1-3]. Among them, only Mn and Fe chains exhibits benchmarks of topological superconductivity with MZMs at the chain ends. In addition to 3d-shell metals as magnetic impurities, 4f-shell magnetic metals could be another option. Among them, Gd shows the highest potential because it has the highest magnetic moment (s = 7/2) in 4f-shell. In this study, we will show that Gd dimers on Nb (110) behave similar as Fe/Mn with two pairs of in-gap states. It could be possible to realize MZMs on Gd chain ends in the future.

O 21.1 Mon 18:00 P2/EG

Shot-noise measurements of single-atom junctions using a scanning tunneling microscope — •Verena Caspari, Idan Tamir, Daniela Rolf, Christian Lotze, and Katharina J. Franke — Fachbereich Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany

Current passing through small constrictions fluctuates due to the discreteness of charge. Measuring this so-called shot noise in atomic-scale superconducting junctions can provide valuable information, from the quanta of charge transferred in the tunneling process to the correlations of the involved tunneling channels. Here, we use a scanning tunneling microscope equipped with a high-frequency, low-temperature amplifier to measure simultaneously the noise characteristics and the differential conductance of two types of Pb-Pb-junctions having different geometries. The first type is created by deposition and approaching single Pb adatoms, while the second type is established by a break-junction technique. We observe a correlation between the noise pattern and the strength of the Josephson current, independent on the method of junction preparation.

O 21.2 Mon 18:00 P2/EG

A second generation millikelvin scanning tunneling microscope with adiabatic demagnetization refrigeration — Taner Esat[1,2], •Denis Krylov[1], Peter Borgens[1,3,7], Xiaosheng Yang[1,3], Peter Coenen[1,4], Vasily Cherepanov[1,4], Andrea Raccanelli[5,7], F. Stefan Tautz[1,2,3], and Ruslan Temirov[1,6] — [1]Peter Grünberg Institute (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Jülich Aachen Research Alliance, Fundamentals of Future Information Technology, 52425 Jülich, Germany — [3]Experimentalphysik IV A, RWTH Aachen University, 52074 Aachen, Germany — [4]mProbes GmbH, 52428 Jülich, Germany — [5]Cryovac GmbH & Co KG, 53842 Troisdorf, Germany — [6]Faculty of Mathematics and Natural Sciences, Institute of Physics II, University of Cologne, 50937 — [7]Current address: Peter Grünberg Institute (Cryo-Lab), Forschungszentrum Jülich, 52425 Jülich, Germany

We present the design of a second generation ultra-high vacuum scanning tunneling microscope (STM) that uses adiabatic demagnetization of electron magnetic moments for controlling its operating temperature down to 30 mK. A high degree of vibrational decoupling promises an outstanding mechanical stability, demonstrated by the first generation of this instrument. Additionally, high frequency cables were implemented in the design in order to enable electron spin resonance experiments.

O 21.3 Mon 18:00 P2/EG

atomic friction on TaS2 over a phase transition — •Yiming Song[1], Dirk Dietzel[1,2], and Andre Schirmeisen[1,2] — [1]Institute of Applied Physics (IAP), Justus-Liebig-Universität Gießen, 35392 Gießen, Germany — [2]Center for Materials Research, Justus-Liebig-Universität Gießen, 35392 Gießen, Germany

Friction force microscopy experiments were performed on tantalum disulfide (TaS2) surfaces as a function of temperature over the phase transition from nearly commensurate charge density wave (NCDW) phase to commensurate CDW phase. A giant frictional peak at the temperature of 187 K which separates CCDW and NCCDW phases when the sample is cooled down is observed. This behavior was investigated in detail by comparing atomic stick-slip motion of the single asperity AFM tip over phase transition. The hysteresis of the first order structural transformation is revealed in stick-slip behaviors during the heating up procedure as well. Besides, the load and velocity dependence of friction on TaS2 surface in CCDW and NCCDW phases have been revealed.

O 21.4 Mon 18:00 P2/EG

Design of a compact dilution refrigerator integrated in a dry mK UHV STM — •Michael Temmen, Simon Gerber, Michael Meyer, and Wulf Wulfhekel — Physikalisches Institut, Karlsruher Institut für Technologie, Karlsruhe, Deutschland

As energy and helium prices are rising we decided to design a new dry, low temperature Scanning Tunneling Microscope with a compact, low ^{3}He volume dilution refrigerator as the main innovation. Special focus was set on the heat exchanger between the still and the mixing chamber as one of the most crucial parts of the system. Next to the standard solution of a tube-in-tube heat exchanger, a new concept of a heat exchanger consisting of two laser cut metal sheets with deep drawn profiles acting as the channels for the Helium and a plain sheet in the middle as a divider is developed. In order to improve heat transfer while keeping the volume minimal, the surface area is increased by electrodeposition of three dimensional porous silver foam. Comparing this concept with the standard solution, an increase in surface area by a factor of 10 could be achieved with a reduction in ^{3}He volume in the exchanger by a factor of 10. The dilution refrigerator is integrated in a small scale cryostat with a closed helium cycle cooled by a pulse tube with a cooling capacity of 400 mW. The complete dilution refrigerator, cryostat and the STM are home-built.

O 21.5   Mon 18:00   P2/EG

Electromagnetic Field Mapping in Plasmonic Nanostructures using Momentum-Resolved Electron Energy-loss Spectroscopy — •Johannes Schultz[1], Jonas Krehl[1], Giulio Guzzinati[2], and Axel Lubk[1,3] — [1]Leibniz-Institut für Festkörper- und Werkstoffforschung Dresden e. V., Helmholtzstraße 20, 01069 Dresden — [2]EMAT, University of Antwerp, Groenenborgerlaan 171, 2020 Antwerp — [3]Institute of Solid State and Materials Physics, Haeckelstraße 3, 01069 Dresden

Localized surface plasmons (LSPs) are collective oscillations of charge carriers arising at interfaces between media of opposite sign of the dielectric functions. Here, spatial confinement of the LSPs, e.g. in nanoparticles (NPs), may lead to enhanced electromagnetic (e.m.) fields of the LSPs due to resonance. This effect is exploited in several application, e.g., surface enhanced Raman spectroscopy. To characterize the e.m. fields scanning transmission electron microscopy in combination with electron energy loss spectroscopy is a frequently used technique due to its high spectral and spatial resolution. Here, the energy loss of the beam electrons (caused by the electric field component of the LSPs parallel to the beam) is measured at different probe positions. This technique has been generalized to additionally probe in-plane field components by measuring the deflection of the beam electrons from their initial trajectory. To that end spectrally resolved deflection maps (so-called $\omega - q$ maps) are recorded at different probe positions which opens up new capabilities to e.g., probe magnetic field contributions of the LSPs at highest spectral and spatial resolution.

O 21.6   Mon 18:00   P2/EG

SpmImage Tycoon: Organize scanning probe microscopy data — •Alexander Riss — Physics Department E20, Technical University of Munich, D-85748 Garching. Germany

The evolution of the field of scanning probe microscopy (SPM) has been associated with development of instrumental capabilities and methods for data acquisition and analysis. However, much less emphasis has been placed on improving the management and organization of the measured datasets. And while datasets can consist of thousands of images and spectra per project, it is not uncommon for researchers to go through each image or spectrum and manually select the channels of interest for each one — only to repeat the same procedure every time they want to analyze their data again.

Here we present a cross-platform application that is designed for fast and effortless organization and basic editing of scanning probe microscopy images and spectra [1]. The application is released under an open-source license and supports automatic channel-of-interest detection, image editing (such as background corrections and contrast adjustment), keywording, star-ratings, powerful search and filtering (e.g., by keywords, data type, location, scan size), as well as export of the data into a PowerPoint-compatible presentation format.

Such easy-to-use tools can lower the entry barrier for aspiring scientists, boost the efficiency of experienced researchers, and help to create and leverage large SPM datasets for machine learning and artificial intelligence applications.

[1] A. Riss. JOSS 7, 4644 (2022)

Electric field control of spin transitions in a dimer system using ESR-STM — •Maneesha Ismail[1], Piotr Kot[2], Janis Siebrecht[1], Haonan Huang[1], and Christan R. Ast[1] — [1]Max-Planck-Institute for Solid State Research, Heisenbergstr. 1, 70569 Stuttgart, Germany — [2]Center for Quantum Nanoscience, Institute for Basic Science, Seoul 03760, Republic of Korea

Since the demonstration of the control of spins on the atomic scale, the technique of ESR-STM has been used extensively to explore the field of spintronics. Here, we present a new approach to ESR-STM which uses the bias voltage as a parameter to tune the energy of the Zeeman transition. We demonstrate electronic control of spin resonance transitions in a single molecule. We could observe a strong dependency of the g-factor and tip-field shift on the electric field. Finally, we demonstrate an avoided crossing in the energy levels of a dimer as a function of bias voltage, which corresponds to an entangled state. This could be an important step towards quantum computations as they rely on entanglement opening a more coherent and easier method of electronic spin control.

O 22: Poster Session: Organic Molecules on Inorganic Substrates I

Time: Monday 18:00–20:00   Location: P2/EG

O 22.1   Mon 18:00   P2/EG

Charge-state lifetimes of single molecules on ultrathin insulating films — •Katharina Kaiser[1,3], Leonard-Alexander Lieske[1], Jascha Repp[2], and Leo Gross[1] — [1]IBM Research - Zurich, Säumerstrasse 4, 8803 Rüschlikon, Switzerland — [2]Department of Physics, University of Regensburg, Universitätsstraße 31, 93053 Regensburg, Germany — [3]Present address: Institut de Physique et de Chimie des Matériaux de Strasbourg, Département Surfaces et Interfaces, 23 Rue du Loess, BP 43, 67034 Strasbourg, France

In scanning tunneling microscopy (STM) experiments of molecules on insulating films, tunneling through molecular resonances goes along with transiently charging the molecule. The transition back to its charge ground state by tunneling through the insulating film crucially determines the charging dynamics of the system and with this is essential for understanding, e.g., excited state formation and luminescence quenching in electroluminescence experiments. The two quantities describing these processes are the average charging and discharging time, the latter being the lifetime of the charged state, and they are accessible in STM: By approaching the tip to the molecule at resonant tunnel conditions up to a regime where charge transport is limited by tunneling through the NaCl film the saturation of the tunnel current, which is a direct measure of the molecule's chargestate lifetime and thus provides a means to study charge and exciton dynamics, can be measured. We report on the chargestate lifetimes of individual molecules adsorbed on NaCl films of different thicknesses on Cu(111) and Au(111), and provide insights into the role of the substrate and the spacer layer.

O 22.2   Mon 18:00   P2/EG

Theoretical Investigation of Tetracen-Adsorption on Cu(111)-Substrate — •Florian Alexander Pfeiffer, Johannes Bilk, and Simone Sanna — Institut for Theoretical Physics, Justus-Liebig-University Gießen, Heinrich-Buff-Ring 16, Gießen, 35392, Hesse, Germany

Due to possible catalytic effects of a substrate, chemical reactions can occur within much smaller timescales on metal surfaces than in solutions. Ullman–coupling of Br–substituents to organic molecules, important to biology, chemistry and medicine, might profit of such catalytic effects. Little is known about this reaction on metallic substrates. Theoretical modelling is crucial for understanding the underlying processes. A first step towards such investigation is the first–principle modelling of tetracene–adsorption on Cu(111). Calculation of adsorption geometry and energy as well as charge transfer between molecule and surface is done utilizing density functional theory (DFT). Our calculations show that dispersion forces (van der Waals corrections) need to be taken into account for adsorption modelling. Adsorption energy and geometry as well as charge transfer suggest physisorption of tetracen at Cu(111). The Tersoff–Hamann–approximation allows for simulating STM–images using the DFT–calculated charge density. The STM–images show p_z orbitals of the benzene rings.

O 22.3   Mon 18:00   P2/EG

Effects of oxygen functionalization on the molecule-substrate coupling — •Jonas Brandhoff, Felix Otto, Maximilian Schaal, Roman Forker, and Torsten Fritz — Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

5,7,12,14-Pentacenetetrone (P4O) is a polycyclic aromatic hydrocarbon which shows promising electronic properties for batteries. Unlike pentacene the π-system is not delocalized over the entire molecule. P4O shows a strong interaction with metal substrates up to a point where the π-system delocalization reemerges partially over the entire molecule. To understand this phenomenon of metallic organic bonding and charge-transfer, as well as the needed interaction strength for enabling a delocalized π-system over the entire molecule, different substrate-P4O systems were investigated. On the one hand, Cu(111) was chosen as a metallic substrate which shows a strong interaction and charge-transfer. On the other hand, the semi-metallic substrate of epitaxial graphene (EG) on SiC(0001) was selected, showing no charge transfer. As an intermediate system, Pt(111) as a noble metal was investigated. Furthermore hexagonal boron-nitride (h-BN) was used to decouple P4O from the Pt(111) substrate. The change in the structure of the adsorbate film was analyzed using STM and LEED. XPS and UPS measurements gain further insights into the electronic properties. Photoemission orbital tomography (POT) was used to characterize the energetic positions of the frontier orbitals.

O 22.4   Mon 18:00   P2/EG

Vectorial Electron Spin Filtering by an All-Chiral Metal-Molecule Heterostructure — •Chetana Badala Viswanatha[1], Johannes Stöckl[1], Benito Arnoldi[1], Sebastian Becker[1,2], Martin Aeschlimann[1], and Benjamin Stadtmüller[1,3] — [1]Department of Physics and Research Center OPTIMAS, University of Kaiserslautern, Erwin-Schrödinger-Straße 46, 67663 Kaiserslautern, Germany — [2]Department of Chemistry, University of Kaiserslautern, Erwin-Schrödinger-Straße 52, 67663 Kaiserslautern, Germany — [3]Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, 55128 Mainz, Germany

Chiral-induced spin selective transmission (CISS) has predominantly been explored in structurally helical molecules on surfaces, where the spin selectivity only affects the spin polarization of the electrons along their direction of prop-

agation. Here, we demonstrate[1] a spin-selective electron transmission for a point-chiral molecule 3-Methylcyclohexanone (3-MCHO) adsorbed on the chiral Cu(643) surface. Using spin- and momentum-resolved photoelectron spectroscopy, we detect a spin-dependent electron transmission through a single layer of 3-MCHO molecules that depends on all three components of the electrons' spin. The findings are attributed to the enantiomer-specific adsorption configuration on the surface. This opens the intriguing opportunity to selectively tune CISS by the enantiospecific molecule-surface interaction in all-chiral heterostructures.

O 22.5   Mon 18:00   P2/EG

Electronic properties of bi- and peri-tetracene on Cu(111) studied by density functional theory — •Nina Kainbacher[1], Maren Klein[2,3], John B. Bauer[3], Holger Bettinger[3], Heiko Peisert[2], and Peter Puschnig[1] — [1]Institute of Physics, NAWI Graz, University of Graz, Austria — [2]Institute of Physical and Theoretical Chemistry, University of Tübingen, Germany — [3]Institute of Organic Chemistry, University of Tübingen, Germany

Zigzag edged nanographenes with two rows of fused linear acenes, called n-periacenes, have gained increasing attention in the area of organic electronics due to their interesting electronic properties. However, the synthesis is challenging because of their chemical instability. Here we show that a well-ordered monolayer of peritetracene, an n-periacene with four benzene rings in a row, can be produced by depositing the precursor 1,1'-bitetracene on Cu(111) and a subsequent heat treatment. The as-deposited and the annealed films are investigated by STM and UPS and by electronic structure calculations within DFT using a repeated slab approach. We determine the optimal adsorption sites by using damped molecular dynamics and empirical dispersion corrections according to Grimme. We then analyze the electronic structure of the organic/metal interfaces, in particular we focus on the (local) density of states and charge rearrangements upon interface formation which is decisive for the energy level alignment and work function changes. Our results clarify that the interaction of peritetracene with the Cu(111) substrate leads to a charge transfer into the LUMO which is consistent with the experimental observations.

O 22.6   Mon 18:00   P2/EG

Decoupling of vanadyl-naphthalocyanine from a metal substrate by monolayer MoS₂ — •J. Rika Simon, Gaël Reecht, Christian Lotze, and Katharina J. Franke — Fachbereich Physik, Freie Universität Berlin, Germany

Phthalocyanines with metal centres are well known for their relative stability on surfaces and are of interest because of the spin they can carry in their metal centres. On metal surfaces, the molecular electronic states are often hydridised with the metal underneath, making it difficult to observe fine details in the electronic structure and inelastic excitations. Using monolayers of semiconducting transition-metal dichalcogenides (TMDCs) as a decoupling layer on top of metal surfaces is a well-established way to allow access to highly resolved dI/dV spectra. Here, we use scanning tunnelling microscopy (STM) to probe the properties of vanadyl-naphthalocyanine (VONc) on MoS₂/Au(111). We observe VONc with molecular centres appearing with different apparent heights, which can be interpreted as different configurations of the central oxygen atom sitting on top or below the molecular macrocycle, as observed previously on the closely related molecule vanadyl-phthalocyanine (VOPc) [1,2]. Additionally, we see sharp molecular states in the semiconducting band gap, which are affected by the perturbation potential of the tip [3], causing them to shift in energy across the VONc molecules.

Ligand Size Controls Surface Chemical Bond: Cobalt Porphyrin versus Cobalt Corrole on the Ag(111) Surface — •Cong Guo, Grigori Pasko, Jan Herritsch, and J. Michael Gottfried — Fachbereich Chemie, Philipps-Universität Marburg

The development of novel functional materials based on biologically relevant molecules such as cobalamins, also referred to as vitamin B$_{12}$, is an important research topic. In particular, cobalt tetrapyrrole complexes which are related to cobalamins are often-used and well-understood model systems. Due to the structural complexity of the ligands, their interaction and bonding at interfaces is still poorly understood. Using XPS, we compare here a cobalt(II) porphyrin with a related cobalt(III) corrole. The latter exhibits a smaller ring size and acts as a trianionic ligand. In the multilayer, the Co 2p signal of the porphyrin shows the typical appearance of a paramagnetic Co^{2+} center. The corresponding Co 2p signal of the corrole has a similar shape indicating the presence of unpaired electrons in the Co 3d subshell. In the monolayer on Ag(111), both complexes are subject to an interfacial charge transfer from the substrate, as can be seen by the Co 2p signals. Thus, the singly occupied orbitals at the cobalt center are accepting electron density from the substrate. However, the N 1s signal and the valence photoemission spectra indicate that the corrole interacts much stronger with the substrate which is confirmed by periodic DFT calculations. Our study reveals that the two adsorbed complexes differ substantially in their overall interaction with the Ag surface, even though cobalt has a similar electronic state in both cases.

O 22.9   Mon 18:00   P2/EG

Charge Transfer on a 2D Insulator: Influence of the Molecular Functionalzation — •Maximilian Schaal, Jonas Brandhoff, Felix Otto, Roman Forker, and Torsten Fritz — Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

2D materials like hexagonal boron nitride (h-BN) are widely used as interlayer to decouple organic molecules from metallic surfaces. Despite the large band gap of 2D h-BN of ≈ 6 eV, there are also indications for a possible charge transfer into organic molecules. This raises the question: What is the reason for the charge transfer on this 2D insulator?

To address this question, we systematically studied the influence of the molecular functionalization on the lateral structure as well as on the charge transfer on 2D h-BN grown by chemical vapor deposition on Ni(111). Therefore, we compare the structural and electronic properties of pentacene (Pen) monolayers with the oxo-derivatives 6,13-pentacenequinone (P2O) and 5,7,12,14-pentacenetetrone (P4O) by using low energy electron diffraction (LEED), differential reflectance spectroscopy (DRS), X-ray and ultraviolet photoelectron spectroscopy (XPS and UPS) as well as photoemission orbital tomography (POT). For P4O on h-BN/Ni(111) we observed a charge transfer while Pen and P2O remain neutral. This will be discussed in terms of energy-level alignment in these 2D organic/inorganic heterostructures.

O 23: Poster: Surface Reactions

Time: Monday 18:00–20:00   Location: P2/EG

O 23.1   Mon 18:00   P2/EG

XPS Studies of 2-Carbethoxy-3-Phenyl-NBD/QC as MOST Energy Storage System — •Felix Hemauer[1], Valentin Schwaab[1], Eva Marie Freiberger[1], Natalie J. Waleska[1], Andreas Leng[1], Hans-Peter Steinrück[1], and Christian Papp[1,2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Freie Universität Berlin, Germany

Molecular solar thermal (MOST) systems are a candidate for storing solar energy in a chemical manner. The energy-lean norbornadiene (NBD) is converted to its energy-rich valence isomer quadricyclane (QC) in a photoconversion reac-

tion, whereby the energy is stored as strain. Molecular design leads to advantageous light-harvesting properties. In a model catalytic approach, we investigated the surface chemistry of the molecule pair 2-carbethoxy-3-phenyl-NBD/QC on Pt(111), Ni(111) and gold by synchrotron radiation-based XPS. Next to in situ observation of the adsorption, temperature-programmed experiments give insights into thermally induced reactions. Hereby, information on the adsorption behavior, the feasibility of the backward reaction of the QC to the NBD derivative, and the respective stability boundaries on the catalyst surfaces is obtained. On Pt(111), the energy release reaction is found to occur between 140 and 230

K. For Ni(111), the back conversion cannot be triggered thermally; instead, individual decomposition routes are monitored. The gold surface shows the highest catalytic activity with an instantaneous reaction upon adsorption at 110 K. The DFG (Project No. 392607742) supported this work. We thank HZB for allocation of synchrotron radiation beamtime.

Multiscale modeling and simulation of texture effects on the corrosion of stainless steel in aqueous media — •VAHID JAMEBOZORGI[1,2], KARSTEN RASIM[3], and CHRISTIAN SCHRÖDER[1,2] — [1]Bielefeld Institute for Applied Materials Research, Bielefeld University of Applied Sciences, 33619 Bielefeld, Germany — [2]Faculty of Physics, Bielefeld University, 33615 Bielefeld, Germany — [3]Miele & Cie. KG, Center for Materials (CFM), Carl-Miele-Straße 29, 33332 Gütersloh

Texture plays a crucial role in physical processes and properties of condensed matter as it is broadly highlighted in the literature. In this work we describe a robust methodology to investigate texture effects which does not suffer from common limitations of quantum based computational approaches in time and space but also can provide the same accuracy as atomistic calculations with orders of magnitude less computational costs. Our methodology is based on the finite element method (FEM) and utilizes 3D digital representations of multi grain microstructures. We demonstrate the efficiency of our approach by studying pitting corrosion in stainless steel. As reflected in literature the irregular geometry of pit expansion through pitting corrosion is mostly caused by texture. We found that the texture significantly affects the pitting corrosion rate and consequently causes various irregular pit growth patterns in granular microstructures. These results are consistent with our DFT and reactive force field molecular dynamics simulations which validate our suggested approach.

O 23.3   Mon 18:00   P2/EG

Model Catalytic Studies on the Thermal Dehydrogenation of 1-Cyclohexylethanol on Pt(111) — •VALENTIN SCHWAAB[1], FELIX HEMAUER[1], EVA MARIE FREIBERGER[1], NATALIE J. WALESKA[1], HANS-PETER STEINRÜCK[1], and CHRISTIAN PAPP[1,2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Freie Universität Berlin, Germany

The transition to a sustainable, renewable-based energy system requires novel energy storage technologies. So-called liquid organic hydrogen carriers (LOHCs) enable the safe storage of green hydrogen at high volumetric energy densities through the reversible hydrogenation of organic compounds. Particularly interesting systems are secondary alcohols as they often exhibit exceptionally low dehydrogenation temperatures in their reaction to the respective ketone.

Herein, we investigated the thermal dehydrogenation of the LOHC-pair of 1-cyclohexylethanol and acetophenone on a Pt(111) model catalyst. To gain fundamental insight into the reaction behavior and thermal stability limits of the two compounds, temperature-programmed X-ray photoelectron spectroscopy (TP-XPS) experiments were carried out. Based on the obtained C 1s and O 1s data, the dehydrogenation of the alcohol and the formation of potential catalyst poisoning decomposition products are discussed.

We acknowledge financial support by the Bavarian Ministry of Economic Affairs, Regional Development and Energy, and by the DFG (Project No. 419654270). We thank HZB for the allocation of synchrotron radiation beamtime.

O 23.4   Mon 18:00   P2/EG

On-Surface Collision Reactions — MATTHEW JAMES TIMM[1], •STEFAN HECHT[2], and LEONHARD GRILL[1] — [1]Institute of Chemistry, University of Graz, Heinrichstraße 28, 8010 Graz, Austria — [2]Department of Chemistry & IRIS Adlershof, Humboldt-Universität zu Berlin, Brook-Taylor-Str. 2, 12489 Berlin, Germany

Collisions between atoms and molecules are required to form chemical bonds, and thus lie at the heart of chemistry. Their outcome depends on several parameters: the collision energy, the miss-distance between the centers of the colliding species (the impact parameter), and on the relative alignment of reagents. Studying such reactions on a surface provides a 2D confinement and allows single-molecule imaging by scanning probe microscopy. For surface reactions, it has been demonstrated that the impact parameter can be selected using a 'surface-molecular-beam' of energetic CF2 'projectiles' on a Cu(110) surface [1-2]. The inherent corrugation of Cu(110) collimates the projectiles, allowing them to be aimed at nearby molecular 'targets' at chosen impact parameters. However, the relative alignment of reagents could not be varied until now, due to the singular possible adsorption configurations of the studied targets. Here, a singly-debrominated molecular target has been chosen as it can adopt multiple adsorption alignments relative to the incoming CF2 projectile, thus providing the missing element required for a more general selection of collision geometry. [1] Anggara, K.; Leung, L.; Timm, M. J.; Hu, Z.; Polanyi, J. C.; Sci Adv., 2018, 4, eaau2821. [2] Anggara, K.; Leung, L.; Timm, M. J.; Hu, Z.; Polanyi, J. C.; Faraday Discuss., 2019, 214, 89-103.

On-Surface Reaction of Tetraphenylporphyrin with Caesium — •LEONARD NEUHAUS, FLORIAN MÜNSTER, KASSANDRA ZOLTNER, MARIE IRENE ALBUS, JAN HERRITSCH, and J. MICHAEL GOTTFRIED — Fachbereich Chemie, Philipps-Universität Marburg, Germany

Tetrapyrroles such as porphyrins and their metal complexes play important roles in living organisms and for various modern technologies. While the surface chemistry of their transition metal complexes has been well studied in the last decades, the complexes of alkali metals are almost completely unknown. Here, we have studied the reaction of tetraphenylporphyrin (H$_2$TPP) with caesium in the multilayer and monolayer on Ag (111). N 1s X-ray photoelectron spectroscopy (XPS) data indicate complete metalation of the porphyrin in both cases. In complementary temperature-programmed reaction (TPR) experiments performed for the multilayer, the desorbing species were clearly identified by mass spectrometry as Cs$_2$TPP. DFT calculations indicate that this stable complex has a bipyramidal structure with Cs ions on both sides of the molecular plane.

Chemicurrent measurements during oxidation of Mg films with varying impact energy — •TOBIAS PROST and HERMANN NIENHAUS — Fakultät für Physik, Universität Duisburg-Essen, Germany

The chemicurrent originating from the oxidation of super thin magnesium films in correlation with the kinetic energies of the impinging particles is investigated. The magnesium layer thickness is kept well below the mean free path in Magnesium (Mg) to reduce the influence of the carrier recombination in the metal film. The I-V characteristics of such Schottky-Diodes show a homogeneous Schottky barrier of 0.68 eV. The reverse current is below 100 pA. Based on the X-Ray photoelectron spectroscopy (XPS) spectra recorded, it can be demonstrated that the magnesium films are not pre-oxidized. A particular focus lays on the determination of the influence of hyperthermic oxygen on the kinetics of the oxidation process. The kinetic energy of the oxygen molecules could be varied between 25 and 300 meV by adding helium. The chemical current measurements with constant kinetic energy confirms the nucleation and growth model. Measurements with different oxygen velocities demonstrate that the reaction efficiency increases with kinetic energy of the molecules.

Defect Engineering of Graphene using Ultra-low energy Ion Implantation — •FELIX JUNGE[1], MANUEL AUGE[1], ZVIADI ZARKUA[2], LINO M.C. PEREIRA[2], and HANS HOFSÄSS[1] — [1]II. Physikalisches Institut, Georg-August-Universität Göttingen — [2]Quantum Solid State Physics, KU Leuven

Doping and defect engineering of graphene and TMD's to change the electrical properties is highly desirable. To achieve this, we use a unique mass-selected ion beam deposition system, which makes it possible to work in an energy range of $10 < E < 600$ eV for implantation and thus to implant into a 2D-lattice. We use electrostatical masking to control the region which get irradiated. Graphene was doped with Boron and subsequently examined by means of Kelvin probe measurements (SKPM). Furthermore, Helium was implanted into graphene using an electrostatic gradient for decceleration of the ions, to implant the sample with different energies at the same time, which was then analysed with Raman spectroscopy. With these experiments we can see the change of the surface potential of the graphene between a doped and undoped surface region on the one hand and the increasing defect density with increasing implantation energy on the other hand. These results are compared by IMINTDYN (a SDTrimSP based Monte Carlo program for ion implantations) simulations.

Financial support by the DFG and the Volkswagen Foundation is gratefully acknowledged.

Sputtering of structured tungsten model surfaces — •MARTINA FELLINGER[1], CHRISTOPHER HAHN[1], CHRISTIAN CUPAK[1], GABRIELE ALBERTI[2], DAVID DELLASEGA[2,3], MATTEO PASSONI[2,3], MATTEO PEDRONI[3], ANDREA UCCELLO[3], ESPEDITO VASSALLO[3], and FRIEDRICH AUMAYR[1] — [1]TU Wien, Institute of Applied Physics, Vienna, Austria — [2]Politecnico di Milano, Department of Energy, Milan, Italy — [3]Istituto per la Scienza e Tecnologia dei Plasmi, Consiglio Nazionale delle Ricerche, Milan, Italy

Erosion of first wall materials in nuclear fusion devices limits the lifetime of plasma-facing materials. In the search for materials with low sputtering yields we have investigated not only the sputtering properties of randomly rough [1] but also of oriented and nano-structured tungsten surfaces. Since oriented tungsten nano-columns have shown a favourable reduction in sputtering yield [2], we have now started also to investigate nano-pyramids. These were obtained depositing a tungsten coating on top of chemically etched silicon substrates. The pyramidal surfaces were then exposed to ion irradiation and the subsequent sputtering process was investigated in situ by using a quartz crystal microbalance measurement setup [3]. We will present the experimental results and compare them to state of the art simulations.

In situ GISAXS observation of ion-induced nanoscale pattern formation on crystalline Ge(001) in the reverse epitaxy regime — •Denise Erb[1], Peco Myint[2,3], Kenneth Evans-Lutherodt[4], Karl Ludwig[4,5], and Stefan Facsko[1] — [1]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Germany — [2]Division of Materials Science and Engineering, Boston University, USA — [3]X-ray Science Division, Argonne National Laboratory, USA — [4]National Synchrotron Light Source II, Brookhaven National Laboratory, USA — [5]Department of Physics, Boston University, USA

The ion-induced nanoscale pattern formation on a crystalline Ge(001) surface is observed in situ by means of grazing incidence small angle x-ray scattering (GISAXS). Analysis of the GISAXS intensity maps yields the temporal development of geometric parameters characterizing the changing pattern morphology. In comparison with theoretical predictions and with simulations of the patterning process based on a continuum equation we find good agreement for the temporal evolution of the polar facet angle, characteristic length, and surface roughness in the nonlinear regime. To achieve this agreement, we included an additional term in the continuum equation which adjusts the pattern anisotropy.

O 24.4　Mon 18:00　P2/EG

Non-ambient Raman spectroscopy combined with ion bombardment — •André Maas, Lucia Skopinski, Stephan Sleziona, Marika Schleberger, and Lars Breuer — Universität Duisburg-Essen, Fakultät für Physik and CENIDE, Germany

Spectroscopic and electronic characterization of materials under non-ambient condition is an ongoing challenge. Irradiation-induced defects under ambient conditions are usually saturated with adsorbates. The direct analysis of the effects caused by unsaturated defects on the crystal structure and its electronic and optoelectronic properties is however essential to gain a deeper understanding of defect generation, defect saturation and the corresponding relaxations of the lattice due to adsorbates.

A novel experimental setup is presented that allows ion bombardment with two different ion sources and subsequent characterization of samples by a mobile Raman spectrometer in ultra high vacuum. The interaction of highly charged ions (Xe^{17+} - Xe^{40+} at around E_{kin} = 200 keV) from an electron beam ion source (EBIS) can be studied at the University of Duisburg-Essen. A second experimental setup utilizes the swift heavy ions (up to 14.8 MeV/u for $^{238}U^{92+}$) from the CRYRING@ESR at the GSI Helmholtzzentrum für Schwerionenforschung in Darmstadt for defect generation.

Another experiment uses a custom-built cell that allows for electrical and optical characterization of samples under high vacuum and at low temperatures ($\simeq$ 77 K).

Ion induced defects in two-dimensional tungsten diselenide boron nitride heterostructure — •Leon Daniel, Stephan Sleziona, Lucia Skopinski, Anke Hierzenberger, Jennifer Schmeink, and Marika Schleberger — Universität Duisburg-Essen, Germany

Monolayer transition metal dichalcogenides (TMDCs) like tungsten diselenide (WSe_2) are highly interesting materials for optoelectronic and valleytronic applications. We used Xe^{q+} ions with E_{kin}=180 keV to deliberately introduce defects into the WSe_2 lattice and compared its optoelectronic properties before and after irradiation with photoluminescence spectroscopy. Encapsulation in hexagonal boron nitride (hBN) isolates the WSe_2 from environmental influences like adsorbates and detrimental interactions with the widely used Si/SiO_2 substrates. We find differences in the photoluminescence response for encapsulated and non-encapsulated WSe_2, which can be explained by the encapsulation preventing saturation of the created vacancies by adsorbates. In particular, there are various localized excitonic states in our different sample systems, and we explain this observation with differing ion interactions with encapsulated and non-encapsulated WSe_2. Furthermore, we observe overall highly increased exciton lifetimes after the irradiation, likely caused by the longer lifetime of the localized excitons.

Ab initio design of Pt-Ir based novel bifunctional electrocatalysts for fuel cell applications — •Halil Ibrahim Sözen[1], Mehtap Oezaslan[2], and Thorsten Klüner[1] — [1]Institute of Chemistry, Carl-von-Ossietzky University of Oldenburg, D-26129 Oldenburg, Germany — [2]Technische Universität Braunschweig, Braunschweig 38106, Germany

Electric vehicles powered by polymer electrolyte membrane fuel cells (PEMFC) have a great potential to reduce a large portion of CO_2 emissions from the transportation sector and facilitate the advent of the hydrogen economy worldwide. However, highly dynamic conditions during the operation of PEMFC in the heavy-duty sector cause hydrogen starvation at the anode electrode, resulting in cell reversal events (< -1.5 V) and therefore carbon oxidation reaction (COR). In this work, we aimed to develop novel bifunctional electrocatalysts for the anode electrode based on Pt-Ir alloys. Our innovative approach involves unifying two functionalities, the hydrogen oxidation reaction (HOR) and oxygen evolution reaction (OER), as an alternative reaction for proton and electron formation to the COR in only one nanoparticle on the same support material. Density functional theory (DFT) based chemisorption energies of H*, O*, OH*, H_2O* and OOH* are reported with the effect of hydroxyl species presence and the effect of pH. Calculated chemisorption energies are implemented to model HOR and OER and plot Gibbs free energy diagrams. Various surfaces such as Pt(111), Pt_3Ir(111), PtIr(111) and Ir(111) have been considered for electrocatalytic reactions and their relative performance is compared.

O 25.2　Mon 18:00　P2/EG

2D Lattice Gas Order-Disorder Transition Observed by LEED and Vibrational Sum Frequency Generation Spectroscopy — •Zhipeng Huang, Tobias Roos, Yujin Tong, and R. Kramer Campen — Faculty of Physics, University of Duisburg-Essen

Order-disorder phase transition of monoatomic superstructures on single crystal surfaces is commonly described by Ising or lattice-gas model. The molecular orientation needs to be considered for modeling the order-disorder transition

of diatomic superstructures on single crystal surfaces, but it is challenge to be accessed by experiments.

Here we present our studies on CO ordered overlayers on Pt(111) surface by the surface sensitive thermal desorption spectroscopy (TDS), low-energy electron diffraction (LEED) and polarization dependent sum-frequency generation spectroscopy (SFG). An order-disorder phase transition of CO overlayer is observed by LEED under in-situ heating. The CO stretch vibrational frequency shifts suddenly when the transition happens. Combining LEED superstructure patterns and polarization dependent sum-frequency generation spectroscopy results, we reveal the changes of CO molecular orientation on Pt(111) surface during the order-disorder phase transition. We model the sudden CO stretch frequency shift caused by phase transition and the systematic shift as a function of coverage. These results demonstrate how the CO intermolecular interactions influence the molecular orientation and the stretch vibrational frequency. They provide insights on the change of microscopic potential energy level during the order-disorder phase transition.

Formation of solid electrolyte interface from polycaprolactone — •Kazem Zhour[1], Andreas Heuer[1], and Diddo Diddens[2] — [1]WWU Münster, Münster, Germany — [2]Institute Münster (IEK-12) Forschungszentrum Jülich GmbH, Münster, Germany

As for liquid electrolytes, studying the formation of the solid-electrolyte interface and its implications is one of the most important topics in solid-state batteries. In this study, DFT and AIMD calculations were performed to study the decompositions of polycaprolactone, one main constituent of the electrolytes, and its ending groups at the interface. Additionally, the computational lithium electrode method was applied to study the formation of the SEI under external voltage. The AIMD results suggest that the fragments are highly reactive on the Lithium slab where the fragmentation can be observed in less than 1 ps. The decomposition was triggered by the electrons transferred from the slab to the fragments. The electrochemical mechanism shows only slightly weaker energet-

ics with respect to the non-electrochemical one, showing that Li anode readily reacts with the polymer. After the formation of passivation layers (Li2O, LiF or Li2CO3) on top of the anode, the calculations show that only one monolayer protects the molecules from being decomposed at the interface at short interval of time, where the LiF layer seems to have the most robust protection as compared to the other layers. The electrochemical window and the decomposition of the polymer fragments in the presence of a Li cation, TFSI anion, or LiTFSI ion pair without explicit interface have also been also investigated.

O 25.4   Mon 18:00   P2/EG

Single-molecule study of Heck coupling on a Cu(111) surface — •Donato Civita[1], Friedrich Esch[2], and Leonhard Grill[1] — [1]Department of Physical Chemistry, University of Graz, Austria — [2]Faculty of Chemistry, TU München, Germany

The interaction of organic molecules with metallic structures is particularly important in heterogeneous catalysis where metallic particles or surfaces help to overcome energy barriers of chemical reactions. This concept is specifically important for Heck cross-coupling, which relies on a palladium catalyst to form a carbon-carbon bond between two different reagents. Model heterogeneous catalysis reactions can be investigated by scanning tunneling microscopy (STM) on metal single crystals. The role of active sites could be determined [1,2], and Heck coupling could be induced thermally [3].

We studied the cross coupling between vinyl-naphthalene (VN) and different halogenated molecules on a Cu(111) surface by STM at low temperatures (7 K). We investigated the bond of the de-halogenated molecules to different atomic structures of the copper surface as well as the thermally induced cross coupling reaction. By the statistical analysis of the products, and STM manipulation of a single metal-organic intermediate we obtain insight into the catalytic activity of the copper surface, and the dependence on the surface morphology.

Cobalt Island Growth on Metallic Surfaces — •Bensu Günay, Christophe Nacci, and Leonhard Grill — University of Graz, Graz, Austria

Molecular-beam epitaxy is an important technique for the fabrication of epitaxial films with reduced dimensionality in the low coverage regime under ultra-high vacuum conditions [1]. Various parameters are important for the morphology of the nanostructures: the flux of the incident atoms, the surface temperature, the source/substrate geometry, and diffusion of the atoms on the surface [2]. In this study, we investigated the growth of cobalt islands on Cu(111) and Au(111) surfaces using different (K-cell and e-beam evaporator) evaporators. The resulting surfaces were then studied by complementary methods: x-ray photoemission spectroscopy (XPS) to analyze the chemical composition of the surface and scanning tunneling microscopy (STM) to investigate the morphology of the islands. The results show how different deposition conditions change the Co growth on the surface.

Instrumentation for high-resolution biomolecule imaging enabled by electrospray ion beam deposition (ES-IBD) — •Lukas Eriksson, Tim Esser, Márkó Grabarics, Paul Fremdling, and Stephan Rauschenbach — University of Oxford, Department of Chemistry, United Kingdom

Elucidating the structure of biomolecules is essential to understanding their function. Direct imaging with cryogenic electron microscopy (cryo-EM) or scanning probe microscopy (SPM) is a powerful approach for finding molecular structure. However, sample preparation can be a major challenge: either very time- and resource-intensive or incompatible with the vacuum environment required by the imaging method.

Here, we explore preparative mass spectrometry as an alternative workflow towards structural elucidation of biomolecules. A novel, custom-built deposition stage extending a commercial mass spectrometer allows for the mass-filtered, soft-landed deposition of a wide mass range of target molecules (m = 100 - 10^6 amu) onto various surfaces, including cryo-EM grids and metal crystals for SPM.[1] This requires extensive control over conditions such as pressure, temperature, ion trajectories, sample surfaces, and sample transfer to obtain clean, chemically pure samples of the desired species in the right (i.e. native) configuration.

Dynamics of contact electrification — •Andre Mölleken, Hermann Nienhaus, and Rolf Möller — Fakultät für Physik, Universität Duisburg-Essen, Germany

Although the electrical charging of objects brought into contact has been observed for centuries, the details of the underlying mechanism are still not yet fully understood. We have developed an experimental method to follow the charge of a small sphere bouncing on a grounded planar electrode on a time scale down to 1 μs. In case of a contact between two metals, it reveals that the sphere is discharged in the moment of contact, which lasts about 6 to 8 μs. However, at the very moment of disruption of the electrical contact, it regains charge far beyond the expectation according to the contact potential difference. The excess charge rises with increasing contact area.

Surface tension measurement of pure water in vacuum — •Paul T. P. Ryan, Jiri Pavelec, Jan Balajka, Michael Schmid, and Ulrike Diebold — Institute of Applied Physics, TU Wien, Austria

Very little is known about the surface tension of pure liquids in contact with their pure gaseous phases, i.e. without the presence of other gases or liquid phase contaminants. This is surprising given that contaminants are known to greatly affect surface tensions values[1]. Recently we have developed a method to dose liquid water onto pristine surfaces in UHV using a small cryostat[2]. We combine this approach with the pedant drop method[3] to measure the surface tension of ultra-clean liquids in contact with their pure gaseous phases. In the design, the ultra-clean liquid is condensed onto a small cryostat placed in a vacuum chamber. A pendant drop is formed and carefully photographed allowing the surface tension of the ultra-clean liquid to be directly determined. For these types of measurements accurate knowledge and control of the temperature, pressure and the optics of system is of paramount importance. How these parameters are precisely controlled in the instrument design will be discussed along with initial measurements of ultra-pure water. High-Resolution Imaging of Protein Complexes Enabled by Electrospray Ion-Beam Deposition Sample Preparation — •Asha Thompson, Tim Esser, Markó Grabarics, Isabelle Legge, and Stephan Rauschenbach — University of Oxford, Department of Chemistry, United Kingdom
Structural characterisation of biological molecules such as proteins is essential for insight into their processes and interactions within cells. Samples of mass-filtered molecules adsorbed onto surfaces can be obtained using preparative mass spectrometry techniques such as electrospray ion-beam deposition (ES-IBD). ES-IBD generates intense beams of native proteins which are soft-landed onto surfaces. This produces uncontaminated samples which can be further characterised by transmission electron microscopy (EM) or scanning probe microscopy (SPM).

Here we present the application of this approach for the imaging of proteins showing examples of soluble and of membrane proteins, such as Human C Reactive protein, ferritin, Beta-galactosidase and Aquaporin-Z. We can show that the shape of the protein, its subunit conformation, and stoichiometry are retained, which points to intact secondary structure. [1] We intend to extend this approach to map the interactions of antibodies and their targets in order to provide information about the binding sight, useful for pharmacology.

RuNNer 2.0: An efficient and modular program for training and evaluating high-dimensional neural network potentials — •Alexander L. M. Knoll[1,2], Marco Eckhoff[3], Jonas A. Finkler[4], Tsz Wai Ko[5], Emir Kocer[1,2], K. Nikolas Lausch[1,2], Moritz R. Schäfer[1,2], Gunnar Schmitz[1,2], Alea Miako Tokita[1,2], and Jörg Behler[1,2] — [1]Lehrstuhl für Theoretische Chemie II, Ruhr-Universität Bochum, 44780 Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, 44780 Bochum, Germany — [3]ETH Zürich, Laboratorium für Physikalische Chemie, 8093 Zürich, Switzerland — [4]Department of Physics, Universität Basel, 4056 Basel, Switzerland — [5]Department of NanoEngineering, University of California, San Diego, CA, USA
Machine learning potentials (MLPs) have become a popular tool for large-scale atomistic simulations in chemistry and materials science. They provide efficient access to highly accurate potential energy surfaces (PES) generated from *ab initio* reference calculations. As methods in this field are becoming increasingly complex and reach maturity, the development of efficient and user-friendly tools is also gaining importance. We present the second major release version of RuNNer, an open source, stand alone software package for the construction and eval-uation of second, third, and fourth generation high-dimensional neural network potentials (HDNNPs). RuNNer 2.0 unifies an entire workflow in a fully MPI-parallel program: from the generation of atomistic descriptors, over the training of a specific machine learning model, to its final application in molecular dynamics codes.

O 26.7 Mon 18:00 P2/EG
Optical Near-field Electron Microscopy — •Ilia Zykov[1], Hanieh Jafarian[1], Barbara Platzer[1], Thomas Juffmann[1], Amin Moradi[2], Guido Stam[2], Sense Jan van der Molen[2], Ruud Tromp[2], Nestor Fabian Lopez Mora[3], Mariana Manuela Amaro[3], Martin Kalbac[3], Martin Hof[3], and Radek Šachl[3] — [1]University of Vienna, Austria — [2]Leiden University, the Netherlands — [3]J. Heyrovsky Institute of Physical Chemistry, the Czech Republic
Lable- and damage-free imaging of the surface processes on the nanometer scales and over extended periods is required in different fields. Various electron microscopy techniques are applied to meet these requirements. However, the use of electrons in probing the sample may affect some specimens. The novel Optical Near-field Electron Microscopy (ONEM) technique [1] is being developed to overcome this drawback. In the ONEM light nondestructively interacts with a sample. The scattered light from the sample is then transformed into electrons by a nm-thick photocathode layer placed in the near-field region of the sample. The nm resolution images are then achieved through an electron readout using the Low Energy Electron Microscope.

The potential application of ONEM in biochemistry can be to follow the protein dynamics in lipid membranes at single protein resolution. In electrochemistry ONEM will be applied to study the nucleation and growth of nanoscale copper clusters without any electron beam effect.

Development of a reflektometer for polarised surface sensitive X-ray Absorption Spectroskopy — •Lukas Voss, Frederic Braun, Franz Eckelt und Dirk Lützenkirchen-Hecht — Bergische Universität Wuppertal, Wuppertal, Deautschland
RefIEXAFS measurements represent a powerful tool for surface-sensitive structure investigations. With the help of high-intensity synchrotron radiation on synchrotron beamlines of the third generation, this measurement method can also be used in a time-resolved mode. In order to keep the construction and adjustment time as short as possible, a simple, compact and transportable reflectometer is to be built in order to give other users easy access to this measurement technology. Here we would like to present the current status of the project with the first measurements.

O 27: Overview Talk Katrin Domke

Time: Tuesday 9:30–10:15　　　　　　　　　　　　　　　　　　　　　　　　　　Location: TRE Phy

Invited Talk O 27.1 Tue 9:30 TRE Phy
Dive right in! Molecular insights into electrochemical surface science — •Katrin F. Domke — Universität Duisburg-Essen, Germany
Surface scientists have become increasingly aware of the importance of expanding the research focus from classical UHV systems to electrochemical settings that adequately represent realistic working conditions of applications based on solid/liquid reactive interfaces, such as (electro)catalysis or energy conversion schemes. Gathering atomistic understanding about the complex interrelation between charge transfer, chemical conversion and interfacial potential in the present of a solvent is one of the most imminent challenges that surface scientists working with solid/liquid interfaces are facing.

Great efforts are being devoted to the development of novel methodologies to elucidate interfacial electrochemistry mechanisms on the molecular scale. In my talk, I will highlight our advances to achieve simultaneous operando plasmon-supported Raman nanoscopy and break-junction experiments. These approaches allow us to gain unprecedented insights into the correlation of chemical, topographic and electronic properties of individual reactive sites at solid/liquid interfaces, such as catalyst structure or (bio)molecular switches in electrolyte under potential control.

O 28: Organic Molecules on Inorganic Substrates III: Adsorption and Growth I

Time: Tuesday 10:30–13:00　　　　　　　　　　　　　　　　　　　　　　　　　　Location: CHE 89

O 28.1 Tue 10:30 CHE 89
Tuning interfaces properties via deposition conditions: thermodynamic's deed and kinetic's contribution — Anna Werkovits, Johannes J. Cartus, Lukas Hörmann, and •Oliver T. Hofmann — Institute of Solid State Physics, Tu Graz
The interface dipole of an inorganic-organic interface depends strongly on the structure, i.e. the polymorph, the organic molecules assume. This is not a subtle effect: In the past years, studies reported work functions differing between up to 3 eV between different polymorphs, illustrating how important it is to control the growth of these interfaces.

In this work, we discuss on the basis of first-principle calcuations how the molecule-substrate, the intermolecular interaction and the size of the molecule affect the relative thermodynamic stability of different phases for different deposition conditions, and how this directly relates to observed work function changes. Based on this, we discuss two ways strategies to tune interface properties. Either, the relative stability can be modified, e.g. by growing the interface in an electric field. Alternatively, it is also possible to exploit kinetic effects during the growth and trap desired phases. Based on the example of TCNE on Cu(111) we discuss how a given phase can be kinetically trapped, and under which circumstances we expect thermodynamic equilibrium to prevail.

O 28.2 Tue 10:45 CHE 89
Homo- and Heterochiral Phases of Quinacridone Monolayers on Ag(110) and Ag(111) — •Ravi Priya, Weishan Wu, Keda Jin, and Peter Jakob — Fachbereich Physik, Philipps-Universität Marburg, Germany
When adsorbed on a surface, parallel-oriented quinacridone (QA) transforms into a chiral species and lateral interaction between neighboring molecules will depend on the types of enantiomers facing each other. On Ag(111) a homochi-

ral phase comprising rows of (identical) QA has been reported that, upon thermal annealing, converts to a heterochiral phase consisting of alternating pairs (dimers) of the two enantiomers [1]. In our study, we have refined the structural analysis of QA/Ag(111) phases and have extended the available database to QA on Ag(110). Besides SPA-LEED, IR-spectroscopy and TDS were employed to characterize the various phases and associated phase transformations in detail. From IRAS and TDS a stronger molecule-substrate interaction is deduced for Ag(110) as compared to Ag(111). In parallel, interfacial dynamical charge transfer (IDCT) is considerably enhanced for QA/Ag(110) which is ascribed to an extra downshift of the QA-LUMO, increasing its DOS at the fermi energy. Interestingly, IDCT vanishes completely upon the transition of the homochiral to the heterochiral arrangement, both on Ag(111) and Ag(110). This could be explained by a completely empty, or a fully occupied LUMO [2]. As this transition is accompanied by a notable increase in the work function, we conclude that the latter applies.

Morphology and luminescence of rubrene nanocrystals: a road to tailor nanoplatelets — •Moha Naeimi, Katharina Engster, Christian Völkner, Regina Lange, Sylvia Speller, and Ingo Barke — University of Rostock, Institute of physics, Rostock, Germany

Rubrene ($C_{42}H_{28}$ 5,6,11,12-tetraphenyltetracene) single crystals with a few monolayers had been reported to have high charge mobility of 43 cm^2/Vs [1] and singlet-fission dynamics [2] which are promising properties for the application of excitons for energy transfer or information processing. We aim for the investigation of the spatial distribution of excitons in molecular assemblies on surfaces, requiring thin films or flat nanocrystals. In the present work, we report on the preparation of rubrene platelets by various methods from simple spin-coating to thermal evaporation and broad growth conditions, followed by a high-rate post-annealing temperature treatment on different types of substrates [3]. Ranging from 10 nm to 150 nm, we show that the thickness of rubrene platelets is widely dependent on the rate and time of temperature treatment as well as on the rubrene coverage on the surface. Moreover, we discuss thermal stability and photo-degradation for different morphologies.

Photoelectron Spectroscopy of N-heterocyclic carbenes on Si(111)($\sqrt{3} \times \sqrt{3}$)R30°-B surface — •Mike Thomas Nehring[1], Robert Zielinski[1], Mowpriya Das[2], Hazem Aldahhak[3], Conor Hogan[5], Uwe Gerstmann[3], Wolf Gero Schmidt[3], Mario Dähne[1], Martin Franz[1], Frank Glorius[2], and Norbert Esser[4] — [1]Institut für Festkörperphysik, Technische Universität Berlin, Berlin, Deutschland — [2]Westfälische Wilhelms-Universität Münster, Organisch-Chemisches Institut, Münster, Deutschland — [3]Institut für Theoretische Materialphysik, Universität Paderborn, Paderborn, Deutschland — [4]Leibniz-Institut für Analytische Wissenschaften - ISAS e.V., Berlin, — [5]Institute for Structure of Matter (ISM-CNR), Rome, Italy

Silicon is the most commonly used element in the industry for manufacturing semiconductor-based components. Semiconductor devices today represent a cornerstone of modern technology, with a multitude of possible applications in research and development. A relatively new area of research is the growth of organic films on modified silicon surfaces. In this work we investigate the adsorption behaviour of various N-heterocyclic carbenes (NHCs) on the Si(111)($\sqrt{3} \times \sqrt{3}$)R30°-B surface. This research is conducted using X-ray photoelectron spectroscopy (XPS). By comparison of the experimental spectra with theoretical calculations it is found that all investigated NHCs bind to the Si adatoms of the Si(111)-B surface in an upright adsorption geometry. In addition, the monolayers show a high thermal stability and large work function reductions.

O 28.5   Tue 11:30   CHE 89

Adsorption and thermal stability of phenyl phosphonic acid on cerium oxide: effect of surface morphology, stoichiometry and composition. — •Viacheslav Kalinovych[1], Lesia Piliai[1], Yuliia Kosto[1], Sascha L. Mehl[2], Tomáš Skála[1], Iva Matolínová[1], Vladimír Matolín[1], Kevin C. Prince[2], and Nataliya Tsud[1] — [1]Charles University, Faculty of Mathematics and Physics, Department of Surface and Plasma Science, V Holešovičkách 2, Prague, 18000, Czech Republic — [2]Elettra-Sincrotrone Trieste S.C.p.A., in Area Science Park, Strada Statale 14, km 163.5, Basovizza (Trieste), 34149, Italy

In the present work, the binding properties and thermal stability of the phosphonate group to several well-ordered cerium oxide systems: stoichiometric CeO2(111), fully reduced Ce2O3(111), Ce6WO12(100) and polycrystalline RF CeO2 were studied. Phenyl phosphonic acid (PPA) has been chosen as a molecule consisting of a phosphonate group and a benzene ring. PPA deposition was performed in UHV conditions. The binding properties and thermal

stabiliy has been investigated in the range of 25-450 °C by synchrotron radiation photoelectron spectroscopy, resonant photoelectron spectroscopy and near-edge X-ray absorption fine structure spectroscopy. This work comprehensively describes the phosphonate group binding to cerium oxide as a function of substrate morphology, stoichiometry, composition and temperature.

O 28.6   Tue 11:45   CHE 89

Adsorption of a Cyclic (Alkyl)(Amino)Carbene on Si(111)($\sqrt{3} \times \sqrt{3}$)R30°-B: Influence of the Defect Density — •Robert Zielinski[1], Mowpriya Das[2], Canan Kosbab[1], Mike Thomas Nehring[1], Mario Dähne[1], Norbert Esser[1,3], Martin Franz[1], and Frank Glorius[2] — [1]Institut für Festkörperphysik, Technische Universität Berlin, Berlin, Deutschland — [2]Westfälische Wilhelms-Universität Münster, Organisch-Chemisches Institut, Münster, Deutschland — [3]Leibniz-Institut für Analytische Wissenschaften - ISAS e.V., Berlin, Germany

N-Heterocyclic carbenes (NHCs) have been shown to be excellent modifiers and anchors for the functionalization of surfaces, but so far mostly on metals. Thus a controlled functionalization of semiconductor surfaces by ordered NHC layers is of great interest. In the present work we investigate the adsorption behavior of cyclohexyl cyclic (alkyl)(amino)carbene (cyCAAC) molecules on the Si(111)($\sqrt{3} \times \sqrt{3}$)R30°-B surface using scanning tunneling microscopy and X-ray photoelectron spectroscopy. We find a self-limited, well-ordered growth of a stable monolayer with large domains characterized by a 3×3 periodicity and an upright adsorption geometry of the molecules. A strong correlation between the domain size and the substrate defect density is found, revealing that the initial molecular adsorption preferentially takes place on a particular type of surface defect. Work function measurements of the cyCAAC monolayer reveal a large reduction of work function.

O 28.7   Tue 12:00   CHE 89

Electronic properties of radical helicene molecules on metallic substrates — •Aleš Cahlík[1], Danyang Liu[1], Carolina A. Marques[1], Ya-Chu Hsieh[2], Yao-Ting Wu[2], Karl-Heinz Ernst[3], and Fabian D. Natterer[1] — [1]Department of Physics, UZH, Zurich, Switzerland — [2]Department of Chemistry, National Cheng Kung University, Tainan, Taiwan — [3]Molecular Surface Science Group, EMPA, Zurich, Switzerland

Helicenes are π-conjugated aromatic compounds with helical shape arising from angularly fused aromatic rings. Radical helicenes combine unpaired electron spins with structural chirality and a π-conjugated framework that can offer intriguing prospects to study the synergy of electronic transport, magnetism and photoactivity. In our work, we employ STM and nc-AFM to investigate an open-shell biradical helicene that we adsorb onto metallic substrates, including magnetic nanoislands. Notably, we observe a Kondo resonance pointing towards the preservation of the open-shell character upon deposition onto Au(111).

O 28.8   Tue 12:15   CHE 89

STM growth studies of 5,14-ol-5,14-diborapentacyclo on low-index coinage metal surfaces — •Wun-Chang Pan[1], Jing Qi[1], Carina Mützel[2], Paula Weber[1], Frank Würthner[2], and Matthias Bode[1] — [1]Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany — [2]Institut für Organische Chemie & Center for Nanosystems Chemistry (CNC), Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany

In recent studies [1, 2], heteroatoms-doped precursors have frequently been used to polymerize graphene nanoribbons with a large variety of structures or dopant heteroatoms. Using cryogenic scanning tunneling microscopy, we investigated the structure of self-assembled 5,14-ol-5,14-diborapentacyclo (CM218) on low-index coinage metal surfaces. The main focus of our study is on CM218 on Ag(111), where we find that molecular clusters and chains coexist with molecular islands. At low annealing temperature $T_{ann} < 100°C$, the islands exhibit a rail track-like structure with a rhomboid-shaped unit cell. Besides, we find irregular clusters and molecular chains. At higher $T_{ann} \geq 180°C$, islands with a honeycomb (HC) structure are observed. Topographic images of these HCs display a pronounced bias dependence. Molecule-functionalized tips allow for high-resolution images of these structures for which we suggest structural models.

Variable Temperature Scanning Tunneling Microscopy Investigation on Pyrene Monolayers — •Patrick Penner, Xianghui Zhang, Berthold Völkel, and Armin Gölzhäuser — Physik Supramolekularer Systeme und Oberflächen, Universität Bielefeld, Bielefeld, Germany

Pyrene (C16H10) monolayers were prepared by physical vapor deposition on Au(111). Afterwards they were investigated with a variable temperature scanning tunneling microscope with the capability to cool the surface down to -80°C. Without prior cooling, it was impossible to image any molecules at room temperature. After reaching a temperature of 10°C first images could be made. In-

dependent of the temperature the molecules seem to be lying flat on the sample, with a next-neighbor distance of 1.05 nm. After cooling down it was possible to scan at room-temperature small domains of pyrenes near edges of gold terraces, as well as single mobile pyrene molecules.

O 28.10 Tue 12:45 CHE 89

Predicting optimal growth conditions for metastable interface structures — •Simon Hollweger, Anna Werkovits, Richard K. Berger, Lukas Hörmann, Johannes Cartus, and Oliver T. Hofmann — Institute of Solid State Physics, University of Technology Graz, Austria

For tailoring organic-inorganic interfaces of organic electronic devices controlling the structure that forms during growth is of high importance. Indeed, interface properties often strongly vary for different interface structures. But growing the structure that has the optimal properties for a certain technical application is nothing but trivial, due to the subtle interplay of thermodynamics and kinetics that strongly depend on the growth conditions like temperature and pressure. Therefore, we study how to change temperature and pressure over time in an optimal way to maximize the concentration of a specific high-performance polymorph. The target structure must then be one that is either thermodynamically or kinetically accessible. Finding optimal processing parameters experimentally is a tedious trial and error task, which can be greatly simplified with theoretical guidance. Using the framework of Optimal Control theory, such optimal temperature and pressure protocols can be obtained. In this talk we will demonstrate how this method can be technically implemented, discuss first applications, and point out its possible pitfalls and limitations for the case of designing organic-inorganic interfaces.

O 29: Supported Nanoclusters: Structure, Reactions and Catalysis

O 29.1 Tue 10:30 CHE 91

There is life after coking for Ir nanocatalyst superlattices — •Antonio J Martínez-Galera[1,2], Haojie Guo[3], Mariano D Jiménez-Sánchez[3], Stefano Franchi[4], Kevin C Prince[4], and José M Gómez-Rodríguez[2,3,5] — [1]Departamento de Física de Materiales, Universidad Autónoma de Madrid, E-28049 Madrid, Spain — [2]Instituto Nicolás Cabrera, Universidad Autónoma de Madrid, E-28049 Madrid, Spain — [3]Departamento de Física de la Materia Condensada, Universidad Autónoma de Madrid, E-28049 Madrid, Spain — [4]Elettra-Sincrotrone Trieste S.C.p.A., in Area Science Park, 34149 Basovizza (Trieste), Italy — [5]Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, E-28049 Madrid, Spain

Achieving superior performance of nanoparticle systems is a major challenge in catalysis. Two main phenomena, occurring during the reactions, hinder the development of the full potential of nanoparticle catalysts: sintering and contamination with carbon containing species, sometimes called coking. Here, we show that Ir nanocrystals, periodically arranged on h-BN supports, can be restored without sintering after contamination by persistent carbon. This restoration yields the complete removal of carbon from the nanocrystals, which keep their crystalline structure, allowing operation without degradation. These findings, together with the possibility of fine tuning the nanocrystals size, confer this nanoparticle system a great potential as a testbed to extract key information about catalysis-mediated oxidation reactions. For the case of the CO oxidation by O2, the existence of chemical processes not observed before in other nanoparticle systems is proven.

O 29.2 Tue 10:45 CHE 91

Formation of the Pd/Co3O4 interface — •Yaroslava Lykhach[1], Maximilian Kastenmeier[1], Lukáš Fusek[1,2], Matteo Farnesi Camellone[3], Tomáš Skála[2], Nataliya Tsud[2], Viktor Johánek[2], Sascha Mehl[4], Josef Mysliveček[2], Simone Piccinin[3], Olaf Brummel[1], Stefano Fabris[3], and Jörg Libuda[1] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [2]Charles University, Prague, Czech Republic — [3]Istituto Officina dei Materiali, CNR-IOM, Trieste, Italy — [4]Elettra-Sincrotrone Trieste SCpA, Basovizza-Trieste, Italy

Metal-oxide interfaces play a major role in the design of advanced functional materials for applications in catalysis, energy storage, and nanoelectronics. We investigated the formation of the metal/oxide interface during deposition of Pd nanoparticles onto a well-ordered Co3O4(111) substrate by means of synchrotron radiation photoelectron spectroscopy (SRPES), density functional theory (DFT), and scanning tunnelling microscopy (STM). DFT predicted strong interaction between Pd and Co3O4(111) which resulted in the growth of two-dimensional Pd islands densely covering the substrate. We observed a charge transfer across the metal/oxide interface resulting in partial oxidation of Pd deposits and partial reduction of Co3O4(111). Based on the analysis of the degree of the reduction of Co3O4(111), we found that the charge transfer at the Pd/Co3O4(111) is confined to the near-surface region of Co3O4(111).

O 29.3 Tue 11:00 CHE 91

Structure of PdPt/CeO2/YSZ model systems in operando methane oxidation — •Jan-Christian Schober[1,2], Silvan Dolling[1,2], Thomas F. Keller[1], and Andreas Stierle[1,2] — [1]DESY, Centre for X-ray and Nanoscience CXNS, Hamburg, Germany — [2]Universität Hamburg, Germany

Due to the high ecological impact of gasoline and diesel fuels, natural gas and biofuel alternatives become more important than ever. Methane is a major component of natural gas and many bio fuels and has a much higher environmental impact than carbon dioxide. Thus, it is vital to ensure the elimination of methane in exhaust gas treatment systems. Pd and PdPt alloy NPs supported by ceria, are among the most active catalysts for the oxidation of methane. Yet, many questions about the interplay of the noble metals with the support, the involvement of palladium oxide species, the role of Pt, and the exact reaction mechanism in the low-temperature regime remain [1,3].

In order to track the active sites and elucidate structure function relationships on an atomistic level we prepare fully epitaxial model systems of PdPt alloy NPs supported by ceria thin films on YSZ single crystals. Using grazing incidence X-ray diffraction techniques in conjunction with our operando catalysis environments we were able to track activity by in-line mass spectrometry and structure of the model catalysts by following the ceria CTRs, as well as Pd, Pt, and their respective oxide Bragg peaks under operando conditions.

Methane activation towards H$_2$ evolution with sub-nanometer Ta clusters supported on Pt(111) — •Tobias Hinke, Kevin Bertrang, Matthias Knechtges, Sebastian Kaiser, and Ueli Heiz — TU Munich, School of Natural Sciences & CRC, Physical Chemistry

The tremendous global energy demand leads to resource shortages as well as environmental consequences. Employing H$_2$ as an alternative energy carrier from abundant feedstocks such as natural gas is one strategy to tackle these issues. However, efficient hydrogen evolution demands for a fundamental understanding to increase H$_2$ availability. For this, model systems can be used to elucidate basic principles in chemical reactions, facilitating the design of tailored catalytic systems. Studies of small cationic Ta-clusters and their oxides in the gas phase exhibit high activity towards the activation of highly inert CH$_4$, yielding Hydrogen, whereas the cluster charge was identified as a key parameter.

These studies are now extended to their supported analogues to approach common catalytic structures. Therefore, Ta$_n$-clusters (n < 30) supported on metal single crystal substrates are investigated under mild conditions in UHV, with regards to their activity towards H$_2$ evolution from CH$_4$ via TPD. Characterization was performed via XPS and STM. Supported Ta$_8$ clusters exhibit size dispersive stability at room temperature and are active towards H$_2$ evolution form CH$_4$.

O 29.5 Tue 11:30 CHE 91

Ta atoms & clusters on Pt(111) - an XPS study — •Kevin Bertrang, Tobias Hinke, Matthias Knechtges, Federico Loi, Alessandro Baraldi, Sebastian Kaiser, and Ueli Heiz — Physical Chemistry, School of Natural Sciences, & Catalysis Research Center, Technical University of Munich

Thin films comprising Ta/Ta$_x$O$_y$ have been extensively studied on Pt surfaces. There is still a lack of profound understanding concerning the chemical interaction in the Ta/Pt interface and how it is affected during film growth and oxidation. In particular, an unambiguous attribution of the oxidation state of Ta is lacking which is largely complicated due to the numerous oxides and sub-oxides it can form.

In a bottom up approach we deposited low coverage of Ta atoms & clusters on a Pt(111) surface and probed the system by means of XPS using synchrotron radiation. Oxidation was studied using both atomic and molecular O$_2$. Stability and surface mobility was studied. At liquid He a high variety of features are observed. In contrast at liquid N$_2$ most Ta species are mobile and agglomerate to form structures stable up to high temperatures.

O 29.6 Tue 11:45 CHE 91

Cu Nanoparticles on Vicinal and Basal ZnO as Model Catalysts for Methanol Synthesis — •Robert Gleissner[1,2], Simon Chung[1], Esko Erik Beck[1,2], Guilherme D. L. Semione[1,2], Michael Wagstaffe[1], Leon Jacobse[1], Steffen Tober[1,2], Gökhan Gizer[4], Christopher Goodwin[3], Marcus Soldemo[3,6], Mikhail Shipilin[1,3], Patrick Lömker[1,3], Christoph Schlueter[1], Peter Amann[3], Olof Gutowski[1], Ann-Christin Dippel[1],

Matthias Muntwiler[5], Vedran Vonk[1], Heshmat Noei[1], and Andreas Stierle[1,2] — [1]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]Universität Hamburg, Germany — [3]University of Stockholm, Sweden — [4]Helmholtz-Zentrum hereon, Gesthaacht, Germany — [5]Paul-Scherrer Institut, Villingen, Switzerland — [6]Stanford University, Stanford, USA

Over recent years, the vicinal ZnO(10-14) surface garnered increased scientific interest, as it combines a high density of surface steps with high stability. However, the role of vicinal ZnO in Cu/ZnO catalysts remained to be investigated. In this study, Cu nanoparticles were grown on vicinal and basal ZnO and studied by STM, LEED, SEM, and ambient pressure XPS, GIXRD, and XRR. On vicinal ZnO, the Cu nanoparticles show a high prevalence of stepped Cu facets, which are interesting for catalytic reactions. Our study elucidates the morphology of the Cu nanoparticles, their interplay with the ZnO support, their stability under oxidation/reduction conditions, and the prospects for improving the activity of Cu/ZnO-based catalysts for methanol synthesis.

O 29.7   Tue 12:00   CHE 91

A hybrid QM/MM framework to study single metal atom adsorption on doped diamond surfaces — •Shayantan Chaudhuri[1], Andrew J. Logsdail[2], and Reinhard J. Maurer[1] — [1]University of Warwick, Coventry, UK — [2]Cardiff University, Cardiff, UK

Polycrystalline boron-doped diamond is widely used as a working electrode material in electrochemistry, and its properties such as a high stability make it an appealing support material for nanostructures for (electro)catalytic applications. Experiments have shown that electrodeposition can lead to the creation of stable small nanoclusters and even single metal adatoms on diamond. We investigate the structural stability and reactivity of single atoms on diamond as predicted by density functional theory. As hybrid functionals are computationally intractable for large-scale periodic surface structures, we use the quantum mechanics/molecular mechanics (QM/MM) methodology to compare different density-functional approximations on equal footing. We investigate the adsorption energy and kinetic stability of metal single atoms on an oxygen-terminated diamond (110) surface and explore the role of structural defects such as vacancies and dopants on metal atom adsorption. Our work forms the foundations for the study of metal nanocluster formation on diamond.

O 29.8   Tue 12:15   CHE 91

Reaction Pathways in Heterogeneous Photoreforming of Tertiary Alcohols — •Martin Tschurl, Clara Aletsee, Paula Neumann, Philip Petzoldt, Carla Courtois, Moritz Eder, and Ueli Heiz — Chair of Physical Chemistry, School of Natural Sciences & Catalysis Research Center, Technische Universität München, Lichtenbergstr. 4, 85748 Garching, Germany

While the oxidation of tertiary alcohols remains a challenge in organic chemistry, heterogeneous photocatalysis opens up new pathways for their conversion. In this contribution, we discuss the selective oxidation of those alcohols under illumination on titania model photocatalysts. We reveal the processes occurring on the surface of a rutile single crystal in studies under ultra-high vacuum conditions and address the role of the pressure gap by comparing those results with

reactions of titania powders at ambient pressure. Furthermore, we demonstrate the impact of co-catalyst loading on the selectivity of the reaction and explain the underlying reaction mechanisms.

O 29.9   Tue 12:30   CHE 91

Bottom-up synthesis and transfer of free-standing nanocluster arrays supported by carbon — •Tobias Hartl[1], Stefan Schulte[1], Moritz Will[1], Pantelis Bampoulis[1,2], Rajendra Singh[3], Jani Kotakoski[3], Jan Knudsen[4], and Thomas Michely[1] — [1]Universität zu Köln — [2]MESA+ Institute for Nanotechnology — [3]Universität Wien — [4]MAX IV Laboratory

Cluster superlattices exhibit unique properties stemming from their small size and dimensionality. However, their use in applications is hampered by their low stability when exposed to application relevant conditions, e.g. ambient pressure or high temperature. We succeeded in synthesizing free-standing cluster superlattice membranes (CSLM) which are stable at these conditions. CSLMs consist of a 2D lattice of similar-sized nanoclusters sandwiched between graphene (Gr) and an amorphous carbon (a-C) matrix. In order to make the membrane useful for experiments in nanocatalysis, it needs to be lifted off from the Ir(111) substrate and flipped over, to expose it's Gr bottom side. This enables the removal of the covering Gr sheet and provides access to the clusters in the a-C matrix. Turning the membrane around requires a double transfer process, which is preceded by water and gas intercalation below the membrane. The transfer process consists of a first pick-up with a PDMS stamp, then a second pick-up from the PDMS stamp onto a polycarbonate stamp and finally the transfer to a new substrate. We present the fabrication and transfer processes of the membranes and explore the thermal stability and the physicochemical properties of this novel nanomaterial via XPS, TEM and STM.

O 29.10   Tue 12:45   CHE 91

Changing surface morphology and chemistry by scalable atmospheric pressure plasma treatment — •Timo Wagner[1], Nicolas Wöhrl[1], Vineetha Vinayakumar[2], Doris Segets[2], and Axel Lorke[1] — [1]Faculty of Physics and CENIDE, University Duisburg-Essen, Germany — [2]Particle Science and Technology (IVG-PST) and CENIDE, University of Duisburg-Essen

Nickel foams provide a large specific surface area. Yet, compared to bulk nickel plates, they are less desirable for industrial applications due to their higher cost and more difficult handling. As part of H2Giga, the hydrogen flagship project by the German Federal Ministry of Education and Research (BMBF), we developed a plasma treatment for industry relevant nickel plates and catalyst particles. In a common manufacturing process for electrolyzers, nickel plates or meshes are first coated with a suspension of catalyst particles. Afterwards the solvents get thermally evaporated, yielding the finished electrode. With our process, the blank nickel surface can be roughened up by exposing it to a nitrogen plasma as a form of pre treatment. Also after coating, an exposure to a nitrogen plasma shows significant morphological changes. The individual particles coalesce to bulbs, that are again interspersed by a sponge-like porous structure. these structures have shown to notably improve the electrochemical performance of the electrodes, decreasing the overpotential by ca. 100mV.

Controlling the charge density wave transition in single-layer TiTe$_{2x}$Se$_{2(1-x)}$ alloys by band gap engineering — •Tommaso Antonelli, Andela Zivanovic, Chiara Bigi, Brendan Edwards, Akhil Rajan, and Phil King — University of St. Andrews

The narrow gap semiconductor monolayer (ML) TiSe$_2$ undergoes a controversial charge density wave transition [1, 2] whose nature is still poorly understood. Recently, a similar instability has been observed in the sister semimetallic compound ML-TiTe$_2$ showing a weaker CDW coupling as compared to the selenide compound [3, 4]. Using molecular beam epitaxy, we grow ML-TiTe$_{2x}$Se$_{2(1-x)}$ alloys to engineer the band gap in the normal phase and tune the CDW coupling in the system. Performing angle-resolved photoemission spectroscopy on the alloy films, we demonstrate the effective semiconductor to semimetal transition in the high-temperature phase band structure and observe the consequent modulation of the CDW critical temperature. Our experimental results are rationalised using a simple theoretical model bringing new insight on how to manipulate this collective phase at the 2D limit.

Charge density wave in 2H-NbSe$_2$ studied by combined STM/nc-AFM — •Nikhil Seeja Sivakumar[1], Marion van Midden Mavric[1], Nora Huijgen[1], Umut Kamber[2], Daniel Wegner[1], Alexander Ako Khajetoorians[1], and Nadine Hauptmann[1] — [1]Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands — [2]Department of Physics, Princeton University, USA

Van der Waals materials exhibit interesting quantum phases such as charge density waves (CDW) which originate from an electronic instability along with structural rearrangements. One example is 2H-NbSe$_2$ which exhibits an incommensurate CDW below 33 K. The origin of the CDW in 2H-NbSe$_2$ is currently understood to be driven by electron-phonon coupling [1]. To characterize the CDW with atomic scale resolution, Scanning Tunneling Microscopy (STM) is frequently used which is sensitive to the convolution of the geometric structure and the local density of states.

Here, we utilize combined low-temperature STM and non-contact Atomic Force Microscopy (STM/nc-AFM) based on the qPlus design to study the CDW at the surface of 2H-NbSe$_2$. We detail the distancedependent contrast of the atomic lattice and the CDW in current and frequency shift images. We further compare force spectroscopy data at selected positions of the CDW unit cell and analyze different force contributions.

Circular dichroism in valence band photoemission from CrGeTe$_3$ — •Honey Boban[1], Mohammed Qahosh[1], Xiao Hou[1], Magdalena Szczepanik[2], Ewa Partyka-Jankowska[2], Tomasz Sobol[2], Tom G Saunderson[3,4], Yuriy Mokrousov[3,4], Mathias Kläui[3], Claus Michael Schneider[1], and Lukasz Plucinski[1] — [1]PGI-6, FZ Jülich, Germany — [2]NSRC SOLARIS, Poland — [3]University of Mainz, Germany — [4]PGI-1, FZ Jülich, Germany

CrGeTe$_3$(CGT) is a layered ferromagnetic semiconductor with a bulk Curie temperature (T$_c$) of 63K[1] and an indirect bandgap of 0.4eV[2]. A previous band structure mapping study of CGT[1] revealed band renormalizations below and above T$_c$ and resonance enhancements at the Cr 3p absorption edge. CGT contains large Te atoms (Z=52), therefore spin-momentum locked splittings, Weyl nodes, and anticrossings are expected due to a combination of ferromagnetism and spin-orbit coupling, as well as the related Berry curvature physics. We performed light-polarization-dependent and temperature-dependent angle-resolved photoemission (ARPES) measurements on surfaces of bulk CGT. We have observed renormalizations in the dichroic ARPES maps below and above T$_c$, which could be indirectly related to magnetic ordering, even though our technique most likely averages spin-up and spin-down domains. Circular dichroic ARPES maps contain an intrinsic contribution due to the orbital angular momentum through dipole selection rules and an extrinsic contribution due to the experimental geometry. Our current work focuses on disentangling the two effects. Ref: [1] PRB **101**, 205125(2020), [2] PRB **98**, 125127(2018)

Investigation of phase-transitions in MoTe$_2$ using ToF-MM — •O. Fedchenko[1], F. Diekmann[2], K. Medjanik[1], M. Kallmayer[3], S. Babenkov[1], D. Vasilyev[1], O. Tkach[1], M. Souliou[4], M. Frachet[4], M. Le Tacon[4], K. Rossnagel[2], A. Winkelmann[5], G. Schönhense[1], and H.-J. Elmers[1] — [1]JGU, Institut für Physik, Mainz, Germany — [2]Institut für Experimentelle und Angewandte Physik, CAU Kiel, Germany — [3]Surface Concept GmbH, Mainz — [4]KIT, IQMT, Karlsruhe, Germany — [5]ACMN, AGH University of Science and Technology, Krakow, Poland

MoTe$_2$ is unique among transition metal dichalcogenides (TMDCs) because it can be grown in both the semiconducting (2H) and semimetallic (1T') phase. The transitions between these phases can be controlled with temperature and doping concentration. Using time-of-flight momentum microscopy (ToF-MM), the thermally-induced inversion symmetry breaking in doped Mo$_{1-x}$W$_x$Te$_2$ is investigated. Pristine MoTe$_2$ and Mo$_{0.98}$W$_{0.02}$Te$_2$ take the 2H phase, which does not show any thermal induced phase transition. For increased W doping concentration we obtain the metastable monoclinic 1T' phase at 300K (RT), which then can be transformed to the orthorhombic T$_d$ phase at T<170 K (LT). Raman and XRD measurements confirm the structural transitions.The T$_d$-phase exhibits topological states identified by Fermi arcs, up to binding energy of E$_B$ = 75 meV.

Geometry-induced spin-filtering in photoemission maps from WTe$_2$ surface states — Tristan Heider[1], Gustav Bihlmayer[2], Jakub Schusser[3,4], Frierich Reinert[4], Jan Minar[3], Stefan Blügel[2], Claus M. Schneider[1], and •Lukasz Plucinski[1] — [1]PGI-6 Forschungszentrum Jülich — [2]PGI-1 Forschungszentrum Jülich — [3]University of West Bohemia, Pilsen, Czech Republic — [4]Experimentelle Physik VII, Universität Würzburg

WTe$_2$ is a semi-metallic quantum material that exhibits non-saturating magnetoresistance and potentially hosts Weyl type-II nodes [1]. Through laser-driven spin-polarized ARPES Fermi surface mapping, we demonstrate highly asymmetric spin textures of electrons photoemitted from the surface states of WTe$_2$ [2]. Such asymmetries are not present in the initial state spin textures, which are bound by time-reversal and crystal lattice mirror plane symmetries. The findings are reproduced qualitatively by theoretical modeling within the one-step model photoemission formalism, and a simple toy-model suggests that a similar effect shall be observed in other materials with low symmetry. Our spin-polarized maps, with detail comparable to the previous spin-integrated maps [3], have been measured using the newly developed high-resolution instrument at PGI-6 in Jülich that is based on a hemispherical analyzer with the scanning lens, an exchange-scattering spin detector, and a cw 6 eV laser.

Observing Duffing oscillations in 2D materials by ultrafast electron imaging — •Alexander Schröder, Lina Hansen, and Sascha Schäfer — Institute of Physics, University of Oldenburg, Germany

Two-dimensional materials are an ideal test bed for probing non-linear mechanical resonances. With sample thicknesses down to the atomic scale, the nonlinear regime of mechanical resonances can be observed even for small actuation forces. Previously, the response of such nano- and micromechanical systems was probed by optical or electronic means, leaving details of the mechanical mode structures and their connection to atomic defects unresolved. Here, we present the nanoscale probing of nonlinear Duffing resonances in free-standing graphite membranes using large-angle convergent-beam diffraction in an ultrafast transmission electron microscope equipped with an event-based electron detector with nanosecond temporal resolution. The vibrational membrane modes are excited by a diode laser beam with a tunable modulation rate and a series of resonances are observed in the MHz frequency range with high quality factors (up to 10^4). As expected for prototypical Duffing resonances, increasing the optical excitation strength yields a strong nonlinear hardening of the oscillator, with an increase in vibrational amplitude, an asymmetric broadening of the resonance line shape, bistable behavior, and a characteristic frequency-dependent phase shift. The novel detection scheme as proposed here is ideally suited for characterizing the behavior of ultra-small resonators difficult to address with other techniques.

O 30.7   Tue 12:00   GER 37

Limitations of supercell extrapolation for charged defects at surfaces & 2D materials — •Christoph Freysoldt[1], Anne Marie Z. Tan[2,3], Richard G. Hennig[2], and Jörg Neugebauer[1] — [1]Max-Planck-Institut für Eisenforschung, Max-Planck-Straße 1, 40237 Düsseldorf, Germany — [2]Department of Materials Science and Engineering, University of Florida, Gainesville, Florida 32611, USA — [3]School of Mechanical and Aerospace Engineering, Nanyang Technological University, Singapore 639798, Singapore

Ab initio calculations of defects often employ the repeated slab approach for its simplicity. Unfortunately, spurious interactions between the defect and its periodic images make it sometimes challenging to estimate the dilute limit, that is relevant for comparison to experiment, from computationally affordable system sizes. A simple and seemingly straightforward approach is to extrapolate from a series of finite supercell sizes to the infinite-size limit, assuming a smooth, polynomial dependence of the energy on inverse supercell size. By means of explicit density-functional theory supercell calculations and simplified electrostatic models we demonstrate that the dependence of the formation energy on supercell size can be more complex than is commonly assumed. We show that this complexity cannot be captured by the simple extrapolation approaches. In contrast, suitable correction schemes are shown to provide rapidly converging results even for 2D materials.

Excited state geometry relaxation of point defects in hexagonal boron nitride — •Alexander Kirchhoff, Thorsten Deilmann, and Michael Rohlfing — Westfälische Wilhelms-Universität Münster, Institut für Festkörpertheorie, Wilhelm-Klemm-Straße 10, 48149 Münster

The optical gap of pristine hexagonal boron nitride is above 5 eV and therefore in the deep UV range. Emitters in the optical regime can act as single photon sources and gained attraction due to their possible room temperature stability. However, their atomic composition is still elusive. Experiments combining spectroscopic methods to probe ground as well as excited state of defects in hBN have revealed the relevance of the dependence of optoelectronic properties on the nuclear geometry.

In our work, this dependence is studied within the framework of density functional theory and the *GW*/BSE approximation. We focus on carbon based defects in hBN and present a detailed analysis of their excitonic spectrum [1]. C$_B$O$_N$ for example has a defect bound exciton at 1.5 eV. We obtain a Stokes shift of about 1 eV by calculating the energy surfaces of ground and excited state.

Semiclassical theory of plasmons in inhomogeneous two-dimensional systems — •Tjacco Koskamp, Koen Reijnders, and Mikhail Katsnelson — Radboud University, Nijmegen, The Netherlands

We consider plasmons, collective oscillations of conduction electrons, in inhomogeneous two-dimensional systems with parabolic dispersion. In recent years, the quantum regime for plasmons has become experimentally accessible. Although these systems can be studied numerically, this approach is limited to relatively small systems. Recently, a comprehensive analytical theory for plasmons based on the semiclassical (WKB) approximation was proposed [1]. It describes plasmons in inhomogeneous three-dimensional systems, and is applicable when the inhomogeneity, in e.g. the electron density, varies smoothly.

In this talk, we extend this theory to plasmons in inhomogeneous two-dimensional systems. We consider the equation of motion for the density matrix and take the electron-electron interaction into account through the RPA. We solve this system of equations self-consistently, carefully separating the in-plane and out-of-plane degrees of freedom. In this way, the effective classical Hamiltonian for plasmons is obtained. Subsequently, we apply this theory to a scattering experiment. We first construct the classical trajectories and then use the semiclassical phase shift to compute the differential scattering cross section.

Hot electron driven charge carrier dynamics at the MoS$_2$/gold interface: a sum frequency generation study — •Tao Yang, Erik Pollmann, Stephan Sleziona, Peter Kratzer, Marika Schleberger, Richard Kramer Campen, and Yujin Tong — Fakultät für Physik, Universität Duisburg-Essen, 47057 Duisburg, Germany

Monolayer transition metal dichalcogenides (TMDCs) have potential applications as optoelectronics and (photo)electrocatalysts due to their fascinating electronic and optical properties. Applying these extraordinary properties to build devices and catalysts, it is often necessary to bring TMDCs into contact with a metallic surface. However, the charge transfer process across the semiconductor-metal interface is still not clear. While the quench of photoluminescence spectra has been reported for monolayer TMDCs on gold, which was understood to be a charge transfer of excited electrons from TMDC monolayer into the metal, it's interesting to ask what happens when the charge carrier is excited from the metal side. Here we use an azimuthal-dependent sum frequency generation combined with a pump-probe scheme to study the effect of the selectively excited hot electrons by 800 nm pump laser on the behavior of excitons of monolayer MoS$_2$. Our results show that the hot electrons from the gold substrate can significantly suppress the formation of excitons.

O 30.11   Tue 13:00   GER 37
Structure and electronic-optical properties of polymeric carbon nitride — •Changbin Im, Björn Kirchhoff, and Timo Jacob — Ulm University, Institute of Electrochemistry, Ulm, Germany

Understanding of the electronic structure and optical properties of polymeric carbon nitrides (PCNs) is of key interest in order to exploit their photo-physical and photo-electrocatalytic capabilities. The numerous defects of typical PCNs, however, present a limitation to computational studies that aim to improve our fundamental understanding of this material class. Here, we demonstrate a systematic thermodynamic study and structural characterization of various heptazine based-PCN models from the viewpoint of electronic and optical properties obtained with hybrid density functional theory (DFT). Our calculations reveal the key structural factors (degree of condensation, interlayer distance, corrugation) that govern the formation of various PCN motifs and their optical properties.[1] We discuss how each of the key factors influences the electronic structure of PCNs. We also suggest the concept of exciton binding energy in PCNs and discuss the polaronic interactions between heptazine units due to the localized exciton nature. Furthermore, we disclose a failure of GGA in the description of correlated electrons that underestimates the energy of the conjugated electrons comparing hybrid DFT. From the results, we could not only deduce a more complete model for the diverse PCN motifs but could additionally derive fundamental trends for future material optimization.

O 31: Focus Session: Ion Beam Interaction with Surfaces and 2D Materials III

Time: Tuesday 10:30–12:45   Location: GER 38

Topical Talk   O 31.1   Tue 10:30   GER 38
Ultra-low energy ion implantation of two-dimensional materials — •Hans Hofsäss[1], Felix Junge[1], Manuel Auge[1], Beata Kardynal[2], Ursel Bangert[3], Martin Wenderoth[4], and Lino Pereira[5] — [1]2nd Institute of Physics, University of Göttingen, Germany — [2]Peter Grünberg Institute, Forschungszentrum Jülich, Germany — [3]Department of Physics, University of Limerick, Ireland — [4]4th Institute of Physics, University of Göttingen, Germany — [5]Department of Physics, KU Leuven, 3001 Leuven, Belgium

Doping of two-dimensional (2D) materials by ion implantation requires unique requirements regarding ion energy, ion beam optics and sample preparation. Efficient substitutional incorporation of low energy ions into the 2D lattice requires energies around 20 eV. We use a low energy mass selected ion beam system with UHV implantation chamber. A 30 keV mass selected ion beam is guided through differential pumping stages and homogenized using a beam sweep. An area of about 1-2 cm^2 can be uniformly irradiated with these ultra-low-energy (ULE) ions with a beam current up to several microAmp. Results for doping of monolayer graphene with B$^+$, N$^+$ an P$^+$ ions and doping of 2D MoS$_2$ with Se$^+$ and Cr$^+$ ions will be presented. We discuss challenges for ULE ion implantation, such as non-flat substrates, ion sources and lateral selective doping. Results for analyses of the implantation efficiency and lateral doping are presented. The simulation of ULE ion implantation using novel Monte Carlo Binary Collision Approximation programs is also discussed.

O 31.2   Tue 11:00   GER 38
Low-Energy Ion Implantation with an electron beam evaporator — •Tom Weinert, Denise Jennifer Erb, Stefan Facsko, René Heller, and Ulrich Kentsch — Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Deutschland

For ion implantation of thin films and in particular of two-dimensional materials, it is necessary to reduce the ion energy down to 10eV. For this purpose, we develop a a simple and robust setup via a new approach. We use an electron beam evaporator to generate the desired ions. This has the advantage of a relatively small energy distribution of the ions, and in addition numerous different metal ions can be generated. An electrostatic analyzer is used to filter out the neutral atoms and to improve the energy distribution of the ion beam to below 5eV. The used ion energy is below 1keV and is suitable for the implantation of very thin surface layers or, after further energy reduction, for implantation in two-dimensional materials. Ion implantation can change the properties of two-dimensional materials, enabling, for example, new electrical, magnetic or catalytic applications.

O 31.3   Tue 11:15   GER 38
Fabrication of 2D magnets by ion implantation of phyllosilicates — Muhammad Zubair Khan[1], Nico Klingner[2], Gregor Hlawacek[2], Aleksandar Matković[1], and •Christian Teichert[1] — [1]Institute of Physics, Montanuniversität Leoben, 8700 Leoben, Austria — [2]Helmholtz-Zentrum Dresden-Rossendorf e.V., 01328 Dresden, Germany

Since the first reports on intrinsically magnetic two-dimensional (2D) materials in 2017 [1,2], the price-to-pay for accessing their monolayers is still the lack of ambient stability. Recently, we demonstrated weak ferromagnetism in 2D Fe:talc

at room temperature and proposed iron-rich phyllosilicates as a promising platform for air-stable magnetic monolayers [3]. Since these minerals are rather rare and since phyllosilicates are hard to synthesize, we suggest here as an alternative ion implantation to tailor the magnetic properties of the phyllosilicates. Nonmagnetic, single-crystalline bulk talc crystals [4] were implanted with 50 keV iron and cobalt ion beams at different substrate temperatures. In all cases, ultra-thin layers could be exfoliated indicating that the layered crystal structure is maintained after ion irradiation. For both ion species, the Mg-OH Raman peak showed a triplet formation implying a successful substitution of Mg by Fe or Co in the talc layers. [1] Gong, C., et al., Nature 546, 265 (2017). Charge exchange of highly charged ions scattered under grazing incidence — •Matthias Werl, Anna Niggas, Friedrich Aumayr, and Richard A. Wilhelm — TU Wien, Institute of Applied Physics, Vienna, Austria

When a highly charged ion approaches a surface, electrons are resonantly captured from the material, starting at distances of $\approx 10 - 25$ Å above the surface. The electrons are captured into shells with $n \approx q_{in}$ (q_{in}: incident charge state), forming a hollow atom (*HA*) - a state where (mostly) high-n shells are populated. In the free case, these excited *HA*s would then decay via a combination of auto-ionization and radiative pathways, recharging the projectile in the process. At very close distances from a surface ($d_I \leq 3$ Å), another process, known as Interatomic Coulombic Decay (*ICD*), can take place. Here, the *HA* quickly decays to its ground state due to electron-electron scattering with electrons from the material.

To study the *HA*s and their free decay, neutralization via *ICD* is to be prevented. This can be achieved if the distance of closest approach is larger than d_I, which happens at very grazing angles. Previous experiments showed that only a minor fraction of charged particles survive up to the detector under an incident angle of $\alpha_{inc} = 1.6°$. Decreasing the incident angle even further ($0.1° \leq \alpha_{inc} \leq 1.0°$), more charged particles are expected to arrive at the detector.

Here, we present our setup to achieve these small incident angles with an accuracy of $\approx \pm 0.2°$ as well as first experimental results for the charge state distribution of the scattered projectiles.

O 31.5   Tue 11:45   GER 38
Green functions simulation of the energy and charge transfer between highly charged ions and 2D materials — •Michael Bonitz[1], Karsten Balzer[2], Hannes Ohldag[1], Jan-Philip Joost[1], Anna Niggas[3], and Richard Arthur Wilhelm[3] — [1]CAU Kiel, Institute for Theoretical Physics and Astrophysics — [2]CAU Kiel, Computing Center — [3]TU Wien, Institute of Applied Physics, Vienna, Austria

We have developed Nonequilibrium Greenfunctions (NEGF) - Ehrenfest dynamics simulations for the energy loss of ions that impact correlated 2D materials. An interesting prediction was an ion-induced increase of the doublon number [1]. Recently, these simulations were extended to highly charged ions and to the associated charge transfer and electron emission. We find reasonable

agreement with the experimental predictions [2]. Here we discuss how these simulations can be extended to longer times and improved selfenergies via our G1-G2 scheme [3], combined with an embedding selfenergy approach [4].

Particle emission from 2d materials induced by highly charged ion impact — •Lucia Skopinski[1], Lars Breuer[1], Silvan Kretschmer[2], Arkady V. Krasheninnikov[2], and Marika Schleberger[1] — [1]Universität Duisburg-Essen, Duisburg, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

Two-dimensional (2d) materials such as graphene or transition metal dichalcogenides are expected to be key materials for novel applications. Defect engineering by highly charged ion (HCI) beams could be a way to modify their unique properties even further. An ion carries energy in the form of kinetic energy E_{kin} and potential energy E_{pot}, the latter corresponding to the energy required to create its respective charge state. Once the ion impinges on the surface, its energy is deposited into the solid and can lead to modifications and sputtering. However, the fundamental mechanisms of defect formation due to HCI-surface interaction are still under investigation.

Here, we discuss the emission of secondary ions and atoms as well as their velocity distribution from a substrate supported 2d material under HCI irradiation. The measured distributions allow a distinction between sputtering driven by the potential and the kinetic energy of the primary ion. The potential sputtering yield of MoS_2 has a similar dependence on the potential energy as the pore formation found in freestanding MoS_2 after irradiation with HCIs. The low velocities of the emitted particles indicate an interaction mechanism connected to electron-phonon coupling.

O 31.7   Tue 12:15   GER 38

Highly charged ion-induced electron emission from atomically thin materials — •Anna Niggas[1], Karsten Balzer[2], Matthias Werl[1], Friedrich Aumayr[1], Michael Bonitz[3], and Richard Arthur Wilhelm[1] — [1]TU Wien, Institute of Applied Physics, Vienna, Austria — [2]Computing Center of Kiel University, Kiel, Germany — [3]Kiel University, Institute for Theoretical Physics and Astrophysics, Kiel, Germany

When a highly charged ion impacts on a material surface, its potential energy, i.e., the sum of the binding energies of all missing electrons, is deposited within the very first surface layers. This, in turn, triggers many processes such as the emission of electrons. While both the electron yield and energy distribution of bulk samples have been extensively studied in the past, data for 2D materials is rather scarce. This is due to the challenging task of separating signals of the 2D material itself from its support structure. Therefore, we developed a coincidence setup correlating ions after transmission with electrons emitted from the material. This allows us to discriminate signals from the support via the ion energy loss in the sample and, consequently, to access the emission from the 2D material alone.

In this contribution we will present our recent studies on the electron emission induced by highly charged ion impact on monolayers of graphene and MoS_2 and their 3D counterparts. We find a 6-fold higher emission yield for graphene compared to MoS_2 and a vanishing contribution of < 10 eV electrons for MoS_2. These findings are supported by simulations of the ion-induced surface charge dynamics.

O 31.8   Tue 12:30   GER 38

Light ion transmission through atomically thin material: insights from non-adiabatic first-principles simulations — •Silvan Kretschmer[1], Arkady V. Krasheninnikov[1], Anna Niggas[2], Lukas Fischer[2], and Richard A. Wilhelm[2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, Dresden, Germany — [2]TU Wien, Institute of Applied Physics, Vienna, Austria

Two-dimensional materials, as surface-only targets, are ideally suited to study the neutralization and deexcitation of charged particles. Using atomistic Ehrenfest dynamics simulations we rationalize the experimental findings obtained for transmission of H^+ and He^+ through graphene and 2D-MoS_2. Here semi-metal and semi-conductor are chosen exemplary to explore potentially different neutralization behaviour. Changes in the electronic structure are calculated along with the energy loss and the charge transfer from the target to the projectile during the transmission and compared to the experiment. Furthermore, low-charge state ions represent a suitable model system to validate the framework of Ehrenfest dynamics to be extended to their highly charged counter parts.

Progress in local growth of III/V-semiconductor structures — •Christian Bruckmann, Jürgen Bläsing, Armin Dadgar, and André Strittmatter — Otto-von-Guericke-Universität Magdeburg, PF4120 Magdeburg, Germany

We recently developed a laser-assisted metalorganic vapor phase epitaxy (LA-MOVPE) for local growth of III/V-semiconductors[1]. The principle is based on local heating of a selected growth area by high-power laser radiation. Metalorganic precursors are fed into the reactor to the locally heated area so that the chemical reactions leading to island growth are confined within the heated area. Thereby, selective area growth can be done without full wafer heating which is advantageous for heteroepitaxy of crystalline materials and monolithic III/V device integration on Si. We report on optimum conditions for homoepitaxial GaAs growth, n- and p-type doping as well as AlGaAs/GaAs heterostructures. We discuss the proper choice of precursors and lateral homogeneity of ternary layers.

O 32.2   Tue 10:45   GER 39

Post-synthesis of copper nitride monolayers from copper oxide films — •Mohammadreza Rostami[1], Biao Yang[1], Francesco Allegretti[1], Lifeng Chi[2], and Johannes V. Barth[1] — [1]Physics Department E20, Technical University of Munich, Garching, 85748, Germany — [2]Institute of Functional Nano & Soft Materials, Collaborative Innovation Center of Suzhou Nano Science and Technology, Soochow University, Suzhou 215123, P. R. China

Copper nitride (CuN) thin films represent insulating layers bearing promise for decoupling functional structures from a metallic copper substrate. [1] Although the nitrogen ion bombardment method was successfully applied for the in-situ preparation of CuN monolayers on Cu surfaces, the reduced domain size limits their application potential. [2] In this work, we have grown extended monolayer CuN films on Cu (111) surfaces by ammonia-mediated post-annealing of copper oxide (CuO) thin films. Structures and properties of CuN and CuO monolayers were characterized by scanning tunneling microscopy and low-energy electron diffraction. The element exchange of nitrogen with oxygen in the respective CuN and CuO layers on Cu (111) surfaces was evidenced by X-ray photoelectron spectroscopy. This oxidation-reduction two-step strategy provides a new approach to fabricate CuN buffer layers. [1] Z. Zhao et al, Adv. Electron. Mater. 2018, 4, 1700367 [2] H. Baek et al, Appl. Phys. Lett. 91, 253106 (2007)

The role of mechanical strain in rare-earth silicide monolayers on Si(111) — •Kris Holtgrewe and Simone Sanna — Justus-Liebig-Universität, Gießen, Deutschland

Rare-earth silicide ($RESi_2$) nanostructures on silicon surfaces provide a very heterogeneous class of lower-dimensional metallic systems supported by a semiconducting substrate. The $RESi_2$ monolayer is a two-dimensional semimetal, which grows on Si(111) by self-organisation. While it has intensively been studied by experimental and theoretical works, there are major misunderstandings about the mechanisms which determine the morphological details of the monolayer. In particular, many previous studies state that mechanical strain is responsible for the structural differences between the $RESi_2$ monolayer on Si(111) (buckled Si honeycomb, vacancy-free), the $RESi_{2-x}$ bulk phase (flat Si honeycomb, vacancy-rich) and the AlB_2 structure (flat Si honeycomb, vacancy-free). This DFT work sheds light on the stability of the established structure model of the monolayer by a combined analysis of the structural details and the electronic band structure. It proves that the buckling of the covering Si honeycomb and the lack of Si vacancies are not due to mechanical strain, but due to charge balance. In this context, the monolayer is structurally more similar to the unstrained $CaSi_2$ structure than to the strained AlB_2 structure, which explains its stability. It is very likely that the misinterpreted role of mechanical strain is transferable to all $RESi_2$ nanostructures.

Electronic and magnetic properties of ultrathin $FeBr_2$ films grown on Bi/Si(111) — •Shigemi Terakawa[1], Jiabao Yang[1], Shinichiro Hatta[2], Hiroshi Okuyama[2], Tetsuya Aruga[2], Niels Schröter[1], and Stuart Parkin[1] — [1]Max Planck Institute of Microstructure Physics, Halle, Germany — [2]Graduate School of Science, Kyoto University, Kyoto, Japan

Mono and a few layers of van der Waals (vdW) magnets are promising two-dimensional (2D) materials to fabricate heterostructures with topological materials to realize novel topological phases via proximity effects, such as the quantum anomalous Hall effect. $FeBr_2$ is a layered Ising antiferromagnet, where the magnetic moments are coupled ferromagnetically in a layer and antiferromagnetically between adjacent layers. We succeeded in the epitaxial growth of ultrathin $FeBr_2$ films using molecular-beam epitaxy on Bi/Si(111) substrate. We observed insulating band structures using angle-resolved photoelectron spectroscopy (ARPES). The valence band top is located at a flat band with a binding energy of 2 eV, which is ascribed to Fe 3d orbitals. At monolayer coverage, the Fe 3d flat band does not change but dispersive bands of Br 4p at 7-8 eV are largely altered due to the disappearance of inter-layer Br-Br coupling in the monolayer film. The monolayer film shows a strong moire pattern in low-energy electron diffraction (LEED), suggesting a strong coupling between the $FeBr_2$ and Bi films. We plan to discuss the magnetic properties of the $FeBr_2$ films from the results of XMCD experiments.

In situ XPS Study on ultrathin Fe_xO_y Films on $SrTiO_3$ — •PIA MARIA DÜRING, TIMO KRIEG, and MARTINA MÜLLER — Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany

Oxide interfaces are emerging as one of the most interesting systems in condensed matter physics as they exhibit a multitude of physical phenomena such as 2D electron/hole gas, superconductivity, or the Spin Hall effect. One of the main processes that controls the physical properties is the oxygen exchange between the film and the substrate. The tunability of the oxygen transfer using different growth parameters opens up the possibility to unravel unexplored properties.

Using our UHV-MBE system, we grow high-quality ultrathin Fe-oxide films on $SrTiO_3$ substrates by systematically varying certain growth parameters. Performing in situ X-ray Photoelectron Spectroscopy and Low Energy Electron Diffraction enables the analysis of the electronic properties and crystalline structure of ultrathin Fe_xO_y films directly after the growth without any atmospheric contamination.

The present work discusses the effect of different growth temperatures, substrate annealing procedures, and film thicknesses of the Fe_xO_y films on the interfacial properties like oxygen vacancies. The results open up the possibility for the emergence of 2D electronic states at the interface by tuning such growth parameters.

MOVPE of Stacked Quantum Dots Layers at 1250 nm Wavelength — •EGE ÖZMEN, ARMIN DADGAR, and ANDRÉ STRITTMATTER — Otto von Guericke University, Magdeburg, Germany

LIDAR, light detection and ranging, is the technology to produce a 3D model of surroundings using semiconductor laser technology. In LIDAR, the return of laser pulses reflected from an object's surface is recorded in time. For optimum control of laser direction, a tightly bundled laser radiation is required. Since the light output from traditional semiconductor edge-emitting lasers is highly divergent, especially along the vertical axis, novel concepts for optical waveguides in laser diodes with lower output divergence have to be considered. Besides, as LIDAR operates in free space, a proper choice for laser wavelength has to be made. The current choice is around 905 nm wavelength which raises concerns about eye safety. Much better eye safety and therefore higher output powers could be realized if high-brilliance lasers operating at 1250 nm wavelength could be used. Here, we report on an optimization of MOVPE growth conditions to obtain up to 10-fold stacks of InGaAs quantum dots on a GaAs(001) substrate. We compare laser structures with 5-10 QD layers for static output characteristics.

About the excitation of island growth orthogonal to the surface in the substrate Pb/Si(111)-(7x7) — •PAUL PHILIP SCHMIDT, LEA FABER, and REGINA HOFFMANN-VOGEL — Institute of Physics and Astronomy, University of Potsdam, 14476 Potsdam-Golm, Germany

With the increasing miniaturization of systems, the phenomena of surface diffusion is becoming more and more relevant. Pb shows anormaly fast mass transport on Si(111)-(7x7) [1,2]. For this system island growth and the behaviour of the wetting layer must be taken into account in order to understand the physical processes at the surface. We investigate the growth of the islands. Si was cleaned by rapid heating to 1200°C. Pb was deposited on the sample by evaporation at room temperature or liquid nitrogen temperature (120K). We create local imbalances of Pb to draw conclusions about diffusion and selectively trigger island growth at individual islands. While we measure the topography with non contact atomic force microscopy, we simultaneously determine the local work function difference with Kelvin probe force microscopy. Our experiments show an energy barrier before ring growth occurs. Once atoms have reached an existing island, ring growth around occurs quickly. In experiments where we do not force this the islands hardly show any growth perpendicular to the surface. Part of the Pb comes from the restructuring of the island, which initially shrinks in the xy-direction.

Solution-Synthesized Extended Graphene Nanoribbons Deposited by High-Vacuum Electrospray Deposition — •SEBASTIAN SCHERB[1], ANTOINE HINAUT[1], XUELIN YAO[2], ALICIA GÖTZ[2,3], SAMIR H. AL-HILFI[2], XIAO-YE WANG[2], YUNBIN HU[2], ZIJIE QIU[2], YIMING SONG[1], KLAUS MÜLLEN[2,3], THILO GLATZEL[1], AKIMITSU NARITA[2], and ERNST MEYER[1] — [1]Department of Physics, University of Basel, Basel, Switzerland — [2]Max Plank Institute for Polymer Research, Mainz, Germany — [3]Department of Chemistry, Johannes Gutenberg University Mainz, Mainz, Germany

Solution-synthesized graphene nanoribbons (GNRs) can facilitate various interesting structures or functionalities, like non-planarity and thermo-labile functional groups, which can be difficult to access via on-surface synthesis [1,2]. However, their deposition and thus study on surfaces remains challenging.

Here, we show high-vacuum electrospray deposition (HVESD) of well-elongated solution-synthesized GNRs on metallic and non-metallic surfaces in UHV. Thereby, we compare three distinct GNRs, exhibiting different average lengths, functional groups, and edge structures. nc-AFM studies at room temperature combined with Raman spectroscopy allow the characterization of individual GNRs and confirm their chemical integrity [3].

Ultra-thin Noble Metal Films on Superconductors — •CHRISTIAN VON BREDOW, PHILIP BECK, LUCAS SCHNEIDER, JENS WIEBE, and ROLAND WIESENDANGER — Department of Physics - University of Hamburg, Hamburg, Germany

Magnet-superconductor hybrid systems involving Rashba-split surface states proximitized by a superconducting substrate are promising platforms for the realization of topological superconductivity [1,2,3]. To that end, a large gap of the superconductor, strong spin-orbit coupling, and a high surface quality that allows for the manipulation of individual magnetic atoms using the tip of a scanning tunneling microscope are strongly desired. In order to engineer a system with the desired properties we investigate the growth and surface-state dispersion of thin noble metal films on the (110)-surface of the elemental superconductor with the highest critical temperature, niobium. Starting from a few monolayer thickness, we observe the well known quasiparticle interference of the Shockley (111) surface state. Bias-dependent data is used to extract the layer-thickness dependence of the band bottom and the effective electron mass.

Fermi liquids, Luttinger integrals, topological invariants ... and magnetic molecules — •ROK ZITKO[1,2], GERMAN G. BLESIO[1,3], LUIS O. MANUEL[3], and ARMANDO A. ALIGIA[4] — [1]Jozef Stefan Institute, Ljubljana, Slovenia — [2]Faculty of Mathematics and Physics, University of Ljubljana, Slovenia — [3]Instituto de Fisica Rosario (CONICET) and Universidad Nacional de Rosario, Argentina — [4]INN CNEA-CONICET, Centro Atomico Bariloche and Instituto Balseiro, Bariloche, Argentina

The ground state of a system of interacting fermions is often a Fermi liquid with elementary excitations that are in a one-to-one correspondence with those of a

non-interacting Fermi gas. A key idea in Landau's theory is the adiabatic connection between the interacting and the non-interacting system. The adiabatic connection does not, however, always exist and there are several impurity problems where the ground state is known to be a Fermi liquid that is not of the Landau type. I will present the case of the two-channel S=1 Kondo model with single-ion magnetic anisotropy which has a topological quantum phase transition separating two different Fermi-liquid phases. I will discuss how the conservation laws constrain the Luttinger integrals so that their linear combinations become topological invariants, and how the modified Friedel sum rules lead to a peculiar variation of the impurity spectral function. I will then show that the

tunneling spectra of iron phthalocyanine molecules on Au(111) surface and of nickelocene molecules on Cu(100) surface can be consistently interpreted in the framework of non-Landau Fermi liquid theory.

Locally driven quantum phase transition cascades in a strongly correlated molecular monolayer — Soroush Arabi[1,2,3], Taner Esat[2,5], Aizhan Sabitova[2,5], Yuqi Wang[2,3], Hovan Lee[6], Cedric Weber[6], Kern Klaus[3,4], F. Stefan Tautz[1,2,5], Ruslan Temirov[2,7], and •Markus Ternes[1,2,5] — [1]Institute of Physics IIB, RWTH Aachen University, 52074 Aachen, Germany — [2]Peter-Grünberg-Institute (PGI 3), Research Center Jülich, 52425 Jülich, Germany — [3]Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany — [4]Institut de Physique, École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland — [5]Jülich Aachen Research Alliance, 52425 Jülich, Germany — [6]King's College London, Theory and Simulation of Condensed Matter, London WC2R 2LS, UK — [7]Institute of Physics II, University of Cologne, 50937 Cologne, Germany

The molecular monolayer of 1,4,5,6-naphthalene tetracarboxylic acid dianhydride on Ag(111) creates a perfectly ordered lattice of π-conjugated organic molecules. Using a movable atomically sharp electrostatic gate we drive this lattice of strongly correlated electrons through a cascade of quantum phase transitions. Performing spec- troscopic imaging with sub-Angstrom resolution, we show that as the gate field is increased, the molecular building blocks change from a Kondo-screened to a paramagnetic phase one by one, enabling us to reconstruct their complex interactions in detail. We anticipate that the supramolecular nature of the system will, in future, allow engineering quantum correlations in arbitrary patterned structures.

O 33.3   Tue 11:15   REC C 213
Engineering antiferromagnetic spin coupling in carbon based nanostructures — •Elia Turco[1], Nils Krane[1], Fupeng Wu[2], Michal Juricek[3], Xinliang Feng[2], Pascal Ruffieux[1], and Roman Fasel[1] — [1]Empa Swiss Federal Laboratories for Materials Science and Technology, Duebendorf, Switzerland — [2]Faculty of Chemistry and Food Chemistry, and Center for Advancing Electronics Dresden, Technical University of Dresden, Germany — [3]Department of Chemistry, University of Zurich, Switzerland

On-surface synthesis offers the possibility to engineer atomically precise nanogaphenes (NGs) with intrinsic magnetic ground states. Unlike atomic magnets, unpaired π-electrons are highly delocalized and prone to hybridize forming entangled quantum states, which are the main requisite for the emerging quantum technologies. Zigzag-edged triangular NGs are regarded as prototypical magnetic building blocks, hosting a total spin S that scales with molecular size [1]. In this contribution, we will present the on-surface synthesis and scanning probe microscopy & spectroscopy of the two smallest S = 1/2 and S = 1 triangulenes on a Au(111) surface, where the Kondo screening of the unpaired spins is a direct evidence of their magnetic ground state. Connecting the two S = 1/2 and S = 1 building blocks into homo- and hetero-dimers an -trimers, we realize multilevel quantum systems with increasing complexity, characterized by multiple inelastic spin excitations. The significant hybridization of the unpaired π-electrons results in strong quantum correlations, which have never been achieved for equivalent atomic systems. [1] J.Su et al. Angew. Chem. 132 (2020)

O 33.4   Tue 11:30   REC C 213
Moiré tuning of spin excitations: individual Fe atoms on MoS_2/Au(111) — •Christian Lotze[1], Sergey Trishin[1], Nils Bogdanoff[1], Felix von Oppen[2], and Katharina J. Franke[1] — [1]Fachbereich Physik, Freie Universität Berlin, Germany — [2]Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin, Germany

Magnetic adatoms on properly designed surfaces constitute exquisite systems for addressing, controlling, and manipulating single quantum spins. Here, we show that monolayers of MoS_2 on a Au(111) surface provide a versatile platform for controllably tuning the coupling between adatom spins and substrate electrons. Even for equivalent adsorption sites with respect to the atomic MoS_2 lattice, we observe that Fe adatoms exhibit behaviors ranging from pure spin excitations, characteristic of negligible exchange and dominant single-ion anisotropy, to a fully developed Kondo resonance, indicating strong exchange and negligible single-ion anisotropy. This tunability emerges from a moiré structure of MoS_2 on Au(111) in conjunction with pronounced many-body renormalizations. We also find striking spectral variations in the immediate vicinity of the Fe atoms, which we explain by quantum interference reflecting the formation of Fe-S hybrid states despite the nominally inert nature of the substrate. Our work establishes monolayer MoS_2 as a tuning layer for adjusting the quantum spin properties over an extraordinarily broad parameter range. The considerable variability can be exploited for quantum spin manipulations.

O 33.5   Tue 11:45   REC C 213
Absence of the Kondo effect for Co on Cu(111) — Neda Noei[1], Roberto Mozara[2], Ana M. Montero[3], Sascha Brinker[3], Niklas Ide[1], Filipe S. M. Guimaraes[3], Alexander I. Lichtenstein[2], Richard Berndt[1], Samir Lounis[3], and •Alexander Weismann[1] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, D-24098 Kiel, Germany — [2]Institut für Theoretische Physik, Universität Hamburg, D-20355 Hamburg, Germany — [3]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, 52425 Jülich, Germany

The zero-bias anomaly in conductance spectra of single Co atoms on Cu(111) observed at $\approx$ 4 K, which has been interpreted as being due to a Kondo resonance, is strongly modified when the Co atoms are attached to monatomic Cu chains. Scanning tunneling spectra measured at 340 mK in magnetic fields exhibit all characteristics of spin-flip excitations. Their dependence on the magnetic field reveals a magnetic anisotropy and suggests a non-collinear spin state indicating that spin-orbit coupling (SOC), which has so far been neglected in theoretical studies of Co/Cu(111), has to be taken into account. According to our density functional theory and multi-orbital quantum Monte Carlo calculations SOC suppresses the Kondo effect for all studied geometries. The interpretation of the zero-bias anomaly in terms of a Kondo resonance is apparently incorrect.

O 33.6   Tue 12:00   REC C 213
Are excitations of the 4f magnetic moment visible to the scanning tunneling spectroscopy? — Daria Kyvala and •Jindrich Kolorenc — Institute of Physics (FZU), Czech Academy of Sciences, Praha, Czech Republic

The inelastic electron tunneling spectroscopy (IETS) has repeatedly proved useful for investigation of spin excitations in transition-metal atoms on surfaces [1,2]. Analogous observations of magnetic excitations in rare-earth atoms remained elusive, the reasoning behind it being that the 4f states that carry the magnetic moment are compact, buried in the atomic core, and the tunneling through a rare-earth atom proceeds via outer, more diffuse orbitals like 5d or 6s. Recently, the exchange coupling between the spin in these outer orbitals and the 4f magnetic moment was observed in IETS as an excitation in the 50–200 meV range [3]. In the same time, some excitations at lower energies were also seen. Employing a variant of the cotunneling theory [4,5] we demonstrate these excitations to be the elusive crystal-field excitations of the 4f magnetic moment. The selection rules prevent the IETS from detecting enough transitions to fully determine the crystal field by itself, but the visible transitions can be used in conjunction with the x-ray absorption spectra [6] to refine the existing estimates of the crystal field. — [1] A. O 33.7   Tue 12:15   REC C 213
Tuning the magnetic anisotropy of two coupled spins in a dinuclear Co(II) complex — Chao Li[1], Roberto Robles[2], Nicolas Lorente[3], Alexander Weismann[1], Richard Berndt[1], and •Manuel Gruber[4] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [2]Centro de Física de Materiales CFM/MPC (CSIC-UPV/EHU), 20018 Donostia-San Sebastián, Spain — [3]Donostia International Physics Center (DIPC), 20018 Donostia-San Sebastian, Spain — [4]Faculty of Physics and CENIDE, University of Duisburg-Essen, 47057 Duisburg, Germany

The magnetic properties of transition-metal ions are often described using a phenomenological spin Hamiltonian, which suggests that S = 1/2 metal ions are isotropic. We investigated a di-nuclear Co(II) complex on Au(111) with low-temperature scanning tunneling microscopy, X-ray magnetic circular dichroism, and density functional theory. The antiferromagnetically coupled Co spins preferentially align along the axis connecting the two Co(II) ions. The magnetic anisotropy is sizable and may be tuned by varying the electronic coupling of the Co(II) ions with the metal electrodes through manipulation of peripheral groups and by approaching the tip toward the complex. These findings may help better describing the magnetic properties of adsorbed molecules, in particular S = 1/2 ions, which are viewed as prototypical systems for quantum operations. Funding from the CRC 1242 is acknowledged.

O 33.8   Tue 12:30   REC C 213
Moiré - induced renormalization of singlet-triplet excitations in antiferromagnetically coupled Mn atoms on MoS_2/Au(111) — •Sergey Trishin[1], Christian Lotze[1], Friedemann Lohss[1], Giada Franceschi[1], Leonid I. Glazman[2], Felix von Oppen[3], and Katharina J. Franke[1] — [1]Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany — [2]Department of Physics, Yale University, New Haven, Connecticut 06520, USA — [3]Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany

The properties of single magnetic atoms can change drastically upon adsorption on a surface, for example due to Kondo-like exchange coupling. The magnitude of these interactions can be tuned by a moiré patterned surface [1]. Here,

we investigate single Mn atoms and dimers on single-layer molybdenum disulfide grown on a Au(111) substrate. The resulting moiré structure enables variations of the Kondo exchange coupling strength. By additionally varying the spacing between single atoms, we can investigate their properties in the direct and indirect exchange coupling regime. We find that at sufficiently close spacings, the Mn atoms form a non-magnetic singlet ground state. However, the singlet-triplet excitation energies vary strongly depending on the dimer location on the moiré structure. We ascribe these variations to a renormalization of the anti-ferromagentic exchange coupling strength.

Stochastic dynamics of individual and coupled orbital memory on black phosphorus — •Hermann Osterhage, Werner M. J. van Weerdenburg, Niels P. E. van Mullekom, Ruben Christianen, Kira Junghans, Eduardo J. Domínguez Vázquez, Hilbert J. Kappen, and Alexander A. Khajetoorians — Radboud University, Nijmegen, The Netherlands

Recently, the dynamics of Co atoms adsorbed on a black phosphorus (BP) surface were shown to emulate a Boltzmann machine (BM) [1]. The BM relies on a tunable multi-well energy landscape, realized in the stochastic switching of coupled atoms which exhibit orbital memory [2]. Stochastic switching between orbital memory states can be induced using scanning tunneling microscopy (STM). The system response depends on interatomic distances and is adaptable to the position of the STM tip and to the applied DC bias [2].

Here, we present the response of individual and coupled Fe and Co atoms on BP to AC input voltages (i.e. frequency and amplitude response), measured using STM down to millikelvin temperatures. We find a frequency response of the orbital memory of single atoms. The changes in orbital state population with varying AC frequency can be derived from the switching dynamics in the DC case. The interatomic coupling is discussed based on changes in switching rates conditioned on the state of a second atom. Also the AC stochastic response in the multi-well limit will be discussed.

Resolving Intervalley Exciton Couplings in Atomically Thin Semiconductors with Multidimensional Spectroscopy — •Lawson Lloyd[1,2], Ryan Wood[2], Fauzia Mujid[2], Siddhartha Sohoni[2], Karen Ji[2], Po-Chieh Ting[2], Jacob Higgins[2], Jiwoong Park[2], and Gregory Engel[2] — [1]Fritz-Haber-Institut, Berlin, Germany — [2]The University of Chicago, Chicago, IL, USA

Atomically thin transition metal dichalcogenides (TMDs) have emerged as promising candidates for next-generation optoelectronic applications. In particular, an optically addressable "valley" degree of freedom at the K/K' points can be used to store and readout information by exploiting the valley-dependent chiral optical selection rules. However, intervalley coupling after optical excitation leads to a loss of the valley polarization on ultrafast timescales. Identifying the microscopic mechanisms driving valley depolarization is therefore critical to advancing useful applications.

Here, leveraging multidimensional electronic spectroscopy, we track the exciton dynamics and couplings in large-area monolayer MoS_2 with femtosecond and valley resolution. We show that intervalley coupling between exciton states occurs both on the timescale of excitation (~10 fs) and with minimal dependence on the excitation fluence, temperature, or sample grain size. These results shed light on the strong many-body interactions governing the femtosecond exciton dynamics in TMDs and the factors limiting the realization of novel technologies built around the valley degree of freedom.

O 34.2   Tue 10:45   TRE Phy

Electron dynamics after a spin- and valley-polarized electronic excitation in WS_2 — •Lasse Münster[1], Sarah Zajusch[1], Raul Perea-Causin[1], Samuel Brem[1], Katsumi Tanimura[1], Jens Güdde[1], Yaroslav Gerasimenko[2], Rupert Huber[2], Ermin Malic[1], Ulrich Höfer[1], and Robert Wallauer[1] — [1]Fachbereich Physik, Philipps-Universität Marburg, Germany — [2]Fachbereich Physik, Universität Regensburg, Germany

The excitonic landscape of monolayer transition metal dichalcogenides (TMDCs) comprises optically accessible bright excitons as well as spin- and momentum-forbidden dark excitonic states. We image the formation process of these states after optical excitation on an ultrashort timescale with time-resolved momentum microscopy.

We excite monolayer WS_2 resonantly to the A 1s exciton with circular polarized light. This excitation leads to a population, which is located purely within the K valley for one helicity and in the K' valley for the other helicity. In the case of an excitation at K, electron scatter to K' and Σ by spin-conserving processes within a few tens of femtoseconds. Furthermore, we observe the formation of spin-forbidden excitons in the K valley and electron scattering towards Σ'. Both of these processes involve a spin-flip and are significantly slower (50 - 100 fs).

O 34.3   Tue 11:00   TRE Phy

Influence of the substrate dielectric permittivity on ultrafast quasiparticles dynamics in WS_2 monolayers — •Subhadra Mohapatra[1,2], Lukas Gierster[1,2], Stefano Calati[1,2], Nicholas Michael Olsen[3], Quiyang Li[3], Xiaoyang Zhu[3], and Julia Stähler[1,2] — [1]Humboldt-Universität zu Berlin, Institut für Chemie — [2]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Abt. Physikalische Chemie, Berlin, Germany — [3]Columbia University

In our recent fluence-and photon energy-dependent studies [1,2] of quasiparticle dynamics in WS_2 monolayers on fused silica (FS) and Si-SiO_2 substrates, we observed that excitonic screening reduces the binding energy of the excitons, however the role of screening due to substrates and the quantitative nature of

dynamic screening due to excitons remained inconclusive. On further investigation of such fluence-dependent quasiparticle dynamics studies using a higher dielectric permittivity of a sapphire substrate, we found that scattering rates, relaxation time constants, and band gap renormalization are not influenced by the dielectric permittivity. On the contrary, the dynamic screening parameter of the excitons is approximately two times higher in FS than Sapphire and Bohr radius is approximately 2.5 % higher in sapphire than for FS, which must be a direct consequence of the increased dielectric permittivity likely leading to more delocalized excitons.

Probing the ultrafast hole-transfer mechanism in a twisted TMD heterostructure — •Marcel Reutzel[1], Jan Philipp Bange[1], David Schmitt[1], Wiebke Bennecke[1], Giuseppe Meneghini[2], AbdulAziz AlMutairi[3], Daniel Steil[1], Sabine Steil[1], R. Thomas Weitz[1], Samuel Brem[2], G. S. Mathijs Jansen[1], Stephan Hofmann[3], Ermin Malic[2], and Stefan Mathias[1] — [1]I. Physikalisches Institut, Georg-August-Universität Göttingen, Göttingen, Germany — [2]Fachbereich Physik, Philipps-Universität, 35032 Marburg, Germany — [3]Department of Engineering, University of Cambridge, Cambridge CB3 0FA, U.K.

In type-II band aligned TMD heterostructures, long-lived interlayer excitons (ILX) can be formed via two different processes: Optically excited intralayer excitons either transfer the exciton's electron or hole component across the interface. Using momentum microscopy [Rev. Sci. Ins. 91, 063905 (2020)], we have shown that the transfer of the exciton's electron proceeds via exciton-phonon scattering and layer hybridized Σ-excitons [Schmitt *et al.*, Nature 608, 499 (2022)].

In this contribution, we show that the Coulomb correlation between the exciton's hole and electron can be used to probe the hole-transfer dynamics: The intralayer exciton's hole transfers from the VBM of MoS_2 into the VBM of WSe_2, which is imprinted onto the photoemission signal as an apparant upshift of the mean photoelectron energy. Our analysis provides new insights on the ultrafast hole-transfer mechanism in the WSe_2/MoS_2 heterostructure, and, more generally, on the photoemission signature of Coulomb correlated electron-hole pairs.

O 34.5   Tue 11:30   TRE Phy

Resolving momentum-dependent phonon buildup at a 1T-TiSe2 surface using diffuse scattering in ultrafast LEED — •Felix Kurtz[1], Tim Dauwe[1], Sergey Yalunin[1], Gero Storeck[2], Jan Gerrit Horstmann[1], Hannes Böckmann-Clemens[1], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Am Fassberg 11, D-37077 Göttingen — [2]4th Physical Institute, University of Göttingen, Friedrich-Hund-Platz 1, D-37077 Göttingen

Electron-phonon and phonon-phonon couplings govern the energy flow into and within the lattice following femtosecond laser excitation. The resulting transient phonon population can be directly deduced from momentum-resolved maps in ultrafast electron diffuse scattering [1]. Here, we employ ultrafast low-energy electron diffraction (ULEED) [2] to investigate structural dynamics and pathways for energy relaxation in the optically-excited charge-density-wave phase of 1T-$TiSe_2$. By analyzing the diffuse scattering background, we track the nonequilibrium evolution of the phonon population and observe strongly momentum-dependent rise times. Specifically, we find a rapid buildup of zone-boundary phonons within few picoseconds, followed by a substantially slower generation of low-energy zone-center acoustic phonons. Our findings are cor-

roborated by *ab-initio* DFT calculations of phonon-phonon scattering rates. We believe that the presented approach is generally applicable to a variety of systems and provides fundamental insights into surface phonon dynamics and relaxation pathways.

Photoemission orbital tomography for excitons — •PETER PUSCHNIG, AN-DREAS WINDISCHBACHER, MELVIN HODŽIĆ, and CHRISTIAN S. KERN — Institute of Physics, NAWI Graz, University of Graz, Austria

In photoemission orbital tomography (POT), the photoemission angular distribution (PAD) of oriented molecular layers is interpreted in terms of the Fourier transform of the initial molecular orbital from which the electron is emitted. Recently, it has been demonstrated that POT can in principle also be applied to optically excited states using a femtosecond pump-probe setup, which images the excited electron-hole pairs of a system, the excitons, on ultrafast time scales [1]. However, a rigorous and generally applicable connection between the measured PAD and the spatial structure of the excitons is lacking. By considering the expansion of the exciton wave function in the product basis of valence and conduction state orbitals, as typically done when solving the electron-hole Bethe-Salpeter equation or Casida's equations in the framework of TDDFT, we demonstrate in this contribution that the PAD is given by the Fourier transform of a coherent sum of the electronic part of the exciton wave function. This relation, which is based on a plane wave final state, as well as the unexpected consequences of the hole for the measured kinetic energy spectrum an exciton is illustrated for a series of organic molecules in the gas phase for which the PAD is also simulated explicitly, and without resorting to a plane-wave final state, by means of a real-time, real-space TDDFT approach.

Ultrafast lattice dynamics of Niobium diselenide ($2H$-NbSe$_2$) — •VICTORIA C. A. TAYLOR[1], YOAV WILLIAM WINDSOR[1,2], HYEIN JUNG[1], and RALPH ERNSTORFER[1,2] — [1]Fritz Haber Institute — [2]TU Berlin

Within the transition metal dichalcogenide family, $2H$-NbSe$_2$ is unusual as it exhibits metallic, charge density wave (CDW), and superconducting phases, evidencing strong electron-lattice interactions. Ultrafast techniques enable investigation of such interactions on femtosecond timescales, and several studies have investigated the ultrafast electronic response of $2H$-NbSe$_2$. However, none have directly probed the ultrafast response of the lattice. We present a femtosecond electron diffraction (FED) study on $2H$-NbSe$_2$ in its metallic phase, probing both coherent and incoherent phononic responses that result from electron-phonon and phonon-phonon scattering. From these data we explore these processes and the associated timescales.

O 34.8   Tue 12:30   TRE Phy
Non-equilibrium dynamics of bulk VSe2 — •WIBKE BRONSCH[1], MANUEL TUNIZ[2], DENNY PUNTEL[2], ALESSANDRO GIAMMARINO[2], FULVIO PARMIGIANI[1,2], and FEDERICO CILENTO[1] — [1]Elettra-Sincrotrone Trieste, Trieste, Italy — [2]Università degli Studi di Trieste, Trieste, Italy

By means of time- and angle-resolved photoemission spectroscopy (tr-ARPES), we investigate the effect of optical excitation on the electronic properties of the transition metal dichalcogenide VSe2. The electronic band structure of VSe2 has recently been subject of investigation ranging from the bulk to the mono-

layer regime, in search for the manifestation of the opening of a band gap in its CDW phase [1,2]. However, at present, only a few studies on the effect of an ultrafast optical excitation are available [1,3]. In our contribution we present a study on the bulk material. By selecting the polarization of the probe pulses, tr-ARPES allows us to disentangle states with different orbital character, originating from the V and Se valence bands. Our tr-ARPES data show indication for a novel photoinduced state near the Fermi level, lasting for several picoseconds after photoexcitation.

Ultrafast charge separation and charge density wave suppression in monolayer TiSe$_2$ on graphite — •SEBASTIAN BUCHBERGER[1,2], CHARLOTTE SANDERS[3], YU ZHANG[3], EMMA SPRINGATE[3], PAULINA MAJCHRZAK[4], JILL MIWA[4], PHILIP HOFMANN[4], SØREN ULSTRUP[4], and PHIL D. C. KING[1] — [1]University of St Andrews, UK — [2]MPI for Chemical Physics of Solids, Dresden, Germany — [3]Central Laser Facility, UK — [4]Aarhus University, Denmark

The properties of two-dimensional materials and their heterostructures are often governed by the interplay of several coexisting interactions which can be difficult to disentangle in equilibrium. Time and angle resolved photoelectron spectroscopy (trARPES) is emerging as a powerful method to investigate such systems, allowing the observation of ultrafast processes such as the buildup of charge screening[1], optically induced bandgap renormalisation[2] and interlayer charge separation[3]. Here we present a trARPES study on monolayer TiSe$_2$ grown epitaxially on graphite. Monolayer TiSe$_2$ is a small indirect bandgap semiconductor that exhibits an unconventional charge density wave (CDW) in its ground state, whose origin and nature are still not fully established[4]. We study how the electronic structure evolves upon photoexcitation, tracking band shifts and spectral weight variations to disentangle charge separation, screening, and dynamical suppression of the CDW.

O 34.10   Tue 13:00   TRE Phy
Manipulation of the charge-density-wave in VTe2 by femtosecond light pulses — •MANUEL TUNIZ[1], WIBKE BRONSCH[2], DENNY PUNTEL[1], GIOVANNI DI SANTO[2], LUCA PETACCIA[2], DAVIDE SORANZIO[3], DAVIDE BIDOGGIA[1], MARIA PERESSI[1], FULVIO PARMIGIANI[1,2], and FEDERICO CILENTO[2] — [1]Dipartimento di Fisica, Università degli Studi di Trieste, Italy — [2]Elettra - Sincrotrone Trieste S.C.p.A., Italy — [3]Institute for Quantum Electronics, ETH Zurich, 8093 Zurich, Switzerland

Comparing equilibrium and out-of-equilibrium angle-resolved photoemission spectroscopy (ARPES and tr-ARPES), we investigate the effect of an optical excitation on the electronic properties of the charge-density wave (CDW) system VTe2. Recently, the modification of the material's electronic structure triggered by CDW formation has been discussed because the strongly orbital-dependent changes may give rise to a topological change in specific bands [1]. In our contribution we show clear modifications to the electronic band structure of VTe2 induced by the emergence of the CDW phase. Moreover, our tr-ARPES experiments open the possibility to perturb the CDW phase and study the relaxation dynamics of this non-equilibrium state to the ground state of the system.

Two-component GW implementation for molecular valence excitations — •QINGLONG LIU, RAMÓN L. PANADÉS-BARRUETA, and DOROTHEA GOLZE — Chair of Theoretical Chemistry, Technische Universit at Dresden, 01062 Dresden, Germany

We present an all-electron *GW* implementation for the computation of charged molecular excitations, that includes scalar relativistic effects and spin-orbit coupling (SOC). Our method is based on a two-component (2c) approach, which can process 2c spinors and their corresponding eigenvalues from different levels of theory. The relativistic input for our 2c *GW* calculation is obtained in two ways: One approach is a non-self-consistent second variation SOC scheme, i.e. a scalar relativistic (SR) calculation is performed followed by an expansion of the spinors on top of the SR eigenvectors [1]. Another approach is the spinors and their eigenvalues are obtained by running a self-consistent relativistic DFT calculation with the X2C method [2]. Our algorithm has been implemented in the FHI-aims program package, which is based on numeric atom-centered orbitals (NAOs). In our 2c *GW* algorithm we combine the all-electron NAO scheme with

the resolution of the identity technique based on the Coulomb metric (RI-V) and use the analytical continuation to evaluate the G_0W_0 self energy. We present results for the numerical validation of our implementation and for the influence of the relativistic input (second variation SOC vs X2C) on the valence excitations of small heavy molecules.

Screened potential in two-dimensional GW calculations within the LAPW framework — •BEN ALEX, SVEN LUBECK, and CLAUDIA DRAXL — Physics Department and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany

To calculate two-dimensional (2D) materials in a three-dimensional periodic code, one has to consider periodically repeated layers. The calculation of quasiparticle energies for 2D materials within the *GW* approximation requires the introduction of a 2D cutoff for the Coulomb potential as the layers would otherwise interact with each other. This cutoff leads to a stronger q dependence of the

dielectric function around $q = 0$ which requires much denser sampling of the first Brillouin zone. In order to address this issue, an analytic expression for the dielectric function was previously derived for a plane-wave basis [1]. This expression is then integrated numerically in a small region around $q = 0$. The goal of this work is to adapt this technique to the linearized augmented planewave + local-orbital (LAPW+lo) basis as implemented in the full-potential all-electron code exciting. We show that also in our case, we obtain a significant computational speedup. Furthermore, this approach is compared with an approach where the dielectric function is interpolated to a denser q-grid.

GW multipole approach for the frequency description of the dielectric screening — •Claudia Cardoso[1], Dario A. Leon[2], Andrea Ferretti[1], Daniele Varsano[1], and Elisa Molinari[1] — [1]S3 Centre, Istituto Nanoscienze, CNR, 41125, Modena (Italy) — [2]Department of Mechanical Engineering and Technology Management, Norwegian University of Life Sciences, 1430, Ås (Norway)

In the present work, we discuss a numerical approach for GW calculations that takes into account the frequency dependence of the screening via a multipole approximation (MPA), an accurate and efficient alternative to current full-frequency methods, that overcomes several limitations of the plasmon pole approximation (PPA).

MPA was recently developed and validated for semiconductors[1]. We now extend the use of MPA to metallic systems by optimizing the frequency sampling for these class of materials and propose a simple method to include the zero q limit of the intra-band contributions. The good agreement between MPA and full frequency results for the calculations of quasi-particle energies, polarizability, self-energy and spectral functions in different metallic systems confirms the accuracy and computational efficiency of the method. Finally, we discuss the physical interpretation of the MPA poles through a comparison with experimental electron energy loss spectra for Cu.

Towards low-scaling GW calculations for 2D materials — •Jan Wilhelm — Institute of Theoretical Physics, University of Regensburg

Semiconducting two-dimensional materials are an ideal platform to study excitons thanks to the strong exciton binding energy and good experimental accessibility of the excitons. The GW+Bethe-Salpeter approach (GW+BSE) has been successful in analyzing excitons in single-layer 2D materials [1], but the application of GW+BSE is challenging for 2D double layers and moiré structures [2]. This is because the large unit cells in these structures contain hundreds to thousands of atoms, resulting in a high computational cost for GW+BSE calculations. In this talk, I will present a low-scaling GW algorithm for 2D materials that potentially allows for the inclusion of more than a thousand atoms in the simulation [3]. This algorithm is based on localized basis functions and can handle periodic boundary conditions and the divergence of Coulomb interactions in the Brillouin zone. I will present first benchmark calculations.

Accelerating core-level GW calculations by combining the contour deformation with the analytic continuation of W — •Ramón L. Panadés Barrueta and Dorothea Golze — Theoretische Chemie, Technische Universität Dresden, Bergstr. 66c, 01062 Dresden, Deutschland

Many-body methods, like the GW approximation, have recently proven to be a highly effective tool for computing core-level excitations [1]. In particular, the contour deformation (CD) is an efficient, scalable and numerically stable approach that has enabled core-level calculations on systems up to 100 atoms [2]. In this work, we reduce the scaling of CD applied to core-levels from $O(N^5)$ to $O(N^4)$, using an analytic continuation of the screened Coulomb interaction W [3]. The new method (CD-WAC) has been implemented in FHI-aims. CD-WAC has been extensively tested on well established benchmark sets like the GW100 and the CORE65, reporting MAEs of less than 5 meV with respect to CD. The theoretical scaling has been confirmed by performing scaling experiments on large acene chains and amorphous carbon. Speedups of 5 times have been attained with CD-WAC for the largest systems.

Many-Body Effects of Metals Investigated by Means of the GW Method — •Zimo Zhou, Nakib Protik, and Claudia Draxl — Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany

Even if semilocal exchange-correlation functionals of density-functional theory (DFT) can capture the overall band structure of many metals well, they fail to obtain the correct position of the d-bands. This leads, for instance, to the underestimation of the interband absorption onset in the corresponding optical spectra as shown for a set of elemental metals [1]. In this work, we provide a systematic investigation of the quasi-particle band structure and the optical properties of this set of materials. To this extent, the self-energy corrections to the DFT results are computed by the GW approach of many-body perturbation theory as implemented in the full-potential all-electron code exciting [2,3]. We show that the optical absorption spectra based on these quasi-particle bands remedy the shortcomings of semi-local DFT, accurately reproducing the experimental counterparts.

Separable Resolution-of-Identity in an all-electron numeric atom-centered basis set framework — •Francisco Delesma[1], Dorothea Golze[2], and Patrick Rinke[1] — [1]Department of Applied Physics, Aalto University, Espoo, Finland — [2]Faculty of Chemistry and Food Chemistry, Technische Universität Dresden, Dresden, Germany

The resolution-of-identity (RI) is a common way in quantum chemistry and computational materials science to reduce the computational cost of two-electron Coulomb integrals, another central entity in computational quantum mechanics. In 2019, Duchemin and Blase proposed the separable-RI approach [1], which preserves the accuracy of the standard, global RI method with the Coulomb metric (RI-V) and permits the formulation of cubic-scaling random-phase approximation (RPA) and Green's function based GW approaches.

In this work, we present the first implementation of the separable-RI in an all-electron numeric atom-centered orbital framework. Separable-RI is implemented in the FHI-aims code [2] and optimized for massively parallel execution. We extend the separable-RI framework beyond the original Hartree-Fock (HF) and GW implementations of Duchemin and Blase to MP2 and RPA, SOSEX and CCSD. Our separable-RI total energies and GW quasiparticle energies for the Thiel test set of small organic molecules reproduce the exact two-electron Coulomb integral calculations within 1 meV or better.

Simulation of proximity effects in epitaxial graphene systems — •Andres David Peña Unigarro[1], Florian Steffen Günther[2,3], and Sibylle Gemming[1] — [1]Institute of Physics, TU Chemnitz, Chemnitz, Germany — [2]IFSC, University of São Paulo, Brazil — [3]UNESP, Brazil

Two-dimensional materials such as graphene are fascinating because they combine mechanical flexibility with unique electronic properties. The next level of complexity, however, comprises the assembly of various 2D materials to generate structures with enhanced characteristics. Using proximity effects, changes in the electronic, optical and transport properties of epitaxial graphene have been pro-

duced while preserving the regular honeycomb structure that can be grown on silicon carbide, SiC. Such modifications can, for instance, be achieved by proximity effects in hetero stacks with intercalate and absorbate layers with other 2D materials or by the presence of a functional integration environment. In the past years, many elements were intercalated below the graphene sheet, forming partly well-defined hetero bilayer systems with different functionalities. As suggested by density functional theory (DFT) studies, elements of the IV group can be used for this purpose. In this case, intercalation of heavy atoms like Pb are expected to introduce additional effects such as spin-orbit coupling to the electron gas of graphene. In this contribution, we present preliminary results obtained with

DFT focusing on the study of modifications of the electronic structure of epitaxial graphene due to proximity effects generated by the intercalation of Pb on buffer layers on SiC.

O 36.2   Tue 18:00   P2/EG

Structural Characterization of a Novel Two-Dimensional Material: Cobalt Sulfide Sheets on Au(111) — •Marcel Rost[1], Mahesh Prabhu[2], Dajo Boden[2], Jörg Meyer[2], and Irene Groot[2] — [1]Huygens-Kamerlingh Onnes Laboratory, Leiden Institute of Physics, Leiden University, 2300 RA Leiden, The Netherlands — [2]Leiden Institute of Chemistry, Leiden University, P.O. Box 9502, 2300 RA Leiden, The Netherlands

Transition metal dichalcogenides (TMDCs) are a type of two-dimensional (2D) material that has been widely investigated by both experimentalists and theoreticians because of their unique properties. In the case of cobalt sulfide, density functional theory (DFT) calculations on free-standing S-Co-S sheets suggest there are no stable 2D cobalt sulfide polymorphs, whereas experimental observations clearly show TMDC-like structures on Au(111). In this study, we resolve this disagreement by using a combination of experimental techniques and DFT calculations, considering the substrate explicitly. We find a 2D CoS(0001)-like sheet on Au(111) that delivers excellent agreement between theory and experiment. Uniquely this sheet exhibits a metallic character, contrary to most TMDCs, and exists due to the stabilizing interactions with the Au(111) substrate.

Carbon Nanomembranes Fabricated from Amorphous Molecular Layers — •Zhen Yao[1], Nikolaus Meyerbröker[2], Yubo Qi[1], Michael Westphal[1], Yang Yang[1], and Armin Gölzhäuser[1] — [1]Bielefeld University, Bielefeld, Germany — [2]CNM Technologies, Bielefeld, Germany

Ultrathin carbon nanomembranes (CNMs), fabricated from crosslinking self-assemblies of molecular precursors, are 2D membranes that possess well-defined physical and chemical properties. With a simple transfer procedure, CNMs can be placed on various supports, enabling versatile applications. Combining high water flux and precise ion selectivity, CNMs are ideal materials for molecular separation and water desalination. However, their practical realization is hindered by the availability of epitaxial metal substrates. Here, we report a new type of CNM fabricated from poly(4-vinylbiphenyl) (PVBP) spin-coated on SiO2/Si substrate. The electron-induced crosslinking results in the formation of a continuous membrane with a thickness of 15 nm. The nanoporous nature of the PBVP-CNM is revealed by water and ion permeation measurements. The membrane possesses a high density of pores, which allows water flux as high as 530 L m-2 h-1 bar-1. It also exhibits the rejection of ions and molecules with sizes >1 nm. A further introduction of a reinforcement porous block copolymer layer simplifies the transfer procedure, resulting in a centimetre-scale CNM-composite that works efficiently for dye rejection. These results suggest a feasible route for large-scale nanoporous membrane fabrication.

O 36.4   Tue 18:00   P2/EG

A New Group of Two-Dimensional Non-van der Waals Materials with Ultra Low Exfoliation Energies — •Tom Barnowsky[1,2], Arkady V. Krasheninnikov[1,3], and Rico Friedrich[1,2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — [2]Theoretical Chemistry, Technische Universität Dresden, 01062 Dresden, Germany — [3]Aalto University, Aalto 00076, Finland

The exfoliation energy, *i.e.* the energy required to separate a single two-dimensional (2D) sheet from a bulk material, is a key factor in whether such 2D systems can be made. Recently, non-van der Waals 2D compounds – materials derived from non-layered bulk counterparts – were outlined as a rich new class of nanoscale materials [1].

In our work, using data-filtering and ab-initio calculations, we propose a group of eight novel non-van der Waals 2D systems [2]. The compounds exhibit ultra-low exfoliation energies close to those of traditional van der Waals bound 2D materials. Especially for the considered sulfides, strong surface relaxations play a key role in the energy gain enabling exfoliation, while the effects of long-range dispersive interactions are minor. The candidates with the smallest exfoliation energies, 2D $SbTlO_3$ and $MnNaCl_3$, exhibit appealing electronic, potential topological, and magnetic features as evident from the calculated band structures.

Silicene's pervasive surface alloy on Ag(111) — Johannes T Küchle[1,2], Aleksandr Baklanov[1], Ari P Seitsonen[3,4], Paul TP Ryan[2,5], Peter Feulner[1], Prashanth Pendem[1], Tien-Lin Lee[2], Matthias Muntwiler[6], Martin Schwarz[1], Felix Haag[1], Johannes V Barth[1], Willi Auwärter[1], •David A Duncan[1,2], and Francesco Allegretti[1] — [1]Physics Department E20, Technische Universität München, Deutschland — [2]Diamond Light Source, Oxfordshire, UK — [3]Département de Chimie, École Normale Supérieure, Paris, France — [4]Université Paris Sciences et Lettres, Sorbonne Université, Paris, France — [5]Imperial College London, UK — [6]Paul Scherrer Institut, Villigen, Switzerland

Silicene is the two-dimensional (2D) allotrope of silicon. So far, the most direct synthesis strategy has been to grow it epitaxially on metal surfaces; however, the effect of the strong silicon-metal interaction on the structure and electronic properties of the metal-supported silicene is generally poorly understood. Here, we consider the (4 × 4)-silicene monolayer (ML) grown on Ag(111), and show that our experimental results refute the common interpretation of this system as a simple buckled, honeycomb ML with a sharp interface to the Ag substrate. Instead, we demonstrate the pervasive presence of a second silicon species, concluded to be a Si/Ag alloy stacked between the 2D silicene and the silver substrate. These findings question the current structural understanding of the silicene/Ag(111) interface and may raise expectations of analogous alloy systems in the stabilization of other 2D materials grown epitaxially on metal surfaces.

Pb-induced proximity effects in epitaxial graphene — Andres David Pena Unigarro, Chitran Ghosal, •Christoph Tegenkamp, and Sibylle Gemming — Institut für Physik, TU Chemnitz, Reichenhainer Str. 70, Chemnitz

A current topic in material science deals with the controlled assembly of various 2D materials to generate structures with new quantum characteristics. Such modifications can be achieved by proximity effects, e.g., by intercalation and adsorption. One promising route is to use epitaxial buffer layer structures on SiC(0001) surfaces, which transforms into a quasi free monolayer graphene with new 2D interface structures upon intercalation. As suggested by density functional theory (DFT) studies, elements of the IV group such as Pb can be used for this purpose. In this case, intercalation of heavy atoms like Pb are expected to introduce additional effects such as spin-orbit coupling to the electron gas of graphene. In this contribution, we investigated the intercalation of Pb on buffer layers on SiC(0001). Suspended and charge neutral graphene emerged, and the intercalated Pb formed plumbene honeycomb lattices, which are rotated by 7.5˚ with respect to graphene. Along with this twist, a proximity-induced modulation of the hopping parameter in graphene opens a band gap of around 30 meV at the Fermi energy, giving rise to a metal-insulator transition. We present first results obtained with DFT focusing on the modifications of graphene's electronic structure in the presence of twisted Pb layers.

Local spectroscopy of acoustic phonons in low-dimensional materials — •Yi Zhang[1], Shaoxiang Sheng[1,2], Susanne Baumann[1], and Sebastian Loth[1,2] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — [2]Max Planck Institute for Solid State Research, Stuttgart, Germany

Coherent acoustic phonons (CAPs) enable ultrafast control of solids and have been exploited for applications in various acoustic devices. THz-induced ultrafast Coulomb forces in a scanning tunnelling microscope (STM) junction can locally generate CAP wave packets that propagate with low losses and form longitudinal acoustic standing waves in a thin Au film on mica [1,2]. Here we develop a discrete lattice model to simulate acoustic phonon propagation in well-defined nanostructures. We predict that transverse acoustic phonons can be detected in 1D chains or in 2D thin films by THz-STM. This enables investigation of mechanical properties and electron-phonon interaction in nano-materials at the atomic scale. [1] S. Sheng, et al. Physical Review Letters 129, 043001 (2022). [2] M. Abdo, et al. ACS Photonics 8, 702-708 (2021).

Impact of screening and relaxation on weakly coupled 2D heterostructures: implications for molecular spin-coupling — Eva Rauls[1], T.T. Nhung Nguyen[2], Christoph Tegenkamp[2], and •Uwe Gerstmann[3] — [1]University of Stavanger, Norway — [2]Technische Universität Chemnitz, Germany — [3]Universität Paderborn, Germany

Phthalocyanines (Pc) at surfaces are prototype molecules which can host magnetic ions in a well-defined surface environment. The precise external control of individual spins, however, require a detailed knowledge of the influence of the substrate. In this combined experimental and theoretical study, we have investigated the influence of different graphene-related substrates onto the structural, electronic and magnetic properties of adsorbed Pb and Mn-phthalocyanines. Formation of almost identical densely packed PbPc molecular layers with strongly tilted molecules were found on n-type and p-type doped 2D templates. On graphite (HOPG), the dispersing molecular states of the less deformed molecular adsorbate stress the importance of substrate mediated interaction and proximity coupling [1]. After substituting Pb by magnetic Mn, the interaction with the substrate is clearly increased. On epitaxial monolayer graphene (MLG) the MnPc experience even the underlying SiC substrate, resulting in a 4×2 reconstructed molecular layer with very specific substrate mediated magnetic coupling.

Honeycomb structure of alkali metal atoms — Jiaqi Cai[1,2,3], •Robin Ohmann[1], Nicolae Atodiresei[4], Hai Chau Nguyen[1], David Duncan[5], Caio Silva[2], Christoph Schlueter[5], Kai Mehlich[1], Thais Chagas[1],

Vasile Caciuc[4], Wouter Jolie[3], Stefan Blügel[4], Tien-Lin Lee[5], Thomas Michely[3], and Carsten Busse[1,2,3] — [1]Department Physik, Universität Siegen, Siegen, Germany — [2]Institut für Materialphysik, Westfälische Wilhelms-Universität Münster, Münster, Germany — [3]II. Physikalisches Institut, Universität zu Köln, Köln, Germany — [4]Peter Grünberg Institut (PGI-1) and Institute for Advanced Simulation (IAS-1), Forschungszentrum Jülich and JARA, Jülich, Germany — [5]Diamond Light Source, Didcot, Oxfordshire, United Kingdom

The formation of honeycomb structures, similar to graphene, is of great scientific and technological interest. Here, we show that the adsorption of Cs on monolayer hexagonal boron nitride (hBN) on Ir(111) substrate kept at elevated temperatures forms a honeycomb lattice. The structure is investigated by scanning tunneling microscopy (STM), X-ray photoelectron spectroscopy (XPS) and X-ray standing waves (XSW) revealing that the Cs atoms are in registry with the moiré pattern of the substrate with a lattice constant of about 30 Å, are partially positively charged and have an adsorption height of 2.9 Å above the hBN layer. The formation is explained via the templating effect of the substrate. Our density functional theory (DFT) results confirm stable binding on the two hill regions of the moiré unit cell and predict a graphene like band structure with a band width of about 1 meV.

O 36.12   Tue 18:00   P2/EG

Unstrained Sb Bilayers on InSb(111)A — Bing Liu[1,2], •Stefan Enzner[1,3], Tim Wagner[1,2], Philipp Eck[1,3], Martin Kamp[2], Giorgio Sangiovanni[1,3], and Ralph Claessen[1,2] — [1]Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, D-97074 Würzburg, Germany — [2]Physikalisches Institut, Universität Würzburg, D-97074 Würzburg, Germany — [3]Institut für Theoretische Physik und Astrophysik, Universität Würzburg, D-97074 Würzburg, Germany

Antimonene, a hexagonal arrangement of staggered Sb, is a promising topological material, which has been widely investigated on various substrates. Recently, it has been grown strain-free on InSb(111)A by forming a moiré structure, despite exhibiting covalent interface bonds.

The moiré supercell is theoretically approximated with varying interface stackings of primitive cells by means of ab initio DFT calculations. This approach reproduces the main structural and electronic observations. The agreement allowed us, to investigate the competition of intra-layer and interface interactions and explain the reconstruction-free growth.

O 37.1   Tue 18:00   P2/EG

Probing alternative pathways for electron transfer across a monomolecular film — Saunak Das[1], Zhiyong Zhao[1], Takanori Fukushima[2], Andreas Terfort[3], and •Michael Zharnikov[1] — [1]Angewandte Physikalische Chemie, Universität Heidelberg, 69120 Heidelberg, Germany — [2]Laboratory for Chemistry and Life Science, Institute of Innovative Research, Tokyo Institute of Technology, Yokohama 226-8503, Japan — [3]Institut für Anorganische und Analytische Chemie, Johann Wolfgang-Goethe-Universität Frankfurt, 60438 Frankfurt am Main, Germany

Charge transport (CT) across a two-dimensional molecular assembly can involve alternative pathways. Using specifically designed monomolecular films we probe (i) competition of intramolecular and intermolecular pathways in a molecular assembly and (ii) competition of different intramolecular pathways within a single molecule. For this purpose, we apply so-called core-hole-clock approach in the framework of resonant Auger electron spectroscopy, allowing the measurement of the characteristic CT time from the terminal tail group of the assembled molecules to the substrate. We show that the intramolecular CT is generally preferable and so-called matrix effects play a negligible role for CT, strongly favoring the through-bond CT model. In the case of availability of several alternative pathways within an individual molecule, a pathway with the highest conductance becomes highly dominant, while other pathways contribute minorly to the entire CT.

O 37.2   Tue 18:00   P2/EG

Pump-probe second harmonic spectroscopy of molecule/metal interfaces — Jinghao Chen[1], Rui Shi[2], Ping Zhou[1], Uwe Bovensiepen[1], Wolfgang Hübner[2], Georg Lefkidis[2], and •Andrea Eschenlohr[1] — [1]Faculty of Physics and CENIDE, Uni Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany — [2]Department of Physics, TU Kaiserslautern, Box 3049, 67653 Kaiserslautern, Germany

Achieving a microscopic understanding of charge transfer dynamics and the relaxation of optically excited electrons and holes at molecule/metal interfaces requires an interface-sensitive analysis on the respective femtosecond timescales. Second harmonic spectroscopy (SHS) is such an interface-sensitive probe in cen-

trosymmetric materials. We perform pump-probe SHS in the visible wavelength range (1.9-2.5 eV) with <20 fs pulse duration. A prototypical molecule/metal interface is prepared by adsorption of iron octaethylporphyrin (FeOEP) molecules on Cu(001) and analyzed *in situ* in ultrahigh vacuum. By comparison with first principles theory, we identify a molecule-induced resonance at about 2.2 eV fundamental photon energy in the SHS of one monolayer of FeOEP/Cu(001). At this resonance, we observe a markedly slower relaxation time of the pump-induced changes in SHS compared to the bare Cu(001) surface, which indicates an increased lifetime of the electronic molecular state.

We thank H. Wende, J. Güdde and E. Riedle for valuable experimental advice, and the German Research Foundation for funding via SPP 1840 QUTIF and Sfb 1242.

O 37.3   Tue 18:00   P2/EG

Second harmonic spectroscopy of Cu(001) surfaces — •Newsha Vesalimahmoud, Jinghao Chen, Mahendra Kabbinahithlu, Ping Zhou, Uwe Bovensiepen, and Andrea Eschenlohr — University of Duisburg-Essen, Faculty of Physics and CENIDE, Lotharstr. 1, 47057 Duisburg, Germany

The nonlinear optical technique of second harmonic generation (SHG) is a surface- and interface-sensitive tool in centrosymmetric materials, which is used to study electron dynamics at metal surfaces. We characterize the polarization and wavelength dependent SHG on a Cu(001) surface using a fundamental beam in the wavelength range of 500 - 700 nm. Polarization dependent measurements show the p-P SHG yield is almost a factor of 1.5 larger than s-P SHG, because more non-zero susceptibility tensor elements are involved in the former and the intrinsic absolute value of $|\chi_{zzz}^{(2)}|$ is much larger than the only relevant component $|\chi_{zxx}^{(2)}|$ in the latter. We also measure the spectral dependence of the SHG intensity, which shows an increase up to a maximum at 2.33 eV. Since the 3d band peak of copper lies about 2.3 eV below Fermi level, a fundamental beam at this photon energy can resonantly excite 3d electrons to the Fermi level, which largely increases the overall probability of SHG processes. Moreover, we discuss electron dynamics analyzed through pump-probe SHG at on and off-resonant photon energies.

O 37.4 Tue 18:00 P2/EG

Formation mechanism of defect levels in rutile TiO$_2$(110) — •XIANG ZHANG, LUKAS GIERSTER, and JULIA STÄHLER — Humboldt-Universität zu Berlin, Institut für Chemie

The electron dynamics at TiO$_2$ surfaces have been widely studied as TiO$_2$ is a prototypical photocatalyst. Recent studies have specifically addressed the Band Gap State (BGS) at 0.8 eV below the Fermi level and have revealed its role as a trapping center for electrons in the conduction band of rutile TiO$_2$(110) (with a trapping time of around 45 fs) [1]. However, the origin of the BGS itself remains debated. Using time-resolved photoelectron spectroscopy, we show here that the BGS must be - at least partially - due to long-lived (>5 μs) photoexcited charge carriers which form a photostationary state in pump-probe experiments. The potential formation mechanism of the BGS and implications of this state for previous time-resolved experiments are discussed.

O 37.5 Tue 18:00 P2/EG

Investigation of low-temperature electron emission properties from sharp needle tips — •MANUEL KNAUFT, STEFAN MEIER, NORBERT SCHÖNENBERGER, and PETER HOMMELHOFF — Department Physik, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), 91058 Erlangen

Spectroscopic and microscopic techniques benefit from the small linewidth of coherent electron sources with high brightness. Reducing the operating temperature of the emitter is known to positively influence coherence of field emitted electron beams. This is especially true for superconducting needle tips as shown for niobium [1].

We present an experimental setup capable of cooling electron emitters to liquid helium temperature in ultra-high vacuum. Irradiation of samples with ultrashort laser pulses is possible through optical access to the chamber. Detection of charged particles is realized by a multi-channel plate. First results for sharp needle tips of various materials are shown. In particular, we investigate the emission characteristics and compare them for field emission and laser triggered emission as a function of temperature.

O 37.6 Tue 18:00 P2/EG

Magnetic field effects on ultrafast driven electrons in topological insulator surface states — •ALEXANDER RIEDEL[1], VANESSA JUNK[1], WOLFGANG HOGGER[1], COSIMO GORINI[2], and KLAUS RICHTER[1] — [1]Institut für Theoretische Physik, Universität Regensburg, Germany — [2]Universite Paris-Saclay, CEA, CNRS, SPEC, 91191, Gif-sur-Yvette, France

When strong-field light pulses of various durations and shapes interact with a solid, their electric field component acts as an a.c. bias accelerating electrons through the bandstructure and driving non perturbative transitions. These processes can lead to high-order harmonic emission of radiation which encodes characteristic properties of the underlying material.

However, in the vast majority of cases the magnetic field component of the pulse is completely neglected in theoretical descriptions. In this contribution we incorporate a magnetic field into the description by adding a Zeeman term into an effective minimal model Hamiltonian describing the surface states of the topological insulator material bismuth telluride. We present how magnetic field components influence the Berry curvature and the transitions induced by the pulse. The resulting currents and higher harmonic spectra are discussed and compared to those in the absence of magnetic field effects. All statements rely on both a semiclassical analysis and full quantum mechanical simulations.

O 37.7 Tue 18:00 P2/EG

Use cases for Picosecond Ultrasonics with X-rays (PUX) — •ALEXANDER VON REPPERT[1], MAXIMILIAN MATTERN[1], STEFFEN ZEUSCHNER[1,2], JAN-ETIENNE PUDELL[1,2,3], MARC HERZOG[1], and MATIAS BARGHEER[1,2] — [1]Institut für Physik und Astronomie, Universität 14476 Potsdam, Potsdam, Germany — [2]Helmholtz-Zentrum Berlin, 12489 Berlin, Germany — [3]European XFEL, 22869 Schenefeld, Germany

Most studies of picosecond ultrasound have been and will be conducted with flexible all-optical setups, but here we discuss scenarios where ultrashort hard x-ray probe pulses excel. We focus on the extraction of the strain response from Bragg peak shifts in the symmetric diffraction condition for layered, nanoscopic structures upon excitation of metallic transducers with femtosecond laser pulses. This type of experiment can yield direct, layer-specific and quantitative information on the shape and amplitude of picosecond strain pulses and the quasi-static strain. The strain response may serve as a proxy for the local energy-density and temperature rise. The presented use-cases encompass ultrahin as well as opaque metal-heterostructures, nanostructures and negative thermal expansion materials, that each pose a challenge to established all-optical techniques.

O 37.8 Tue 18:00 P2/EG

Photocatalysis on anataseTiO2(101) in real-time — •HESHMAT NOEI[1,2], MICHAEL WAGSTAFFE[1], ADRIAN DOMINGUEZ-CASTRO[3], LUKAS WENTHAUS[1], STEFFEN PALUTKE[1], DMYTRO KUTNYAKHOV[1], MICHAEL HEBER[1], FEDERICO PRESSACCO[1], SIRHEI DZIARZHYTSKI[1], HELENA GLEISSNER[1], VERENA KRISTIN

GUPTA[1], ADRIEL DOMINGUEZ[1], THOMAS FRAUENHEIM[3], ANGEL RUBIO[4], and ANDREAS STIERLE[1] — [1]Deutsches Elektronen-Synchrotron (DESY), Hamburg, Germany — [2]The Hamburg Centre for Ultrafast Imaging, Hamburg, Germany — [3]Bremen Center for Computational Material Science (BCCMS), D-28359, Bremen, Germany — [4]Max Planck Institute for the Structure and Dynamics of Matter, D-22761, Hamburg, Germany

Obtaining mechanistic insight surrounding interfacial charge transfer and the role of intermediate species during photocatalysis on metal oxide surfaces is challenging due to their ultrafast nature. By applying ultra-fast optical pump-soft X-ray probe experiments at FLASH in DESY, we have obtained first insight into the activation mechanism of CO photooxidation to CO2 on rutile and anatase TiO2 surfaces and charge transfer at the interfacxe of water and TiO2(101). By using an optical laser of 800 nm and a FEL energy of 647.8 eV, the changes in the Ti 2p, O 1s and C 1s core levels have been monitored on a picosecond timescale.

O 37.9 Tue 18:00 P2/EG

Ultrafast UV pulse generation at the SXP instrument of the European XFEL — •EKATERINA TIKHODEEVA[1], PATRIK GRYCHTOL[1], MARCUS SEIDEL[2], CHRISTOPH M. HEYL[2], VAHAGN VARDANYAN[1], DAVID DOBLAS-JIMENEZ[1], and MANUEL IZQUIERDO[1] — [1]European XFEL, Schenefeld, Germany — [2]DESY, Hamburg, Germany

At the European XFEL a new instrument, the Soft X-ray Port (SXP), is currently under commissioning. Located downstream of the SASE 3 soft X-ray undulator system, it will provide femtosecond photon pulses with variable polarization in the energy range between 260 eV and 3000 eV at MHz repetition rates. Up to 10^{12} photons per pulse will be focus at the interaction region in a micrometer spot size resulting in an intensity of more than 10^{18} W/cm^2. The energy range will enable the complete electronical, chemical and atomic characterization of solids, surfaces and interfaces using femtosecond time-resolved soft X-ray photo-electron spectroscopy. Moreover, two powerful pump lasers operating in a broad spectral range from the mid-infrared to the ultraviolet region will be available. Herriott multi-pass cells (HMPC) will be used to compress their pulses into the few femtosecond range paving the way for ultrafast pump-probe investigations at the SXP instrument combining intense and tunable soft X-rays with the versatile optical lasers. In this contribution, the development of the HMCP and the optical laser system will be presented.

O 37.10 Tue 18:00 P2/EG

Transferring photonic orbital angular momentum to metals — •JANNIS LESSMEISTER[1], TOBIAS EUL[1], EVA PRINZ[1], SEBASTIAN HEDWIG[1], MARTIN AESCHLIMANN[1], and BENJAMIN STADTMÜLLER[1,2] — [1]Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, Germany

Optical fields can carry an orbital angular momentum (OAM) in helical beams with an azimuthal phase dependence. Since the discovery of this phenomenon in 1992 [1], the interaction of photonic OAM with matter has become a steadily growing field of research. After an initial focus on atoms and molecules, in the last years, scientists also began investigating solids [2]. For example, recent studies revealed that the so-called twisted light can drive photocurrents [3] and affects ultrafast demagnetization dynamics [4].

In our research, we apply time- and angle-resolved photoelectron spectroscopy (TR-ARPES) to gain new insight into the influence of photonic OAM on the hot carrier dynamics in metals. Specifically, we investigated the influence of the added orbital angular momentum on the optical excitation efficency of photoelectrons from the spin-split band structure of Rashba surface states and the hot carrier dynamics of spin-dependent carriers in the ferromagnet Ni.

Combining THz-ARPES and THz-HHG to study electrical currents at buried interfaces of topological insulators — •TIM BERGMEIER, SUGURU ITO, JENS GÜDDE, and ULRICH HÖFER — Fachbereich Physik, Philipps-UniversitätMarburg, Germany

Angle-resolved photoemission spectroscopy (ARPES) combined with terahertz (THz) excitation has shown to provide a subcycle-resolved momentum space view of lightwave-driven Dirac currents in the surface band of topological insulators [1]. At high electric field strength, these currents have shown to give rise to a unique type of efficient high-harmonic generation (HHG) that reflects the unusual transport properties of the Dirac electrons [2]. As a pure optical technique, THz-HHG is able to access also deeply buried interfaces, but lacks band structure information.

Here, we present an experimental setup which combines both techniques in order to study first the impact of thin protection layers on the current transport in a topologically protected band. The correlation of the time-resolved band structure information provided by THz-ARPES with the properties of THz-HHG will

then allow us to apply the latter for thick layers as will be required for device applications. The setup includes the generation of THz-pulses with field strengths up to 10 MV/cm over a frequency range of 12-80 THz, and of ultrashort 400-nm probe pulses for two-photon photoemission with subcycle time resolution at a repetition rate of 200 kHz.

A narrow bandwidth extreme ultra-violet light source for time- and angle-resolved photoemission spectroscopy — QINDA GUO[1], MACIEJ DENDZIK[1], ANTONIJA GRUBIŠIĆ-ČABO[1], MAGNUS H. BERNTSEN[1], CONG LI[1], •WANYU CHEN[1], BHARTI MATTA[2], ULRICH STARKE[2], BJÖRN HESSMO[1], JONAS WEISSENRIEDER[1], and OSCAR TJERNBERG[1] — [1]Department of Applied Physics, KTH Royal Institute of Technology, Hannes Alfvéns väg 12, 114 19 Stockholm, Sweden — [2]Max Planck Institute for Solid State Research, Heisenbergstraße 1, 70569 Stuttgart, Germany

Here, we present a high repetition rate, narrow bandwidth, extreme ultraviolet photon source for time- and angle-resolved photoemission spectroscopy. The narrow bandwidth pulses ΔE = 9, 14, and 18 meV for photon energies hν = 10.8, 18.1, and 25.3 eV are generated through high harmonic generation using ultraviolet drive pulses with relatively long pulse lengths (461 fs). The high harmonic generation setup employs an annular drive beam in tight focusing geometry at a repetition rate of 250 kHz. Photon energy selection is achieved by a spherical focusing grating, which provides high efficiency photon flux with only a small amount of focus size increase (~30%) and temporal broadening (6.8%). A two

stage optical-parametric amplifier provides < 100 fs tunable pump pulses from 0.65 μm to 9 μm. Combined with a time-of-flight electron analyzer, the setup enables for high-resolution studies of ultrafast dynamics over the whole surface Brillouin zone in most quantum materials.

O 37.13   Tue 18:00   P2/EG

Time Resolved Photoelectron Spectroscopy of Thiophen based Conjugated Donor Aceptor Polymers for Organic Photovoltaic — •TOBIAS REIKER[1], PRADNY PHANSE[1], NILS FABIAN KLEIMEIER[1], ZITONG LIU[2], ADRIAN URBAN[1], DEQING ZHANG[2], and HELMUT ZACHARIAS[1] — [1]Center for Soft Nanoscience, University of Münster, Germany — [2]Institute of Chemistry, Chinese Academy of Science, Beijing, China

Thiophene-based polymers are promising candidates for solar cell, OLED or transistor applications. An internal donor - acceptor system is formed by coupling thiophene polymers with pyrrole chains. We report results of temporally resolved photoemission studies on thiophene polymers on silicon substrates. The charge transport behaviour can be tuned by different alkyl side chains since they influence the electronic structure and aggregation. A direct assessment of the intramolecular and intermolecular dynamics may guide synthesis routes. With pF8T2, pDPP4T, pDPP4T-1 and pDPTTT we investigated the electronic dynamics of high hole-mobility organic semiconductors. Either the backbone or the side chains were modified. With the blend of pDPP4T-1 and a Fullerene we compare the excitation dynamics of singe component und blended OPV. These different molecular configurations are intended to provide insights into the change in electron configuration due to both backbone modification and intermolecular packing.

Engineering two-dimensional metal-organic networks on ferromagnetic surfaces — •MARTIN ANSTETT[1], LU LYU[1], KA MAN YU[1], MARTIN AESCHLIMANN[1], and BENJAMIN STADTMÜLLER[1,2] — [1]Department of Physics and Research Center OPTIMAS, University of Kaiserslautern, 67663 Kaiserslautern, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, Germany

Two-dimensional metal-organic networks (MONs) on noble-metal surfaces have been identified as versatile nanoarchitecture to manipulate electronic and magnetic properties at surfaces. In this contribution, we discuss the growth and the structure formation of a Co-T4PT network on epitaxial Co films grown on an Au(111) single crystal. Using scanning tunnelling microscopy, we will show that the T4PT molecules can coordinate with native Co adatoms forming a long-range ordered two-dimensional porous network structure. This network can further act as a decoupling and templating layer for the subsequent growth of C60 guest molecules. For a C60 sub-monolayer, we find that the periodicity of the network structure mainly determines the adsorption configurations of isolated C60 molecules while the structural properties of ordered C60 islands on the Co-T4PT network are substantially influenced by the intermolecular interaction between the C60 molecules. The findings show that the MON system can be a very flexible template to tailor the interfacial properties of molecular assemblies for molecular-based spintronics and electronics.

O 38.2   Tue 18:00   P2/EG

Film growth and stabilty of the Ionic Liquid $[C_1C_1Im][Tf_2N]$ on Pt(111) — •TIMO TALWAR, STEPHEN MASSICOT, AFRA GEZMIS, CYNTHIA FERNÁNDEZ, LEONHARD WINTER, FLORIAN MAIER, and HANS-PETER STEINRÜCK — Lehrstuhl für Physikalische Chemie 2, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstr. 3, 91058 Erlangen

Solid catalyst with Ionic Liquid Layer (SCILL) is a new catalytic concept using the advantageous properties of Ionic Liquids (ILs) to improve the catalytic performance such as selectivity and long-term stability of a solid catalyst by the coated IL. In this context, extensive knowledge about the IL-metal interface properties is highly desired.

In this study, the growth and thermal behavior of ultrathin films of 1,3-dimethylimidazolium bis[(trifluoromethyl)sulfonyl]imide $[C_1C_1Im][Tf_2N]$ on Pt(111) are investigated under UHV conditions. The films are prepared in vacuum by physical vapor deposition and measured by angle-resolved and temperature-programmed X-ray photoelectron spectroscopy. Complementary information is gained by Scanning Tunneling Microscopy. At 200 K, an intact closed wetting layer can be deposited on Pt(111). The underlying growth mode is 2D up to 0.5 ML (a closed wetting layer) and moderate 3D for higher coverages. At higher temperatures up to 360 K, the IL continuously decomposes leading to desorption of volatile decomposition products. We will compare this behavior to previous results for this IL on the less-reactive Cu(111) and on the non-reactive Au(111) surface.

We acknowledge support by the DFG (SFB 1452 CLINT).

O 38.3   Tue 18:00   P2/EG

Thiahelicene non-covalent molecular wires on Cu(111) — •GEMA NAVARRO[1], ANTOINE HINAUT[1], SHUYU HUANG[1], THILO GLATZEL[1], AKIMITSU NARITA[2], and ERNST MEYER[1] — [1]Department of Physics, University of Basel, Klingelbergstrasse 82, 4056 Basel, Switzerland. — [2]Okinawa Institute of Science and Technology Graduate University, Okinawa 904-0495, Japan

In recent years molecular nanowires have attained a paramount interest due to their potential application in the next generation of nanodevice. Therefore, researchers have been focused in the development of novel synthetic routes to achieve stable nanowires, also in the influence of heteroatoms doping to control optical or electronic properties [1]. Usually, the on-surface synthesis approach is adopted due to the robustness and versatile chemistry reactions available [2].

In the present study, we explore the deposition of thiahelicene molecules on Cu(111) as possible candidates for nanowires formation. Sample preparation and measurements were carried out at room temperature in an UHV system and the images were acquired by a non-contact AFM microscope. AFM-micrographic images illustrated the formation of molecular wires along the monocrystalline terraces. The growth process of the molecular wires retains the three-fold symmetry of the substrate, although, some defect points can be distinguished in their structure. In addition, the high mobility of the molecules indicates a weakly interaction with the copper surface.

Fabrication of Kondo Lattice via On-surface Reactions — •JUNG-CHING LIU[1], RÉMY PAWLAK[1], XING WANG[2], CHAO LI[1], OUTHMANE CHAHIB[1], PING ZHOU[2], ROBERT HÄNER[2], SILVIO DECURTINS[2], ULRICH ASCHAUER[2], SHI-XIA LIU[2], and ERNST MEYER[1] — [1]Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel — [2]Department of Chemistry and Biochemistry, University of Bern, Freiestrasse 3, CH-3012 Bern

Magnetic atoms assembled in different lattices can exhibit various characteristics, such as spin frustration, heavy fermion, or spin textures via RKKY interaction[1]. Different from scanning probe tip manipulation[2] or e-beam evaporation[3], we perform on-surface reaction to realize magnetic lattice using pyrene-4,5,9,10-tetraone (PTO) and Fe on Ag(111)[4]. The STM and AFM structural investigation at 4K shows 1:1 coordination of PTO and Fe, resulting in 1D chains which further self-assemble into the close-packed pattern. Tunneling spectra measured at 1K confirm Kondo resonance localized on Fe atoms, with moderate dispersion on PTO. The dip lineshape of the Kondo resonance could indicate the spin-1 state on Fe[5]. The successful synthesis of magnetic organometallic structures demonstrates the tunability of Kondo lattice structure by changing molecule species. We believe our work enables fundamental studies of spin-spin and spin-substrate interactions with different spin lattices.[1] Moro-Lagares et al. Nat. Comm. 10, 2211 (2019)[2]Nadj-Perge et al. Growth and structure of *p*-6P thin films as templates for organic heterosystems - a LEEM/PEEM study — •Franz Niklas Knoop, Winfried Daum, and Klaus Stallberg — Institute of Energy Research and Physical Technologies, TU Clausthal, Germany

The charge carrier dynamics at the contact of two organic semiconductors are strongly influenced by the molecular and mesoscopic structure of the interface. A systematic study of such structure-related effects on the carrier dynamics requires well defined and controllable model systems. Single-crystalline metals are suitable substrates for the epitaxial growth of well-ordered organic layers, but the carrier dynamics are strongly modified by the presence of a conductive surface. Therefore, we explore a different approach for the formation of organic/organic model systems: rod-like molecules such as para-sexiphenyl (*p*-6P) are known to form highly ordered layers on weakly interacting amorphous substrates like SiO_2. These layers are suitable templates for the consecutive epitaxial growth of organic heterostructures. By thermal evaporation under ultrahigh vacuum conditions we deposit *p*-6P films with nominal mono- and bilayer thicknesses on natively oxidized silicon. Characterization with low-energy electron microscopy (LEEM) and atomic force microscopy (AFM) reveals coherent films which comprise single crystalline domains of upright-standing molecules. We discuss the influence of different growth parameters on the film structure and present results from two-photon photoemission electron microscopy (2P-PEEM). Moreover, first results from experiments with organic/organic heterosystems are also presented.

Understanding the role of adsorbed CTAB in anisotropic nanostructure growth — •Esmée Berger[1], Narjes Khosravian[1], Joakim Löfgren[2], and Paul Erhart[1] — [1]Department of Physics, Chalmers University of Technology, Gothenburg, Sweden — [2]Department of Applied Physics, Aalto University, Espoo, Finland

A crucial step towards improved control over the shapes and sizes of wet-chemically synthesized nanostructures is a detailed theoretical understanding of the growth mechanism's different aspects. One of these aspects is the adsorption of surfactants, for example cetyltrimethylammonium bromide (CTAB), which is commonly used for structural tuning and increased stability. In water, CTAB exhibits a complex phase diagram, with a number of different liquid crystal-like phases. The complexity of the system is further increased during nanostructure growth, due to the presence of surfaces. Recent studies have indicated that the micellar phase of CTAB is the primary mechanism for anisotropic growth of silica and gold nanoparticles. These results were, however, based on a single value of the CTAB surface density. To properly understand the role of CTAB during anisotropic growth of nanostructures, a surface phase diagram must be established. In this work, we develop an understanding of the surface phase diagram from a modeling perspective, by means of molecular dynamics simulations.

Implementation of a silicon wafer into an UHV STM system for low temperature molecular depositions — •Ken Kolar, Grant Simpson, Christophe Nacci, and Leonhard Grill — Uni Graz, Graz, Austria

Sublimation temperatures of organic molecules typically rise as the number of constituting atoms is increased. This can lead to fragmentation and other experimental difficulties during molecular deposition if a standard sublimation Knudsen cell is used. One of the possibilities to overcome this problem is the deposition of molecules using the "energy sudden" sublimation from a silicon wafer. We have installed such a system in our ultrahigh vacuum chamber and used it for depositions onto the sample that is kept at cryogenic temperatures during the preparation. Here, we present how such a device was implemented in our setup, together with first scannning tunneling microscopy (STM) images of the test depositions.

SURMOF ZIF-67 Thin Films for Catalytic Water Oxidation Reaction — •Jimin Song, Alexei Nefedov, Stefan Heissler, Christof Wöll, and Yuemin Wang — Institute of Functional Interfaces, Karlsruhe Institute of Technology, 76344, Eggenstein-Leopoldshafen, Germany

Metal-organic frameworks emerged as promising electrocatalysts to tackle urgent energy and environmental problems. Surface-coordinated MOF thin films (SURMOFs) were grown via a liquid phase epitaxial layer-by-layer method, endowed with precisely controlled thickness, preferred growth orientation and highly-ordered surface. For the first time, high-quality crystalline ZIF-67 SURMOF thin films were fabricated and employed in water oxidation reaction (OER). The transformation from ZIF-67 to CoOOH was observed after the water oxidation reaction by applying IRRAS, Raman and XPS measurements. Meantime, the thickness of the thin film decreased from 100 nm to 20 nm. The overpotential was reduced from 468 to 375 mA/cm2 by doping with boron and nickel.

O 39.2   Tue 18:00   P2/EG

SFG microscopy of ferroelectric domains in Barium Titanate — •Dorothee Mader[1], Daniel Lourens[2], Maarten Kwaaitaal[2], Richarda Niemann[1], Sören Wasserroth[1], Sandy Gewinner[1], Marco De Pas[1], Wieland Schöllkopf[1], Martin Wolf[1], Andrei Kirilyuk[2], Sebastian Maehrlein[1], and Alexander Paarmann[1] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Radboud Universiteit, Nijmegen, The Netherlands

Phonons exhibit a mostly unexplored leverage on ferroic order and its dynamics. Exploring the possibility of phonon-driven changes to the ferroelectric order provides an attractive route for potential applications of ferroelectric devices. Here, infrared-visible (IR-VIS) sumfrequency generation (SFG) microscopy with IR-sub-wavelength resolution [1] is employed combining resonant phonon excitation and ferroelectric domain imaging of barium titanate [BTO]. BTO is a non-centrosymmetric perovskite oxide with a strong ferroelectric polarization in its tetragonal phase at room temperature. Typically, BTO samples exhibit a multi-domain structure. Using the FHI Infrared (IR) free electron laser (FEL) in the range of 400-800 cm^{-1} different phonon modes of BTO are accessible. After characterization of the samples using linear optical techniques like polarization microscopy and infrared spectroscopy, the nonlinear optical properties of the ferroelectric domains are investigated using SFG-microscopy. By mapping phonon resonances in domains and domain walls, this approach may enable in-depth understanding of the underlying physics of domain formation. [1] R. Niemann et al., Appl. Phys. Lett. 120, 131102 (2022).

O 39.3   Tue 18:00   P2/EG

Investigating Heterogeneous Catalysts by Design of Experiments — •Christian Kunkel, Frederic Felsen, Sina Stocker, Christoph Scheurer, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin, Germany

Bringing new and improved heterogeneous catalysts to market can be economically and ecologically rewarding. Yet, catalyst development is tedious, as a plethora of experimental factors in synthesis, formation and operation potentially influence achievable educt conversion and/or product selectivity. In the planning phase of an investigation, such influences can often only inadequately be assessed based on literature knowledge, individual experience and chemical intuition, resulting in a too narrow scope of experimentation. Data-driven approaches are less biased, potentially offering a way out. Still, the amount of recordable experimental data remains to be a limiting factor even with modern (automated) multi-reactor setups, where only a few dozen data points are acquired in reasonable time. In this contribution we therefore illustrate the practical application of highly-efficient optimally designed experiments. Leveraging simultaneous factor-changes, these jointly extract a maximum of information from each experimental run. Using examples from our ongoing investigation of thin-film and powder catalysts, we illustrate how this approach leads to significant insights on catalytic behavior over a larger number of factors. With additional information coming from multiple characterization techniques, we also demonstrate how catalyst development can strongly benefit from jointly coordinated data-driven experimental efforts.

O 39.4   Tue 18:00   P2/EG

Operando sXRD study of copper-zinc-alumina (CZA) model systems under methanol synthesis conditions — •Erik Beck[1,2], Vedran Vonk[1,2], Heshmat Noei[1,2], and Andreas Stierle[1,2] — [1]Centre for X-ray and Nano Science, Hamburg, Germany — [2]German Electron Synchrotron DESY, Hamburg, Germany

Methanol synthesis from gas mixtures of H2, CO and CO2 is an important industrial process in which copper-zinc-alumina (CZA) has been identified as a high performing catalyst. Typically, the products and reactants are gases used at pressures of >30 bar and a temperature of 250-300 degree C. Because of the dynamic nature of the catalyst under such industrial conditions, the underlying mechanisms and reaction paths are still under debate, since the traditional surface science techniques cannot be used at such high pressures. In order to bridge this pressure gap and gather structural information of the system in real operando conditions, we designed a special experimental setup for synchrotron-based high pressure SXRD. By using dedicated Cu and Zn UHV MBE growth chambers, we were able to prepare epitaxial model systems of the CZA catalysts composed of epitaxial Cu nanoparticles on Al2O3 single crystal surfaces. We performed

operando high energy x-ray diffraction experiments on such model catalysts at up to 30 bar and 300degC at the High Energy Materials Science Beamline at DESY and we were able to follow the structural changes of the Cu nanoparticles during oxidation and reduction in different gas compositions.

O 39.5   Tue 18:00   P2/EG

Surface phase transitions in doped manganite thin films — •Leonard Schüler, Tim Titze, Stefan Mathias, Daniel Steil, and Vasily Moshnyaga — I. Physikalisches Institut, Georg-August-Universität Göttingen

The symmetry breaking at the surface of strongly correlated $La_{1-x}Sr_xMnO_3$ (LSMO) thin films leads to a modification of orbital occupation compared to the bulk resulting in the formation of intrinsic magnetic and electric surface phases. To obtain a phase diagram of possible surface states, LSMO films with Sr doping over the complete range $x = 0 - 1$ were prepared by metalorganic aerosol deposition and have been investigated by both surface-enhanced Raman spectroscopy (SERS) and pump-probe optical (SE-PPR) reflectivity. Temperature-dependent SERS reveals magnetic phase transitions by anomalous frequency shifts of the MnO_6 octahedra's stretching mode resulting from spin-phonon coupling, as well as changes in Mn orbital occupation inferred by enhanced Raman activity of vibrational Jahn-Teller modes at the surface. Furthermore, ultrafast dynamics studied by SE-PPR reveals a surface phase transition, which is not present in the bulk LSMO.

O 39.6   Tue 18:00   P2/EG

Laser pump X-ray probe investigations of the dynamics at the liquid-vapour interface of alkali halogenide salt solutions — •Lukas Petersdorf[1], Svenja Hövelmann[1,2], Rajendra Giri[1], Nicolas Hayen[1], Karin Hansen[1], Philipp Jordt[1], Andrea Sartori[1], Matthias Greve[1], Florian Bertram[2], Olaf Magnussen[1], and Bridget Murphy[1,3] — [1]University of Kiel (IEAP), Kiel — [2]DESY, Hamburg — [3]RHL, Kiel

Detailed knowledge of the surface of alkali halogenide solutions is fundamental for understanding atmospheric effects and developing technological applications such as solar thermal cells. Surface dynamics of such systems ranging from fs to s, can be studied in detail by pump-probe techniques. Our Laser pump-X-ray probe studies are based on photoionization processes at the interface induced by a 258 nm laser pulse and pumping electron solvation dynamics and ion rearrangements. With auspicious quantum yield and surface structure, the pump-probe studies were performed on salt solutions (NaI, RbBr, ErCl3). We apply the surface sensitive techniques time resolved XRR and GIXRF to investigate the responding structural changes. A sensor monitored sample environment allows us to distinguish between laser induced and solution dependent dynamics. Upon laser excitation, changes in the specular reflectivity occur on the ms to s scale. Electron density and surface roughness change near the interface indicate a rearrangement of the ion concentration. Within the framework of the DAPHNE4NFDI project, the analysis will be supported by artificial neural networks in order to allow in-operando experimental decisions.

Si(553)-Au and Si(775)-Au surface reconstructions with a genetic algorithm approach — •Leonard M. Verhoff and Simone Sanna — Instutute for theoretical physics, Giessen, Germany

It was found by simulations and experiments, that Au atoms on a Si(553)- and Si(755)-surface form metallic nanowires. However, their precise atomic structure is still under discussion.

In this work, the respective surface reconstructions with N adatoms are searched, using a genetic algorithm implemented in the program *CALYPSO*. Genetic algorithms are reported to be efficient methods for structure predictions.

In the first generation, all Au atoms are distributed randomly on the surface, meaning every adatom introduces 3 degrees of freedom. For each generated structure, the fitness, i.e. the configuration's free energy, is then calculated from first principles with density functional theory implemented in *VASP*.

The next generation's individuals are created by moving every structure in the $3N$-dimensional space towards the structure that minimizes the fitness so far. To avoid getting stuck in a local energy minimum, 20% of the structured are created randomly in each generation.

The last step is repeated, until a certain convergence criterion is reached.

O 40.2   Tue 18:00   P2/EG

Assessing and processing the surface quality of free-standing wurtzite GaN in ultra-high vacuum — •Mohammadreza Rostami[1], Biao Yang[1], Felix Haag[1], Francesco Allegretti[1], Lifeng Chi[2], Martin Stutzmann[3], and Johannes V. Barth[1] — [1]Physics Department E20, Technical University of Munich, Garching, 85748, Germany — [2]Institute of Functional Nano & Soft Materials, Collaborative Innovation Center of Suzhou Nano Science and Technology, Soochow University, Suzhou 215123, P. R. China — [3]Walter Schottky Institute and Physics Department, Technical University of Munich, 85748 Garching, Germany

Gallium nitride (GaN) is proposed as an alternative candidate to metallic substrates for assembling organic molecular structures 1. However, the formation of a persistent surface oxide layer in air considerably limits the use of GaN for well-defined interfaces 1. We have investigated n-type free-standing c-plane wurtzite GaN crystals. The effect of electron bombardment on the surface quality of free-standing GaN during ammonia annealing was studied. Surface cleaning and full removal of the oxide layer on GaN surfaces could be reproducibly achieved via sputtering and annealing cycles, leading to substantial roughening of the GaN surface. Although ammonia annealing with electron bombardment increased the N/Ga atoms ratio, the surface morphology remained rough. In addition, the on-surface chemistry of 1,3,5-Tris(4-bromophenyl) benzene (TBB) 2 was studied on the cleaned GaN surface. [1] V. Bermudez, Surf. Sci. Rep. 72 (4), 147-315 (2017) [2] M. Fritton et al. J. Am. Chem. Soc 141 (12), 4824-4832 (2019)

O 40.3   Tue 18:00   P2/EG

A super-cycle approach to atomic layer deposition of indium-gallium-zinc oxide at low temperature — Ali Mahmoodinezhad[1], Carlos Morales[1], Małgorzata Kot[1], Franziska Naumann[2], Paul Plate[2], •Karsten Henkel[1], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Germany — [2]SENTECH Instruments GmbH, Berlin, Germany

The continuing development of multifunctional devices needs novel multicomponent oxide layers, demanding a high control of both composition and thickness during their preparation. To this end, single metal oxides exhibiting high structural quality and conformity have successfully been grown by atomic layer deposition (ALD). However, the deposition of more complex compounds with specific optical and electrical properties is still challenging. In this work, we follow a bottom-up approach to design an ALD super-cycle to grow mixed indium-gallium-zinc oxide (IGZO) films with a controllable composition. For the formation of the individual indium, gallium, and zinc oxides, we found the use of plasma-enhanced ALD (PEALD) at 150 °C to be favorable when using the organometallic precursors trimethylindium, trimethylgallium, and diethylzinc together with oxygen plasma. The PEALD approach of IGZO films can particularly overcome a nucleation delay within the ZnO sub-cycle known from thermal ALD, achieving a higher growth per cycle and improving the quality and composition homogeneity of the films as shown by in-situ spectroscopic ellipsometry and ex-situ X-ray photoelectron spectroscopy.

O 40.4   Tue 18:00   P2/EG

Adsorption of spike amino acids, asparagine and cysteine, on the surface of model catalyst TiO2 — •Miguel Blanco Garcia[1], Mona Kohantorabi[1], Michael Wagstaffe[1], Mohammad Tehrani[1], Silvan Dolling[1], Andreas Stierle[1,2], and Heshmat Noei[1] — [1]Deutsches Elektronen-Synchrotron DESY, Notkestraße 85, 22607 Hamburg, Germany — [2]Mathematics, Informatics, and Natural Sciences (MIN) Faculty, University of Hamburg, 20354 Hamburg, Germany

Titanium oxides are excellent candidates for the inactivation of viruses using light due to their photocatalytic properties [1]. In this study we are aiming to determine the mechanism of inactivation of SARS-CoV-2 on TiO2 under ultraviolet treatment [2]. The two most abundant amino acids in the spike protein of the SARS-CoV-2 virus (cysteine and asparagine) [3] are adsorb under UHV and aqueous solution on TiO2 surfaces. Surface sensitive techniques such as X-ray photoelectron spectroscopy shows changes in the amino acids upon UV treatment. Furthermore, scanning tunneling microscopy demonstrates the disposition of the amino acid molecules on the surface and the changes upon UV irradiation. GISAXS data was obtain at DESY P03 for the adsorption in aqueous solution, to understand the adsorption geometry and self-assembly of the cysteine amino acids on the rutile and anatase TiO2 surfaces.

O 41: Poster: Supported Nanoclusters

Time: Tuesday 18:00–20:00   Location: P2/EG

O 41.1   Tue 18:00   P2/EG

Nano-SMSI - FePt clusters on graphene/Rh(111) — •Natalie J. Waleska[1], Eva Marie Freiberger[1], Felix Hemauer[1], Valentin Schwaab[1], and Christian Papp[1,2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Freie Universität Berlin, Germany

Strong metal-support interaction is found for particles supported on particular metal oxide surfaces leading, inter alia, to the encapsulation of the particle by a thin layer of the metal oxide support. As a result the adsorption ability is decreased strongly but also specific site blocking is found, offering new opportunities for site selective reactions.

In this work, we investigated graphene-supported FePt clusters on the Rh(111) single crystal surface by in situ high-resolution XPS and the utilization of CO as a probe molecule. The FePt clusters were prepared by successively depositing Fe (1.27 ML) and Pt (0.14 ML) on the graphene/Rh(111) substrate. Oxidation of Fe was achieved by beam induced CO dissociation. Heating of the FePt/graphene/Rh(111) sample to 550 K results in cluster ripening and the encapsulation of Pt by a thin FeO layer due to SMSI. Further increase of the temperature to 900 K, leads to the decomposition of the Fe oxide layer and the intercalation of Fe. Additionally the formation of a FePt alloy was observed at elevated temperature.

We thank Helmholtz-Zentrum Berlin for allocation of synchrotron-radiation beamtime and BESSY II staff for support during beamtime. This work was funded by the DFG within SFB 953 "Synthetic Carbon Allotropes" (Project #182849149).

O 41.2   Tue 18:00   P2/EG

Beyond Amorphous Carbon as an Embedding Material for Cluster Superlattice Membranes — •Stefan Schulte[1,2], Tobias Hartl[1], Alexei Preobrajenski[3], Jan Knudsen[3], and Thomas Michely[1] — [1]II. Physikalisches Institut, Universität zu Köln, Germany — [2]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany — [3]MAX IV Laboratory, Lund University, Sweden

Cluster super lattice membranes constitute a novel 2D template material that has recently been described (T. Hartl et al., ACS Nano, 2020). So far, metal nano clusters on a graphene or hexagonal boron nitride support were embedded in an amorphous C matrix. This provides mechanical and thermal stability to the clusters, but a non-conductive embedding material, that allows for selective removal of the support structure is sought after. Here, embedding of cluster superlattices in B is presented and embedded clusters are characterized by STM and XPS. Embedding in B exhibit mechanical and thermal stability similar to amorphous C, e.g., Ir clusters on a graphene support embedded by a few monolayers of B remain in excellent order up to 750 K. This opens the pathway to electronic characterization of the nano clusters as well as removal of the support layer to expose stable clusters to ambient conditions. Further, preliminary results on CeO_2 embedding will be presented. CeO_2 embedded metal clusters are a promising material in few-atom catalysis processes.

O 41.3   Tue 18:00   P2/EG

H_2 Evolution from Methane Activated by Ta_8 Clusters on Pt(111) — •Matthias Knechtges, Tobias Hinke, Kevin Bertrang, Sebastian Kaiser, Nikita Levin, Martin Tschurl, and Ueli Heiz — TU Munich, School of Natural Sciences & Catalysis Research Center, Chair of Physical Chemistry

Methane as the main component of natural gas contains the highest energy density of all hydrocarbons but the activation poses great challenges, due to the high activation barrier of the *C-H* bonds.

Pathways to convert methane into valuable products at mild conditions are investigated in the UHV. Gas phase studies revealed that $Ta_8O_2^+$ catalytically converts methane to ethane and hydrogen at room temperature. The charge and oxygen density of the clusters appear to have great impact on their activity towards methane[1].

By employing a substrate manipulating the electronic and geometric structure of the clusters, the model system approaches to industrial heterogenous catalysis. Therefore, metallic Ta_8 clusters were deposited on different surfaces known for their electron drawing properties in analogy to the oxygen atoms in the $Ta_8O_2^+$. While no activity towards methane was observed Ta_8/SiO_2, hydrogen evolution was found after methane exposition on $Ta_8/Pt(111)$ in temperature programmed desorption(TPD) experiments.

Characterization by scanning tunnel microscopy showed randomly monodispersed flat arrangements and XPS to observe oxidation states.

O 41.4   Tue 18:00   P2/EG

Influence of Strong Metal-Support Interactions on the Photoactivity of Pt-loaded TiO_2(110) — •Lucia Mengel, Philip Petzoldt, Moritz Eder, Martin Tschurl, and Ueli Heiz — Chair of Physical Chemistry, School of Natural Sciences & Caly- sis Research Center, Technische Universität München, Lichtenbergstr. 4, 85748 Garching, Germany

Pt-loaded TiO_2(110) is well-known for its capability of alcohol photoreforming. The hole-mediated photooxidation reaction yields hydrogen next to valuable organic compounds such as formaldehyde. The concept of encapsulation of clusters or nanoparticles by a metal oxide overlayer under reductive conditions is well established and has been extensively studied using a variety of techniques. Such encapsulations caused by strong metal-support interactions (SMSI) are a promising tool in photo-/electrocatalysis to improve catalyst selectivity and high-temperature stability. However, there is a lack of mechanistic understanding on the influence of an SMSI overlayer on the photocatalytic hydrogen evolution reaction.

In this poster, we discuss the influence of SMSI on the photoactivity of Pt-loaded TiO_2(110). As model reaction, methanol photoreforming is studied by catalytic measurements. We focus in particular on effects with relevance to the evolution of hydrogen, as TiO_x layers may impede the back reaction in full water splitting and thus have potential to replace currently predominant chromium oxide compounds.

O 42: Poster: Nanostructures at Surfaces

Time: Tuesday 18:00–20:00   Location: P2/EG

O 42.1   Tue 18:00   P2/EG

Nanostructuring of surfaces by slow highly charged ions — •Ayman El-Said[1], Rene Heller[2], and Stefan Facsko[2] — [1]Physics Department and Interdisciplinary Research Center for Advanced Materials, King Fahd University of Petroleum and Minerals, Dhahran 31261, Saudi Arabia — [2]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany

Recently, considerable research efforts were devoted to the fabrication of extremely small nanostructures of significant potential in nanophotonics and nanoelectronics applications. Slow highly charged ions (HCI), as a promising nanotechnological tool, were successfully utilized for the creation of surface nanostructures in various solids [1]. Based on both the type of the material and ion beam parameters, nanostructures of different shapes (pits, caldera-like, hillocks) and sizes were obtained [2,3]. Here, we review the research progress on HCI-induced nanostructuring and the used theoretical approaches for understanding the creation mechanisms of the observed surface structures.

O 42.2   Tue 18:00   P2/EG

Quantum simulator to emulate lower dimensional physics and chemistry — •E. Sierda, X. Huang, D. Badrtdinov, B. Kiraly, E. J. Knol, A.M.H. Krieg, N.M.M. Aarts, G. C. Groenenboom, M. I. Katsnelson, M. Rösner, D. Wegner, and A. A. Khajetoorians — Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands

Designing materials with tailored physical and chemical properties requires a quantitative understanding of interacting quantum systems. In order to provide predictability, a promising route is to create bottom-up platforms, where the electronic properties of individual and interacting atoms can be emulated in a tunable manner. Here, we present a quantum simulator based on patterned Cs ions embedded in a 2DEG on the surface of semiconducting InSb(110). We use this platform to emulate the structure and orbital landscape of planar organic molecules. Using STM/STS and ab initio calculations, we show that an artificial atom can be derived from localized states of patterned Cs ions. The resultant potential can be used to couple artificial atoms, leading to bonding and anti-bonding states as well as to different orbital symmetries. Based on these artificial orbitals, we emulate molecular orbitals of known organic molecules, including anti-aromatic molecules, based on various atomic structures. In a different limit where Cs atoms are much closer, this quantum simulator can also be used to probe the effect of e-e interactions. Our experimental data suggest that dense structures exhibit many-body

effects which can be extended to complex quantum states based on arbitrary lattices.

O 42.3 Tue 18:00 P2/EG

Transition Metal Nanoparticles on Graphene: Influence of Temperature — •Kai Besocke, Mahboobeh Ravankhah, and Mathias Getzlaff — Institut für Angewandte Physik, Heinrich-Heine-Universität Düsseldorf

With its unique properties, such as high quality crystal structure, excellent electrical conductivity and high tensile strength, graphene is a promising substrate for fabricating nanocomposites.

In our research on supported transition metal nanoparticles we are investigating the influence of graphene as a substrate for the deposition of metallic nanoparticles and the influence of subsequent heating. In this contribution we present our results concerning the size distribution of $Fe_{0.5}Ni_{0.5}$-Nanoparticles on CVD-graphene surfaces.

The graphene surfaces are prepared on a cobalt thin film on a W(110) substrate. The particles under investigation are produced by means of Ar magnetron sputtering in a Haberland source and aggregation takes place in a He atmosphere. We analyze the behaviour of particles several nm in diameter at temperatures up to 500 °C.

Particle distributions are analyzed via STM and it will be discussed, whether the nanoparticles show different behaviour upon heating on graphene compared to other surfaces.

O 42.4 Tue 18:00 P2/EG

Activity of cerium oxide thin films prepared by atomic layer deposition using custom and commercial precursors — •Yuliia Kosto[1], Carlos Morales[1], Anjana Devi[2], Karsten Henkel[1], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Konrad-Zuse-Strasse 1, Cottbus 03046, Germany — [2]Inorganic Materials Chemistry, Ruhr University Bochum, Universitätsstraße 150, Bochum 44801, Germany

Atomic layer deposition (ALD) allows preparation of conformal coatings with possibility to control their thickness at the submonolayer level, making it a good tool for depositing active layers on 3D structures. Our group is working on cerium oxide-based materials for hydrogen detection, which is difficult at ambient conditions due to the low sensitivity and long response time of the sensors. The cerium oxide layers prepared by ALD contain a lot of defects and provide an opportunity to overcome these complications. Thickness and morphology of the oxide films play an important role in defining the Ce3+/Ce4+ ratio, as well as the interface with the used substrate. Here, we compare cerium oxide thin films deposited by ALD techniques on SiO2 and Al2O3 substrates. The results reveal that the interface to the substrate can considerably influence the reactivity of the cerium oxide toward hydrogen and oxygen. Preparation of the oxides using two different precursors (commercial Ce(thd)4 and custom Ce(dpdmg)3) has been demonstrated to affect the redox properties of the films, their reactivity, and the reversibility.

O 42.5 Tue 18:00 P2/EG

Local work function on Graphene Nanoribbons on Au(111) — •Daniel Rothhardt[1], Tilmann Klamroth[2], Amina Kimouche[1], and Regina Hoffmann-Vogel[1] — [1]Institute of Physics and Astronomy, University of Potsdam, Karl-Liebknecht-Str. 24-25, 14476 Potsdam-Golm, Germany — [2]Institute of Chemistry, University of Potsdam, Karl-Liebknecht-Str. 24-25, 14476 Potsdam-Golm, Germany

Graphene nanoribbons (GNRs) exhibit remarkable electronic properties due to the nature of the charge carriers and local confinements [1]. The local work function difference (LCDP) was investigated using an ultra-high-vacuum non-contact mode AFM and in addition to the topography, the local differences in the contact potential were recorded using the method of Kelvin Probe Force Microscopy. A charge transfer between the GNRs and the underlying gold substrate can be detected in the LCPD images which verifies the p-doping of the GNRS [2]. We observed a modification of the work function along the edges of the GNRs, which is due to the screening of the Au(111) of electrostatic fields from the GNR. Density functional theory (DFT) calculation supports the experimental findings.

O 42.6 Tue 18:00 P2/EG

Spin Switching in Self-Assembled Tetramers on Ag(111) — •Sven Johannsen[1], Sascha Ossinger[2], Sascha Schüddekopf[1], Jan Grunwald[3], Alexander Hermann[4], Troels Markussen[5], Heiko Wende[4], Felix Tuczek[3], Manuel Gruber[4], and Richard Berndt[1] — [1]Institute of Experimental and Applied Physics, CAU Kiel, Germany — [2]Department of Chemistry, University of Basel, Switzerland — [3]Institute of Inorganic Chemistry, CAU Kiel, Germany — [4]Faculty of Physics and CENIDE, University of Duisburg-Essen, Germany — [5]Synopsys Denmark, Fruebjergvej 3, 2100 Copenhagen, Denmark

Spin-crossover (SCO) molecules can be switched between a low spin (LS) state and a high spin (HS) state. Adsorption to a surface can lead to a drastic change of the SCO behaviour. We present a low-temperature scanning-tunneling-microscope investigation of the switching characteristics of metal-based SCO molecules organized in tetramers on a Ag(111) surface. Via the injection of current pulses two molecules per tetramer can be reversibly switched. In addition, these molecules may be switched remotely by applying the excitation to one of the other two molecules of the tetramers. The latter molecules themselves are immutable. We induced tens of thousands of switching events using different currents and voltages and observed that the switching yields that are 2 to 3 orders of magnitude larger compared to previous results. We show that the switching is likely linked to a spin transition and also report three-state switching that involves charging of a molecule.

O 42.7 Tue 18:00 P2/EG

Simulation of electronic transport in 2D networks — •Tim Güldenpfennig, Markus Gruschwitz, and Christoph Tegenkamp — Institut für Physik, TU Chemnitz, Reichenhainerstr. 70, 09126 Chemnitz

Interclation of atomic hydrogen into to the interface of buffer layer systems on SiC(0001) was shown to be powerful method to realize almost charge neutral quasi free monolayer graphene. This concept works also for intercalation of various metals (e.g. Pb, Sn, In) coming along with the formation of new 2D interface structures in proximity to graphene. However, defects within the buffer layer are often required for the intercalation of larger elements, thus the homogeneity of the intercalated areas depend strongly on the quality of the buffer layer and intercalation parameters. As a result, the quasi free monolayer graphene resembles a network structure rather than a homogeneous 2D phase.

In order to deduce the conductivity from our transport measurements done with a 4 point probe STM, we performed simulations. By means of COMSOL java api and the MPh library, the simulations were controlled via self-written python scripts. Next to the import of experimental data measured with high resolution SEM, own network structures were designed to study systematically the effect of anisotropy and inhomogeneities in 2D systems.

O 42.8 Tue 18:00 P2/EG

Preparation and STM study of clean Nb(111) surfaces — •Julia Goedecke[1], Maciej Bazarnik[2], and Roland Wiesendanger[1] — [1]Dept. of Physics, University of Hamburg, D-20355 Hamburg, Germany — [2]Institute of Physics, Poznan University of Technology, Piotrowo 3, 60-965 Poznan, Poland

Niobium with its highest transition temperature among all elemental superconductors has become a favorable substrate for realizing well-defined low-dimensional magnet-superconductor hybrid systems exhibiting novel types of exotic electronic states such as Majorana zero-energy modes. While a preparation procedure for obtaining atomically clean Nb(110) substrates has previously been reported, a suitable preparation method for clean Nb(111) surfaces is still lacking. Here, we report a recipe for cleaning Nb(111) surfaces based on an atomic hydrogen treatment followed by short flashes to elevated temperatures. The atomic surface structure of clean Nb(111) is investigated by high-resolution scanning tunneling microscopy (STM), revealing a surface reconstruction with a reduced atom density compared to the (111) plane of a bcc crystal.

O 42.9 Tue 18:00 P2/EG

Pulling single polar molecular wires by atomic force microscopy — •Christophe Nacci and Leonhard Grill — Institute of Chemistry, University of Graz, Graz, Austria

The frictional properties of individual nanostructures are strongly influenced by the low dimensionality and reduced size. Probing how they respond mechanically on different surfaces is essential to understand how the static and dynamic friction depend on the interplay between chemical composition and structural commensurability. Here, we report the vertical pulling of DAD molecular wires [1] off metal surfaces by non-contact atomic force microscopy (AFM), performed under ultrahigh vacuum and at low temperatures. The chemical structure of DAD polar wires is made of a regular alternation of donor (D) and acceptor (A) units. The mechanical response of single isolated molecular wires is probed by force spectroscopy. To further explore the role of structural commensurability between polymers and surface, the polar wires are also grown on ultrathin insulating NaCl films on metal surfaces.

O 42.10 Tue 18:00 P2/EG

XRR Analysis of Al2O3 coated and mid-T baked niobium for future implementation in SIS-based SRF cavities — •Artem Zaidman[1,2], Getnet Kacha Deyu[2], Marc Wenskat[2], Vedran Vonk[1], Robert Zierold[3], Robert Blick[3,4], Wolfgang Hillert[2], and Andreas Stierle[1,2] — [1]Deutsches Elektronen-SynchrDeutsches Elektronen-Synchrotron DESY, Germany — [2]Institute of Experimental Physics, Universität Hamburg, Germany — [3]Center for Hybrid Nanostructures (CHyN), Universität Hamburg, Germany — [4]Materials Science and Engineering, University of Wisconsin-Madison, United States

Bulk niobium is currently the most used material for RF surfaces. A new approach proposed by Gurevich [1] suggests the use of a superconductor-insulator-superconductor structure (SIS) to achieve higher accelerating fields and reduced

surface resistance beyond the thermodynamic limits of Nb. As an intermediate step to pursue this model and in coordination with a similar procedure performed on a single-cell niobium cavity, a mechanically polished two-grain-Nb sample was coated with a 36 nm Al2O3 thin film via thermal atomic layer deposition (ALD) to create an insulating layer and baked for 3h at 300°C (mid-T bake) [2]. An XRR analysis of the sample was taken at each processing step to follow the changes in the niobium native oxide thickness and composition.

[1] A. Gurevich, Appl. Phys. Lett. 88, 012511 (2006) [2] S. Posen, et al., Phys. Rev. Applied 13, 014024 (2020)

O 42.11   Tue 18:00   P2/EG

Oxidation of α-Al$_2$O$_3$(0001)-supported Pt-Rh alloy nanoparticles — •Ming-Chao Kao, Simon Chung, Thomas F. Keller, Vedran Vonk, and Andreas Stierle — Deutsches Elektronen-Synchrotron DESY, Center for x-ray and Nanoscience CXNS, Hamburg 22607, Germany

Metal oxide supported platinum-rhodium bimetallic alloy nanoparticles are widely deployed in the field of heterogeneous catalysis, where they often undergo oxidation-reduction cycles. To better understand the oxidation process, we monitored the nanoparticles in-situ by Grazing Incidence X-ray Diffraction (GIXRD) as a function of different alloy compositions. By heteroepitaxial growth, α-Al$_2$O$_3$(0001) substrate supported Pt, Rh, and Pt-Rh alloy nanoparticles were grown via molecular beam epitaxy. The samples were characterized by SEM, AFM, XRR, and GIXRD. The aim of this study is to uncover the oxide formation on the NPs as a function of oxygen partial pressure and temperature. The oxidation experiment is performed with an in-situ oxidation chamber, which enables experiments to be carried out up to an oxygen pressure of 1000 mbar at 450°C. From the in-situ XRD experiments performed at constant temperature

and increasing oxygen pressure, the following phenomena are deduced: particle sintering, selective oxidation, epitaxial strain, and the formation of Rh$_2$O$_3$ bulk oxide on (111)-oriented nanoparticles. Furthermore, composition-dependent changes together with selective oxidation and epitaxial strain were observed.

O 42.12   Tue 18:00   P2/EG

Structural and magnetic properties of epitaxial iron oxide nanoislands on SrTiO$_3$ — •Steffen Tober, Mai H. Hamed, Yifan Xu, Asmaa Qdemat, Connie Bednarski-Meinke, Ulrich Rücker, Oleg Petracic, Emmanuel Kentzinger, and Thomas Brückel — Jülich Centre for Neutron Science (JCNS) and Peter Grünberg Institut (PGI), JARA-FIT, Forschungszentrum Jülich

The chemical, electronic and magnetic properties of Fe$_x$O$_y$/oxide substrate heterostructures depend on substrate interactions and the flexible chemistry of the iron oxides, resulting in conductive or insulating, ferri- or antiferromagnetic phases. The reduced geometry of Fe$_{3-\delta}$O$_4$ nanoislands grown by reactive molecular beam epitaxy enables further tuning of electronic and magnetic properties for applications in catalysts and magnetoelectric devices [1]. We present the structural and magnetic characterisation of Fe$_{3-\delta}$O$_4$ nanoislands on (001) oriented SrTiO$_3$ with mixed SrO/TiO$_2$ and stepped TiO$_2$ surface terminations by reflection high-energy electron diffraction (RHEED), grazing incidence small angle X-ray scattering (GISAXS) and SQUID magnetometry [2,3]. Our findings indicate the growth of crystalline, evenly shaped, ferrimagnetic islands. These results form the basis for further experiments probing the local electronic and magnetic structure of the nanoislands.

Quantitative Modeling of Scattering-type Scanning Near-field Optical Microscope (s-SNOM) with the Finite Element Method Utilizing the Software JCMSuite — •Dinghe Dai, Dario Siebenkotten, Richard Ciesielski, and Bernd Kästner — Physikalisch-Technische Bundesanstalt, Abbestr. 2-12, 10587 Berlin

Scattering-type scanning near-field optical microscopy (s-SNOM), where local field enhancement is created with an oscillating nanotip, is widely applied in the nanoscale characterization of nanostructures, surface polaritons, and biomolecular systems. s-SNOM requires quantitative evaluation schemes with analytical models or simulation methods, among which the Finite Dipole Model [1] is a sophisticated model to calculate the near-field scattering for bulk materials. Nevertheless, it cannot model the full tip size or surface nanostructures. To solve this, a numerical model, based on the finite element method (FEM) software JCMSuite, is developed. The model describes the electromagnetic field over several orders of magnitude in physical size. At various infrared incident wavelengths (μm), the electromagnetic fields are simulated for different tip-sample gaps (nm) and demodulated at harmonics of the tapping frequency to eliminate background field effects. The agreement and deviation of amplitude and phase spectra between both models across multiple demodulation orders are discussed. The FEM by JCMSuite combined with field demodulation is a credible quantitative s-SNOM simulation method especially interesting for complex multilayer and nanooptical structures.

Switching nonlinear emission patterns of plasmonic nanostructures — •Valentin Dichtl, Kilian Wittman, Thorsten Schumacher, and Markus Lippitz — Experimental Physics III, University of Bayreuth, Germany

The nonlinear third-order material response of noble metals allows to shape the third-harmonic near field around a plasmonic nanostructure [1]. The corresponding spatial emission pattern of the third harmonic hot spots changes drastically when slightly tuning the fundamental wavelength over a linear resonance of the nanorod. This raises the question of whether similar behavior can be found for other nonlinear emission processes.

Here, we demonstrate by hyperspectral imaging that not only the third- but also the second-harmonic and especially the two- (or multi-) photon excited luminescence (TPPL) emission changes spatially, when tuning over the plasmon resonance. We discuss spatial and spectral differences between these processes. The outlook is targeted towards selectively exciting single quantum emitters in the nearfield. As first step into this direction we present differences in the spatial change of luminescence of a dye film with respect to the underlying emission pattern.

O 43.3   Tue 18:00   P2/EG

Deep learning for the extraction of optical parameters of multilayer samples in scanning near-field optical microscopy — •Dario Siebenkotten, Lara Harren, Clemens Elster, and Bernd Kästner — Physikalisch-Technische Bundesanstalt, Abbestr. 2-12, 10587 Berlin

Scattering-type scanning near-field optical microscopy (s-SNOM) is a powerful method for optical material characterization at the nanoscale. However, owing to the complex interaction between tip and sample, extensive modelling is needed for the extraction of optical parameters, particularly for layered samples. The extraction of optical parameters typically requires fitting, which quickly becomes unstable [1] and can be very time intensive due to the complexity of the models. Deep Learning algorithms offer a fast alternative for the optical parameter extraction but have only been applied to bulk materials. Here, we show the extension of these approaches to systems consisting of one and two layers of polar crystals exhibiting surface phonon-polariton resonances on top of a substrate by training neural networks with model data. We present the trained neural networks and discuss the extraction accuracy for the cases of one and two layered samples. While this study is limited to polar crystals, the application to other systems, defined for example by free charge carriers or band transitions, is straight forward. [1] McArdle et al. Phys. Rev. Research 2, 023272 (2020)

O 43.4   Tue 18:00   P2/EG

Nonlinear near-field optical microscopy (NNOM) for plasmonic skyrmions — •Florian Mangold, Bettina Frank, and Harald Giessen — 4th Physics Institute, Research Center SCoPE, and IQST, University of Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany

In recent years, plasmonic skyrmions have become a growing field of research. The state-of-the-art detection is done with PEEM (photoemission electron microscopy) or SNOM (scanning near-field optical microscopy) measurements.

An alternative to these methods is nonlinear near-field optical microscopy (NNOM) which uses an optical nonlinear process to image evanescent waves on the sub-wavelength-scale and enables real-time imaging of surface waves. By combining information from real and Fourier-space images, it is possible to calculate the phase and the amplitude of all electric field components.

The NNOM setup will be used to complement PEEM and SNOM measurements and gives us additional possibilities to investigate topological features in plasmonics such as quasicrystals, skyrmions and skyrmion bags.

O 43.5   Tue 18:00   P2/EG

Greyscale lithography with photoresist for plasmonic coupling — •Julian Alin, Michael Seidel, Thorsten Schumacher, and Markus Lippitz — Experimental Physics III, University of Bayreuth, Germany

Integrated plasmonic nanocircuits promise to play a major role for future applications of quantum optical technologies. Therefore stable, bright and narrowband single-photon sources are required, such as self assembled epitaxially

grown GaAs quantum dots [1]. Crucial for the coupling of such a quantum dot to a waveguide is, that for a high efficiency the waveguide has to be placed close to the quantum dot. However, the spatial proximity to the surrounding semiconductor material with a high refractive index strongly attenuates the surface plasmon propagation. In order to solve this problem we try to create a structure where the waveguide will be close to the quantum dot, but far away from the semiconductor material (a few hundred nanometers). To achieve this trough-like structure the idea is to apply a photoresist on a GaAs-sample, write a trough with a focussed gaussian laser beam and place a waveguide at this position. We discuss experiments on such structures with waveguides on glass substrates and first steps on GaAs wafers.

O 43.6   Tue 18:00   P2/EG

Resistive heating of monocrystalline plasmonic resonators — •Jacob Syndikus, Luka Zurak, Jessica Meier, Bert Hecht, and Thorsten Feichtner — Nanooptics & Biophotonics Group, Experimental Physics 5, RCCM, JMU Würzburg, Am Hubland, D-97074 Würzburg, Germany

Plasmonic resonators can focus light down to sub-diffraction-limited near-field intensity volumes by collective oscillations of photons and electrons. Therefore, they are hot candidates for electro-optical devices with minimal footprint, bridging the gap between fiber communication and electronics or even being optical switches by themselves. To achieve this, the plasmonic properties have to be actively tuned, the faster the better.

Here we show experimentally the modulation of the wavelength dependent scattering intensity by a gold nanorod in the MHz range by resistive heating. Application of an AC voltage heats the gold material by several tens of Kelvin, changing the electron energy density and with it the dielectric constant ε_{Au}. The small volume and the electrical contacts ensure fast heat dissipation. We fabricate the structures from monocrystalline goldflakes by means of Ga- and He-ion beam milling and measure the changes in the resonance curves via white light laser illumination and modelocking detection. Numerical models show that GHz modulation is feasible to be realized which makes the technique interesting for applications.

O 43.7   Tue 18:00   P2/EG

Electrochemistry of the surface of electrically contacted plasmonic resonators — •Paul Mörk, Luka Zurak, Jessica Meier, Bert Hecht, and Thorsten Feichtner — Nano-Optics & Biophotonics Group, Experimental Physics 5, University of Würzburg, Am Hubland, 97074 Würzburg, Germany

Catalytic processes on gold surfaces are well known to enhance electrochemical processes. When the gold is showing geometric features on the nanometer scale, plasmonic resonances in the visible wavelength range can occur. This establishes additional degrees of freedom (photon routing, heating, hot electron generation) to tailor an efficient material for photo-electrochemical processes interesting for energy applications like water splitting or CO_2 reduction.

Here we show the results of experiments with directly electrically connected plasmonic resonantors made via focused ion beam milling from monocrystalline gold flakes. Under ambient conditions without any further chemical added we observe a resonance shift by several ten of nanometers on a time scale of seconds when applying a electrical potential as high as 20 Volts to the gold surface. The effect reverses when the bias voltage is switched of on the time scale of hours. We present evidence that we observe the electrochemical oxidation and reduction of gold mediated by the omnipresent waterlayer covering every surface with nanometer thickness and deliver an outlook to the application within electrochemical cells.

O 43.8   Tue 18:00   P2/EG

Exciton lifetime of decoupled phthalocyanine molecules — •Amandeep Sagwal[1,2], Jiří Doležal[1], Rodrigo Cezar De Campos Ferreira[1], Petr Kahan[1], and Martin Švec[1,3] — [1]Institute of Physics, Czech Academy of Sciences; Praha, Czech Republic — [2]Faculty of Mathematics and Physics, Charles University; Czech Republic — [3]Institute of Organic Chemistry and Biochemistry, Czech Academy of Sciences; Czech Republic

A few layers of NaCl decoupling layer on metal are sufficient to prevent the nonradiative quenching of the excited state in phthalocyanine [1] and observe fluorescence in the far field from the molecule located in the junction of a scanning tunneling microscope (STM). First attempts to measure the lifetimes of exciton in the nanocavity suggested lifetimes of hundreds of picoseconds [2,3] but later studies pointed towards a transient charge state lifetime involved in the electroluminescence excitation process [4,5] and estimated the lifetime to be several orders of magnitude lower, due to the Purcell effect of the plasmonic nanocavity. Here, we use a pulsed supercontinuum laser to reveal the radiative decay of the excited state of the molecules with and without the presence of nanocavity.

Invited Talk   O 44.1   Wed 9:30   TRE Phy
Spins on Surfaces: A Gateway to the Quantum World — •Christian R. Ast — MPI for Solid State Research, Stuttgart

Many exotic phenomena that are of current interest today rely on the quantum mechanical spin. With the focus on the atomic scale, placing spins on different surfaces has been a remarkably successful platform. Over the past decades, spins as they occur in atoms and molecules have been placed not only on insulat-

ing layers to decouple them from the environment and isolate their properties, but also on interacting normal and superconducting substrates. In this way, a plethora of different effects and concepts could be studied including, but not limited to the Kondo effect, Yu-Shiba-Rusinov states and by extension Majorana bound states, electron spin resonance as well as inelastic spin-flip spectroscopy. Here, I will present an overview of the field as well as recent developments in spins on surfaces at the atomic scale.

O 45: Focus Session: Scanning Probe Microscopy with Quartz Sensors I

Atomic Force Microscopy (AFM) was quickly adopted in science and engineering, but it took a while until the field of surface could benefit from it. 2023 marks the 25th anniversary of the introduction of the qPlus sensor. This stiff and self sensing force sensor made from quartz that often uses an etched metal tip as known from scanning tunneling microscopy (STM) replaced the silicon cantilever and allowed new types of experiments and new domains of precision. Scientists used it to resolve the structure of organic molecules with atomic resolution, to obtain subatomic spatial resolution, to image spin structures and spin lifetimes, to measure lateral forces, to detect tiny water molecules, to image oxides and other insulating surfaces with atomic resolution. Operation in ambient conditions, ultrahigh vacuum (UHV), low (4 K) and ultralow temperatures (10 mK) and in high magnetic fields as well as in an electrochemical cell was demonstrated.

Organizer: Franz Giessibl (U Regensburg)

Time: Wednesday 10:30–12:30   Location: CHE 89

O 45.1   Wed 10:30   CHE 89
The genesis of the qPlus sensor — •Franz Giessibl — Institute of Experimental and Applied Physics, University of Regensburg, Universitätsstraße 31, 93053 Regensburg

In 1985, Gerd Binnig found exile from the STM frenzy at IBM Rüschlikon by a one year move to Stanford, the heart of silicon valley, and built the first atomic force microscope (AFM) together with Christoph Gerber and Calvin Quate [1]. Therefore, it is not surprising that the core of all AFMs, the cantilever, was soon

micromachined from Si. Even the first successful imaging of Si 7x7 relied on piezoresistive Si cantilevers in the frequency modulation mode, albeit at an insanely large oscillation amplitude of 34 nm [2]. Benchmarking, widely used in management consulting, led to the conviction that quartz tuning forks with their utmost frequency stability would be a promising alternative. The phantastic frequency stability of the quartz forks used in Swatch watches and the realization that their stiffness allows sub-Angstrom oscillation amplitudes led to the invention of the qPlus sensor. Its stability, small amplitudes and low noise soon enabled subatomic resolution by AFM [3]. While qPlus sensors are standard in vacuum today, it is open if widespread application in ambient or liquid environments will become attractive, although atomic resolution has been demonstrated [4]. On surface reaction of azaTrux molecules on Au (111) — •OUTHMANE CHAHIB[1], JUNG-CHING LIU[1], CHAO LI[1], XUNSHAN LIU[2], ULI ASCHAUER[2], SILVIO DECURTINS[2], SHI-XIA LIU[2], ERNST MEYER[1], and RÉMY PAWLAK[1] — [1]Department of Physics, University of Basel, Klingelbergstrasse 82, 4056 Basel, Switzerland — [2]Department of Chemistry and Biochemistry, University of Bern, Freiestrasse 3, 3012 Bern, Switzerland

One promising way to miniaturize electronic devices is to use "bottom-up" techniques, where functional organic molecules acting as elementary nanometer-sized "building blocks" are assembled or reacted on surfaces. Here we explore the on-surface reaction f 7,12-dibromo-5H-indeno[1,2-a]indolo-[3,2-c]carbazol-15(10H)-one molecules (AzaTrux) on the Au(111) surface into graphene nanostructures. Structural and electronic properties of nanostructures are characterized by scanning tunneling microscopy (STM) and atomic force microscopy (AFM) with CO-terminated tips. Using force spectroscopy, we further probe the donor-acceptor character of these nanostructures.

O 45.4   Wed 11:30   CHE 89

A two dimensional array of radical molecules on Pb(111) — JUNG-CHING LIU[1], CHAO LI[1], H. CHEN[2], PING ZHOU[3], XUNSHAN LIU[3], ULRICH ASCHAUER[3], SILVIO DECURTINS[3], SHI-XIA LIU[3], WULF WULFHEKEL[2], ERNST MEYER[1], and •RÉMY PAWLAK[1] — [1]University of Basel, Basel, Switzerland — [2]Karlsruhe Institute of Technology, Karlsruhe, Germany — [3]University of Bern, Bern, Switzerland

The assembly of molecules to form a quantum dot array is of interest for quantum computing with the highest areal density. In this contribution, we show the supramolecular assembly of 4,5,9,10-tetrabromo-1,3,6,8-tetraazapyrene (TB-TAP) molecules on superconducting Pb(111), self-organized in neighboring rows of radicals and neutral molecules [1]. By triggering a local field with a STM/AFM microscope at low temperature, we show that individual occupied molecules can be discharged efficiently, revealing Coulomb rings in spatial dI/dV maps. Charged molecules host spin 1/2, which is validated by dI/dV spectroscopy with μeV resolution through the observation of a pair of in-gap Yu-Shiba-Rusinov (YSR) states in the supra-conducting gap. The unpaired electron cloud extends spatially over the entire molecule and interacts with neighbouring electrons, resulting in the formation of YSR bands along the entire molecular domain. [1] J.C. Liu et al. submitted.

O 45.5   Wed 11:45   CHE 89

Self-Assembly Study of 1,2,10,11,12,14-hexafluoropentacene on a Au(111) surface by HR-AFM — •MIGUEL WICHE[1], MAXIMILIAN DREHER[2], ANDRÉ SCHIRMEISEN[1], GREGOR WITTE[2], and DANIEL EBELING[1] — [1]Institute of Applied Physics, Justus Liebig University Giessen, Germany — [2]Fachbereich Physik, Philipps-Universität Marburg, Germany

The electronic properties of 2D organic materials highly depend on the orientation of the molecules inside the molecular thin film. For designing new materials with tailored functionality, it is important to understand the self-assembly processes of the individual molecular building blocks on surfaces. For example, the role of intermolecular halogen bonds for the molecular arrangement is not well understood. A powerful tool to investigate assembly processes in a step-by-step fashion is the bond imaging AFM method, which is based on operating qPlus sensors under UHV conditions at low temperatures with CO-functionalized tips. Here, the onset of the self-assembly process of individual partially fluorinated 1,2,10,11,12,14-hexafluoropentacene molecules on Au(111) is studied. Therefore, the molecules are first evaporated onto a cold surface (around 6K) where molecular diffusion is negligible. The formation of small clusters with closely packed molecules all facing in the same direction is induced by subsequent heating steps to temperatures up to 50K. At higher temperatures (80-300K) also larger islands form. After each heating step, the sample is cooled down to 5K for determining the precise bonding angles and length of the intermolecular F···H contacts via bond imaging AFM.

O 45.6   Wed 12:00   CHE 89

On-surface synthesis of PAHs by strain and the concerted motion of adatoms. — •BENJAMIN MALLADA[1,2], BRUNO DE LA TORRE[1,2], JESUS I. MENDIETA-MORENO[2], ADAM MATEJ[1,2], MIKULAS MATOUSEK[3], JIRI BRABEC[3], LIBOR VEIS[3], TIMOTHEE CADART[3], MARTIN KOTORA[4], and PAVEL JELINEK[1,2] — [1]Czech Advanced Technology and Research Institute (CATRIN), Olomouc, Czech Republic — [2]Institute of Physics, Czech Academy of Sciences, Prague, Czech Republic — [3]J. Heyrovsky Institute of Physical Chemistry, Prague, Czech Republic — [4]Department of Organic Chemistry, Charles University, Prague, Czech Republic

The kinetic control of the synthesis of polycyclic aromatic hydrocarbons (PAH) is one of the most desired features in organic synthesis. In this work, we report the synthesis and characterization by STM/nc-AFM of several PAHs from one single precursor in which two different kinetic-driven mechanisms control the possible products at high temperatures. In the first mechanism, we show that the surface-induced mechanical constraints on a strained helical reactant leads to the synthesis of planar objects with non-benzenoid rings. In the second mechanism, the chemical pathway is mediated by an unusual C-C bond cleavage of the helical reactant mediated by the concerted motion of individual gold adatoms. These observations, supported by DFT and state-of-the-art QM/MM calculations, render a scenario where the molecular internal stress and the adatoms' role enable routes to the kinetic control of selected chemical reactions.

O 45.7   Wed 12:15   CHE 89

Monitoring of molecular configurations in SPM-based molecular manipulation — JOSHUA SCHEIDT[1], ALEXANDER DIENER[1], MICHAEL MAIWORM[2], KLAUS-ROBERT MÜLLER[3], ROLF FINDEISEN[2], KURT DRIESSENS[4], F. STEFAN TAUTZ[1], and •CHRISTIAN WAGNER[1] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany — [2]Control and Cyber-Physical Systems Laboratory, Technische Universität Darmstadt, Germany — [3]Machine Learning Group, Technische Universität Berlin, Germany — [4]Data Science and Knowledge Engineering, Maastricht University, The Netherlands

Molecular manipulation with the SPM tip as an actuator allows creating a wide variety of molecular junction configurations. Unfortunately, the precise atomic locations in such a junction, which strongly impact its mechanical and electronic properties, cannot be observed directly. Here, we present and benchmark an approach that enables such a configuration monitoring. It overcomes the most important challenges: the need for accurate yet fast simulations, the disparity between scalar observation quantities like a force gradient and a high-dimensional unknown molecular configuration, the vast configuration space to be searched, and the need to operate on the few-minutes time scales of typical experiments. This is achieved by combining a finite state automaton to store and rapidly access the results of atomistic molecular simulations, and a particle filter to search for likely manipulation trajectories, given an input sequence of observations. We are able to assign systematic differences in generic features in force gradient data to well-defined atomic configurations for the first time.

O 46: Electron-Driven Processes at Surfaces and Interfaces

On the energy transfer mechanism in hyperthermal H atom scattering from surfaces — •Nils Hertl[1], Connor L. Box[1], and Reinhard J. Maurer[1,2] — [1]Department of Chemistry, University of Warwick, UK — [2]Department of Physics, University of Warwick, UK

Adsorption of atomic and molecular hydrogen on surfaces is the gateway to many important chemical processes in nature. Hence, it is important to understand their adsorption mechanism if we want to understand the relevant elementary processes of these adsorbates on surfaces.

In the recent years, a series of detailed theoretical and experimental investigations of energy transfer between H atoms and a variety of material surfaces have been performed. The investigated substrates range from noble gas surfaces with a detour to semiconductors to late fcc transition metal surfaces. Transition metal surfaces with adsorbates were investigated, too. For all studies, a UHV apparatus, specifically designed for H atom scattering, has been used. The complementary theory relies on molecular dynamics simulation, where electronic excitations are described within the framework of molecular dynamics with electronic friction. The friction coefficient is treated within the local density friction approximation (LDFA).

In this talk, I will briefly revisit those studies and on the basis of them, I will formulate a couple of general concepts relevant to atom scattering from surfaces. Furthermore, I will also present first efforts to apply methods which go beyond the framework of LDFA friction for hyperthermal H atom scattering.

O 46.2   Wed 10:45   CHE 91

Simulations of H atom scattering from p(2×2) O/Pt(111) surface with orbital-dependent friction — •Connor L. Box[1], Nils Hertl[1], and Reinhard J. Maurer[1,2] — [1]Department of Chemistry, University of Warwick, United Kingdom — [2]Department of Physics, University of Warwick, United Kingdom

The experimentally recorded nonadiabatic energy loss that occurs during H atom scattering from a range of clean metal surfaces is well reproduced by the molecular dynamics with electronic friction method using effective medium theory for the potential energy surface and the local-density friction approximation for the electronic friction. [1] However, it was recently reported that this method is not capable of reproducing the inelastic scattering of H atoms on the oxygen-covered Pt(111) surface. [2] We present inelastic scattering energy loss distributions for this system with an efficient ML representation of the orbital-dependent friction coefficients calculated using linear response theory based upon density functional theory. This approach additionally accounts for the anisotropy of the electronic friction tensor and the effect of the oxygen adatom on the surface electronic structure. O 46.3   Wed 11:00   CHE 91

Power discontinuity and shift of the energy onset of a molecular de-bromination reaction induced by hot-electron tunneling — Ana Barragan[1], Roberto Robles[1], Nicolas Lorente[1,3], and •Lucia Vitali[1,2,3] — [1]Centro de Física de Materiales CFM/MPC (CSIC-UPV/EHU), San Sebastián, Spain — [2]Ikerbasque Research Foundation for Science, Bilbao Spain — [3]Donostia International Physics Center (DIPC), San Sebastian

Understanding the mechanism of molecular dissociation under applied bias is a fundamental requirement to progress in (electro)- catalysis as well as in (opto)-electronics. The working conditions of a molecular-based device and the stability of chemical bonds can be addressed in metal*organic junctions by injecting electrons in tunneling conditions. Here, we have correlated the energy of de-bromination of an aryl group with its density of states in a self-assembled dimeric structure of 4'-bromo-4-mercaptobiphenyl adsorbed on an Au(111) surface. We have observed that the electron-energy range where the molecule is chemically stable can be extended, shifting the bias threshold for the rupture of the -C-Br bond continuously from about 2.4 to 4.4 V by changing the electron current. Correspondingly, the power needed for the dissociation drops sharply at 3.6 V, identifying different reaction regimes and the contribution of different molecular resonance states.

O 46.4   Wed 11:15   CHE 91

Quantum transport on anisotropic surfaces revealed by MONA — •Manuel Seitz[1], Andreas Christ[1], Markus Leisegang[1], Jacek Waluk[2], and Matthias Bode[1] — [1]Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany — [2]Institute of Physical Chemistry, Polish Academy of Sciences, ul. Kasprzaka 44/52, 01-224 Warsaw, Poland

The ability to detect how charge carriers propagate in well-defined bands is of great importance for the exploitation of novel materials, e.g., in the context of spintronics or topological insulators. We developed the molecular nanoprobe (MONA) technique [1] to investigate the details of quantum transport. It utilizes a single molecule to detect ballistic charge carriers injected by the tip of a scanning tunneling microscope (STM). In this study, we investigate charge carrier transport in the structurally anisotropic Cu(110) surface which exhibits a surface state at the Y-point of the surface Brillouin zone [2]. We performed directional-, distance-, and energy-dependent measurements that reveal an unexpectedly rich anisotropic behavior. The results can be explained by the combined influence of the band structure-dependent transport path and the molecular excitation.

Understanding triplet-exciton transfer dynamics at the Si-tetracene interface — •Marvin Krenz — Universität Paderborn

Singlet-exciton fission in a tetracene overlayer and the subsequent triplet-exciton transfer into a silicon solar cell appears as promising approach to harvest high-energy photons [1]. However, the details of the exciton transfer and its dependence on the interface atomic structure are not understood. In the present contribution we employ ab initio non-adiabatic molecular dynamics to study the exciton transfer in atomistic detail. It is found that interface defects as well as thermal activation are instrumental for the exciton transfer from the organic overlayer into the Si bulk material.

O 46.6   Wed 11:45   CHE 91

Uni-directional translation of a novel adsorbate motor — •Grant J. Simpson[1], Mats Persson[2], and Leonhard Grill[1] — [1]University of Graz, Graz, Austria — [2]University of Liverpool, Liverpool, UK

Molecular motors are fascinating objects that can undergo uni-directional motion on the nanoscale. In order to independently perform meaningful work, they typically must switch between two potential energy surfaces to achieve directed motion. However, their rather complex structures often mean that their function on a surface is hindered. Here, we present a novel 'adsorbate motor' which performs strictly uni-directional translational upon excitation from the tip of a scanning tunneling microscope - in contrast to thermally induced motion of the same molecules that follows the principle of microscopic reversibility, resulting in random movement. The resulting 100% uni-directionality is then harnessed in order to perform meaningful work exemplified by the transport of single molecules across a metal surface.

O 46.7   Wed 12:00   CHE 91

Extreme magnetoresistance in high-mobility Al_2O_3/$SrTiO_3$ heterostructures — •Dennis Christensen — Technical University of Denmark, Department of Energy Conversion and Storage, 2800 Kgs Lyngby, Denmark

The heterostructure formed by depositing spinel γ-Al_2O_3 on perovskite $SrTiO_3$ exhibits a range of exciting properties including room temperature epitaxial growth [1,2], high electron mobility [3,4], a strain-tunable magnetic order [5] and a reordering of the t_{2g} bands due to the broken symmetry at the spinel/perovskite interface [6]. Here, I explore the magnetotransport properties of γ-Al_2O_3/$SrTiO_3$ and show that it exhibits a very large magnetoresistance exceeding 80,000% at 16 T and 2 K. When increasing the magnetic field, the field dependence of the magnetoresistance transitions from quadratic to linear with no saturation observed up to 16 T. I discuss the origin of this behaviour in relation to mechanisms known to produce large, unsaturated magnetoresistance.

O 47: 2D Materials II: Growth, Structure and Substrate Interaction I

Time: Wednesday 10:30–13:00　　　　　　　　　　　　　　　　　　　　　　　　Location: GER 37

O 47.1　Wed 10:30　GER 37

Two-Dimensional Non-van der Waals Materials from Data-Driven Research — Tom Barnowsky[1,2], Mahdi Ghorbani-Asl[1], Stefano Curtarolo[3], Arkady V. Krasheninnikov[1,4], and •Rico Friedrich[1,2,3] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden — [2]TU Dresden — [3]Duke University, Durham, USA — [4]Aalto University, Aalto, Finland

While two-dimensional (2D) materials are traditionally derived from bulk layered compounds bonded by weak van der Waals (vdW) forces, the recent surprising experimental realization of non-vdW 2D compounds obtained from non-layered crystals [1] foreshadows a new direction in 2D systems research.

Here, we present several dozens of candidates of this novel materials class derived from applying data-driven research methodologies in conjunction with autonomous *ab initio* calculations [2,3]. We find that the oxidation state of the surface cations of the 2D sheets is an enabling descriptor regarding the manufacturing of these systems as it determines their exfoliation energy: small oxidation states promote easy peel off [2]. When extending the set from oxides to sulfides and chlorides, the exfoliation energy becomes ultra low due to strong surface relaxations [3]. The candidates exhibit a wide range of appealing electronic, optical and magnetic properties making these systems an attractive platform for fundamental and applied nanoscience.

Phase Transitions of the BlueP-Au-network on Au(111) by Intercalation of Potassium — Philip Grimm, •Felix Otto, Maximilian Schaal, Florentine Friedrich, Roman Forker, and Torsten Fritz — Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

In 2014, a new elemental semiconductor was postulated: Blue Phosphorene (BlueP). This monolayer of P atoms offers a layer thickness-dependent band gap and high charge carrier mobility. However, the synthesis of a highly ordered and stable monolayer of BlueP is still a challenge and could only be achieved on gold substrates by constructing a Au-P network. This undesirable coupling, which leads to a change in electronic properties, could be mitigated by the intercalation of potassium. The goal is to synthesize a free-standing monolayer of BlueP. The effects of substrate temperature during K deposition and the order of deposition of phosphorus and potassium on Au(111) were investigated. Structural properties were characterized by LEED and RHEED, chemical properties by XPS, and electronic properties by photoelectron spectroscopy methods ((AR)UPS and PMM). In the end, a (2×2) superstructure is obtained. This superstructure exhibited the most promising electronic properties, which were very close to those of the free-standing BlueP. It is assumed that K and P together form the basis of the (2×2) superstructure, since the reactive bonds of potassium could be saturated and stabilized by phosphorus. At temperatures of 250 °C, the BlueP-Au network dissolves under the influence of potassium deposition and various intermediates are formed.

O 47.3　Wed 11:00　GER 37

Structural and chemical characterization of epitaxially grown FeBr$_2$ on Au(111) — •S. E. Hadjadj[1], C. Gonzalez-Orellana[2], J. Lawrence[3], D. Bikaljevic[4,5], M. Pena-Diaz[2], P. Gargiani[6], L. Aballe[6], J. Naumann[7], M. A. Nino[6], M. Foerster[6], S. Ruiz-Gomez[8], S. Thakur[1], I. Kumberg[1], J. Taylor[9], J. Hayes[1], J. Torres[1], C. Luo[9], F. Radu[9], D. G. de Oteyza[3], W. Kuch[1], J. I. Pascual[4], C. Rogero[2,3], and M. Ilyn[2] — [1]Freie Universität Berlin, Institut für Experimentalphysik, Germany — [2]Centro de Fisica de Materiales, Donostia, Spain — [3]Donostia International Physics Center, Spain — [4]CIC nanoGUNE-BRTA, Donostia, Spain — [5]Institute of Physical Chemistry, University of Innsbruck, Austria — [6]ALBA Synchrotron Light Source, Spain — [7]Freie Universität Berlin, Dahlem Center for Complex Quantum Systems, Germany — [8]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [9]Helmholtz-Zentrum Berlin, Germany

We present structural, chemical and magnetic properties of the van–der–Waals material FeBr$_2$ on Au(111) with thicknesses from submonolayer to multilayer. We observe that the first layer on Au(111) shows a dominant superstructure. The chemical characterization by XPS and XAS shows that the material is growing in the same composition for different thicknesses. The magnetic characterization by XMCD reveals that the magnetic moment increases with increasing thickness.

O 47.4　Wed 11:15　GER 37

Formation of Europium transition metal surface compounds and its protection below hBN — •Alaa Mohammed Idris Bakhit[1,2], Khadiza Ali[3,4], Anna A. Makarova[4,5], Igor Piš[6], Federica Bondino[6], and Frederik Schiller[1,4] — [1]MPC, San Sebastián, Spain — [2]Universidad del País Vasco, San Sebastián, Spain — [3]Chalmers University of Technology, Göteborg, Sweden — [4]DIPC, San Sebastián, Spain — [5]FU Berlin, Germany — [6]IOM-CNR, Trieste, Italy

We present a comparative study of the electronic and structural properties of hBN on curved transition metal (TM) substrates, namely, Ni, Rh and Pt crystals and their modifications after Eu intercalation. hBN was grown by CVD processes. The growth quality depends strongly on the lattice mismatch and the overlayer-substrate interaction. The interface properties could be influenced by tuning the substrate material and its step density. That was shown by hBN growth on curved crystals that feature strong (Ni), medium (Rh) or weak (Pt) substrate interaction. The structural properties were investigated by Low-energy electron diffraction (LEED) and scanning tunnelling microscopy (STM). Stable facets are formed upon hBN growth on the substrates, which are changed after Eu intercalation. A formation of Eu-TM alloy is detected. The electronic structure was characterized by X-ray photoelectron spectroscopy (XPS) and angle-resolved photoemission measurements (ARPES). We studied the possible protection of Eu by the hBN layer. We observe that Eu protection was incomplete due to defects and hBN growth boundaries which resulted in Eu oxidation.

O 47.5　Wed 11:30　GER 37

Interaction of Au and Rh metals with h-BN on Rh(111) from theoretical calculations — •Krisztián Palotás — Wigner Research Center for Physics, Budapest, Hungary — ELKH-SZTE Reaction Kinetics and Surface Chemistry Research Group, Szeged, Hungary

Based on density functional theory calculations, the interaction of Au and Rh metal deposits with hexagonal boron nitride (h-BN) monolayer on a Rh(111) substrate in different model systems is studied. Significant differences in the metals' adsorption, growth and intercalation mechanisms are identified [1]. As an example, the formation of a 19-atoms Rh island in the pore of the nanomesh exhibits 3D growth, in contrast to a 2D island formation of Au [2]. We found that nitrogen vacancies and Rh show systematically lower energy barrier for atomic intercalation than boron vacancies and Au. Intercalation through the middle of a BN-divacancy provided the smallest energy barriers in our considered model systems. Our theoretical results provide a microscopic understanding of related experimental results [1].

O 47.6　Wed 11:45　GER 37

Local Electronic Structure of h-BN on Pt(110) — •Marco Thaler[1], Florian Mittendorfer[2], Erminald Bertel[1], and Laerte Patera[1] — [1]Institute of Physical Chemistry, University of Innsbruck, Austria — [2]Institute of Applied Physics and Center for Computational Materials Science, Vienna University of Technology, Austria

The growth of large-scale single-orientation hexagonal boron nitride (h-BN) monolayer has been recently achieved on the Pt(110) surface, exploiting the inversion of the normal substrate-adsorbate relation [1]. Here we performed Scanning Tunneling Spectroscopy to locally probe the electronic structure of h-BN and investigate the bonding configuration in detail. The moiré pattern arising from the mismatch with the substrate is observed to induce a modulation of the conduction band onset of h-BN and a shift of the Pt-related state, implying varying interaction energies. In agreement with density functional theory, the local density of states near the Fermi energy indicates a localized covalent bonding between h-BN and Pt, causing a (1xn)-missing row reconstruction of the Pt(110) surface. O 47.7　Wed 12:00　GER 37

Chemical vapor deposition of high optical quality large area monolayer Janus transition metal dichalcogenides — •A. George[1], Z. Gan[1], I. Paradisanos[2], A. Estrada-Real[2], J. Picker[1], E. Najafidehaghani[1], F. Davies[3], C. Neumann[1], C. Robert[2], K. Watanabe[4], T. Taniguchi[4], X. Marie[2], J. Biskupek[5], M. Mundszinger[5], R. Leiter[5], U. Kaiser[5], A. Krasheninnikov[3], B. Urbaszek[2], and A. Turchanin[1] — [1]Friedrich Schiller University Jena, Jena, Germany — [2]Université de Toulouse, Toulouse, France — [3]Helmholtz-Centre Dresden Rossendorf, Dresden, Germany — [4]National Institute for Materials Science, Tsukuba, Japan — [5]University of Ulm, Ulm, Germany

Large scale chemical vapor deposition growth of Janus SeMoS monolayers is reported, with the asymmetric top (Se) and bottom (S) chalcogen atomic planes with respect to the central transition metal (Mo) atoms. The formation of these 2D semiconductor monolayers takes place upon the thermodynamically driven exchange of the bottom Se atoms of the initially grown $MoSe_2$ single crystals on gold foils with S atoms. The growth process is characterized by complementary experimental techniques including Raman and X-ray photoelectron spectroscopy, transmission electron microscopy, and the growth mechanisms are rationalized by first-principles calculations. The remarkably high optical quality of the synthesized Janus monolayers is demonstrated by optical and magneto-optical measurements which reveal the strong exciton-phonon coupling and enable to obtain an exciton g-factor of -3.3. (Adv. Mater. 34, 2022, 2205226)

O 47.8   Wed 12:15   GER 37

Preparation and characterization of carborane based nanomembranes — •Martha Frey[1], Julian Picker[1], Jakub Višňák[2], Christof Neumann[1], Tomáš Baše[2], and Andrey Turchanin[1] — [1]Friedrich Schiller University Jena, Institute of Physical Chemistry, Lessingstraße 10, 07743 Jena, Germany — [2]The Czech Academy of Sciences, Institute of Inorganic Chemistry, 250 68 Husinec-Rez, c.p. 1001, Czech Republic

Carboranes are electron-delocalized molecular clusters containing boron, carbon, and hydrogen. Because of their high chemical and thermal stability as well as their structural variability, they are interesting for a wide range of applications including nanoscale engineering, catalysis, and boron neutron capture therapy. Here, we present the fabrication of a novel boron-based two-dimensional (2D) material via electron irradiation induced cross-linking of carborane self-assembled monolayers (SAMs) on silver substrates. Using the double-cage molecule 1,2-dicarba-*closo*-dodecaborane-9,12-dithiol, the fabrication of a mechanically stable and continuous ~1 nm thin membrane was achieved. The self-assembly, cross-linking and transfer of the resulting nanomembranes onto grids have been characterized with different complementary surface-sensitive techniques including X-ray photoelectron spectroscopy (XPS), low-energy electron diffraction (LEED), ultraviolet photoelectron spectroscopy (UPS) and scanning electron microscopy (SEM).

O 47.9   Wed 12:30   GER 37

A Metastable Pentagonal 2D Material Synthesized by Symmetry-Driven Epitaxy — •Lina Liu[1,2] and Yong Chen[1,2] — [1]Department of Physics and Astronomy, Purdue University, West Lafayette, Indiana, 47907, USA — [2]Institute of Physics and Astronomy and Villum Centers for Dirac Materials and for Hybrid Quantum Materials and Devices, Aarhus University, 8000 Aarhus-C, Denmark

Most two-dimensional (2D) materials experimentally studied so far have hexagons as their building blocks. Only a few exceptions, such as PdSe2, are lower in energy in pentagonal phases and exhibit pentagons as the building blocks. Such pentagonal 2D materials demonstrate unprecedented properties and unique applications originated from low-symmetry lattice geometries. While theory has predicted a large number of pentagonal 2D materials, many of them are metastable and their experimental realization is difficult. Here, we report the first synthesis of a metastable pentagonal 2D material, the pentagonal PdTe2 monolayer, by symmetry-driven epitaxy. Scanning tunneling microscopy is used to characterize the monolayer pentagonal PdTe2, which demonstrates well-ordered low-symmetry atomic arrangements. Theoretical calculations, along with angle-resolved photoemission spectroscopy, reveal the band structures of monolayer pentagonal PdTe2. In contrast to the narrow bandgap of monolayer hexagonal PdTe2, monolayer pentagonal PdTe2 is a semiconductor with a much bigger indirect bandgap of 1.08 eV. Our work opens an avenue for the synthesis of new, pentagon-based 2D materials and gives great opportunities to explore their applications such as multifunctional electronics.

O 47.10   Wed 12:45   GER 37

The transformation of 2D honeycombs into dodecagonal quasicrystals — •Stefan Förster, Loi Vinh Tran, Martin Haller, Sebastian Schenk, and Wolf Widdra — Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, 06120 Halle, Germany

Oxide quasicrystals are 2D materials with an aperiodic dodecagonal symmetry [1]. Starting from a binary oxide Ti_2O_3 honeycomb structure on Pt(111), the Ti_nO_n ring structure with n=6 is transformed into a network of rings with ring sizes of n= 4, 5, 7 and 10 in the presence of Ba atoms. In these networks, n=7 rings host one Ba atom and n=10 rings host two [23].

In this contribution, the basic mechanisms for the network transformation are discussed. Stone-Wales transformations are the key mechanism to realize n=4...7 rings. In addition, by incorporating an additional oxygen atom, two neighboring n=6 rings convert into a n=10 ring [3]. The amount of Ba controls this conversion process and leads to a sequence of long-range ordered structures including a well-defined quasicrystal.

O 48: Focus Session: Semiconductor Surface Chemistry – from Reaction Mechanisms to Well-Ordered Interfaces I

The interest in the properties of semiconductor surfaces and chemical reactions on these surfaces is driven by a large range of current and future applications. They are spanning from conventional microelectronics over molecular electronics, atomic scale and quantum devices to photo(-electro)-chemical processes for large-scale synthesis of chemicals such as hydrogen and ammonia. In this focus session, the wide variety of topics in semiconductor surface chemistry is illustrated in the same way as the common aspects of the field are emphasized. In particular, the question how to control the reactivity on semiconductor surfaces, which is typically governed by the high localization of charge at the surface dangling bonds, will be addressed for the different systems. A larger part of the session will be dedicated to the reaction of organic molecules on semiconductor surfaces and how the control of these reactions can lead to the synthesis of ordered organic architectures with well-controlled properties on semiconductor surfaces.

Organizer: Michael Dürr (U Giessen)

Surface functionalization of semiconductors: Introducing spectroscopic labels, monolayer control for ultra-shallow doping, and providing surface passivation for atomically-precise processes — •Andrew Teplyakov — 112 Lammot DuPont Laboratory, Department of Chemistry and Biochemistry, University of Delaware, Newark, DE 19716, USA

Over the last several decades, chemistry for surface functionalization of semiconductors went through a number of directional changes that were largely dictated by the technology development. Some of the recent work in our group has been targeting modification of both flat surfaces and the surfaces of nanoparticular semiconductor materials to introduce spectroscopic labels, provide monolayer control for ultra-shallow doping, and also to control the passivation of surfaces for atomically-precise processes. This presentation will start with applying the basic principles of surface chemical design to silicon surfaces. Specifically, I will cover the solution reactions of boron- and nitrogen-containing compounds with hydrogen- and chlorine-terminated silicon surfaces. Parallels and major

differences between the chemistry of (100) and (111) crystal faces of silicon will be examined. The reactions of the same surfaces with metalorganic precursor molecules will be presented to evaluate the role of minority sites (defects) in atomically-precise processing. Finally, the parallels between surface chemical modification of flat silicon surfaces and metal oxide nanomaterials will be examined and the challenges in connecting physical and chemical properties of these materials will be evaluated.

O 48.2   Wed 11:00   GER 38

Theoretical studies on surface stabilities of $FeCuO_2$ and $CuBi_2O_4$ — •Julian Bessner, Stefanie Bogenrieder, Björn Kirchhoff, and Timo Jacob — Ulm University, Institute of Electrochemistry, D-89081 Ulm

Ammonia is the most important component in fertilizers, as 80% of the worldwide production goes into fertilizers.[1] Currently, the energetically expensive Haber-Bosch process is used to break the triple bond of N_2. In the last years, the photoelectrochemical (PEC) reduction of nitrogen has gained attention, pro-

viding a more affordable and sustainable ammonia production. To this end, $CuFeO_2$ and $CuBi_2O_4$ are investigated as materials for photocathodes as promising alternatives for the conversion of solar energy into chemical fuels.[2, 3] So far, most theoretical and experimental studies on these materials had focused on bulk properties. Here, we perform Density Functional Theory calculations (DFT+U) to analyze their electronic properties, thermodynamic stability of different surfaces and adsorption energy trends for the nitrogen reduction reaction (NRR) intermediates. Additionally, the influence of an aqueous surrounding on the stability of the surfaces and reaction intermediates thereon will be investigated using the hybrid QMMM simulation approach (SAFIRES) implemented in ASE and GPAW, which to this end will be extended to be compatible with periodic surface models.

Topical Talk O 48.3 Wed 11:15 GER 38
Growth of organic monolayers on Si(111) — •Martin Franz — Technische Universität Berlin, Institut für Festkörperphysik, Berlin, Germany
The ever-growing number of semiconductor based applications leads to an increasing demand for a modification or functionalization of surfaces with organic molecules. However, while the formation of self-assembled monolayers of organic molecules is well established on metal surfaces, the high density of dangling bonds present on most clean semiconductor surfaces typically reduces the mobility of molecules preventing an ordered growth. A route to overcome this constraint is the modification of the surface, allowing to precisely adjust the substrate-molecule interaction enabling a controlled growth.

In this talk, examples of organic films on modified Si(111) surfaces are given, which were investigated using scanning tunneling microscopy as well as tunneling and photoelectron spectroscopy. A prominent example in this regard is the boron-modified Si(111)$\sqrt{3} \times \sqrt{3}$R30°-B surface. Here, results for N-heterocyclic carbenes, which form highly ordered monolayers with promising properties [1], and for cobalt phthalocyanine [2-3] are discussed. Further examples given include the influence of surface defects on the molecular adsorption process and the use of indium-modified Si(111) as substrate [4].

O 48.4 Wed 11:45 GER 38
Organic molecular architectures synthesized by means of solution-based click chemistry on functionalized silicon surfaces — •Timo Glaser[1], Jannick Alexander Peters[1], Christian Länger[1], Dominik Scharf[2], Jannick Meinecke[2], Ulrich Koert[2], and Michael Dürr[1] — [1]Institut für Angewandte Physik und Zentrum für Materialforschung, Justus-Liebig-Universität Giessen, Germany — [2]Fachbereich Chemie, Philipps-Universität Marburg, Germany
The application of organic click chemistry to selectively functionalized silicon surfaces may open the route to synthesizing new organic molecular architectures on silicon. However, this scheme seems to be an experimental contradiction since click reactions are performed in the presence of a catalyst dissolved in a solvent whereas the highly reactive Si(001) surface is prepared and stored under UHV conditions. Here we show how to combine surface functionalization performed under UHV conditions with solution-based alkyne-azide click reactions. The UHV-based functionalization of Si(001) was realized via chemoselective adsorption of ethinyl cyclopropyl cyclooctyne (ECCO) from the gas phase. The samples were then directly transferred from UHV into the reaction solution where alternating layers of bisazide and bisalkine were coupled subsequently step by step without exposure to ambient conditions. Each reaction step was monitored by means of XPS in UHV and the selectivity of the reaction schemes in use was demonstrated. Using optimized copper(I) catalysts, reaction yields of up to 75 % were obtained.

Towards Ab Initio Design of Internal Interfaces - The Adsorption of Cyclooctyne on Semiconductor Surfaces — •Hendrik Weiske and Ralf Tonner-Zech — Universität Leipzig, Germany
Modern Society is massively influenced by technological progress, specifically the development of the electronics industry. The controlled functionalization of semiconductor interfaces with organic molecules offers new possibilities to advance the application range of classical semiconductors. The chemoselective attachment of multifunctional organic molecules is the first step in forming well-defined organic/semiconductor interfaces.
Previously, we investigated the functionalization of Si(001) surfaces extensively [1,2]. This research focussed on bifunctional cyclooctyne, which attaches to Si(001) via its strained triple bond. This work is extended here to various semiconducting substrates, such as Ge(001), to predict new and promising interfaces. The reactivity and fundamental bonding interactions are studied using various computational methods, such as pEDA, AIMD, and NEB.
We acknowledge funding from the DFG via SFB1083.

Towards dynamic holograms with electrically switchable polymer metasurfaces: materials apsects — •Dominik Ludescher, Julian Karst, Mario Hentschel, and Harald Giessen — 4th Physics Institute and Research Center SCoPE, University of Stuttgart, Germany
Holography is considered as an innovative technology that is predicted to have a significant impact on numerous fields of application such as virtual, mixed, augmented reality, medical technology, and future displays. Overlaying digital information with the real world is the general concept of augmented reality. Yet, for concepts such as 3D holographic video conferencing or surgery planning, high-resolution and high-performance dynamic holograms are inevitable. To achieve this goal, nanophotonic plasmonic approaches are considered as a very promising platform. Here, we introduce active plasmonic metasurfaces for dynamic holography based on electrically switchable metallic polymer nanoantennas. The used polymer material incorporates a metal-to-insulator phase transition in the infrared spectral range which is driven by CMOS compatible voltages of only +/-1 V. In combination with possible pixel sizes below 1 micron, this makes the polymer metasurface ideally suited for holographic display applications. Additionally, using variable angle spectroscopic ellipsometry, we investigate the optical properties of such metallic polymers. In particular, we analyze their complex dielectric function and the associated zero epsilon region around the plasma wavelength. This will lay the foundation to shift the plasmonic metasurface operation to the visible spectral range.

O 49.2 Wed 10:45 WIL A317
Sampling polar THz nearfields using nonpolar Stark-effect — •Moritz B. Heindl[1], Nicholas Kirkwood[2], Tobias Lauster[3], Markus Retsch[3], Paul Mulvaney[2], and Georg Herink[1] — [1]Experimental Physics VIII, University of Bayreuth, Germany — [2]ARC Centre of Excellence in Exciton Science, School of Chemistry, University of Melbourne, Australia — [3]Physical Chemistry I, University of Bayreuth, Germany

Quantum-Probe Field Microscopy (QFIM) enables the imaging of ultrafast THz nearfield waveforms with a conventional fluorescence microscope at optical resolution [1]. Although the underlying quantum-confined Stark-effect scales quadratically in typical configurations, we are able to resolve the full polarity of the THz nearfields utilizing alternative approaches. Specifically, we employ a carrier-envelope phase shift of the driving THz waveform or external biasing of the THz nearfield, as we discuss in this contribution.

O 49.3 Wed 11:00 WIL A317
Double resonant, monocrystalline plasmonic gratings evolutionary optimized for enhanced SERS sensing — •Thorsten Feichtner[1], Katja Höflich[2], Enno Schatz[1], Amro Swedan[3], Paul Mörk[1], and Muhammad Bashouti[3,4] — [1]Nanooptics & Biophotonics Group, Experimental Physics 5, RCCM, JMU Würzburg, Am Hubland, D-97074 Würzburg, Germany — [2]Photonic Quantum Technologies, FBH gGmbH Leibniz-Institut für Höchstfrequenztechnik, Gustav-Kirchhoff-Str. 4, D-12489 Berlin, Germany — [3]IKI for Nanoscale Science & Technology, BGU of the Negev, Beer-Sheva 8410501, Israel — [4]Department of Solar Energy and Environmental Physics, SIDEER, J. Blaustein Institutes for Desert Research, BGU of the Negev, Midreshet Ben-Gurion, 8499000, Israel
Surface enhanced Raman spectroscopy (SERS) is an extremely sensitive nonlinear method to detect vibrational energy levels of molecules using visible light. However, most SERS substrates available today are quite inhomogeneous.

Here we provide experimental evidence of an efficient and homogeneous SERS substrate consisting of numerically evolutionary optimized two-dimensional gratings made from straight monocrystalline metal wires. The combination of

grating resonance and plasmonic gap resonance allows to enhance both excitation of the molecules and emission of the Raman signal, which have to be treated separately to unlock the full potential of SERS. Many experiments comparing gratings, materials and analytes will be presented to illustrate the underlying physical mechanisms and the huge potential for applications.

O 49.4 Wed 11:15 WIL A317
Topological insulating phase in non-Hermitian plasmonic waveguide arrays — •Helene Wetter[1], Stefan Linden[1], and Julian Schmitt[2] — [1]Physikalisches Institut, Universität Bonn, Kreuzbergweg 24, 53115-Bonn, Germany — [2]Institut für Angewandte Physik, Universität Bonn, Wegelerstr. 8, 53115-Bonn, Germany

Arrays of evanescently coupled plasmonic waveguides are a powerful platform to investigate topological properties of one-dimensional lattices. The underlying principle is the mathematical equivalence between the single-particle tight-binding Schrödinger equation and the coupled mode equation. By tailoring the loss distribution, we utilize non-Hermiticity as a new approach to induce topological phases in otherwise trivial systems. We employ dielectric loaded surface plasmon polariton waveguides fabricated on a thin gold film. Additional losses are introduced to specific waveguides by deposition of a thin layer of chromium below the respective waveguides. Considering a unit cell of four waveguides, a topologically nontrivial lattice can be created by adding an equal amount of losses to the two central waveguides of the unit cell. In contrast, losses on either the first or the last two waveguides of a unit cell correspond to a trivial lattice. Using leakage radiation microscopy, we observe localized states at the edge of the nontrivial lattice (edge mode) as well as at the interface between the nontrivial and the trivial lattice (interface mode). Conversely, the trivial lattice does not provide a localized edge mode. Thus, the topological properties can solely be controlled by the design of the unit cell.

O 49.5 Wed 11:30 WIL A317
Plasmonics of Silica Encapsulated Au@Ag Nanoparticles — •Johannes Schultz[1], Felizitas Kirner[2], Pavel Potapov[1], Bernd Büchner[1,3], Axel Lubk[1,3], and Elena Sturm[2] — [1]Leibniz-Institut für Festkörper- und Werkstoffforschung Dresden e. V., Helmholtzstraße 20, 01069 Dresden — [2]Department of Chemistry, University of Konstanz, Universitätsstraße 10, 78457 Konstanz — [3]Institute of Solid State and Materials Physics, Haeckelstraße 3, 01069 Dresden

Localized Surface Plasmons (LSPs) are collective charge oscillations arising at interfaces between media of opposite sign of the corresponding dielectric functions. Here, spatial confinement of the LSPs, e.g. in nanoparticles (NPs), may lead to resonant amplification of the corresponding electromagnetic (e.m.) fields. This effect is exploited in several application, e.g., surface enhanced Raman spectroscopy or plasmonic solar cells. Depending on the application, this requires specific control of the spectral positions of the LSPs. Since the latter depend on both, the dielectric function of the NP and the surrounding, tuning of the LSPs can be realized by varying the dielectric environment of the NP. Here, a novel synthesis method was used to encapsulate silver nanocubes with silica layers of uniform and adjustable thickness in the range between 8 and 22 nm to tune the dielectric environment and hence the excitation energies of the LSPs with high precision over a broad spectral range between 2.55 and 3.25 eV. Furthermore, resonant coupling between Mie-type resonances at the silica-vacuum interface and the LSPs was found which leads to an e.m. field enhancement in the range of 100 %.

O 49.6 Wed 11:45 WIL A317
Strain-driven thermal and optical instability in Ag/a-Si hyperbolic metamaterials — •Lea Forster[1,2], Jose L. Ocana-Pujol[1], Ralph Spolenak[1], and Henning Galinski[1] — [1]Laboratory of Nanometallurgy, ETH Zurich, Switzerland — [2]Laboratory for Multifunctional Ferroic Materials, ETH Zurich, Switzerland

In a hyperbolic metamaterial system of silver/amorphous-silicon multilayers we investigated the thermal instability which arises upon heating. Our analysis demonstrates that this instability is governed by the minimization of interfacial energy and anisotropic elastic strain energy caused by the mismatch of thermal expansion coefficients. Interestingly, the stacking order of the multilayer influences which of these two energy contributions dominates. We observed this behavior by a combination of FIB-SEM tomography, finite element simulations, and optical spectroscopy. Our results show that the thermal instability initiates at 300 ˚C, while the hyperbolic dispersion despite increased structural

disorder persists up to 500 ˚C. These findings can lead to a better understanding of thermal instabilities in multilayers and may assist in the design of hyperbolic metamaterials for high-temperature applications.

O 49.7 Wed 12:00 WIL A317
Optical grating couplers for the excitation of Bloch surface waves — •Sebastian Henn, Marius Grundmann, and Chris Sturm — Universität Leipzig, Faculty of Physics and Earth Sciences, Felix Bloch Institute for Solid State Physics, Linnéstr. 5, 04103 Leipzig, Germany

In this contribution we demonstrate experimentally the control of the propagation of Bloch Surface Waves (BSW) in the transparent spectral range. BSW exist along the interface of a distributed Bragg reflector (DBR) with a thin top layer of a specified thickness to the ambient. Using shallow optical diffraction gratings with a sub-micron lattice constant, incident light is coupled into and out of the Bloch modes, which propagate along the surface between the gratings. The low-loss nature of evanescent BSW leads to long-range lateral propagation, on the order of micrometers, making this an interesting candidate for on-chip devices, for example by coupling to excitons, i.e. exciton-polariton applications. We give an overview of the fabrication processes as well as the results regarding the optical excitation of BSW by means of imaging ellipsometry, which is supported by rigorous coupled-wave analysis modelling.

O 49.8 Wed 12:15 WIL A317
Reconfigurable and polarization-dependent perfect absorber for large-area emissivity control based on the plasmonic phase-change material In₃SbTe₂ — •Lukas Conrads[1], Natalie Honné[1], Andreas Ulm[2], Andreas Hessler[1], Matthias Wuttig[1], Robert Schmitt[2], and Thomas Taubner[1] — [1]I. Institute of Physics (IA), RWTH Aachen University — [2]Fraunhofer IPT

Metasurfaces with perfect infrared absorption promise integrated filters and compact, tailorable detector elements for thermal radiation. Phase-change materials (PCMs) are prime candidates for active, non-volatile absorption tuning [1]. In this work, we show flexible encoding of different absorption/emission properties within a metasurface. We employ the plasmonic PCM In₃SbTe₂ (IST) [2] to obtain control over the emissivity by patterning an adaptable perfect absorber metasurface. Using a commercial direct laser writing setup, we locally switch the IST from an amorphous dielectric into a crystalline metallic state and write nanoscale stripe gratings of cm-size above a reflecting mirror. We demonstrate modification of already written patterns by changing the laser power and thus the IST stripe width to encode different polarization-sensitive patterns with nearly perfect absorption into the same metasurface. Finally, we measure an apparent local temperature pattern due to our large-area emissivity shaping metasurface with a conventional thermal camera [3]. Our results pave the way towards low-cost, large-area and adaptable patterning of metasurfaces.

O 49.9 Wed 12:30 WIL A317
Sensing at the ultimate volume limit: Refractive index sensing in atto-liter volumes using Mie voids — •Serkan Arslan[1], Huong Tran[1], Julian Karst[1], Lida Shamsafar[1], Thomas Weiss[2], Harald Giessen[1], and Mario Hentschel[1] — [1]4th Physics Institute and Research Center SCoPE, University of Stuttgart, Stuttgart, Germany — [2]Institute of Physics, University of Graz, and NAWI Graz, 8010 Graz, Austria

Traditional nanophotonic sensing schemes utilize dielectric or metallic nanoparticles, which confine far-field radiation in dispersive and lossy media. Apart from ill-defined sensing volumes and moderate sensitivities, these structures suffer from the generally limited access to the modal field, which is key for sensing performance. Recently, a novel strategy for dielectric nanophotonics has been demonstrated, namely, the resonant confinement of light in air. Voids created in high-index dielectric host materials support localized resonant modes with exceptional properties. In particular, due to the confinement in air, these structures benefit from the full access to the modal field inside the void. We utilize these so-called Mie voids for refractive index sensing on the single void level with unprecedented small sensing volumes in the range of 100 attoliter and sensitivities on the order of 500 nm per refractive index unit. Strikingly, the sensitivity as well as the scattering cross sections of the voids are large enough to even identify different analytes with bare eye in an optical microscope. The combination of our Mie void sensor platform with appropriate surface functionalization will even enable specificity to biological or other analytes of interest.

Growth and magnetism of ultrathin Fe films on Ta(110) — •Reiner Brüning, Roberto Lo Conte, Kirsten von Bergmann, and Roland Wiesendanger — Institut für Nanostruktur- und Festkörperphysik, Universität Hamburg

The field of hybrid systems, where magnetism and superconductivity are interacting with each other, is a field which is attracting more and more attention in recent years. Spin-polarized scanning tunneling microscopy (SP-STM) is an ideal tool to study the magnetic as well as the superconducting properties and investigate the interplay between each other.

Here, we investigate ultrathin Fe films on the anisotropic (110) surface of the elemental superconductor Ta by SP-STM. For the pseudomorphic Fe monolayer, theory has predicted [1] interesting magnetic ground states depending on the interlayer distance [1], e. g. a magnetic spin spiral with a period of 6 nm.

We observe pseudomorphic growth for sub-monolayer coverage, however, for higher coverage we find several different structures. Two of these three different reconstructions have been observed previously also for Fe on Nb(110) [2]. For the pseudomorphic Fe monolayer on Ta(110), we indeed find a spin spiral with a period of roughly 6 nm as the magnetic ground state at zero field.

Spin polarization in polyalanine molecules: the role of coupling, chirality and coordination — •T. N. Ha Nguyen[1], L. L.T. Baczewski[2], and C. Tegenkamp[1] — [1]Solid Surface Analysis, Technische Universität Chemnitz, Germany — [2]Institute of Physics, Polish Academy of Sciences, Al. Lotnikow, Warszawa, Poland

Propagation of electrons along helical polyalanine-based backbone structures comes along with a robust spin polarization effect. How- ever, studies on a molecular scale are still rare, although this length scale provides direct insight into the role of molecular properties. The self-assembly process and electronic transmission properties of race- mats of right and left handed *-helix polyalanine (DL-PA) molecules from solution on atomically smooth and magnetically switchable Al2O3/Pt/Au/Co/Au substrates was investigated by ambient scanning tunneling microscopy and spectroscopy. For various lengths of molecules with and without a cysteine termination, we studied the spin polarization in detail. The phase separation into well-ordered enantiopure hexagonal phases and hetero-dimer structures (DL-PA) allow for the analysis of the spin polarization of PA molecules in different environments. The spin polarization reaches up to 70% for chemisorbed molecules arranged in an hexagonal phase. Our results clearly demonstrate that both the coupling as well as the ordering and coordination are important in order to achieve a high spin-polarization in chiral systems.

Robust Monolayers of Endohedral Fullerenes: Towards Highly Ordered Arrays of Single Molecule Magnets and Spin Qubits — •Lukas Spree[1], Luciano Colazzo[1], Caroline Hommel[1], Andreas Heinrich[1], and Alexey Popov[2] — [1]IBS Center for Quantum Nanoscience, Seoul, South Korea — [2]Leibnitz Institute for Solid State and Materials Research

In 2012 $DySc_2N@C_{80}$ was the first endohedral fullerene proven to be a single molecule magnet. Ten years and many fullerene based single molecule magnets later, lanthanide dimetal fullerenes show high blocking temperatures of magnetization approaching 30 K and suppression of quantum tunnelling of magnetization at zero magnetic field due to coupling of two magnetic moments via an electron in a singly occupied molecular orbital. The isostructural non-magnetic versions of these molecules with Y or Sc dimers show long T_2 times and might be promising candidates for spin qubits. A great advantage of fullerene based molecules is their exceptional chemical stability.

For future research the deposition of fullerene based single molecule magnets in ordered layers is desirable to control intermolecular interactions and ease measurements with scanning probe techniques. Several causes for disorder can be identified and one approach to counteract them is chemical functionalization of the fullerene cage to promote self-assembly of monolayers. A challenge with the direct deposition of functionalized fullerenes on a substrate is a mismatch of the distance between potential binding sites and the size of the fullerenes. Therefore, templating with tetrapyrrole complexes is investigated.

O 50.4   Wed 11:15   REC C 213

Tuning the magnetic properties of self-assembled molecular networks on Au(111) and graphene — •Adam J. Watson, Koen Houtsma, Mihaela Enache, Antonija Grubišić Čabo, and Meike Stöhr — Zernike Institute for Advanced Materials, University of Groningen, 9747 AG, Groningen, The Netherlands

The ability to manipulate the spin state of low dimensional magnetic networks is of emerging interest and forms the basis of prospective technologies in the atomic limit. These include molecule-based quantum computers and spintronic devices, which require addressable spin architectures. Recently, two-dimensional (2D) networks have been prepared using the methods of on-surface supramolecular self-assembly, exhibiting a variety of different magnetic exchange interactions which are experimentally accessible. [1]

In this work, we performed scanning tunnelling spectroscopy (STS) and x-ray magnetic circular dichroism (XMCD) measurements to characterize the magnetic properties of self-assembled networks of a cyano-functionalized cobalt-porphyrin derivative (CoTCPP) on Au(111) [2] and graphene. Kondo and XMCD measurements indicate a variation in spin-substrate coupling with bonding motif, and variations in magnetic moment and spin distribution. These results highlight the importance of the bonding motif within supramolecular architectures, and the role of the substrate, in tuning molecular magnetism.

Turning by hydrogen adsorption an exchange frustrated spin-spiral into elliptical magnetic skyrmions — Timo Knispel[1], Vasily Tseplyaev[2], Markus Hoffmann[2], Gustav Bihlmayer[2], Stefan Blügel[2], Thomas Michely[1], and •Jeison Fischer[1] — [1]II Physikalisches Institut, Universität zu Köln, Zülpicher Str. 77, 50937 Cologne, Germany — [2]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany

Spin-spiral states may emerge either from the frustration of Heisenberg-type exchange interactions or from the competition of exchange and the relativistic Dzyaloshinskii-Moriya interaction resulting in atomic scale and mesoscale textures, respectively. However, to turn frustration-stabilized spin-spirals into skyrmions, high magnetic fields are required, hardly achievable in the lab. We report on a new principle using hydrogen adsorption to unwind an exchange-stabilized spin-spiral into skyrmions at accessible fields. With spin-polarized scanning tunneling microscopy we identify an atomic scale right-handed Néel-type spin spiral on the double layer Fe on Ir(110). Density functional theory calculations confirm the spin spiral is mainly frustration-stabilized with a formation energy of -12 meV/Fe with respect to ferromagnetic state. A field of the order of 80 T would be required to unwind the spin spiral. After adsorption of hydrogen, we observe that the nature of the spin spiral becomes of Dzyaloshinskii-type

with a seven times longer period. Elliptical skyrmions can be formed at moderate magnetic fields.

O 51.2   Wed 11:45   REC C 213

Aging in the self-induced spin glass Nd(0001) — •Lorena Niggli, Julian H. Strik, Anand Kamlapure, Mikhail I. Katsnelson, Daniel Wegner, and Alexander A. Khajetoorians — Institute for Molecules and Materials, Radboud University, Nijmegen, the Netherlands

Elemental neodymium has been shown to be a self-induced spin glass, where glassy behaviour stems solely from the frustrated nature of the magnetic interactions [1]. This is in contrast to traditional spin glasses, where the presence of disorder is essential toward realizing glassy behaviour. The magnetic state of Nd(0001) is characterized by a lack of long range order, but exhibits local non-collinear order (Q-states). Upon increasing the temperature, neodymium displays an unusual magnetic phase transition from a self-induced spin glass to a long-range ordered multi-Q phase [2]. Here, we explore the aging behaviour of Nd(0001) in its self-induced spin glass state using spin-polarized scanning tunneling microscopy in varying magnetic fields and variable temperature. We explore how the favourability of the Q-states evolves as we age the system and relate these changes to the preferred structure of the ordered phase. These observations indicate that neodymium may be a multi-well system, which deviates

from the traditional energy landscape expected of prototypical spin glass systems, thus providing a new platform to study aging dynamics as well as dynamic heterogeneity.

Magnetic Phase Transition in MoS$_2$ detected with AFM — Alexina Ollier[1,2], •Akash Gupta[1], Marcin Kisiel[1], Mehdi Ramezani[1,2], Andreas Baumgartner[1,2], Christian Schönenberger[1,2], and Ernst Meyer[2] — [1]Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel — [2]Swiss Nanoscience Institute, Klingelbergstrasse 82, CH-4056 Basel

Low doping electron-electron interactions in monolayer MoS$_2$ lead to a ferromagnetic spin order, whereas larger occupation of spin-polarized energy bands results in paramagnetism. The electron density of MoS$_2$ might be tuned with gate voltage, thus providing the switch ability of the ferromagnetic to paramagnetic first-order phase transition. Spontaneous phase transition in two-dimensional semiconductor gated MoS$_2$ monolayer is detected by magnetic force spectroscopy.

An abrupt and reproducible changes of the magnetic force were observed at doping concentration equal to $n_c = 3.0 \times 10^{12}$ cm^{-2} and are attributed to ferromagnetic to paramagnetic phase change. Linear dependence of force versus external magnetic field was noted in the paramagnetic state, whereas no such dependence was found in already polarised ferromagnetic state. The extracted spin susceptibility confirms the correlated electron system and the observed hysteresis of the measured magnetic force is a strong hint for first-order type of transition.

O 51.4   Wed 12:15   REC C 213
Electron Spin-Polarizing Mechanisms in Chiral CuO and CoO$_x$ Catalyst Surfaces — •Paul Valerian Möllers[1], Jimeng Wei[2], Supriya Ghosh[2], Soma Salamon[3], Manfred Bartsch[1], Heiko Wende[3], David Waldeck[2], and Helmut Zacharias[1] — [1]Center for Soft Nanoscience, WWU Münster, Germany — [2]Department of Chemistry, University of Pittsburgh, Pittsburgh, USA — [3]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), Universität Duisburg-Essen, Germany

Spin-polarized catalytic surfaces can greatly enhance the selectivity of chemical reactions, e.g., in a photoinduced water splitting process. Here, we present new insights into the mechanisms that give rise to the spin polarization in chiral cupric oxide[1] (CuO) and cobalt oxide[2] (CoO$_x$) layers deposited using a method pioneered by Switzer et al.[3] Photoelectrons were excited with deep-UV laser pulses and their average spin polarization (SP) was measured. For CuO layers, the energy dependence of the spin polarization reveals that the measured SP values can be rationalized assuming an intrinsic SP in the chiral oxide layer and a chirality-induced spin selectivity (CISS)-related spin filtering of the electrons.[4] On chiral CoO$_x$ layers, the SP was found to depend on the Co oxidation state, which allows for reversible switching of the preferred spin orientation. The results support efforts towards a rational design of further spin-selective catalytic oxide materials. [1]K.B. Ghosh et al., *J. Phys. Chem. C* **123**, 3024 (2019) [2]S. Ghosh

O 51.5   Wed 12:30   REC C 213
Magnetic circular dichroism of oxygen-passivated and bare Fe(100) in threshold PEEM — •David Huber[1], Friederike Wührl[1], Maximilian Paleschke[1,2], Frank Schumann[3], Stefan Förster[1], and Wolf Widdra[1] — [1]Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany — [2]Institute of Atomic and Molecular Sciences (IAMS), Academia Sinica, Taipei, Taiwan — [3]Max Planck Institute of Microstructure Physics, Halle (Saale), Germany

Magnetic circular dichroism (MCD) in threshold PEEM enables imaging of in-plane and out-of-plane oriented ferromagnetic domains in real and momentum space [1, 2]. Here, we compare PEEM and ARPES data for Fe(100) and the oxygen-passivated Fe(100)-(1×1)-O. Imaging the in-plane domains we observe four different asymmetry levels, which we assign to the four magnetization vectors pointing in the high symmetry directions. The observed asymmetry values vary from 3% up to 5,5% comparing Fe(100)-(1×1)-O and Fe(100). The domain-specific momentum space measurements on Fe(100) are thereby in good agreement with relativistic photoemission calculations [2]. Through off-normal photoemission we increase the sensitivity of the method by one order of magnitude in comparison to previous reports [1].

Utilizing symmetry for magnetic domain imaging via PEEM — •Frank O. Schumann[1], Jürgen Henk[2], Maximilian Paleschke[2], Cheng-Tien Chiang[3], and Wolf Widdra[2] — [1]Max-Planck Institut für Mikrostrukturphysik, Halle, Germany — [2]Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, Germany — [3]Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan

It is a well-established fact that the photoemission intensity depends on the polarization state of the light and magnetization direction. For a microscopic description it is vital to include both the spin-orbit and exchange interaction on an equal footing. A photoelectron emission microscope (PEEM) allows the detection of all emitted electrons in the hemisphere. The magnetic contrast is achieved by collecting intensity images with circular polarized light of different helicities. Computing the difference images reveals magnetic domains in the real space imaging mode. In the momentum imaging the angle-resolved photoemission intensity becomes accessible. Symmetry considerations dictate a relation in momentum space of the asymmetry signal from opposite domains. We illustrate these insights by photoemission calculations on an Fe(100) surface for photon energies in the threshold region. These we compare with recent experiments on an Fe(100) surface employing a PEEM in this photon energy range. We discuss the benefit of selecting a window of the momentum of electrons which reach the detector. A careful choice of the allowed momentum range of the detected electrons leads to a selectivity of the magnetization direction of domains.

In-situ spectro-microscopy of single PtRh nanoparticles during oxidation — •Jagrati Dwivedi[1], Lydia Bachmann[1,2], Arno Jeromin[1], Liviu C. Tănase[3], Aarti Tiwari[3], Lucas Caldas[3], Thomas Schmidt[3], Thomas F. Keller[1,2], Beatriz Roldán Cuenya[3], and Andreas Stierle[1,2] — [1]CXNS, Deutsches Elektronen-Synchrotron DESY, D-22607 Hamburg, Germany — [2]Physics Department, University of Hamburg, D-20355 Hamburg, Germany — [3]Department of Interface Science, Fritz-Haber-Institut der Max-Planck Gesellschaft, D-14195 Berlin, Germany

Heterogeneous catalysts are an integral part of industrial scale energy production, conversion and storage. However, a detailed understanding of how their shape, size, structural arrangement and chemical composition affect catalytic activity, selectivity and lifetime remains far from understood. The characterization under catalytic conditions remains challenging, therefore, a spectroscopic analysis of individual PtRh nanoparticles can provide direct evidence of the adsorbed species and their oxidation state. Here, we examined core-shell arranged PtRh nanoparticles on niobium-doped STO single crystals that were achieved by dewetting a homogeneous Pt film and subsequent overgrowth with Rh. Ex situ Scanning Auger Microscopy before and after the oxidation showed that the overgrown Rh is sintering. Spatially resolved in situ X-ray photoemission at BESSY II indicates the formation of Rh$_2$O$_3$ at partial oxygen pressure. While the nanoparticles surface composition reflects the oxidation and H$_2$ reduction, the shape of the nanoparticles remains rather unchanged under the applied conditions.

Probing Au(111) Surface Reconstruction by Electrocatalytic Reactions — •Johannes M. Hermann[1], Areeg Abdelrahman[1], Ludwig A. Kibler[1], and Timo Jacob[1,2,3] — [1]Institute of Electrochemistry, Ulm University, Ulm, Germany. — [2]Helmholtz-Institute-Ulm (HIU), Ulm, Germany. — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany.

Au(111) is an extensively studied single crystal and its thermodynamically most stable surface is reconstructed under UHV conditions. Besides the thermally reconstructed and the unreconstructed Au(111) surfaces, in addition, there is also a potential-induced reconstruction in electrochemical environments. The phase transition between the reconstructed and unreconstructed Au(111) electrode surfaces has mostly been investigated by means of *in situ* scanning tunneling microscopy. Kinetic studies are sparse and in the case of potential-induced reconstruction limited to *in situ* surface X-ray scattering. Since the electrocatalytic hydrogen evolution reaction (HER) on gold electrodes is strongly structure-sensitive, here we show how it can be used to monitor structural changes of the Au(111) surface [1]. The electrocatalytic activity is highest directly after the surface reconstruction had been lifted, and decreases while the potential-induced reconstruction proceeds, following a simple first-order rate law. In contrast to expectations from conventional electrode kinetics, the rate of the reconstruction process decreases with more negative potential, as the reconstructed surface is stabilized by increasing negative excess charge. Transition metal carbides vs platinum as catalysts for H2 dissociation and hydrogenation of ethylene and acetylene — •CARLOS JIMENEZ-OROZCO[1], ELIZABETH FLOREZ[1], and JOSE RODRIGUEZ[2] — [1]Faculty of Basic Sciences, University of Medellin, Medellin, Colombia — [2]Chemistry Division, Brookhaven National Laboratory, USA

Hydrogenation reactions are key in the chemical industry, many of them use the scarce Pt-group metals as catalysts, limiting their usage in the long term. Transition metal carbides (TMC) emerge as an alternative material. Among TMC, tungsten carbide (WC) stands out as the active phase or as support of metals. There is still a lack in the understanding of the WC performance, limiting their modulation and applications. Here, density functional theory was used to study the performance of WC in hydrogenation of acetylene (C2H2) and ethylene (C2H4) as probe molecules, together with the H2 dissociation capability of WC. Hence, Pt, Pt/WC (Pt monolayer) and WC were compared. Hydrogen surface coverage and atomistic thermodynamics were used to achieve more realistic models. The H2 dissociation on Pt/WC has a Pt-like behavior at high coverage. The pristine WC surface becomes as a machine for H2 dissociation in a wide rage of T and P, achieving high surface coverages. The Pt/WC has the capability to hydrogenate selectively C2H2 into C2H4, avoiding surface poisoning. The results put WC and Pt/WC under the spotlight as a promising systems alternative to Pt for hydrogenation reactions at several T and P conditions and for the selective transformation of C2H2 into C2H4.

Modeling and Design of Single-Atom Alloy Catalysts — RAFFAELE CHEULA and •MIE ANDERSEN — Department of Physics and Astronomy, Aarhus University, Denmark

In this contribution we apply molecular simulations and machine learning (ML) to study CO_2 hydrogenation (reverse water-gas shift) on single-atom alloy (SAA) catalysts, i.e., diluted bimetallic materials. SAAs have been shown to be able to break the scaling relationships that limit conventional catalysts [1]. We target a wide combinatorial space of elements of the periodic table, which makes a direct study with density-functional theory (DFT) computationally prohibitive. Therefore, we produce a database of DFT-calculated energies on a limited number of SAAs and apply physics-inspired ML techniques for the extrapolation to a wide range of materials. We use a graph-based Gaussian Process Regression ML model (WWL-GPR [2]) to calculate adsorption energies, and simpler models (e.g., multivariate regressions) to estimate the activation energies of the new materials. We employ microkinetic modeling to simulate the reaction kinetics; then, we apply sensitivity analysis and uncertainty quantification to identify the parameters that can improve the model predictions, and we refine them with additional DFT calculations. The application of the framework to CO_2 hydrogenation allows us to rationalize how reaction mechanisms and catalytic activity change with the catalyst composition, paving the way toward the design and nano-engineering of SAA catalysts.

Data-centric approach for uncovering rules to describe the CO_2 activation at metal catalysts — •HERZAIN I. RIVERA-ARRIETA, LUCAS FOPPA, and MATTHIAS SCHEFFLER — The NOMAD Laboratory at the Fritz-Haber-Institut der Max-Planck-Gesellschaft and IRIS-Adlershof of the Humboldt-Universität zu Berlin, Germany

Using CO_2 as a building block in the production of chemicals and fuels requires, in a first step, the activation of this molecule [1]. The materials space is practically infinite, but only a handful of them may enable an effective CO_2 activation. Therefore, this work focuses on the use of artificial intelligence to speed up finding new catalysts for this process. Single-atom alloys (SAA) of transition metals not only provide good model systems, but also show potential as heterogeneous catalysts [2]. Using the mBEEF functional to perform the DFT modeling of the interaction between CO_2 and different surface terminations in Cu-, Zn-, and Pd-based SAA, we generated a dataset including 50 physicochemical parameters characterizing the geometry, and electronic properties of the adsorption sites where the molecule is activated in each material. Then, we applied the subgroup-discovery (SGD) approach [3] to uncover rules correlating key parameters in the SAA with indicators of the CO_2 activation, e.g., a large C−O bond elongation. Having access to these SGD-rules, which only depend on the material, allows a fast screening and prediction of potentially effective catalysts.

Machine learning interatomic potential for metallic and oxidized copper surfaces — •FELIX RICCIUS, NICOLAS BERGMANN, NICOLAS G. HÖRMANN, HENDRIK H. HEENEN, and KARSTEN REUTER — Fritz-Haber-Institut der MPG, Berlin, Germany

Copper (Cu) is a promising catalyst for the electrochemical reduction of CO_2 to chemicals and fuels since it yields many possible reduction products. The selectivity between these products is hypothesized to be altered by partial oxidation of the catalysts* surface. The extent of Cu surface oxidation, as well as accompanying morphological transformations are, however, unclear. Predictive atomistic simulations could potentially uncover this surface chemistry but time and length scales necessary for the required sampling are intractable by first-principles methods. Machine learning interatomic potentials (MLIP) trained to first principle data can overcome this limitation by retaining predictive accuracy at a fraction of the computational cost. In this work, we use Gaussian Approximation Potentials to train a MLIP for metallic Cu and Cu oxides. We design a workflow tailored to the problem at hand. Via iterative parallel tempering simulations, we sample the relevant phase space for Cu oxidation at various oxidation states during training. We demonstrate the viability of our approach, which results in a reliable potential capable of describing the chemically important regions of the configuration space. The potential gives access to (surface)phase diagrams and surface reconstruction phenomena following surface reduction and oxidation. The atomic insight may shine light on the role of (surface)oxidation in Cu electrocatalysts.

Selectivity Trends and Role of Adsorbate–Adsorbate Interactions in CO Hydrogenation on Rhodium Catalysts — •MARTIN DEIMEL[1,2], HECTOR PRATS[3], MICHAEL SEIBT[2], KARSTEN REUTER[1], and MIE ANDERSEN[4] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]Chair for Theoretical Chemistry, Technical University of Munich, Germany — [3]Department of Chemical Engineering, University College London, UK — [4]Aarhus Institute of Advanced Studies and Department of Physics and Astronomy, Aarhus University, Denmark

Rh is one of the most promising elemental catalysts for the conversion of syngas (CO and H_2) into hydrocarbons and oxygenates, especially toward valuable higher oxygenates. Experimentally, an inverse relationship between activity and selectivity of the main products methane and acetaldehyde was identified with conflicting explanations for this trend.[1,2] Here, we revisit the question of the role played by step and terrace sites, represented by the Rh(211) and Rh(111) facets, on activity and selectivity trends.[3] We use an accelerated kinetic Monte Carlo (KMC) approach including a cluster expansion to treat lateral interactions. By comparing our results to corresponding mean-field models and experiment,[1,2] we find that only the KMC models can correctly capture the experimental selectivity trends and that quantitatively correct activity predictions require correction for well-known errors in the density functional theory parametrization of our models.

Estimating Free Energy Barriers for Heterogeneous Catalytic Reactions with Machine Learning Potentials and Umbrella Sampling — •SINA STOCKER[1], GÁBOR CSÁNYI[2], KARSTEN REUTER[1], and JOHANNES T. MARGRAF[1] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]University of Cambridge, United Kingdom

Predictive-quality first-principles based microkinetic models are increasingly used to analyze (and subsequently optimize) reaction mechanisms in heterogeneous catalysis. In full rigor, such models require the knowledge of all possible elementary reaction steps and their corresponding reaction barriers. Unfortunately, for complex catalytic processes (such as the generation of ethanol from syngas) the number of possible steps is so large that an exhaustive first-principles calculation of all barriers becomes prohibitively expensive.

To overcome this limitation, we develop machine learned (ML) interatomic potentials to model the early steps of syngas conversion on Rhodium. These ML potentials can be used to determine free energy reaction barriers at a fraction of the computational cost of the underlying first-principles method. Specifically, we use here the Gaussian Approximation Potential (GAP) framework and explore iterative training in combination with umbrella sampling for the CHO decomposition as an example.

A systematic DFT+U and Quantum Monte Carlo benchmark of magnetic two-dimensional (2D) CrX$_3$ (X = I, Br, Cl, F) — •Daniel Wines, Kamal Choudhary, and Francesca Tavazza — Materials Science and Engineering Division, National Institute of Standards and Technology (NIST), Gaithersburg, MD 20899, USA

The search for two-dimensional (2D) magnetic materials has attracted a great deal of attention because of the experimental synthesis of 2D CrI$_3$, which has a measured Curie temperature of 45 K. Often times, these monolayers have a higher degree of electron correlation and require more sophisticated methods beyond density functional theory (DFT). Diffusion Monte Carlo (DMC) is a correlated electronic structure method that has been demonstrated successful for a wide variety of systems, since it has a weaker dependence on the Hubbard parameter (U) and density functional. In this study we designed a workflow that combines DFT+U and DMC in order to treat 2D correlated magnetic systems. We chose monolayer CrX$_3$ (X = I, Br, Cl, F), with a stronger focus on CrI$_3$ and CrBr$_3$, as a case study due to the fact that they have been experimentally realized and have a finite critical temperature. With this DFT+U and DMC workflow and the analytical method of Torelli and Olsen, we estimated an upper bound of 43.56 K for the T$_c$ of CrI$_3$ and 20.78 K for the T$_c$ of CrBr$_3$, in addition to analyzing the spin densities and magnetic properties with DMC and DFT+U. We expect that running this workflow for a well-known material class will aid in the future discovery and characterization of lesser known and more complex correlated 2D magnetic materials.

TREX: an integrated HPC software platform for quantum Monte Carlo calculations — •Claudia Filippi — University of Twente, Enschede, The Netherlands

I will present the software development strategy and current achievements of the European Center of Excellence TREX "Targeting Real chemical accuracy at the EXascale" [1]. TREX focuses on methods at the high-end in the accuracy ladder of electronic structure approaches and, in particular, on quantum Monte Carlo methods which are uniquely positioned to fully exploit the massive parallelism of upcoming architectures. The main objective of TREX is the development of a user-friendly and open-source software suite, which integrates quantum Monte Carlo codes within an interoperable, high-performance platform. Core of our software efforts is the creation of the following two libraries:

TREXIO: A common I/O library and file format for easily exchanging data between applications, facilitating high-throughput computing workflows [2];

QMCkl: A library of computational kernels, written together by quantum Monte Carlo and HPC experts, to perform common CPU-intensive quantum Monte Carlo tasks [3].

Exciton-phonon coupling in luminescence of indirect band-gap materials — Matteo Zanfrognini[1,2], Fulvio Paleari[1], Daniele Varsano[1], and •Ludger Wirtz[3] — [1]Centro S3, CNR-Istituto Nanoscienze, Modena, Italy — [2]Università di Modena e Reggio Emilia, Modena, Italy — [3]Department of Physics and Materials Science, University of Luxembourg, Luxembourg

Layered, quasi-2D materials, such as hexagonal boron nitride (hBN) are known to display very strong excitonic effects due to the concentration of excitons in two dimensions and due to the relatively weak dielectric screening. If the band-gap of the material is indirect, the dispersion of the lowest lying exciton can have a minimum at a finite wave vector q. Upon absorption of a photon and excitation to a vertical (q=0) exciton, the system will relax to the finite-q exciton. Luminescence then entails the absorption/emission of a phonon with wave vector q. We present a computational approach for phonon-assisted luminescence in the presence of strong excitonic effects using two approaches: (i) a finite-displacement approach for the exciton-phonon coupling and (ii) a diagrammatic approach, calculating the q-dependent exciton-phonon coupling from the exciton eigenvectors and electron/hole-phonon scattering matrix elements. We show that the methodology quantitatively explains recent measurements of different stackings of BN layers. [1]

A combined G$_0$W$_0$/BSE scheme of characterizing photoexcitations in hydroxylated rutile TiO$_2$(110) — •Savio Laricchia, Andrea Ferretti, Daniele Varsano, and Claudia Cardoso — Centro S3, CNR-Istituto Nanoscienze, 41125 Modena, Italy

In reduced TiO$_2$, electronic transitions originating from polaronic excess electrons in surface-localized band-gap sta tes (BGS) are known to contribute to the photoabsorption and to the photocatalytic response of TiO$_2$ in the visible region. Recent state-selective studies using two-photon photoemission (2PPE) spectroscopy have also identified an alternative photoexcitation mechanism contributing to the photoabsorption of the reduced surface (110) of rutile TiO$_2$. This process involves d-d excitations from BGS arising from surface and subsurface defects, including bridging hydroxyls and oxygen vacancies. Density Functional Theory (DFT) has been used to determine the character of the electronic excited states involved in a $d_{t_{2g}}$-$d_{t_{2g}}$ transitions, but its accuracy is questioned by its theoretical framework: DFT is in principle exact for ground state systems and does not describe interacting photogenerated electron-hole pairs, i.e. the excitons. This has highlighted the need to move beyond the DFT formalism, by working within a many-body perturbation theory (MBPT) framework. It will be shown how a G$_0$W$_0$ method, combined with the solution of the Bethe-Salpeter equation (BSE), provides a powerful tool for characterizing from first principles the optical excitations from BGS identified by 2PPE experiments on hydroxylated TiO$_2$(110).

Scaling the Way for All-Electron XPS Simulations to CalculateAbsolute Binding Energies of Surface Superstructures — •Dylan Morgan[1], Sam Hall[1], Benedikt Klein[1,2], Matthew Stoodley[1,2], and Reinhard Maurer[1] — [1]Department of Chemistry, University of Warwick, United Kingdom — [2]Diamond Light Source, Harwell Science and Innovation Campus, United Kingdom

First principles simulations of x-ray photoemission spectroscopy (XPS) and near-edge x-ray absorption fine-structure (NEXAFS) crucially support the assignment of surface spectra composed of many overlapping signatures. Core-level constrained Density Functional Theory calculations based on the Δ-SCF method are commonly used to predict relative XPS binding energy (BE) shifts but often fail to predict absolute BEs. The all-electron numeric atomic orbital code FHI-aims enables an accurate prediction of absolute BEs, but the legacy code lacked computational scalability to address large systems and robustness with respect to localisation of the core hole. We present a redesign of the core-hole constrained code in FHI-aims that delivers improvements to the scalability and robustness of core-hole constrained calculations in FHI-aims. We demonstrate the improved scaling behaviour and employ the new code to simulate core-level spectroscopic fingerprints of graphene moire superstructures. The code refactorisation forms the basis to expand the code towards improved core hole localisation methods and the rigorous treatment of relativistic effects for core-level spectra beyond the 1s shell.

Efficient diagonalization of BSE electron-hole Hamiltonian using group theory — •Jörn Stöhler[1,2], Dmitrii Nabok[1], Stefan Blügel[1], and Christoph Friedrich[1] — [1]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, Germany — [2]RWTH Aachen University, Germany

The Bethe-Salpeter equation (BSE) is the state-of-the-art method for the calculation of optical absorption and electron-energy loss spectra including excitonic effects. We solve the BSE by diagonalizing an effective electron-hole Hamiltonian. Often, a high number of **k**-points is needed to converge the BSE spectra, which leads to a large size of the Hamiltonian matrix and makes its diagonalization very expensive. In this work [1], we use the full spatial symmetry group to transform the electron-hole product basis into a symmetry-adapted product basis, which brings the Hamiltonian into a block-diagonal form and speeds up the subsequent diagonalization. The basis transformation is sparse and causes little overhead. We provide an implementation of our method in the FLAPW code Spex and demonstrate speedups of 36, 52, 12 for Si, BN, and monolayer MoS$_2$, respectively.

We acknowledge financial support by MaX CoE funded by the EU through H2020-INFRAEDI-2018 (project: GA 824143).

Excitonic effects on quadratic optical photoresponse tensors of semiconductors — •Peio Garcia-Goricelaya[1] and Julen Ibañez-Azpiroz[1,2] — [1]Centro de Física de Materiales, University of the Basque Country UPV/EHU, Spain — [2]IKERBASQUE, Basque Foundation for Science, Spain

We present a general ab initio scheme for including many-body excitonic effects in the non-linear optical photoresponse up to second order. Our practical implementation starts from the length-gauge formulation of the single-particle non-interacting optical photoresponse tensors [1] that are efficiently calculated

using Wannier interpolation [2]. Subsequently, excitonic corrections are included in the many-body interacting current-density response tensors by means of Dyson-like equations derived within TD-CDFT. These equations allow a natural connection with the formalism of the single-particle picture and the Wannier-interpolation scheme respecting the tensorial character of the response. We employ this scheme to assess the impact of excitonic effects on several quadratic optical processes as the second-harmonic generation and the shift-current bulk photovoltaic effect in technologically appealing semiconductors.

Electronic and optical properties of $CoFe_2O_4$ from density functional theory calculations, including many-body effects — •Shohreh Rafiezadeh[1], Vijaya Begum-Hudde[1,2], and Rossitza Pentcheva[1] — [1]Department of Physics University of Duisburg-Essen, Germany — [2]University of Illinois at Urbana-Champaign, USA

$CoFe_2O_4$ is a ferrimagnetic semiconductor that finds application as an anode material in photocatalytic water splitting. We present a comprehensive study of the electronic and optical properties of bulk $CoFe_2O_4$ using density functional theory calculations and many-body perturbation theory to clarify the broad range of reported band gaps both experimentally (0.55-4.1 eV)[1] and theoretically (0.9-1.90 eV). Starting with different exchange-correlation functionals, we obtain a direct band gap of 1.38 [PBE+(U=4 eV)], 1.69 eV [SCAN+(U=3 eV)], and an indirect gap of 2.02 eV (HSE06). Including quasiparticle corrections within G_0W_0 enhances and renders indirect band gaps for all functionals of 1.78, 1.95 and 2.17 eV, respectively. Excitonic effects are accounted for by solving the Bethe Salpeter equation and result in the lowest threshold for optical transitions at 1.50 eV (SCAN) and 1.61 eV (HSE06), followed by peaks at ∼ 2.0, 3.5 and 5.0 eV, in agreement with experiment highlighting the importance of electron-hole interactions. Support by DFG- within CRC/TRR 247, project B04, and computational time at MagnitUDE is gratefully acknowledged. [1] S. Singh and N. Khare, Sci. Rep. **8**, 6522 (2018).

Peering into interfacial water by qPlus-based atomic force microscopy — •Ying Jiang — International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, P. R. China

Water/solid interfaces are a central theme across an incredibly broad range of scientific and technological processes. Scanning probe microscopy (SPM) has been extensively applied to probe interfacial water, but there exist two longstanding limitations in the past decades, which makes SPM fall short compared with conventional spectroscopic methods. First, it is very difficult to image H atoms of water molecule directly; Second, it is highly possible to disturb the fragile H-bonding water structure during the imaging process. To this end, we have developed a new imaging method based on qPlus-type atomic force microscopy (AFM), which is sensitive to H and non-invasive to water structure. The key lies in probing the high-order electrostatic force between the quadrupole-like CO-terminated tip and the polar water molecules at large tip-water distances. In this talk, I will showcase the application of this technique to probe water clusters, ion hydrates, 2D ice and even bulk ice surface [1-4]. The possibility of combing qPlus-AFM with quantum sensing technology to perform nanoscale NMR measurement of interfacial water will be also briefly discussed [5-6].

Water Dimer-Driven DNA Base Superstructure with Mismatched Hydrogen Bonding — Shuning Cai[1], Lauri Kurki[1], •Chen Xu[1], Adam S. Adam[1,2], and Peter Liljeroth[1] — [1]Department of Applied Physics, Aalto University, 00076 Aalto, Espoo, Finland — [2]WPI Nano Life Science Institute (WPI-NanoLSI), Kanazawa University, Kakuma-machi, Kanazawa 920-1192, Japan

The existence of water dimers in equilibrium water vapor at room temperature and their anomalous properties revealed by recent studies suggest the benchmark role of water dimers in both experiments and theory. However, there have been limited observations of individual water dimers due to the challenge of water separation and generation at the single-molecule level. Here, we achieve real-space imaging of individual confined water dimers embedded inside a self-assembled layer of a DNA base, adenine, on Ag(111). The hydration of the adenine layers by these water dimers causes a local surface chiral inversion in such a way that the neighboring homochiral adenine molecules become heterochiral after hydration, resulting in a mismatched hydrogen-bond pattern between neighboring adenine molecules. Furthermore, theoretical simulation and calculations corroborate the mutual influence between the adenine superstructure and these dynamic confined water dimers. The observation of single confined water dimers offers an unprecedented approach to studying the fundamental forms of water clusters and their interaction with the local chemical environment.

Nanosacle 3D printing technique by using the nanopipette-combined quartz tuning fork-atomic force microscope — •Sangmin An — Department of Physics, Institute of Photonics and Information Technology, Jeonbuk National University, Jeonju 54896, South Korea

Materials can be classified by hardness, such as gold represented by hard materials having elasticity and water represented by soft materials having viscosity. However, at the nanoscale, even solid gold exhibits viscosity [1], while liquid water also exhibits elasticity [2] revealed by a quartz tuning fork-atomic force microscope (QTF-AFM), which has the intrinsic properties of high stiffness and high sensitivity. In this presentation, I discuss how this QTF-AFM can be applied as the nanoscale 3D printing technique combined with nanopipette [3,4], which are typically used in biotechnology, along with showing the results of the elasticity and viscosity of water. In addition, I share the results of nanoscratching [5] and nanosensor [6] schemes which can be realized with the nanorod-combined QTF-AFM instead of nanopipette.

Atomic-scale imaging of muscovite mica and its interaction with water — •Giada Franceschi[1], Pavel Kocan[2], Andrea Conti[1], Sebastian Brandstetter[1], Jan Balajka[1], Igor Sokolovic[1], Jiri Pavelec[1], Markus Valtiner[1], Martin Setvin[2], Florian Mittendorfer[1], Michael Schmid[1], and Ulrike Diebold[1] — [1]Inst. Appl. Phys., TU Wien, Wiedner Hauptstr. 8-

10/E134, 1040 Vienna, Austria — [2]Dept. Surface and Plasma Phys., Charles University in Prague, V Holesovickach 2, 180 00 Prague, Czech Republic

Muscovite mica is an abundant potassium aluminosilicate enjoying wide popularity in surface and interfacial science. Its prevalence is partly due to its extraordinary cleaving properties: The easily obtained atomically flat terraces are ideal for fundamental studies. To date, it is established that the cleaved surface is decorated by K^+ ions,[1] but their intrinsic ordering and their precise hydration mechanisms are not known. Here, we use non-contact atomic force microscopy to image the K^+ distribution of cleaved mica and investigate their interaction with water under ultra-high vacuum conditions. After cleaving, the ions are arranged with short-range order, which we interpret with support from theory.[2] Dosing water vapor at 100 K causes various hydration arrangements, consistent with previous theoretical studies, and clustering at increasing water coverage. Exposure to ultra-clean liquid water[3] induces ion mobility and substitution by protons. *[1] Christenson et al., Surf. Sci. Reports 71, 367 (2016). [2] Franceschi et al., submitted. Surface structure of dry and hydrated α-Al_2O_3(0001) — Johanna Hütner[1], David Kugler[1,2], Michael Schmid[1], Ulrike Diebold[1], and •Jan Balajka[1] — [1]Institute of Applied Physics, TU Wien, Vienna, Austria — [2]CEITEC, Brno, Czech Republic

Corundum α-Al_2O_3 is an important ceramic also widely used as a support for heterogeneous catalysis. Due to similar Al coordination, α-Al_2O_3 is an important model system for naturally occurring minerals, such as aluminosilicate clays. Detailed studies of alumina surfaces have been stymied by its insulating nature but successfully performed with atomic force microscopy [1]. We used noncontact AFM to investigate the $(\sqrt{31} \times \sqrt{31})$R9°-reconstructed Al_2O_3(0001)

surface formed upon high-temperature annealing. The reactivity of surface sites is strongly affected by hydroxylation. However, complete surface hydroxylation requires high pressures of water vapor (1 Torr) [2] that cannot be easily achieved in a conventional ultrahigh vacuum system. We explored the interaction of the Al_2O_3(0001) surface with varying pressures of water vapor as well as ultrapure liquid water dosed with a UHV-compatible dispenser [3]. The results will provide new insights into the hydration of environmental substrates. [1] J. V. Lauritsen, et al., *Phys. Rev. Lett.* 103, 076103 (2009) [2] P. J. Eng, et al., *Science* 288, 1029 (2000) [3] J. Balajka, et al., *Rev. Sci. Instrum.* 89, 8, 083906 (2018)

Atomic-scale imaging of the cleaved feldspar microcline (001) surface and its interaction with water — •Luca Lezuo, Andrea Conti, Jan Balajka, Igor Sokolović, Florian Mittendorfer, Michael Schmid, Ulrike Diebold, and Giada Franceschi — Institute of Applied Physics, TU Wien, Wiedner Hauptstrasse 8-10/E134, 1040 Wien, Austria

Feldspar microcline ($KAlSi_3O_8$), abundant in the Earth's crust and present as dust particles in the atmosphere, is known to be one of the best ice nucleators. The exact processes driving the interaction of microcline with water have been studied intensively [1], but atomic-scale investigations remain elusive.

We present experimental, atomic-scale studies of the microcline-water interaction. The surfaces were prepared by UHV cleaving and analysed with non-contact atomic force microscopy (nc-AFM) and x-ray photoelectron spectroscopy (XPS). The cleaved surface consists of a honeycomb array that we assign to differently back-bonded O atoms. Dosing water vapour at 100 K causes the appearance of a hexagonal lattice and the gradual formation of a connected water network. DFT calculations help us to rationalize our experimental results.

Bias-dependent conductivity switching and rectification in metallocene-based molecular junctions — Yangbiao Liu[1], Andika Asyuda[1], Heinrich Lang[2], Egbert Zojer[3], and •Michael Zharnikov[1] — [1]Angewandte Physikalische Chemie, Universität Heidelberg, 69120 Heidelberg, Germany — [2]Fakultät für Naturwissenschaften, Anorganische Chemie, Technische Universität Chemnitz, D-09107 Chemnitz, Germany — [3]Institute of Solid State Physics, NAWI Graz, Graz University of Technology, 8010 Graz, Austria

Self-assembled monolayers (SAMs) of ferrocenyl/ruthenocenyl-substituted biphenylthiolates and fluorenethiolates on Au(111) exhibit two distinct conductance states (CS) in two-terminal junctions featuring a sharp tip of eutectic GaIn as top electrode. When only negatively biasing the junction, the original, high CS is preserved, while the junction is switched to a low CS when applying only positive biases. Comparing the current values for these two states, one gets an effective rectification ratio of more than 1000 - a value comparable to the best performing molecular diodes but attained already at particularly low voltages. Significantly, the switching between the conduction states is reversible and the initial, high CS can be recovered by the application of a negative bias. Moreover, as shown by the example of one of the SAMs studied, when sweeping the junction alternatingly to the maximum positive and negative bias voltages (as usually done in literature), fully symmetric J-V curves are observed. This means that for a symmetric sweeping of the junction, the effective rectification disappears.

Sensing properties of cerium oxide as an electrode material for the detection of glucose — •Anastasiia Deineko[1], Viacheslav Kalinovych[1], Sascha L. Mehl[2], Yevheniia Lobko[1], Yurii Yakovlev[1], Tomáš Skála[1], Kevin C. Prince[2], Vladimír Matolín[1], Iva Matolínová[1], and Nataliya Tsud[1] — [1]Charles University, Faculty of Mathematics and Physics, Department of Surface and Plasma Science, Prague, Czech Republic — [2]Elettra-Sincrotrone Trieste S.C.p.A., Basovizza, Trieste, Italy

Detection of glucose level in biological liquids is of great importance nowadays because of the growing number of people with diabetes. A variety of oxides is used as electrode material for biosensors and cerium oxide is among them due to its unique properties. In this study characterization of the cerium oxide was performed by surface analysis techniques using photoelectron and absorption spectroscopies (XPS, SRPES, RPES, NEXAFS) in combination with electrochemical measurements. Photoemission based analysis provided information on changes in the oxidation state of cerium cations on the surface and in the subsurface layers of the oxide film, and whether glucose chemically bonds to the oxide. While electrochemical testing, namely cyclic voltammetry and chronoamperometry, was used to explore the sensing properties of polycrystalline cerium oxide films in reaction with glucose in the PBS working solution. The CeO_2 working elec-

trode sensitivity and pH range of sensor stability were determined and discussed in view of the enzymatic properties of cerium oxide. Keywords: cerium oxide, glucose, photoelectron spectroscopy, electrochemistry, biosensor.

O 55.4   Wed 15:45   CHE 91

PTCDA mediated Ag(111) step reconstruction as precursor to pinwheel phase — •Danyang Liu[1], Aleš Cahlík[1], Carolina A. Marques[1], Jens Oppliger[1], Ruslan Temirov[2,3], and Fabian D. Natterer[1] — [1]Department of Physics, University of Zurich, Winterthurerstrasse 190, CH-8057 Zurich, Switzerland — [2]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany — [3]University of Cologne, Faculty of Mathematics and Natural Sciences, Institute of Physics II, 50937 Cologne, Germany

PTCDA (3,4,9,10-Perylenetetracarboxylic dianhydride) forming herringbone islands on Ag(111) is the most striking phase and the prototypical metal-supported organic semiconductor. When we co-deposit PTCDA and Ag on Ag(111) at room temperature, we find that prior to their self-assembly into PTCDA herringbone islands, the molecules implant themselves into and reshape the Ag step edges. The PTCDA-decorated-Ag steps are curved and, depending on whether the Ag steps originate from screw dislocations or a terrace, cause steps reconstruction into multilayer high spirals or isolated Ag islands that both exhibit quantum confinement. At higher coverages, the PTCDA decorated steps may nucleate a distinct pinwheel phase that occasionally proceeds to form

a metal-organic framework. Annealing to higher temperatures straightens the PTCDA/Ag steps and may grow more pinwheel phase PTCDA patches, showing yet another tuning knob for organometallic surface science.

Growth of ordered two-dimensional cobalt phthalocyanine films on a one-dimensional substrate — •Milan Kubicki, Susi Lindner-Franz, Mario Dähne, and Martin Franz — Technische Universität Berlin, Institut für Festkörperphysik, Berlin, Germany

The formation of self-assembled layers of organic materials on solid surfaces is an important subject because of their possible application in advanced (opto-)electronic devices. While such a formation of self-assembled monolayers is well established on metal surfaces, the growth on silicon surfaces is much less studied.

Using scanning tunneling microscopy (STM) the molecular arrangement of cobalt phthalocyanine (CoPc) molecules on the In-Si(111)(4×1) surface is studied [1]. CoPc belongs to the transition metal phthalocyanines being a class of organic semiconductors, which has been already employed e.g. in organic light emitting diodes, in organic photovoltaic cells, and in organic field-effect transistors.

Our data demonstrate that for low CoPc coverages the molecules are highly mobile along the In-Si nanowires. By approaching the saturation coverage, the CoPc molecules stabilize each other by forming a highly ordered two-dimensional monolayer. Based on STM observations a structure model with a (4×4) periodicity could be developed, which precisely explains the experimental observations.

Topical Talk   O 55.6   Wed 16:15   CHE 91

Towards Understanding and Controlling On-Surface Reactions and Self-Assembly Mechanisms — •Daniel Ebeling — Institute of Applied Physics, Justus Liebig University Giessen, Heinrich-Buff-Ring 16, 35392 Giessen, Germany

The ability to construct organic nanomaterials with atomic precision is the key for applications in molecular electronics as the (opto-)electronic properties of such quantum materials depend on their atomic structure and size. To develop new strategies for synthesizing organic nanomaterials on surfaces, in-depth knowledge about the reaction processes and self-assembly mechanisms is needed. This can be revealed by visualizing the chemical structure and orientation of individual reaction intermediates using bond imaging atomic force microscopy (AFM).

In this presentation, recent results will be discussed that offer an approach for tuning the self-assembly process of halogenated compounds via reversing the binding selectivity of intermolecular halogen bonds. [1] A strategy for building covalent nanostructures one molecule at a time on an inert sodium chloride surface via scanning probe manipulation is also presented. This enables synthesizing elusive covalent nanoarchitectures, studying structural modifications and revealing pathways of intermolecular reactions. [2] Moreover, possibilities for tweaking the bond imaging technique using torsional and flexural higher eigenmodes of qPlus sensors will be illustrated. [3]

Molecular orientation of DHTAP on the nanostructured Cu-CuO stripe phase — •Claudia López-Posadas[1], Antony Thomas[2], Thomas Leoni[2], Olivier Siri[2], Conrad Becker[2], and Peter Zeppenfeld[1] — [1]Institute of Experimental Physics, Johannes Kepler University Linz, Altenberger Str. 69, 4040 Linz, Austria — [2]Aix-Marseille University, CNRS, CINaM, UMR 7325, F-13288 Marseille, France

We have studied the preferential adsorption, structure and molecular orientation of 5,14-dihydro-5,7,12,14-tetraazapentacene (DHTAP) layers on the regularly patterned Cu-CuO stripe phase obtained by sub-monolayer oxygen adsorption on the Cu(110) surface. Using Reflectance Difference Spectroscopy (RDS) and Scanning Tunneling Microscopy (STM) we find that the DHTAP molecules preferentially adsorb on the Cu (110) stripes, where they are always lying flat with their long molecular axis aligned parallel to the [-110]-direction. In contrast, on the subsequently covered Cu(110)-(2x1)O stripes, the DHTAP molecules are aligned with their long molecular axis parallel to the [001]-direction. The evolution of the RDS signal allows to monitor the sequential adsorption and orientation of DHTAP during monolayer formation and the subsequent multilayer growth for different oxygen pre-coverages and, hence, different Cu and CuO stripe widths. Interestingly, beyond the first monolayer, the DHTAP molecules

adopt a preferential orientation which critically depends on the initial oxygen coverage, revealing the influence of the Cu-CuO stripe width and the possibility to tune the overall optical anisotropy of these films.

Oxygen-induced reorientation of organometallic chains on Cu(110) — •Ilias Gazizullin, Christophe Nacci, and Leonhard Grill — Physical Chemistry Department, University of Graz, Heinrichstraße 28, Graz, Austria

The deposition of molecules onto crystalline surfaces allows their investigation at the single-molecule level by scanning tunneling microscopy (STM). It furthermore gives access to the controllable on-surface synthesis of covalent polymers [1]. Here, we have studied dibromo-p-terphenyl molecules on Cu(110) and on the Cu(110)-(2x1)O striped phase under ultra-high vacuum conditions with low-temperature STM.

Previously, the Cu(110)-(2x1)O striped phase was used as a template for the synthesis of organometallic structures having different sizes and shapes depending on the width of copper stripes [2]. The focus of our study is how pre- or post-adsorbed oxygen and annealing, which is necessary for covalent polymerization, affect the molecular adsorption on the surface. It turns out that on the striped phase the molecules form organometallic chains on the copper areas, oriented in at least three surface directions. Increasing the sample temperature from 300 K to 450 K induces a reorientation of the organometallic chains, which occurs due to stabilization of the reoriented OM chains by embedding in the Cu-O phase.

Simulations of 1D Supramolecular Chains on Gold with Explicit Surface–Substrate Interactions — •Krystof Brezina[1,2], Hubert Beck[1], Mariana Rossi[2], and Ondrej Marsalek[1] — [1]Charles University, Faculty of Mathematics and Physics, Prague, Czech Republic — [2]Max-Planck-Institut für Struktur und Dynamik der Materie, Hamburg, Germany

2,5-diaminobenzoquinone-1,4-diimine molecules deposited on Au(111) have been observed in AFM experiments to assemble into 1D hydrogen-bonded chains, which exhibit different geometries and mechanical properties depending on the conditions at the deposition [1]. While a complete explanation of this behavior remains elusive, it is clear that nuclear quantum effects on the hydrogen bonding play an important role. To clarify this effect, we aim at performing path integral molecular dynamics with *ab initio*-quality potentials, in a system that explicitly takes into account molecules and the surface. Here, we discuss the methodological advances needed to generate meaningful training sets for the neural network potentials that substitute the reference *ab initio* method, in particular when a reaction needs to be well described [2]. We show the nature of the relevant proton-transfer *ab initio* potential energy surfaces as well as initial results focusing on the specific effects of the surface on the geometry of the molecules and on the character of the nuclear quantum effects in the chains.

Controlled Formation of Porous 2D Lattices from C_3 Symmetric Ph$_6$-Me-Tribenzotriquinacene-OAc$_3$ — •Markus Leisegang[1], Sinem Toksabay[1], Andreas Christ[1], Patrick Härtl[1], Johannes Krebs[1], Todd B. Marder[1], Soumyajyoti Haldar[2], Stefan Heinze[2], Matthias Bode[1], and Anke Krueger[1,3] — [1]Universität Würzburg, Germany — [2]Universität Kiel, Germany — [3]Universität Stuttgart, Germany

The on-surface self-assembly of molecules is a promising approach to control the properties of resulting 2D lattices. Usually, planar molecules are utilized to prepare flat, structurally confined molecular layers, with only a few recent examples of warped precursors [1,2]. However, detailed control of the superstructures is limited thus far. Herein, we report the temperature-controlled self-assembly of a bowl-shaped, acetylated C_3-symmetric hexaphenyltribenzotriquinacene derivative on Cu(111). Combining scanning tunneling microscopy (STM) and density functional theory (DFT) confirms the formation of highly differing arrangements starting with π-stacked bowl-to-bowl dimers at low coverage at room temperature via chiral honeycomb structures, an intermediate trigonal superstructure, followed by a fully carbon-based, flattened hexagonal superstructure formed by on-surface deacetylation, which is proposed as a precursor for holey graphene networks with unique defect structures [3].

Te on Pt(111): Structure and Growth of Surface Tellurides and Pt_xTe_y Films — Tilman Kisslinger, Alexandra Schewski, Andreas Raabgrund, Hannah Loh, Lutz Hammer, and •M. Alexander Schneider — Lehrstuhl für Festkörperphysik, FAU Erlangen-Nürnberg, Staudtstr. 7, 91058 Erlangen

By LEED-IV, STM and DFT we investigated the tellurization of Pt(111) in UHV. For Te coverages $\Theta < 0.5$ ML surface tellurides are formed. In this coverage regime and after thermal annealing, we find only two well ordered surface telluride structures with (3×3) and (10×10) periodicity, the former was mistaken for a defective $PtTe_2$ film [1]. Our LEED-IV structure analyses determine the atomic structure and show that the Pt(111) surface undergoes massive reconstructions upon reaction with Te.

For $\Theta > 0.5$ ML, compact islands develop which eventually coalesce to a complete platinum telluride layer. Again by LEED-IV analyses we find that the first layer is a Pt_2Te_2 layer on which as second layer a $PtTe_2$ film can be grown. Both form an overlayer where 7×7 film unit cells lie on 10×10 Pt(111) unit cells. Furthermore, we find that the interface to the Pt(111) bulk still contains the ≈ 0.5 ML Te originally bound in the (10×10) superstructure. Electronic properties of the films determined by STS and implications for the MBE growth of transition metal dichalcogenides by surface tellurization will be discussed.

Electronic, chemical and structural properties of ultrathin Ta_2NiSe_5 flakes — •Kathrin Küster[1], Yuanshan Zhang[1], Dennis Huang[1], Ulrich Starke[1], and Hidenori Takagi[1,2,3] — [1]Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany — [2]Institute for Functional Matter and Quantum Technologies, University of Stuttgart, 70569 Stuttgart, Germany — [3]Department of Physics, University of Tokyo, 113-0033 Tokyo, Japan

The excitonic insulator is a theoretically proposed state of matter wherein a macroscopic condensate of electron-hole pairs, i.e., excitons, spontaneously forms below a transition temperature. The 2D-layered chalcogenide Ta_2NiSe_5 has arisen as a leading candidate of an excitonic insulator in a bulk crystal. Here we prepared ultrathin films (down to 2 nm) of Ta_2NiSe_5 and analyzed their structural, electronic and chemical properties with a NanoESCA (Scienta Omicron) on a local scale. Angle-resolved photoelectron spectroscopy (ARPES), X-ray photoelectron spectroscopy (XPS), together with photoelectron emission microscopy (PEEM) and imaging XPS give detailed insight into the thickness dependent properties of the flakes. By exposure to UV-light we observe a contrast change in the PEEM images which is caused by a strong modification of the work function of the flakes, which we tentatively relate to a phase transition of the Ta_2NiSe_5 flakes.

Transition from fractal-dendritic to compact islands for the 2D-ferroelectric SnSe on graphene/Ir(111) — Paulus Aleksa, Sammer Iqbal, Muhammad Ali Martuza, Jiaqi Cai, Thais Chagas, Robin Ohmann, and •Carsten Busse — Universität Siegen, Germany

Monolayer islands of the 2D-ferroelectric SnSe have been grown by MBE under UHV conditions using inert and weakly interacting graphene on Ir(111) as the substrate. After deposition at room temperature, fractal-dendritic islands are observed in STM. The preferential growth directions are aligned with high-symmetry directions of the substrate. Upon annealing the islands become more compact. At 560 K they exhbit their equilibrium shape, higher temperatures lead to desoprtion. The equilibrium shape cannot be simply explained by minimization of the number of unsaturated bonds around the perimeter of an island with given area. The model has to be extended to incorporate the polar character of SnSe, leading to island edges that are charged in dependence of their orientation.

Reaction of submonolayer amounts of Ti and Te on Au(111) — •Andreas Raabgrund, Tilman Kisslinger, Lutz Hammer, and M. Alexander Schneider — Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

Titanium ditelluride ($TiTe_2$) belongs to the family of layered 2D transition metal dichalcogenides. It achieved a lot of attention due to the emergence of a charge density wave in the single layer limit. Thicker films, however, do not show this transition [1]. Aiming the MBE growth of $TiTe_2$ we investigated the initial growth of titanium telluride structures on Au(111) both structurally and electronically by STM, STS, LEED-IV structural analysis, and DFT. For a Te coverage of 0.4 ML and a Ti coverage of 0.2 ML on Au(111) a chain-like $(5 \times \sqrt{3})_{rect}$ superstructure is formed. Our LEED-IV best-fit structure with a Pendry R factor of 0.11 (redundancy $\rho = 9.6$) reveals incorporated Ti atoms each of which forms bonds to two Te atoms residing in approximately hollow positions. Our findings regarding the $(5 \times \sqrt{3})_{rect}$ superstructure disprove the proposed $TiTe_2$ monolayer on Au(111) [2]. STS shows an approximately 0.5 eV (FWHM) wide peak at +1 V

which we can correlate to the density of Ti d-states as obtained from DFT.

Monolayers of $CoCl_2$ and $CoBr_2$ on Au(111) - Chemical, magnetic and structural investigation — •Samuel Kerschbaumer[1], Sebastien Hadjadj[2], Andrea Aguirre Baños[3], Danilo Longo[3], Wolfgang Kuch[2], José Ignacio Pascual[3], Celia Rogero[1], and Maxim Ilyn[1] — [1]Centro de Fisica de Materiales (CSIC/UPV-EHU), 20018 Donostia-San Sebastian, Spain — [2]Institut für Experimentalphysik, Freie Universität Berlin, 14195 Berlin, Germany — [3]CIC nanoGUNE-BRTA, 20018 Donostia-San Sebastian, Spain

Magnetic 2D materials have gained increasing interest, due to their potential applications. But while many theoretical calculations predict magnetic order in various 2D materials [1], only few have been experimentally measured [2]. A very promising classes of materials are transition metal halides (TMHs), as many of them crystallise in Van der Waals layered structures, making them easily cleavable, while their partially filled d orbitals generate the perfect foundation for magnetic order, further increasing their attractiveness for future nanotechnologies. In this talk chemical, magnetic and structural properties of single-layer $CoCl_2$ and $CoBr_2$ on Au(111) by scanning tunelling microscopy (STM), X-ray photoelectron spectroscopy (XPS), low energy electron diffraction (LEED) and X-ray absorption spectroscopy (XAS/XMCD) will be presented.

O 56.6   Wed 16:15   GER 37

Structure determination of mono- and few-layers of the 2D-ferroelectric SnSe on graphene on Ir(111) — •Dina Wilks[1], Paulus Aleksa[1], Simon Chung[2], Peter Modregger[1], Dmitri V. Novikov[3], Vedran Vonk[2], Andreas Stierle[2,4], and Carsten Busse[1] — [1]Physics Department, University of Siegen, Germany — [2]Nanolabor Centre for X-ray and Nano Science CXNS, Germany — [3]Deutsches Elektronen-Synchrotron DESY, Germany — [4]Physics Department, University of Hamburg, Germany

For conventional ferroelectrics the critical temperature T_c quickly falls below technically feasible values for very thin films. This is not the case for two-dimensional materials. Theory predicts strong ferroelectricity for group-IV monochalcogenides, where individual layers are puckered sheets with a phosphorene-like structure. For SnSe, stable ferroelectricity of monolayers at room temperature has been shown by controlled microscopic manipulation. Here, we provide the missing structure determination of these monolayers.
We use surface X-ray diffraction to determine the structure of SnSe mono- and few-layers, the influence of the substrate, and the difference in stacking between a few-layered system and the bulk. SnSe films are prepared by MBE using graphene on Ir(111) as an inert and weakly interacting substrate. We observe one phase with three different orientations of monolayer SnSe islands with respect to graphene, while for the few-layered system two phases are found, each with three different orientations. A change in structure with rising temperature for both systems is seen, which hints towards T_c.

O 56.7   Wed 16:30   GER 37

Electronic properties of epitaxially grown monolayer and bilayer VS_2 on Au(111) — •Mikhail Fonin[1], Sabina Simon[1], Felix Förschner[1], Jannik Dornseiff[1], Julia Tesch[1], Elena Voloshina[2], and Yuriy S. Dedkov[2] — [1]Department of Physics, University of Konstanz, 78457 Konstanz, Germany — [2]Department of Physics, Shanghai University, 99 Shangda Road, 200444 Shanghai, China

Electronic properties of metallic two-dimensional materials can be strongly influenced by the supporting substrates, upon charge transfer or hybridization effects. In this context, suppression of many-body states in metallic transition metal dichalcogenides epitaxially grown on metallic substrates was recently reported [1]. By combination of scanning tunneling microscopy and first principle calculations we study monolayers and bilayers of VS_2 epitaxially grown on Au(111). We investigate the electronic properties of the monolayer and observe a metallic state with the presence of the incommensurate charge density wave state. Going form monolayer to bilayer VS_2, we observe an evolution from the metallic state to an insulating state.

O 56.8   Wed 16:45   GER 37

Vanadium sulphides on graphene on Ir(111): polymorphs, charge density waves, layer dependency — •Camiel van Efferen[1], Joshua Hall[1], Virgínia Boix[2], Tobias Wekking[1], Nikolay Vinogradov[3], Alexei Preobrajenski[3], Jan Knudsen[2], Jeison Fischer[1], Wouter Jolie[1], and Thomas Michely[1] — [1]Universität zu Köln — [2]Lund University — [3]MAX IV Laboratory

Among 2D materials, vanadium based compounds like VS_2 have attracted substantial research interest due to their predicted electronically correlated and magnetic ground states. However, the charge density wave (CDW) in monolayer (ML) VS_2 and VSe_2 competes with predicted magnetic ground states. This has led to new research directions attempting to unlock the magnetic moment of the V atoms, e.g. via defect creation, alloying or the intercalation of atoms between VS_2 layers.

Here, we present a comprehensive X-ray photoemission spectroscopy and scanning tunneling microscopy study of few-layer, quasi-freestanding V_4S_7 and V_5S_8 on Gr/Ir(111), which are created via annealing of stoichiometric VS_2. Annealing ML VS_2 without background S pressure removes S atoms from the top layer of VS_2, creating the striped compound V_4S_7. In contrast, annealing ML VS_2 in a S atmosphere forms V_5S_8, where V atoms have self-intercalated between the VS_2 layers in a 2×2 pattern. Surprisingly, we find that V_5S_8 has a layer-dependent CDW at low temperature, with bilayer V_5S_8 exhibiting a $\sqrt{3} \times \sqrt{3}$ CDW, while the trilayer hosts a striped CDW phase akin to that of ML VS_2.

Nucleation stage for the oriented growth of tantalum sulfide monolayers on Au(111) — •THAIS CHAGAS[1], KAI MEHLICH[1], ABDUS SAMAD[2], CATHERINE GROVER[1], DANIELA DOMBROWSKI[1,3], JIAQI CAI[1], UDO SCHWINGENSCHLÖGL[2], and CARSTEN BUSSE[1] — [1]Department Physik, Universität Siegen, Siegen, Germany — [2]Physical Science and Engineering Division, King Abdullah University of Science and Technology, Thuwal, Saudi Arabia — [3]Institut für Materialphysik, Westfälische Wilhelms-Universität Münster, Münster, Germany

We study the nucleation stage in the epitaxial growth of monolayer TaS_2 as a model system for monolayer transition metal sulfides. The growth was done under ultra-high vacuum conditions with Au(111) as a substrate on which the metal atoms are evaporated, and the sulfur is provided from a background of H_2S. Using scanning tunneling microscopy (STM), we find small trimers with a well-defined triangular shape that act as nuclei for the further growth of extended tantalum sulfide monolayers. We identify these trimers as TaS_3 using density functional theory (DFT). We propose that the unique orientation of the trimers is the cause of the well-defined orientation of a complete TaS_2 layer found under favorable growth conditions.

Growth and structure of two-dimensional single-layer HfS_2 on Au(111) — •MONIKA SCHIED, PAOLO LACOVIG, and SILVANO LIZZIT — Elettra-Sincrotrone Trieste

HfS_2 is a promising 2D material for low-power semiconductor devices due to its predicted high electron mobility and low contact resistance for n-type carrier transport. For actual applications, layers with excellent structural and electronic properties are needed. However, films with the necessary quality are only available from exfoliation, which is neither scalable nor very reproducible and only few experimental studies on a single-layer (SL) of HfS_2 have been performed so far. In analogy to the growth of high-quality SL transition metal dichalcogenides (TMDCs) such as MoS_2 and WS_2 [1,2] we have epitaxially grown an ordered layer of HfS_2 on Au(111) by chemical vapour deposition (CVD). Monitoring the S 2p and Hf 4f core levels in real time by fast X-ray photoelectron spectroscopy (XPS) allows the fine-tuning of the relevant parameters – such as the dosing rate and temperature – during the growth. The characterization by X-ray photoelectron diffraction (XPD) and low-energy electron diffraction (LEED) gives insight into the crystal structure of the film grown in this way.

Incorporation of arsenic into silicon (001) and germanium (001) for atomic-scale device fabrication. — •STEVEN R. SCHOFIELD — London Centre for Nanotechnology, University College London, 17-19 Gordon St, WC1H 0AH, United Kingdom

Atomic-scale electronic devices can be fabricated via the deterministic placement of individual donor atoms in semiconductors. The commonly-used technique involves the thermal decomposition of phosphine on the Si(001) surface and the patterning of a hydrogen resist layer for spatial control. However, it is now established that the desorption of phosphorus from the surface during the thermal incorporation anneal limits the scale-up of this method, e.g., for the fabrication of large numbers of qubits. In this talk, I will present exciting new work in our group demonstrating the excellent characteristics of arsine adsorption to both Si(001) and Ge(001) for the creation of atomic-scale devices. I will present combined scanning tunnelling microscopy and density functional theory work demonstrating that arsenic incorporates into the Ge(001) surface at room temperature when exposed to arsine, thus eliminating the need for the thermal anneal that is so problematic for phosphine on Si(001). Furthermore, I will present soft x-ray angle-resolved photoelectron spectroscopy (SX-ARPES) measurements of delta-doped layers in silicon that demonstrate higher confinement for arsenic layers compared to phosphorus layers. Our new results offer exciting opportunities for the fabrication of donor-based devices and their scale-up to the large numbers of qubits required for the fabrication of technological quantum devices.

Controlling tip-induced reaction products of surface-adsorbed organic species on Si(001) — •ALEXA ADAMKIEWICZ[1], TAMAM BOHAMUD[1,2], MARCEL REUTZEL[1], GERSON METTE[1], ULRICH HÖFER[1], and MICHAEL DÜRR[1,2] — [1]Department of Physics, Philipps University Marburg, Germany — [2]Institute of Applied Physics, Justus Liebig University Giessen, Germany

Tip-induced electronic excitation via STM can give access to alternative reaction channels beyond thermal activation. We showed for the cleavage of tetrahydrofuran (THF) on Si(001) that excitation by the tunneling electrons leads to new final products, which can be selectively addressed by the type of excitation [1]. Here, we present the influence of the detailed configuration of the organic adsorbates on tip-induced ether cleavage. Due to the linear molecular structure of diethyl ether (Et_2O), the adsorbates undergo fragmentation when cleaved, thus leading to a higher degree of freedom compared to the ring-shaped THF. The final products differ significantly for both species. Furthermore, we show that upon high voltage scans, covalently bound Et_2O fragments can be further reacted into more complex configurations which are thermally not accessible [2].

Semiconductor surface chemistry towards hybrid interfaces with ab initio approaches — •RALF TONNER-ZECH — Universität Leipzig, Leipzig, Germany

Exploiting concepts from molecular chemistry helps to improve our understanding of organic molecules reacting with semiconductor surfaces like silicon or germanium. Electronic structure analysis reveals concepts like Pauli repulsion or nucleophilic substitution reactions. Starting from this, hybrid interfaces can step by step be designed and analysed. The talk will focus on the associated challenges for theory encompassing model building, accuracy, adsorption kinetics and conceptual understanding. Finally, interface design from theory will be outlined.

Oxygen vacancy occupancy influences oxygen evolution on $BiVO_4$ — •NICKLAS ÖSTERBACKA, HASSAN OUHBI, and JULIA WIKTOR — Chalmers University of Technology, Gothenburg, Sweden

Bismuth vanadate, $BiVO_4$, is one of the best semiconductor photoanode materials for photoelectrochemical water splitting. Oxygen vacancies are abundant in the material and greatly affect its photoelectrochemical properties. If present at the surface, these defects could additionally directly influence the oxygen evolution reaction. The electronic occupancy of the defect states may also play a role, but are seldom considered in mechanistic studies.

In this work, we use hybrid density functional theory to show that the surface oxygen vacancy in bismuth vanadate is most stable in its fully ionized state. We investigate how this affects the mechanics of the oxygen evolution reaction and compare the pathway with those involving the unionized surface vacancy and the defect-free surface. To quantify whether or not vacancy ionization is beneficial, the thermodynamic overpotentials required to drive the reaction are also computed and compared.

Adsorption and photocatalytic inactivation of SARS-CoV-2 and virus like particles on the surface of anatase TiO2(101) — •MONA KOHANTORABI[1], MICHAEL WAGSTAFFE[1], MARCUS CREUTZBURG[1], ESKO ERICK BECK[1], JOHANNES ROESSLER[2], REINHARD ZEIDLER[2], ALEXANDER HERRMANN[3], MARTIN FEUERHERD[3], GREGOR EBERT[3], GABRIELA GUÉDEZ[4], CHRISTIAN LÖW[4], ROLAND THUENAUER[4], THOMAS F. KELLER[1,5], BENEDIKT SOCHOR[6], MATTHIAS

Schwartzkopf[6], Andrei Chumakov[6], Stephan V. Roth[6], Ulrike Protzer[3], Wolfgang Hammerschmidt[2], Andreas Stierle[1,5], and Heshmat Noei[1] — [1]Centre for X-ray and Nano Science, DESY — [2]Helmholtz Zentrum München — [3]Technical University of Munich — [4]Centre for Structural Systems Biology, DESY — [5]Department of Physics, University of Hamburg — [6]Deutsches Elektronen-Synchrotron

In this contribution, adsorption of SARS-CoV-2 and SARS-CoV-2 like particles (VLPs) were investigated on the surface of the model photocatalyst $TiO2(101)$. The samples were analyzed by grazing-incidence small-angle X-ray scattering (GISAXS), atomic force microscopy (AFM), transmission electron microscopy and X-ray photoelectron spectroscopy to obtain insight into the interaction of the SARS-CoV-2 and VLPs with the surface of $TiO2(101)$. Furthermore, the UV induced photo inactivation of adsorbed species was investigated. AFM and GISAXS results on the UV-treated sample suggested that adsorbed viral particles undergo damage and photocatalytic oxidation on the surface of $TiO2$ which can affect the structural proteins.

O 57.6   Wed 16:45   GER 38

Ab initio description of surface restructuring and phase boundaries under realistic conditions — •Yuanyuan Zhou[1,3], Chunye Zhu[1,2], Matthias Scheffler[1], and Luca M Ghiringhelli[1] — [1]The NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft and IRIS-Adlershof of the Humboldt-Universität zu Berlin — [2]School of Advanced Manufacturing, Guangdong University of Technology, Jieyang 515200, China — [3]Department of Physics, Technical University of Denmark, Kongens Lyngby, 2800, Denmark

A reliable description of surfaces equilibria in a reactive gas is a prerequisite for understanding mechanism of heterogeneous catalysis. However, studying phase equilibria at *ab initio* level, is a formidable challenge, especially for systems with sluggish barriers. In this work [Zhou *et al.* Phys. Rev. Lett. 128, 246101(2022)], we introduce a fully *ab initio* approach to determine temperature-pressure ($T-p$) surface phase diagram and to evaluate phase equilibria of surfaces in a gas phase. For this purpose, our replica-exchange grand-canonical (REGC) method [Zhou *et al.* Phys. Rev. B. 100, 174106(2019)], is extended by evaluating the heat capacity, $C_v(T, p)$, as function of T and p, thus locating phase boundaries where $C_v(T, p)$ shows ridges. The approach is demonstrated by addressing open questions for the Si(100) surface in a H_2 gas phase. 25 distinct stable surface phases are identified, most of which have not been observed experimentally, so far. The results also show that Si-Si-bonds forming/breaking is the driving force behind the experimentally 3×1 and 2×1 phase transition.

Simultaneous Strong Coupling of the H- and J-Bands of Molecular Aggregates in Microcavities — •Roland Schäfer[1], Lukas Böhner[1], Manuela Schiek[2,3], Klaus Meerholz[1], and Klas Lindfors[1] — [1]Department für Chemie, Universität zu Köln, 50939 Köln, Germany — [2]LIOS & ZONA, Johannes Kepler Universität, 4040 Linz, Austria — [3]Institut für Physik, Carl von Ossietzky Universität Oldenburg, 26129 Oldenburg, Germany

We simultaneously strongly couple the H- and J-bands of aggregates of a merocyanine dye (HB238 [1]) to cavity photons. This is achieved by tuning the $3\lambda/2$- and 1λ mode of a planar microcavity to the spectral positions of the H- and J-bands, respectively. Strong coupling behavior is confirmed via the observation of Rabi-splitting of both bands in angle-resolved reflectivity spectra.

Due to the orientation of the aggregates J-polaritons can be observed with s- and p-polarized light, while the H-polaritons can only be accessed with p-polarized light and a non-normal angle of incidence. Therefore, our system supports two or four polaritons, depending on the polarization, making it an interesting platform to study strong light-matter coupling.

Two-Dimensional Electronic Spectroscopy of Strong Exciton-Surface Plasmon Polariton Coupling — •Daniel Timmer[1], Moritz Gittinger[1], Thomas Quenzel[1], Sven Stephan[1], Jennifer Zablocki[2], Arne Lützen[2], Jin-Hui Zhong[1], Martin Silies[1], Antonietta De Sio[1], and Christoph Lienau[1] — [1]University of Oldenburg, Germany — [2]University of Bonn, Germany

The creation of hybrid light-matter systems due to strong coupling is of major current interest for material science. Of special interest are dipolar interactions between molecular excitons (X) and plasmonic resonators, such as surface plasmon polaritons (SPP). Sufficiently strong coupling to vacuum field fluctuations allows for the coherent flow of energy between X and SPP, i.e. Rabi oscillations, forming new hybridized upper (UP) and lower (LP) polariton states [1]. We explore these strong coupling phenomena and especially their dynamics using two-dimensional electronic spectroscopy (2DES). Here, strong coupling predicts notorious "oscillating cross-peaks" between diagonal UP and LP peaks in a 2DES map. We investigate the polariton dynamics of a prototypical system for X-SPP coupling, a J-aggregate coated periodic gold slit array. In our measurements, the strongly coupled system indeed shows these hallmarks: Rabi oscillations of 2DES cross-peaks. Surprisingly, however, spatial modulations of the plasmon field seem to result in both strongly and weakly coupled excitons, which can then undergo coherent population transfer via the SPP. This conclusion is further supported by FDTD and Frenkel exciton model simulations. [1]: Vasa, Parinda, et al., Nat. Photon 7.2, 128-132 (2013).

Phase-locked photon-electron interaction without a laser — •Nahid Talebi — Institute for Experimental and Applied Physics, Kiel University, 24107 Kiel, Germany

Ultrafast electron-photon spectroscopy in electron microscopes commonly requires ultrafast laser setups. Photoemission from an engineered electron source is used to generate pulsed electrons, interacting with a sample that is excited by the ultrafast laser pulse at a specified time delay. Thus, developing an ultrafast electron microscope demands the exploitation of extrinsic laser excitations and complex synchronization schemes. Here, we present an inverse approach based on cathodoluminescence spectroscopy to introduce internal radiation sources in an electron microscope. Our method is based on a sequential interaction of the electron beam with an electron-driven photon source (EDPHS) and the investigated sample. An electron-driven photon source in an electron microscope generates phase-locked photons that are mutually coherent with the near-field distribution of the swift electron. Due to their different velocities, one can readily change the delay between the photons and electrons arriving at the sample by changing the distance between the EDPHS and the sample. We demonstrate the mutual coherence between the radiations from the EDPHS and the sample by performing interferometry with a combined system of an EDPHS and a WSe_2 flake. We assert the mutual frequency and momentum-dependent correlation of the EDPHS and sample radiation, and determine experimentally the degree of mutual coherence of up to 27%.

Layer-resolved resonance intensity of evanescent polariton modes — Nikolai C. Passler[1], Giulia Carini[1], Dmitry N. Chigrin[2,3], and •Alexander Paarmann[1] — [1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin — [2]DWI - Leibniz-Institut für Interaktive Materialien, Aachen — [3]Institute of Physics (1A), RWTH Aachen University, Aachen

Most nanophotonic approaches rely on polaritons to confine light to the nanoscale. In particular heterostructures of strongly anisotropic polar crystals have been of key interest recently, where the twist angles between different anisotropic layers key be leveraged to create and control exotic polaritonic states [1]. To guide the designs of such multi-parameter systems, low-cost simulation tools are invaluable. Common approaches like employing the reflection coefficient under evanescent excitation enable analysis of the polariton resonances without the need to specify the exact experimental arrangement, but lack layer-specific information. Here [2], we introduce a formalism based on a 4x4 transfer matrix algorithm [3] and energy flow analysis using the Poynting vector [4], that provides full depth-resolved information even for evanescent wave excitation. We illustrate the power of the approach by analysing a state-of-the-art example of twisted bilayer molybdenum trioxide [1].

Observation of multi-quantum phenomena in molecular films strongly coupled to surface plasmons using ultrafast laser spectroscopy — •Simon Büttner[1], Matthias Hensen[1], Katja Mayershofer[1], Maximilian Rödel[2], Jens Pflaum[2], and Tobias Brixner[1] — [1]Institut für Physikalische und Theoretische Chemie, Universität Würzburg, Am Hubland, 97074 Würzburg, Ger-

many — [2]Experimental Physics VI, University of Würzburg, Am Hubland, 97074 Würzburg, Germany

Multi-quantum phenomena such as exciton–exciton annihilation can be used to study exciton diffusion [1], which is a key process in optoelectronic devices like solar cells. Recently, our group has developed a method to isolate different multi-quantum signals using transient absorption (TA) spectroscopy. This novel method makes it possible to filter out the interaction of a distinct number of quasiparticles and their time evolution. Here, we use this method together with a new ultrafast laser setup that allows us to shape and detect femtosecond laser pulses at a repetition rate of 100 kHz. As a model system we investigate a thin Zinc phthalocyanine (ZnPc) film on a surface-plasmon-supporting gold substrate. Strong coupling between ZnPc excitons and surface plasmons leads to the formation of plexcitons [2], and thus to a delocalization of charge carriers, which is of particular interest for increasing charge carrier mobilities. In this work we focus on the influence of the strong coupling on the quasiparticle diffusion.

Resonant imaging of infrared light confinement using phonon polaritons in sub-diffractional 4H-SiC nanostructures — •RICHARDA NIEMANN[1], SÖREN WASSERROTH[1], GUANYU LU[2], CHRISTOPHER R. GUBBIN[3], MARTIN WOLF[1], SIMONE DE LIBERATO[3], JOSHUA D. CALDWELL[2], and ALEXANDER PAARMANN[1] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Vanderbilt University, Nashville, USA — [3]University of Southampton, UK

Confinement of light to deeply sub-wavelength scales can be achieved using polaritons spatially confined to sub-diffractional nanostructures. Next to well-established plasmon polariton approaches, phonon polaritons supported in nanostructures made from polar dielectric crystals are a promising tool for the infrared spectral range [1].

Here, we study localized phonon polariton resonances in sub-diffractional 4H-SiC nanostructures using infrared super-resolution sum-frequency generation (SFG) microscopy [2], employing our institute's infrared free-electron laser [3]. With this technique we achieve high sensitivity to optical field enhancement associated with the spatial confinement of light. Simultaneously it is providing sub-diffractional imaging resolution, naturally enabling to study polaritons on their intrinsic length scales.

Nano-scale Plasmonic Su-Schrieffer-Heeger Chains — •BENEDIKT SCHURR[1,4], PHILIPP GRIMM[1], TOBIAS HELBIG[2], TOBIAS HOFMANN[2], LUKAS WEHMEIER[3], FELIX G. KAPS[3], THORSTEN FEICHTNER[1,4], MONIKA EMMERLING[1], SUSANNE C. KEHR[3], LUKAS ENG[3,4], RONNY THOMALE[2,4], and BERT HECHT[1,4] — [1]NanoOptics & Biophotonics Group, Experimental Physics 5, University of Würzburg, Am Hubland, 97074 Würzburg, Germany — [2]Institute for Theoretical Physics and Astrophysics, University of Würzburg, Am Hubland, 97074 Würzburg, Germany — [3]Institut für Angewandte Physik, Technische Universität Dresden, 01062 Dresden, Germany — [4]Würzburg-Dresden Cluster of Excellence ct.qmat, University of Würzburg, Am Hubland, 97074 Würzburg, Germany

The tight-binding Su-Schrieffer-Heeger (SSH) model describes 1D periodic chains of resonators with alternating coupling strengths. For certain configu-

rations, topologically protected collective states occur at the edges. Here, we propose a plasmonic chain SSH-system with alternating few-nanometer gaps, fabricated from mono-crystalline Au-microplatelets by means of He-ion beam milling. Full FDTD simulations show the occurrence of edge modes for such geometries in real space. The frequency at which edge states occur can be fully controlled via particle size and the next-neighbour coupling via the gaps. Scattering scanning near-field optical microscopy (sSNOM) experiments provide first evidence for the presence of topologically protected edge states.

O 58.8　　Wed 17:00　　WIL A317
Directional leaky polaritons in anisotropic crystals — XIANG NI[1], •GIULIA CARINI[2], WEILIANG MA[3], ENRICO M. RENZI[1], EMANUELE GALIFFI[1], SÖREN T. WASSERROTH[2], MARTIN WOLF[2], PEINING LI[3], ALEXANDER PAARMANN[2], and ANDREA ALÙ[1] — [1]CUNY, New York, USA — [2]FHI, Berlin, Germany — [3]HUST, Wuhan, China

For quite a few years now, natural hyperbolic materials have been attracting significant attention due to their ability of engaging strong interactions between light and their IR active phonon resonances. The hybridized light-matter quasi-particles arising in their bulk, known as hyperbolic phonon polaritons, display large momenta and highly directional propagation stemming from their open topology.

In our contribution, we demonstrate a new class of directional polaritons supported in the lower reststrahlen band of calcite, that feature lenticular isofrequency contours. These novel polaritons, dubbed Leaky Polaritons (LPs), arise in the type-I in-plane hyperbolic region as hybridized states between extraordinary surface-bound and ordinary propagating bulk modes. Despite their closed topology, they support highly directional, long-range, sub-diffractive propagation at the interface. Their dispersion curve also crosses the free-space light cone, providing radiative far-field coupling to both sides of the interface.

To observe the features of LPs experimentally, we employed polariton spectroscopy, far-field probing and near-field imaging, revealing their lenticular dispersion curve, their high directionality, their long lifetime and real-space propagation.

O 58.9　　Wed 17:15　　WIL A317
Anticrossing of a plasmonic nanoresonator mode and a single quantum dot at room temperature — •DANIEL FRIEDRICH[1], JIN QIN[1], BENEDIKT SCHURR[1], TOMMASO TUFARELLI[2], HEIKO GROSS[1], and BERT HECHT[1] — [1]NanoOptics & Biophotonics Group, Experimental Physics 5, University of Würzburg, Germany — [2]School of Mathematical Sciences and Centre for the Mathematics and Theoretical Physics of Quantum Non-Equilibrium Systems, University of Nottingham, United Kingdom

At ambient conditions strong coupling (SC) is achieved due to the extremely small mode volume of plasmonic nanoresonators and the broadband spectral overlap between emitter and nanocavity. This results in ultrafast energy transfer which overcomes dephasing. Normal mode splittings in luminescence spectra of single quantum systems coupled to plasmonic nanoresonators have been reported and exploited to estimate the light-matter coupling strength *g*. However, there is only sketchy evidence for the hallmark of single-emitter strong coupling, the anticrossing of emitter and cavity resonances. Here, we exploit the light-induced oxygen-dependent blue-shift of individual CdSe/ZnS semiconductor quantum dots to tune their transition energy across the weakly radiative resonance of a scanning plasmonic slit resonator. The observed anticrossing in photoluminescence spectra recorded as a function of time provide clear proof of SC as well as a solid measure for the single-emitter coupling strength consistent with classical field simulations and a quantum model including dissipation.

Interplay of Inversion Symmetry Breaking and Spin-Orbit Coupling — •MAXIMILIAN ÜNZELMANN — Experimentelle Physik 7, Universität Würzburg and Würzburg-Dresden Cluster of Excellence ct.qmat

Inversion symmetry breaking (ISB) in crystalline solids provides an essential way of modifying electronic structures. For example, in combination with spin-orbit coupling (SOC), ISB allows for a lifting of spin degeneracy without the need for magnetism. Moreover, it is a source of Berry curvature, which is of fundamental importance in topological quantum matter. In this talk, two scenarios will be discussed, in which the interplay of ISB with SOC plays an important role: (i) At surfaces or interfaces, where inversion symmetry is inherently broken and the Rashba effect [1] enforces a locking of the electrons spin perpendicular to its momentum and (ii) in Weyl semimetals whose three-dimensional crystal structure has no inversion center, leading to the formation of Berry curvature monopoles, i.e., quantized topological charges [2].

As will be highlighted in this presentation, we find that ISB-induced unquenching of the so-called (atomic) orbital angular momentum (OAM) in the Bloch wave functions constitutes a key mechanism underlying the physics of both the Rashba effect and Weyl semimetals. Angle-resolved photoemission with variable light polarization provides detailed experimental access to the respective momentum-space orbital textures.

Establishing fundamentals of ARPES spin textures with the model material PtTe$_2$ — •Mohammed Qahosh[1,2], Gustav Bihlmayer[2], Jakub Schusser[3], Muthu Masilamani[3], Friedrich Reinert[3], Claus M. Schneider[1], and Lukasz Plucinski[1] — [1]PGI-6 Forschungszentrum-Jülich — [2]PGI-1/IAS-1 Forschungszentrum-Jülich — [3]Experimentelle Physik VII and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg

A novel quantum material PtTe$_2$ is used to establish the connection between spin textures of angle-resolved photoemission spectroscopy (ARPES) and initial state spin textures. The crystal structure of 1T-PtTe$_2$ is trigonal, belongs to the space group 164 (P$\bar{3}$m1), that contains mirror planes and inversion symmetry. Since bulk 1T-PtTe$_2$ is both inversion-symmetric and non-magnetic, no bulk spin-polarized bands are allowed due to the Kramers degeneracy. At the surface, a non-zero spin polarization is expected due to the broken inversion symmetry, however, it must obey the mirror and time-reversal symmetries. We measured the dependence of the spin-polarization on the symmetries of the ARPES setup. This is performed in two geometries, with the reaction plane parallel to $\bar{K}$-$\bar{\Gamma}$-$\bar{K}$ and $\bar{M}$-$\bar{\Gamma}$-$\bar{M}$ reciprocal directions, i.e. either along or orthogonal to the crystal mirror plane. The measured spin texture is symmetric when the reaction plane is parallel to $\bar{K}$-$\bar{\Gamma}$-$\bar{K}$. However, we see asymmetries in the spin texture when the reaction plane is parallel to $\bar{M}$-$\bar{\Gamma}$-$\bar{M}$. For surface states, the asymmetries are due to the geometry-induced spin filtering in ARPES [1]. For bulk states, the effect might be additionally related to the asymmetric initial state dispersions.

Surface electronic structure of Re(0001): A spin-resolved photoemission study — •Marcel Holtmann[1], Peter Krüger[2], Koji Miyamoto[3], Taichi Okuda[3], Shiv Kumar[3], Kenya Shimada[3], and Markus Donath[1] — [1]Physikalisches Institut, WWU Münster, Germany — [2]Institut für Festkörpertheorie, WWU Münster, Germany — [3]HiSOR, Hiroshima University, Japan

The surface electronic structure of Re(0001) has been investigated in a combined experimental and theoretical study. (Spin- and) angle-resolved photoemission was employed to unravel the spin-dependent $E(\mathbf{k}_\parallel)$ dispersion along the $\bar{\Gamma}\,\bar{M}$ and $\bar{\Gamma}\,\bar{K}$ directions. The results are compared with band structures from density-functional theory. Moreover, transitions into final states have been considered by inclusion of the corresponding matrix elements. A spin-orbit-induced mixing of Shockley- and Tamm-type surface states around $\bar{\Gamma}$ and close to E_F was reported recently [1]. Here, we extend the analysis to a wider $E(\mathbf{k}_\parallel)$ range showcasing a multitude of electronic states along the $\bar{\Gamma}\,\bar{M}$ and $\bar{\Gamma}\,\bar{K}$ directions. In particular, Rashba-type spin splittings are observed around the high-symmetry $\bar{\Gamma}$ and $\bar{M}$ points. At variance with theoretical predictions [2], which describe a perfect hcp(0001) surface, we do not find any out-of-plane spin polarization. This is caused by monoatomic steps of a real Re(0001) surface with alternating terminations, which lead on average to an effective sixfold surface symmetry and vanishing net out-of-plane spin polarization.

Spectroscopic evidence for a new type of surface resonance at noble-metal surfaces — •Tobias Eul[1], Jürgen Braun[2], Benjamin Stadtmüller[1,3], Hubert Ebert[2], and Martin Aeschlimann[1] — [1]Technische Universität Kaiserslautern and Research Center OPTIMAS, 67663 Kaiserslautern, Germany — [2]Department Chemie, Ludwig-Maximilians-Universität München, 81377 München, Germany — [3]Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany

We investigated the surface and bulk properties of the pristine (110) surface of silver using threshold photoemission by excitation with light of 5.9 eV. Using a momentum microscope, we identified two distinct transitions along the $\bar{\Gamma}\bar{Y}$-direction of the crystal. The first one is a so far unknown surface resonance on the (110) noble-metal surface, exhibiting an exceptionally large bulk character that has so far been elusive in surface sensitive experiments. The second one stems from the well-known bulklike Mahan cone oriented along the ΓL-direction inside the crystal but projected onto the (110)-surface cut. The existence of the new state is confirmed by photocurrent calculations, and its character is analyzed.

O 59.6   Wed 16:30   REC C 213

One monolayer of Tl on Ag(111): Hybridization of image-potential states with Tl states — •Sven Schemmelmann[1], Patrick Härtl[2], Peter Krüger[3], Matthias Bode[2], and Markus Donath[1] — [1]Physikalisches Institut, Westfälische Wilhelms-Universität, Münster — [2]Physikalisches Institut, Experimentelle Physik II, Universität Würzburg — [3]Institut für Festkörpertheorie, Westfälische Wilhelms-Universität, Münster

For one atomic layer of Tl on Ag(111) a moiré superstructure is observed. The unoccupied electronic structure of this superstructure is investigated by spin- and angle-resolved inverse photoemission. The experimental results are interpreted on the basis of DFT calculations. We observe several Tl-induced surface states and an image-potential state mainly located several Å in front of the surface. Surprisingly, we find a hybridization of this image state with a downward dispersing Tl band. This leads to spin-dependent spectral intensities that vary rapidly close to the hybridization point. The calculations show an expeditious change of the charge density from a resonant image-potential state towards a Tl-induced surface state in dependence of $\mathbf{k}_\parallel$.

Bulk and surface electronic structure of tunnel barrier Nb$_3$Br$_8$ in the field-free Josephson diode — •Mihir Date[1,2], Jonas.A. Krieger[1], Emily.C. McFarlane[1], Vicky Hasse[3], Claudia Felser[3], Stuart.S.P Parkin[1], Matthew Watson[2], and Niels.B.M Schröter[1] — [1]MPI-Halle, Weinberg 2, 06120 Halle (Saale), Germany — [2]Diamond Light Source Ltd. Didcot, OX11 0DE, United Kingdom — [3]MPI-CPfS, Nöthnitzer Straße 40, 01187 Dresden, Germany

In this work, we report the bulk and surface electronic structure of Nb$_3$Br$_8$ probed using angle resolved photoemission spectroscopy (ARPES). Nb$_3$Br$_8$ is predicted to host trivial metallic surface states (obstructed surface states (OSS)) when cleaved between specific layers [1]. Although our in-plane electronic structure is consistent with the calculated orbital resolved bandstructure, we do not observe any signatures of the OSS. Nevertheless, the doubling of periodicity of the ARPES signal along the out-of-plane momentum direction, as compared to the Brillouin zone dimension, hints towards dimerization between alternate layers through the OSS. We discuss our results in connection with the recent discovery of the field-free Josephson diode effect in the $NbSe_2/Nb_3Br_8/NbSe_2$ heterostructures [2].

Termination dependent many-body interactions of the surface states of PdCoO$_2$ revealed by ARPES-based microscopy — •Gesa-Roxanne Siemann[1], Edgar Abarca Morales[1,2], Philip A. E. Murgatroyd[1], Tommaso Antonelli[1], Seunghyun Khim[2], Matthew Watson[3], Cephise Cacho[3], Andrew P. Mackenzie[1,2], and Phil D. C. King[1] — [1]University of St Andrews, UK — [2]MPI for Chemical Physics of Solids, Dresden, Germany — [3]Diamond Light Source, UK

The layered ABO_2 structure of the delafossite oxides yields markedly different electronic structures at their A- and BO_2-terminated surfaces which are either electron- (A-termination) or hole-doped (BO_2-termination) with respect to the bulk[1]. A prominent example is PdCoO$_2$ where a giant Rashba effect can be observed on the CoO$_2$ terminated surface[2], while the Pd terminated surface hosts ferromagnetic states which are absent in the bulk[3,4]. However, the study of these states has often been hampered by the size of domains of each distinct surface termination. Here we show how these problems can be circumvented using micro-ARPES performed in a spatially-resolved mode. Our measurements further reveal strong signatures of self-energy modulations on both surfaces due to coupling to bosonic modes, making them the ideal playground to study varying coupling mechanisms and their tunability in the same sample. The Meservey-Tedrow-Fulde vortex in epitaxial aluminum near the monolayer limit — •Werner M.J. van Weerdenburg[1], Anand Kamlapure[1], Eirik Fyhn Holm[2], Niels P.E. van Mullekom[1], Xiaochun Huang[1], Manuel Steinbrecher[1], Peter Krogstrup[3], Jacob Linder[2], and Alexander A. Khajetoorians[1] — [1]Institute for Molecules and Materials, Radboud University Nijmegen, the Netherlands — [2]Center for Quantum Spintronics, Norwegian University of Science and Technology, NO-7491 Trondheim, Norway — [3]NNF Quantum Computing Programme, Niels Bohr Institute, University of Copenhagen, Denmark

The critical magnetic field of 2D superconductors is greatly enhanced for fields parallel to the 2D plane. In the case of aluminum, this gives rise to a spin-splitting of the coherence peaks, referred to as the Meservey-Tedrow-Fulde (MTF) effect. In the MTF regime, it has been proposed that unconventional odd-frequency (ω_o) spin-triplet pairing is promoted [1], but their presence is experimentally hard to detect.

Here, we study vortices in thin epitaxial Al films on Si(111) in the MTF regime by applying a vector magnetic field with a large in-plane component, and find experimental evidence of odd-frequency pairing [2]. Strikingly, we find that the shape of the vortex structure is strongly modified and exhibits a gapless region. Numerical simulations confirm a connection between this vortex shape and the presence of ω_o pairing, highlighted by a paramagnetic Meissner effect.

Exploring polaron stability and defect structures in $Li_4Ti_5O_{12}$ (LTO): A combined theoretical and experimental approach — •Yu-Te Chan[1], Matthias Kick[2], Cristina Grosu[2], Christoph Scheurer[1], and Harald Oberhofer[3] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]Massachusetts Institute of Technology, Cambridge, USA — [3]University of Bayreuth, Bayreuth, Germany
Spinel $Li_4Ti_5O_{12}$ (LTO) is a promising anode material for next-generation all-solid-state Li-ion batteries (ASSB) due to its "zero strain" charge/discharge behavior. Pristine LTO suffers from poor ionic and electronic conductivity. Oxygen vacancies, produced by tailored sintering protocols, yield a performant, blue LTO material. Vacancy induced polarons have been proposed as one of the origins of increased electronic conductivity. However, detailed knowledge about polaron stability, distribution, and dynamics in LTO bulk and surface have been lacking. By performing *Hubbard corrected density functional theory* (DFT+U) calculations we are able to show that in fact polaron formation and a possible polaron hopping mechanism can not only play a significant role in enhancing electronic conductivity but boost Li^+ diffusion nearby, in line with the experimentally observed improved conductivities.[1,2] In combination with positron lifetime spectroscopy data and machine learning models, we arrive at a rather complete picture of the bulk vs. surface defect chemistry in LTO particles and the resulting mixed ionic electronic conductivity. Investigation of the water structure at the (001) and (010) orthoclase surfaces with three-dimensional atomic force microscopy — •Franziska Sabath, Ralf Bechstein, and Angelika Kühnle — Physical Chemistry I, Bielefeld University, Universitätsstraße 25, 33615 Bielefeld
Feldspars are the most abundant minerals in the Earth's crust and belong to the most effective group of mineral ice nucleating particles (INP) in the atmosphere. In the crystal structure, potassium, sodium or calcium, among others, are incorporated as counterions in varying ratios. Potassium-rich feldspars are more effective INPs than the other feldspars. A representative of a potassium-rich feldspar is orthoclase. Unlike other INPs, such as silver iodide, the surfaces of feldspar do not have an ice-like structure. Therefore, it is interesting to know what other factors, such as hydroxyl groups on the surfaces or defect sites, are responsible for the high ice nucleating efficiency of K-feldspars. In particular, the water structure at the interface of K-feldspars is of interest. Here, we show the three-dimensional water structure at the two natural cleavage planes of orthoclase, the (001) and the (010) surfaces, using tree-dimensional atomic force microscopy (AFM).

Influence of substrate on supramolecular nanostructures at the solid-liquid interface — •Baoxin Jia[1], Mihaela Enache[1], Sandra Miguez-Lago[2], Milan Kivala[2], and Meike Stöhr[1] — [1]Zernike Institute for Advanced Materials, University of Groningen, Netherlands — [2]Institute of Organic Chemistry, University of Heidelberg, Germany
Self-assembly of supramolecular nanostructures at the solid-liquid interface has gained increasing academic interest in past recent years. Substrates can influence molecule-substrate interactions, which plays an important role in determining supramolecular nanostructures. In this study, we used scanning tunneling microscopy (STM) to investigate the self-assembly of two carboxylic acids at the nonanoic acid-solid interface. We performed the experiments on four substrates: HOPG, MoS2, Au(111), and graphene/Cu foil. We also measured the water contact angle of these four substrates to obtain some information on the molecule-substrate interaction. The STM measurements showed that, on HOPG and graphene/Cu foil, both carboxylic acids can form porous and close-packed structures, which depends on the bias voltage polarity during STM measurements. On MoS2, both carboxylic acids did not form stable self-assembled structures. On Au(111), both carboxylic acids only formed short range-ordered structures in very diluted solutions. The results reveal that the interplay between molecule-substrate, solvent-substrate and molecule-molecule interactions is important to the formation of supramolecular nanostructures at the solid-liquid interface.

Hydrophobic pockets on the hydrophilic In_2O_3(111) surface — Christian Ritterhoff[1], •Bernd Meyer[1], Ulrike Diebold[2], and Margareta Wagner[2] — [1]Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg, Germany — [2]Institute of Applied Physics, TU Wien, Austria
Clean oxide surfaces are generally hydrophilic. Water molecules anchor at undercoordinated surface cations that act as Lewis acid sites, and they are stabilized by H bonds to surface oxygens. However, for In_2O_3(111), DFT calculations predict a deviation from this general rule, which has been confirmed by TPD, XPS, STM and AFM experiments. In UHV, the first nine water molecules cover only a part of the unit cell. Within the H-bonded network three out of the nine water dissociate. Additional molecules pile up above the OH groups. The rest of the unit cell is unfavorable for adsorption and remains water-free, despite offering undercoordinated In and O sites. The first water layer thus shows ordering into nanoscopic 3D water clusters separated by hydrophobic pockets. Beyond UHV, our *ab initio* MD simulations of a liquid water layer demonstrate the robustness of the strongly hydrophobic behavior of this region in the unit cell.

Facet-dependent surface charge and hydration of SrTiO3 nanoparticles at variable pH — •Igor Siretanu, Su Shaoqiang, Bastian Mei, Dirk van den Ende, Guido Mul, and Frieder Mugele — Physics of Complex Fluids and Photocatalytic Synthesis Groups, MESA+ Institute, Faculty of Science and Technology, University of Twente, PO Box 217, 7500 AE Enschede, The Netherlands
Anisotropy of shape and surface properties determine the functionality of faceted nanoparticles in various contexts including facet selective colloidal self-assembly, biosensing, improved photo/electrocatalytic activity and ions uptake. The characteristic surface proprieties and function of solid-liquid interfaces of crystalline faceted nanoparticles are believed to be essential for their performance but remains poorly understood and difficult to characterize and quantify. We use dual scale Atomic Force Microscopy to measure electrostatic and hydration forces of faceted SrTiO3 nanoparticles in aqueous electrolyte at variable pH. We demonstrate (i) the ability to quantify strongly facet-dependent surface charges yielding isoelectric points of the dominant {100} and {110} facets that differ by as much as 2 pH units, ii) fluids composition controlled facet-dependent accumulation of oppositely charged (SiO2) particles, and iii) that atomic scale defects can be resolved but are in fact rare for the samples investigated. Atomically resolved images and facet-dependent hydration structure suggest a microscopic hydration and charge generation mechanism.

Watching Redox Activation of Gold for Water Electrolysis live: An in-situ Experiment at Home — Christoph Griesser, Daniel Winkler, Toni Moser, Engelbert Portenkirchner, and •Julia Kunze-Liebhäuser — Institute of Physical Chemistry, University of Innsbruck, Innrain 52c, Innsbruck, 6020 Austria
A fundamental understanding of processes that take place at the solid/liquid interface is of utmost importance for a rational design of (electro-)catalysts, and key for advancing energy conversion and storage technologies. We could show with in-situ electrochemical near ambient pressure X-ray photoelectron spectroscopy (NAP-XPS) that metallic Au, in alkaline media, reversibly oxidizes to Au^+ at potentials prior to and during the early oxygen evolution reaction (OER), while it reversibly oxidizes to Au^{3+} at potentials where the OER takes place at high rates. This has previously not been clearly demonstrated in-situ, so that the redox chemistry of Au in alkaline media remains a highly debated topic in the electrochemical community to date. We demonstrate the implementation of a simple, affordable and in-situ/operando- method to track dynamic processes taking place at the electrified solid/liquid interface, utilizing a lab-based NAP-XPS system with a conventional Al Kα X-ray source. The method has the potential to become a gamechanger in applied (electro-)catalysis research, which makes our contribution appealing for scientists following either fundamental or applied research interests.

Structure and Reactivity of an Ionic Liquid on Cu(111) investigated by Scanning Probe Microscopy, Photoelectron Spectroscopy and Simulations — Rajan Adhikari[1], Stephen Massicot[1], Lukas Fromm[2], •Simon Jaekel[1], Timo Talwar[1], Afra Gezmis[1], Manuel Meusel[1], Andreas Bayer[1], Florian Maier[1], Andreas Görling[2], and Hans-Peter Steinrück[1] — [1]Chair of Physical Chemistry II, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstraße 3, 91058 Erlangen, Germany — [2]Chair of Theoretical Chemistry,

Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstraße 3, 91058 Erlangen, Germany

We studied the adsorption and reaction behaviour of the ionic liquid (IL) 1,3-dimethylimidazolium bis[(trifluoromethyl)sulfonyl]imide ($[C_1C_1Im][Tf_2N]$) on Cu(111) in UHV. Our nc-AFM and STM results show that the IL transitions from an ordered structure observed after annealing at 200 K into a different ordered structure and disordered islands after extended annealing at 300 K. Complementary, ARXPS reveals that the IL initially adsorbs intact and that no IL desorption occurs until 300 K but that a significant fraction of the IL is converted to a new species. We correlate the remaining unshifted peaks to the ordered phases observed in AFM and the shifted peaks to decomposition products, which appear as disordered islands. From DFT, we obtain additional information on the structure of the ordered phases and the interaction of the IL with the substrate.

O 60.7   Wed 16:30   TRE Phy

Influence of Interfacial Water and Cations on the Oxidation of CO at the Platinum/Ionic Liquid Interface — •Björn Ratschmeier, Gina Ross, Andre Kemna, and Björn Braunschweig — University Münster, Institute of Physical Chemistry, Münster, Germany

CO oxidation is fundamental key for complete oxidation of small alcohols on Pt catalysts in fuel cells. So far, room-temperature ionic liquids (RTIL) have been used to modify the selectivity in electrocatalysis. In order to understand the mechanism of CO oxidation in RTIL we have investigated this reaction at the Pt(111)/1-butyl-3-methylimidazolium trifluorosulfonylimide [BMIM][NTf_2] electrode/electrolyte interface as a function of H_2O concentration and electrode potential using *in situ* sum-frequency generation (SFG) spectroscopy and infrared absorption spectroscopy (IRAS). Using SFG spectroscopy, we address the changes of CO molecules on Pt(111), while we monitor bulk electrolyte changes with IRAS using vibrational bands from H_2O, CO_2 and CO. The presence of water in [BMIM][NTf_2] shifts the CO onset potential by more than 200 mV with increased H_2O concentration from 0.01 to 1.5 M, which we relate to the incorporation and availability of water at the electrode/electrolyte interface. The nature of the RTIL cation has also a large effect on the surface excess of H_2O since RTILs which are prone to form closed-packed structures like [BMMIM][NTf_2] can block the incorporation of H_2O and lead to more sluggish CO oxidation with larger overpotentials and oxidation in a much broader potential.

O 60.8   Wed 16:45   TRE Phy

Resolving the structure of Cu(100) in iodine containing solutions — •Nicolas G. Hörmann, Nicolas Bergmann, Karsten Reuter, Beatriz Roldán Cuenya, Georg H. Simon, and Christopher S. Kley — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany

We present results from our joint experimental and theoretical effort to identify the structure of iodine adlayers on Cu(100) in electrochemical environment – a first step towards understanding the origin of the influence of iodine on the electrocatalytic carbon dioxide reduction (CO2RR) on Cu. In particular, we resolve stable interface structures as a function of the potential by a detailed analysis of theoretical predictions from density functional theory calculations and in-situ EC-AFM measurements. These results are complemented by the comparison of experimental and theoretically simulated Cyclic Voltammograms [1,2], which provide additional information on electrosorption reactions and thereby the interface composition as a function of the potential.

O 60.9   Wed 17:00   TRE Phy

Non-Random Island Nucleation in the Electrochemical Roughening on Pt(111) — •Marcel Rost[1], Leon Jacobse[2], and Marc Koper[3] — [1]Huygens-Kamerlingh Onnes Laboratory, Leiden University, Niels Bohrweg 2, 2333 CA Leiden, The Netherlands — [2]Centre for X-ray and Nano Science CXNS, Deutsches Elektronen-Synchrotron DESY, Notkestrasse 85, D-22607 Hamburg, Germany — [3]Leiden Institute of Chemistry, Leiden University, Einsteinweg 55, 2333 CC Leiden, The Netherlands

Many chemical surface systems develop ordered nano-islands during repeated reaction and restoration. Platinum is used in electrochemical energy applications, like fuel cells and electrolysers, although it is scarce, expensive, and degrades.

During oxidation-reduction cycles, simulating device operation, nucleation and growth of nano-islands occurs that eventually enhances the dissolution. Preventing nucleation would be the most effective solution. However, little is known about the atomic details of the nucleation; a process almost impossible to observe.

Here, we analyze the nuclei-distance distribution mapping out the underlying atomic mechanism: a rarely observed, non-random nucleation takes place. Special, preferential nucleation sites that a priori do not exist, develop initially via a precursor and eventually form a semi-ordered Pt-oxide structure.

This precursor mechanism seems to be general, possibly explaining also the nano-island formation on other surfaces/reactions.

O 60.10   Wed 17:15   TRE Phy

Electrochemical re-structuring of the InP(100)-HCl interface monitored by operando reflection anisotropy spectroscopy — •Margot Guidat[1,2], Mario Löw[2], Daniel Lörch[1], Vibhav Yadav[1], Jongmin Kim[1,2], and Matthias M. May[1,2] — [1]Institute of Physical and Theoretical Chemistry, Universität Tübingen, Germany — [2]Institute of Theoretical Chemistry, Universität Ulm, Germany

A possible way to achieve a low-carbon energy system consists of hydrogen production by photoelectrochemical water splitting. Here, III-V semiconductors play an important role due to their high solar-to-hydrogen efficiencies. However, surface corrosion limits the overall performance of photoelectrochemical devices. Studies have reported that interface functionalization is a way to protect the surface. In this work, we monitor the potential-dependent restructuring of the electrochemical InP(100) interface in HCl by operando reflection anisotropy spectroscopy (RAS) [1]. We investigate the effect of electrolyte concentration on the ordering and stabilization of the surface film formed at cathodic potentials. Computational RAS qualitatively supports the formation of an $InCl_x$ layer. The latter is further investigated quantitatively with other characterization techniques. Fitting RA-transients measured under applied potentials with adsorption isotherm models gives insight into the lifetime of the involved processes and their adsorption energies. O 60.11   Wed 17:30   TRE Phy

A femtosecond resolved view of vibrationally assisted electron transfer across the metal/aqueous interface — •Zhipeng Huang, Manuel Bridger, Oscar Andres Naranjo-Montoya, Alexander Tarasevitch, Uwe Bovensiepen, Yujin Tong, and R. Kramer Campen — Faculty of Physics, University of Duisburg-Essen

Understanding heterogeneous charge transfer is crucial if we are to build the best electrolyzers, fuel cells and photoelectrochemical water splitting devices that chemistry allows. Since the elementary processes involved have characteristic timescales ranging from femto- to milliseconds, direct simulation of all relevant processes is not generally possible.

Here we demonstrate experimentally, using a novel two photon photovoltage approach, that for a prototypical system, a ferrocene terminate alkane thiol self-assembled monolayer (SAM) on gold in contact with aqueous electrolyte, charge transfer from the Au to the ferrocene can be induced by vibrational excitation of the ferrocene aromatic CH. Intriguingly the energy of the aromatic CH vibration, 0.38 eV, is a large fraction of the effective solvent interaction strength inferred for the ferrocene/ferrocenium system in prior electrochemical studies: 0.85 eV. Our results thus imply that, solvent may effect reduction/oxidation rates in electrocatalysis by coupling to a few, perhaps widely different in energy, vibrations. If shown to be generally true such a picture would suggest the necessity of moving beyond a single effective solvent interaction in theoretical descriptions of heterogeneous electron transfer.

O 60.12   Wed 17:45   TRE Phy

Dynamic Polymorph Formation of a Trimesic Acid Derivative at Solid-Liquid Interface — •Richa Arjariya[1], Vipin Mishra[1], Gagandeep Kaur[1], Sandeep Verma[1], Markus Lackinger[2], and Thiruvancheril G Gopakumar[1] — [1]Department of Chemistry, Indian Institute of Technology Kanpur, Kanpur, UP-208016, India — [2]Department of Physics, Technical University of Munich, James- Franck-Strasse 1, Garching 85748 and Deutsches Museum, Museumsinsel 1, Munich 80538, Germany

In this work we show the self-assembly of a tricarboxylic acid derivative of trimesic acid (BTA) at heptanoic acid-, nonanoic acid-graphite interface. At both interfaces BTA forms a trimer based-self-assembly, super-flower (SF) pattern. The spontaneously formed SF pattern is observed to be dynamically converting to a dimer-based assembly, chicken-wire pattern (CW), at heptanoic acid-graphite interface while scanning. Interestingly, at nonanoic acid-graphite interface, SF pattern remains stable and not converted to CW pattern. We attribute that the formation energy of both SF and CW patterns is comparable. The difference in the stability of different patterns in heptanoic acid and nonanoic acid is most likely related to the solubility of BTA in these solvents.[1,2] 1) T. N. Ha, T. G. Gopakumar, M. Hietschold, J. Phys. Chem. C, 2011, 115, 21743. 2) M. Lackinger, S. Griessl, W. M. Heckl, M. Hietschold and G. W. Flynn, Langmuir, 2005, 21, 11, 4984-4988

Phase transitions in the two-dimensional Su-Schrieffer-Heeger model —
•Changan Li[1], Songbo Zhang[2], Sangjun Choi[1], Jan Budich[3], and Björn
Trauzettel[1] — [1]Institute for theoretical physics and astrophysics, University
of Würzburg, Wuerzburg, Germany — [2]Department of Physics, University of
Zürich, Winterthurerstrasse 190 8057, Zürich, Switzerland — [3]Institute of The-
oretical Physics, Technische Universität Dresden, 01062 Dresden, Germany
The 2D Su-Schrieffer-Heeger (SSH) model is endowed with rich topological
physics. First we show that the random flux can induce a metal-band insulator
transition in the 2D SSH, thus reporting the first example of such a transition.
Remarkably, we find that the resulting insulating phase can even be a higher-
order topological insulator with zero-energy corner modes and fractional cor-
ner charges. Employing both level statistics and finite-size scaling analysis, we
characterize the metal-band insulator transition and numerically extract its crit-
ical exponent. By proposing another inclined 2D SSH model, a deformed one,
we show that a pair of Dirac points protected by space-time inversion symme-
try appear in the semimetallic phase. Interestingly, the locations of these Dirac
points are not pinned to any high-symmetry points of the Brillouin zone but
highly tunable through parameter modulations. Moreover, the merging of two
Dirac points undergoes a topological phase transition, which leads to either an
anisotropic topological insulating phase or a nodal-line metallic phase.

O 61.2   Wed 15:15   TRE Ma

**Ab initio embedding approach for carbon defects in hexagonal boron nitride:
A new platform to probe environmental screening** — •Danis Badrtdinov[1],
Magdalena Grzeszczyk[2], Alexander Hampel[3], Cyrus Dreyer[3,4], Ma-
ciej Koperski[2], and Malte Rösner[1] — [1]Radboud University, Nijmegen, The
Netherlands — [2]National University of Singapore, Singapore — [3]Flatiron Insti-
tute, USA — [4]Stony Brook University, USA
Correlated defects in layered van der Waals hosts hold high promises for realiz-
ing quantum technologies, as they allow for various possibilities to control defect
properties, e.g., via altering the host thickness or by changing the substrate ma-
terial. A quantitative description of the defect ground and excited states taking
the details of the impurity environment into account is, however, a considerable
challenge for conventional density-functional theory (DFT) based methods as
the impurities might be correlated and dielectric environmental screening is not
fully accounted for in DFT. To tackle these challenges we apply and extend an
embedding approach that treat the defect states within exact many-body theory,
while DFT is used as a starting point to describe the bulk host material. We
study various carbon defects embedded in hexagonal boron nitride (hBN), al-
lowing us to disentangle all mechanisms responsible for the alteration of defect
properties including modifications to the impurity structure and changes in the
environmental screening upon thinning down the hBN host. Our new embed-
ding approach paves the way for improved identification of defects in layered
materials and to tailor their properties.

Nonequilibrium electron dynamics in a two-sites Hubbard model — •Jakub
Wronowicz and Yaroslav Pavlyukh — Department of Theoretical Physics,
Wrocław University of Science and Technology
Electron dynamics in a two-sites Hubbard model is studied using the nonequilib-
rium Green's function approach using formalism developed in [1]. We focus on
the electron dynamics arising in the adiabatic switching scenario. Many-body
approximations are classified according to the channel of the Bethe-Salpeter
equation in which electronic correlations are explicitly treated. They give rise
to the so-called second Born, T-matrix and GW approximations. In each of
these cases, the model is reduced to a system of ordinary differential equations,
which resemble equations of motion for a driven harmonic oscillator with time-
dependent frequencies. We discuss transient solutions for the off-diagonal den-
sity matrix. Analytical result for the steady state in second Born approxima-
tion is compared with the exact solution. It is further shown numerically that in
the large Hubbard-U limit the T-matrix in the particle-hole channel and spin-
adapted GW approximations converge to the same solution.

**Time-linear quantum transport simulations with correlated nonequilib-
rium Green's functions** — •Riku Tuovinen[1], Yaroslav Pavlyukh[2], En-
rico Perfetto[3], and Gianluca Stefanucci[3] — [1]Department of Physics,
Nanoscience Center, University of Jyväskylä, Finland — [2]Department of The-
oretical Physics, Wroclaw University of Science and Technology, Poland —
[3]Dipartimento di Fisica, Università di Roma Tor Vergata, Italy

We present a time-linear scaling method for open and correlated quantum sys-
tems. The method inherits from many-body theory [1] the possibility of selecting
the most relevant scattering processes, thereby paving the way for real-time char-
acterizations of correlated ultrafast phenomena in quantum transport. The open
system dynamics is described in terms of an embedding correlator from which
the transient current can be calculated via the Meir-Wingreen formula [2]. We
efficiently implement the method through a combination with recent time-linear
schemes for closed systems [3]. Electron-electron and electron-phonon interac-
tions can be treated on equal footing while preserving all fundametal conserva-
tion laws. We employ the method by studying transport of correlated electron-
hole pairs in semiconductors [4].

Topical Talk   O 61.5   Wed 16:15   TRE Ma

Challenges in modelling correlated electronic matter — •Roser Valenti —
Institute of Theoretical Physics, Goethe University Frankfurt, Frankfurt, Ger-
many
The microscopic modelling of correlated electronic matter from first principles
poses a fundamental theoretical challenge due to the many-body character of
the systems. In recent years there have been a few internationally coordinated
efforts in theoretical method development to generate a common platform of
benchmarked software tools including dynamical mean field theory and exten-
sions.
In this talk I will present some of the challenges we face in such an endeavour
and illustrate them with some examples on models and materials.
Funding from the DFG through QUAST FOR 5249-449872909 is acknowl-
edged.

**Electron-Phonon Interactions from DFPT within an All-Electron Frame-
work** — •Sebastian Tillack, Pasquale Pavone, and Claudia Draxl —
Humboldt-Universität zu Berlin and IRIS Adlershof, 12489 Berlin, Germany
The interplay between electrons and the motions of nuclei in solids, described
in terms of phonons, play a crucial role in the modeling of functional materi-
als, particularly for understanding temperature dependent effects. We present an
implementation of density-functional perturbation theory (DFPT) within a full-
potential all-electron framework as implemented in the code exciting [1]. Our
implementation allows one to compute phonons as well as the linear response to
external electric fields. We use DFPT calculations to study lattice vibrations and
electron-phonon interactions (EPIs) by means of many-body perturbation the-
ory in β-Ga_2O_3. The electron self-energy contribution is computed as a function
of temperature from which various properties such as quasi-particle energies,
electron linewidths, and spectral functions are derived. We further incorporate
many-body electron-electron interactions described by the GW method. Be-
yond that, our work creates the foundation for a fully *ab initio* study of the effect
of EPIs on optical excitations.

**Calculation of phonon spectra with the FLAPW method using Density Func-
tion Perturbation Theory** — •Alexander Neukirchen, Christian-Roman
Gerhorst, Gregor Michalicek, Daniel Wortmann, Gustav Bihlmayer,
and Stefan Blügel — Peter Grünberg Institute and Institute for Advanced Sim-
ulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany
Computing phonons applying density functional perturbation theory (DFPT)
within all-electron DFT methods is a well-known challenge due to the displace-
ment of muffin-tin spheres and sphere-centered basis functions. In this talk, we
present our current results of the phonon dispersion based on our implementa-
tion of the DFPT approach in the FLEUR code [1] (www.flapw.de), an implemen-
tation of the full-potential linearized augmented plane wave (FLAPW) method.
We highlight the good agreement of our preliminary results with phonon disper-
sions obtained with the finite displacement method for which the FLEUR code
has been combined with the phonopy tool (www.phonopy.github.io/phonopy/).
We discuss the numerical challenges involved in calculating meV quantites on
top of large ground state energies typical for all-electron methods and how we
addressed them.
This work has been supported by the Helmholtz Postdoc Programme (VHPD-
022) and by the MaX Center of Excellence funded by the EU through the H2020-

Electron-phonon interaction using a localized Gaussian basis set — •Gerrit Johannes Mann, Thorsten Deilmann, and Michael Rohlfing — Institute of Solid State Theory, University of Münster, Germany
Electron-phonon interaction is a crucial mechanism in solid state physics that is responsible for a multitude of phenomena. However, in electronic structure calculations it is usually neglected. We developed an ab-initio implementation on top of density functional theory that combines finite differences calculations with the perturbative Allen-Heine-Cardona framework in order to calculate the temperature-dependent renormalization of the electronic bandstructure due to electron-phonon interaction using a basis set of localized Gaussian orbitals. This implementation circumvents the limiting problems of previous implementations while maintaining a good agreement with the literature. The calculated Fan-Migdal zero-point renormalization of the direct band gap of silicon amounts to about 15 meV compared to 20 meV in the literature. Also the temperature-dependence of the renormalization agrees similarly well.

O 62: Focus Session: Wissenschaftskommunikation / Outreach (joint session HL/O/TT)

Im wissenschaftlichen Umfeld wird Maßnahmen der Öffentlichkeitsarbeit eine zunehmend größere Bedeutung zugemessen, - aus der Gesellschaft heraus und auch durch die großen Fördereinrichtungen und die DPG. Dabei geht es nicht nur um die Ergebnisse der Forschung, sondern auch darum, Prozesse und Methoden von wissenschaftlicher Arbeit transparent abzubilden – eine Aufgabe, die prinzipiell alle Forschenden übernehmen können. In diesem Symposium sollen erfolgreiche Projekte der Wissenschaftskommunikation, insbesondere aus dem Bereich der Festkörperphysik, vorgestellt werden. In ihrer Gesamtheit sollen sie das Spektrum der Wissenschaftskommunikation hinsichtlich des finanziellen und zeitlichen Aufwands aufzeigen und Methoden für unterschiedliche Zielgruppen vorstellen.

So dient diese Session sowohl als Ideengeber und Inspiration als auch als eine Art Netzwerk-Treffen zum Austausch über die Wissenschaftskommunikation in unterschiedlichen Kontexten.

experimentamus! Forschendes Lernen von Physik und Chemie in der Grundschule — •Sebastian Schlücker — Universität Duisburg-Essen, Campus Essen
Der Sachunterricht in der Primarstufe ist ein Konglomerat aus allen Natur- und Gesellschaftswissenschaften, erst in der Sekundarstufe findet eine Aufspaltung in die einzelnen Fächer statt. Zudem unterrichten viele Grundschul-Lehrkräfte fachfremd. Auch der Zeitaufwand für die Vorbereitung von Experimenten ist nicht unerheblich. Wie also kann man trotz dieser Hürden kindgerechte physikalische und chemische Experimente bereits in der Grundschule einführen?

Ich berichte aus 10 Jahren Erfahrung mit dem Projekt experimentamus!. Dabei handelt es sich um einen Kanon aus ca. 40 Experimenten für die Klassen 2 bis 4, welcher die Themen Licht, Wärme, Magnetismus, Wasser, Luft, Feuer und Elektrizität mit einem kindgerechten Alltagsbezug abdeckt. Anstelle des darlegenden Lernens wird auf das Forschende Lernen gesetzt: Frage - Hypothese - Experiment - Beobachtung - Erklärung; diese fünf Stationen des wissenschaftlichen Erkenntnisprozesses werden immer wieder durchlaufen. Ganz im Sinne Martin Wagenscheins wird dabei nach der exemplarischen und sokratischen Methode vorgegangen. Die praktische Implementierung umfasst 1. Materialkisten für alle Themen, 2. kompakte und leicht verständliche Informationshefter für die Lehrkräfte, sowie 3. Lernheftchen für alle SuS. Am Ende möchte ich über Erfahrungen und Herausforderungen im Rahmen dieses Projektes berichten und Ideen für eine mögliche weitere Verbreitung vorstellen.

O 62.2　Wed 15:30　POT 81
Internal interfaces - goals and realisation of a scientific image film — •Ulrich Höfer[1,2] and Michael Dürr[2,3] — [1]Fachbereich Physik, Philipps-Universität Marburg — [2]SFB 1083, www.internal-interfaces.de — [3]Institut für Angewandte Physik, Justus-Liebig-Universität Giessen, Germany
Funded by the German Science Foundation (DFG), a professional film maker has produced an image film about the research conducted in the Collaborative Research Center SFB 1083 "Structure and Dynamics of Internal Interfaces". The six-minute video clip takes the non-specialist on a journey down to atomic scale to show the progress at the forefront of research at solid/solid interfaces. It is not a demanding educational film. Rather, it is a visually stunning piece that looks like science fiction taken straight out of a movie, with tracking shots that take the viewer down to the nanometer scale, with flights through luminous molecules, exotic excitons, and space-filling laser labs. The film also has a very impressive soundtrack. Gustav Holst's (1874-1934) composition "The Planets" was re-orchestrated especially for this film. It is available on the youtube channel of the DFG (https://www.youtube.com/watch?v=_-mDt0NzHrc). Visitors of Chemikum Marburg can watch the German version on a 4K OLED screen, a device actually based on microscopic processes at interfaces investigated by SFB 1083.

The idea behind the creation of a professional film, its conceptional design and the necessary steps towards its realization will be outlined.

O 62.3　Wed 15:45　POT 81
Outreach activities of SFB 1083 @ Chemikum Marburg — •Christof Wegscheid-Gerlach, Luise Cleres, Ina Budde, Karl-Heinz Muth, and Marion Enssle — Chemikum Marburg / SFB1083
The diffusion of concepts, methods, and visions of the SFB 1083 on Structure and Dynamics of Internal Interfaces into the general public is our general goal. To this end project Ö makes use of the institution Chemikum Marburg e.V., whose basic idea is to fascinate the public excited about natural sciences. The experiments offered here, stand for chemical, biological, pharmaceutical, and physical subjects related with daily phenomena or beyond. We will give an overview about the introduction of basic ideas and methods of SFB 1083 to the public as well as the institution Chemikum Marburg. The contents of the individual offers, such as experiments within the regular workspace, the workshops for the Girls' Day and the compilation of special workshops that are offered to give high-school students an understanding of the research content of the SFB 1083 are presented. An additional topic is the linking of basic research to applications for regenerative energy resources. Hydrogen fuel cells are well-known to the general public and rely on functional internal interfaces. An additional workshop which was prepared in cooperation with the district Marburg-Biedenkopf gives an overview about production, storage, and application of hydrogen as a new energy resource. We will also share various occasions at Chemikum Marburg where further outreach activities represent SFB 1083.

Under the Microscope – spotlighting materials and nano science — •Svenja Lohmann and Pranoti Kshirsagar — The Science Talk, Germany
Real Scientists Nano is a science communication project dedicated to materials and nano science. Despite the widespread relevance of materials science to everyday life, we feel that dedicated science communication in this area is much rarer than in other fields. Our aim is to provide a platform for active materials and nano scientists to directly communicate their science and life as a scientist to the public. The use of social media thereby provides a very low threshold to science communication as basically the only requirement is to have an account. We have the goal to showcase the scientific community in all its diversity, and so far (12/2022) had guest scientists from more than 30 countries of origin as well as various fields and career stages. The two main pillars of the Real Scientists Nano project are the @RealSci_Nano Twitter account and the Under the Microscope podcast. Our guest scientists are interviewed for one podcast episode, and subsequently get to tweet from the account for one week following the rotation curation concept. We let curating scientist decide for themselves what they would like to tweet about. The form and content therefore vary greatly. Many of our scientists report from their everyday life, and are for example live-tweeting from a conference, uploading videos or photos from the lab or sending the occasional "stuck in meetings, will return later" tweet. Science communication on social media thus gives the opportunity to open a direct and real-time window into the scientist's life.

Phyphox – A pocketful of physics — •Christoph Stampfer — JARA-FIT and 2nd Institute of Physics, RWTH Aachen University, 52074 Aachen, Germany — Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich, 52425 Jülich, Germany

Most smartphones are used to make phone calls, to write short messages, surf the Internet or check e-mails. However, they can do much more: With the help of the integrated sensors and the free app "phyphox" (abbreviation for Physical Phone Experiments), pupils, students, and teachers and interested others can independently perform and develop physics experiments. For example, the app can use the accelerometer to record pendulum movements and determine the rotational acceleration in a salad spinner, or the air pressure sensor to determine time-resolved differences in altitude and thus the speed of an elevator. The didactic potential of the app is great, as the students are picked up on ground that is very familiar and attractive to them (smartphones) and are introduced to experimental natural sciences in a playful way and with an extremely low barrier (zero cost, i.e. only one click away). The app helps to get students excited about scientific and technical questions and contexts at an early age. The app is available free of charge for Android and iOS (more information can be found at www.phyphox.org). In my presentation, I will go into the concept of phyphox, introduce the range of functions and show a number of application examples.

Chair PR representative as a doctoral student's secondary task: A field report — •Paula M. Weber, Felix Friedrich, and Manuel Seitz — Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany

Especially in recent years, it has become more important to communicate one's scientific work and methods to the public in order to show that in the scientific world, knowledge can only be created through research and the scientific process. Yet, extra time besides research is often limited and it is thus difficult to get into science communication. In this talk, I would like to present how PhD students can use their interest in science communication to benefit their own research group as a part-time PR representative.

In the first part of my talk, I will report on our efforts to attract new bachelor and master students. This advertising is focused on an audience with a scientific background, such that lab tours and advertising posters may contain scientific language and references. The second part is about communication with the general public, who usually know physics from their school days. Here, I will report on how we presented our research activities at the Night of Science in Physics and at the "Highlights der Physik" in Würzburg.

Working part-time as a PR representative could encourage doctoral students to try their hand at science communication and develop the associated communication skills.

O 62.7 Wed 17:45 POT 81
Real or Fake - A format in science communication that encourages critical thinking — •Tobias Löffler — Institut für Angewandte Physik Düsseldorf
The outreach format "Real or Fake" aims to train the audience in an critical approach to credible-sounding facts.

It is aimed at the general public and specifically at young people. At the same time, it offers an easy introduction for scientists to audience-oriented communication of science on stage. The format can be performed in front of a live audience or as an interactive online event. It has been proven to work as implemented into science festivals, nights of sciences, as a public individual event and also as part of events with constrained settings - such as outreach events at schools or as part of conferences.

"Real or Fake" was developed in 2017 by scientists around the Berlin March for Science who later founded Besserwissen e.V. with the goal to promote the format and support new organisers. I do cooprate with them since 2019 and have organized more than ten "Real or Fake" events since then.

In my talk, I will present the concept and its origins, give an overview of successful events and show what to do and what support one can get, if one wants to organize a "Real or Fake" event.

Invited Talk O 62.8 Wed 18:00 POT 81
Physics for school and the public at the LMU — •Dr. Cecilia Scorza-Lesch — Fakultät für Physik der LMU, München
Germany lives from research and technology. Physics, as the basis of all empirical sciences and technologies, has a very special, fundamental role to play. The Faculty of Physics at LMU, the largest in Germany, comprises nine research areas, three centres and two excellence clusters. In this talk we will present the approach we use to successfully communicate our various topics of modern research, the role of physics in our daily lives and in the fight against global warming to the schools and the public in a participatory way.

O 63: Poster: Data Management

Time: Wednesday 18:00–20:00 Location: P2/EG

O 63.1 Wed 18:00 P2/EG
SciCat - a meta data catalog and research data management system — •Linus Pithan[1], Massimiliano Novelli[2], Dylan McReynolds[3], Laura Shemilt[4], Carlo Minotti[5], Anastasiia Pylypenko[1], Alexander Gerlach[1], Alexander Hinderhofer[1], Stephan Egli[5], Tobias Richter[2], and Frank Schreiber[1] — [1]Uni Tübingen, DAPHNE (DE) — [2]European Spallation Source (DK/SE) — [3]Lawrence Berkeley National Laboratory (USA) (US) — [4]The Rosalind Franklin Institute (UK) — [5]Paul Scherrer Institut (CH)

SciCat is a modern and flexible data catalogue that facilitates research data management on multiple scales and thereby suits the needs of large scale research facilities, individual research groups (e.g. at universities) as well as scientific communities. SciCat [1] was initially built to serve Photon- and Neutron sources (in the beginning developed at PSI and ESS, later suppored by ExPaNDS & PaNOSC and further institutions). Through the engagement of DAPHNE4NFDI (DAta from PHoton and Neutron Experiments) in the SciCat project there are new use cases emerging especially - but not exclusively - for small scale installations. The use of an homogenized interface (API) to create and search datasets SciCat can e.g. also be used as infrastructure backbone for machine learning (ML) projects in communities by serving datasets for validation, testing and training of ML models. On this poster we aim to give an overview on specific use-cases of SciCat within DAPHNE, which may serve as blueprints to use SciCat also in other scientific communities.

O 63.2 Wed 18:00 P2/EG
A local solution for automated data acquisition and storage in catalysis — •Abdulrhman Moshantaf[1], Mike Wesemann[1], Patrick Oppermann[1], Heinz Junkes[1], Robert Schlögl[1,2], and Annette Trunschke[1] — [1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin (Germany) — [2]Max Planck Institute for Chemical Energy Conversion, Mühlheim 45470 (Germany)

In order to solve the current challenge in catalysis research in the development of new, scalable catalysts for hydrogen-based future technologies, a better integration of theory and experiment is required. The necessary data exchange demands extensive digitalization in catalysis. Experimental data must be generated reproducibly and with sufficient diversity, and must be available in machine-readable form. Artificial intelligence can then contribute to the discovery of correlations. We have developed a concept for a local data infrastructure and implemented it in a catalysis laboratory. In research projects, handbooks are written (preferably in machine-readable form) detailing how experimental data are obtained, including the definition of benchmark catalysts. To implement the concept of handbooks, automated systems for data acquisition and storage have been designed. Such a system consists of (i) EPICS for communication with devices and data acquisition, (ii) a database (archive), (iii) an archiving appliance for storing time series, (iv) Phoebus for creating graphical user interfaces, (v) Python/Bluesky/Jupyter notebooks for creating automations and evaluations, and (vi) S3 storage for long-term storage.

O 64: Poster: Graphene

Time: Wednesday 18:00–20:00   Location: P2/EG

O 64.1   Wed 18:00   P2/EG

An STM and XPS study of graphene on Rh (111) as a substrate for on-surface assembly of Pt-complexes — •Majid Shaker, Natalie J. Waleska, Simon Jaekel, Eva Marie Freiberger, Valentin Schwaab, Felix Hemauer, Rajan Adhikari, Christian Papp, and Hans-Peter Steinrück — Lehrstuhl für Physikalische Chemie II, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstr. 3, Erlangen 91058, Germany

Single platinum atoms have interesting properties and can play an important role in on-surface catalysis. One route to prepare small Pt nanoclusters or even single isolated Pt atoms is to deposit small amounts of Pt on the Moiré structure of 2D materials on lattice-mismatched transition metal surfaces. Such Moiré patterns e.g. of graphene can act as template for the formation of NCs with a narrow size distribution. In this study, a monolayer of graphene was successfully grown on the surface of a Rh(111) single crystal from ethylene (C2H4) as precursor under ultra-high vacuum (UHV). Very small Pt NCs (down to individual atoms) were formed in the valleys of graphene to further act as a transition metal center for the formation of metal complexes by providing appropriate ligands. Scanning tunneling microscopy and synchrotron radiation-based X-ray photoelectron spectroscopy were employed to evaluate the formed inorganic complexes.

We thank Helmholtz-Zentrum Berlin for allocation of synchrotron-radiation beamtime and the BESSY II staff for support during beamtime. This work was funded by the DFG through SFB 953.

Graphene on Ru(0001): Layer-Specific and Moiré-Site- Dependent Phonon Excitations — Johannes Halle, Nicolas Néel, •Rebecca Cizek, and Jörg Kröger — Technische Universität Ilmenau

Graphene phonons are excited by the local injection of electrons and holes from the tip of a scanning tunneling microscope. Despite the strong graphene-Ru(0001) hybridization, monolayer graphene unexpectedly exhibits pronounced phonon signatures in inelastic electron tunneling spectroscopy. Spatially resolved spectroscopy reveals that the strength of the phonon signal depends on the site of the moiré lattice with a substantial red-shift of phonon energies compared to those of free graphene. Bilayer graphene gives rise to more pronounced spectral signatures of vibrational quanta with energies nearly matching the free graphene phonon energies. Spectroscopy data of bilayer graphene indicate moreover the presence of a Dirac cone plasmon excitation.

O 64.3   Wed 18:00   P2/EG

DFT study on the ORR mechanism on carbon nitride materials — •Jana Koenigsdorff, Changbin Im, Björn Kirchhoff, and Timo Jacob — Ulm University, Institute of Electrochemistry, D-89081 Ulm

Polymeric carbon nitrides (PCNs) have rapidly gained attention over the last years due to their promising physicochemical properties.[1] With their adjustable narrow bandgap and high visible light responsivity, PCNs are considered as promising potential photo-(electro)-catalysts for various industrial processes such as H_2O_2 formation or CO_2 reduction.[2][3] However, numerous structural and photophysical properties of this material class are not completely understood and hinder in-depth comprehension of the reaction pathways.[2] Most simulation studies that attempted to gain a deeper insight into the reaction mechanisms were based on simple, highly ordered PCN models.[1] However, PCNs obtained by thermal processes often exhibit inhomogeneity and a variety of microstructural motifs.[2] In this study, we therefore perform DFT calculations to investigate the mechanism of H_2O_2 formation with various PCN models of different degrees of condensation and structural composition in order to screen a wide range of adsorption sites. We are convinced that with this approach, we can establish structure-reactivity relationships that can be used to derive understanding-driven material optimization strategies.

O 64.4   Wed 18:00   P2/EG

Electronic magneto-transport in epitaxial graphene covered with Bi(110) islands — •Sergii Sologub[1,2], Julian Koch[2], Chitran Ghosal[2], and Christoph Tegenkamp[2] — [1]Institute of Physics, NAS of Ukraine, Nauki avenue 46, 03028 Kyiv — [2]Institut für Physik, TU Chemnitz, Reichenhainerstr. 70, 09126 Chemnitz

Magneto-conductance and Hall voltage of epitaxial graphene formed on SiC and covered with ultrathin Bi islands were measured within the range of ±4 T. The structure and morphology of Bi coverages of average thickness up to 4 bilayers, MBE-grown at RT as well as after-annealed, were determined by SPA-LEED and STM techniques. The coverage was found to consist of needle-like (110) islands with "magic" widths and thicknesses.

The analysis of the low-field part of the magneto-conductance reveals a transition from weak-localization (WL) to weak antilocalization (WAL) with increasing Bi coverage and allows to characterize the scattering of conduction electrons by determining electron scattering lengths, namely inelastic-dephasing, intervalley and intervalley symmetry breaking ones. The correlation of the average sizes of and distance between Bi(110) islands for different coverages with the characteristic lengths demonstrate the role of electron scattering on edges and within the islands in the WL-WAL transition. Calculated dependencies of Hall and magneto-resistance allow determining changes of the electron density induced by Bi adsorption and reveal the contribution of electron-electron interaction in electronic transport.

O 64.5   Wed 18:00   P2/EG

Organic Molecules on Graphene grown on a Pt(111) surface — •Shilpa Panchami Raj, Christophe Nacci, and Leonhard Grill — University of Graz

Graphene, a flat monolayer of carbon atoms with two-dimensional honeycomb lattice, exhibits unique properties. If grown on a Pt(111) surface, only weak interaction is found between the substrate and the graphene sheet. This renders it an interesting system to decouple organic molecules on the graphene layer from the metal underneath as they might preserve their electronic structure In this work, we present a scanning tunneling microscopy (STM) study under ultrahigh vacuum (UHV) with the deposition of different organic molecules on graphene that was epitaxially grown on a Pt(111) substrate. Experiments were done at cryogenic temperatures of 5 K, which allows to image single molecules in a stable fashion and also to manipulate them with the tip of the STM in a controlled way. Adsorption properties of the molecules are studied in view of the characteristic Moiré pattern of the graphene/Pt(111) system. Moreover, first attempts will be presented how chemical reactions can be induced on this system.

O 64.6   Wed 18:00   P2/EG

Electronic band structure of Pb intercalated graphene on SiC and the influence of electron doping — •Bharti Matta[1], Philipp Rosenzweig[1], Kathrin Küster[1], Craig Polley[2], and Ulrich Starke[1] — [1]Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany — [2]MAX IV Laboratory, Lund University, Fotongatan 2, Lund 22484, Sweden

Intercalation is a powerful way of modifying the properties of epitaxial graphene and stabilizing two-dimensional (2D) intercalant layers at the graphene/SiC interface. In this work, we show that the charge neutrality of Pb intercalated quasi-freestanding monolayer graphene on SiC involves charge transfer from both the intercalant and the substrate. Synchrotron based angle resolved photoelectron spectroscopy measurements demonstrate the (1×1) order of the Pb layer with respect to SiC. The interlayer bands cross the Fermi level, confirming the metallic nature of intercalated Pb. Furthermore, constant initial state mapping shows no dispersion of the Pb bands with photon energy, proving the 2D nature of the intercalant layer. Polarization dependent measurements retrieve a mainly in-plane orbital character for the Pb band branches closer to the Fermi energy. Potassium deposition induces strong n-doping in the graphene layer ($E_D \approx 1.1$ eV). However, the Pb bands do not show any noticeable change, which suggests that the charge transfer from the potassium layer occurs predominantly into the graphene. Supported by DFG through FOR 5242.

O 64.7   Wed 18:00   P2/EG

Terahertz harmonic generation from graphite pencil drawings — •Atiqa Arshad, Segey Kovalev, and Jan Christoph — Helmoltz Zentrum Dresden (HZDR)

Harmonic generation is a general characteristic of driven nonlinear systems. It can serve as an efficient tool for investigating the fundamental principles that govern the underlying ultrafast nonlinear dynamics. Here we report on terahertz third harmonic generation (THG) from graphite pencil drawings on paper. We demonstrate that the terahertz(THz)-THG efficiency at an excitation frequency of 0.5 THz in graphite is comparable to that of single-layer graphene pump field strengths on the order of 100 kV/cm-1. The THG efficiency in graphite exhibits a significantly less pronounced saturation behavior at high incident fields and thus may even surpass that of graphene at extreme pump field strengths. The less pronounced saturation can be attributed to more efficient heat dissipation in multilayer graphite flakes compared to single-layer graphene. The feasibility of using easy-to-produce graphite-based structures opens up new possibilities for highly accessible, modifiable, and nearly cost-free THz frequency multipliers. Besides the implementation of graphite-based THz frequency converters, the developed technique could be used for nonlinear THz imaging, offering the possibility to image graphite drawings covered by other materials.

O 64.8   Wed 18:00   P2/EG

In-situ monolayer graphene growth on Ru(10$\bar{1}$0): an electron microscopy study — •Cathy Sulaiman, Lukas Schewe, Lars Buss, Moritz Ewert, and Jan Ingo Flege — Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Germany

During the last decade, the controlled growth of monolayer (MLG) and bilayer graphene has extensively been studied on the hexagonal Ru(0001) surface, which is a system that is known to form strong chemical bonds at the metal-graphene interface. Yet, little attention was paid to the influence of the substrate orientation that was demonstrated to have a significant impact for graphene growth on the Ir(001) and Ir(111) surfaces, the latter exhibiting a weak coupling between the graphene and the support. Therefore, in this study we have grown graphene on the rectangular Ru(10$\bar{1}$0) surface by segregation and ethylene-supported chemical vapor deposition. A photoemission and low-energy electron microscope (PEEM & LEEM) has been utilized to directly characterize the MLG growth process with respect to variations in substrate temperature and step orientation. The expansion of the MLG islands is compared to the well-established carpet-growth mode on the Ru(0001) surface. These results have been complemented by probing of the occupied and unoccupied electronic structure of the islands using PEEM and intensity-voltage LEEM. Furthermore, the existence of two preferential surface reconstructions is identified via micro-illumination low-energy electron diffraction (LEED), whose spatial distribution is revealed by employing dark-field LEEM imaging.

O 64.9   Wed 18:00   P2/EG

Band structure and charge carrier dynamics of a Pb-intercalated graphene sheet on Ni(111) — •Eva Sophia Walther[1], Katharina Hilgert[1], Christina Schott[1], Sebastian Hedwig[1], Ka Man Yu[1], Martin Aeschlimann[1], and Benjamin Stadtmüller[1,2] — [1]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern, Germany — [2]Institute of Physics, Material Science in Mainz, JGU Mainz, Germany

The discovery of graphene acted as a starting point for the vast research field of 2D materials. However, on metal surfaces, most of the enthusiasm for exploring graphene's unique properties has been tempered by the strong interaction with its substrate, which results in severe changes in its electronic properties. One way to reduce the graphene-surface interactions is the intercalation of heavy metal atoms between the graphene and the underlying substrate. In our work, we use the highly reactive Ni(111) surface as a graphene substrate. On this surface, the linear dispersion of the Dirac cone is severely distorted and the K-point is located far below the Fermi energy. Here, we will show that Pb intercalation recovers the linear dispersion of the free-standing graphene. Using time- and momentum-resolved photoemission, we will further determine the influence of the Pb intercalation for the ultrafast charge carriers dynamics at the K-point of the Gr/Ni(111) interface.

O 64.10   Wed 18:00   P2/EG

Controlled fabrication of the graphene/Mn$_5$Ge$_3$ interface via Mn intercalation — •Vivien Enenkel[1], Yuriy Dedkov[2], Elena Voloshina[2], and Mikhail Fonin[1] — [1]Fachbereich Physik, Universität Konstanz, Universtätsstraße 10, 78457 Konstanz, Germany — [2]Department of Physics, Shanghai University, 99 Shangda Road, 200444 Shanghai, China

Mn-based intermetallic compounds have recently been in focus of intensive research owing to their outstanding magnetic properties. In particular, epitaxial Mn$_5$Ge$_3$/Ge interfaces [1] are regarded to have the potential for the realization of efficient spin injection and manipulation in semiconductor structures compatible with the existing Si technology. Furthermore, for graphene on Mn$_5$Ge$_3$

an exchange splitting of the π states is predicted, with the two spin channels exhibiting a large difference in charge carrier mobility [2]. Here, we report on the fabrication of epitaxial graphene/Mn$_5$Ge$_3$ by Mn-intercalation at the graphene/Ge(110) interface, initially prepared by atomic carbon deposition on Ge(110) [3]. Depending on the sample temperature different phases can be generated, including Mn$_5$Ge$_3$, whose structure and electronic properties are studied by low-temperature scanning tunneling microscopy and spectroscopy.

Force-Field Development for Graphene-Graphite Water Systems — •Otto Schullian and Roland Netz — Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany

The wetting behavior of water on graphene/graphite surfaces is strongly dependent on the force fields chosen for the water-carbon interaction. Previously developed force fields were optimized to reproduce a specific contact angle for water on graphite (in the range of 85° to 95°). However, experiments show that the contact angle for water on graphite depends strongly on the preparation of the surface; they suggest that freshly exfoliated graphite has a surprisingly hydrophilic contact angle of 60°±13°, whereas old and potentially contaminated graphite surfaces are much more hydrophobic. For graphene the variance in contact angle is even more dramatic, ranging from 10° to 127°.

Here, we simulate contact angles for a range of water-carbon interaction strengths for one to five layers of graphene to provide the necessary parameters for a whole range of contact angles (30°-115°). In this way, one can tune the wetting behavior in simulation. From our results, we see that the graphene with no underlying support has a contact angle 2°-20° higher than the corresponding graphite system depending on the interaction strength. In addition, we investigate the frequency-dependent friction on flat graphene and graphite as a function of the interaction strength and the number of graphene layers via the Green-Kubo relation including a hydrodynamic correction.

Raman features of graphene and Weyl semimetals beyond the standard nonadiabatic theory — •Nina Girotto and Dino Novko — Institute of Physics, Zagreb, Croatia

Although graphene has already been thoroughly studied with Raman spectroscopy, there still exists a disagreement about the broadening mechanisms of the E2g mode and its actual temperature dependence [Nano Lett. 10, 466 (2010)]. Along with the importance of the nonadiabatic effects in graphene, higher order electron-phonon scattering processes also significantly impact the phonon spectrum. Specifically, the electron-phonon-induced lifetime and energy renormalization of the electron-hole pair excitations bring additional temperature dependence in the electron-coupled phonon modes and their corresponding linewidths. The nonadiabatic theory relying on first principles calculations, developed in [Phys. Rev. B 98, 041112(R) (2018)], is here successfully applied to graphene in various doping regimes and to Weyl semimetals, which contain a 3-dimensional analog of Dirac points in the electron band structure and are, therefore, excellent candidates for achieving a nonadiabatic regime.

Topological insulator Bi2Se3: the effect of doping with Fe, Ru, Os, and Mo — •Frantisek Maca[1], Stanislav Cichon[1], Vaclav Drchal[1], Katerina Horakova[1], Irena Kratochvilova[1], Jan Lancok[1], Vladimir Chab[1], Patrik Cermak[2], Cestmír Drasar[2], and Jiri Navratil[2] — [1]Institute of Physics CAS, Praha, Czech Republic — [2]University of Pardubice, Pardubice, Czech Republic

Doping is one of the most suitable ways of tuning the electronic properties of topological insulators (TI) and a promising means of a band gap opening. We report a reliable method for preparation of high-quality single crystal substrates Bi2Se3 containing anti-site defects and vacancies and doped with VIIIB and VIB columns elements.

We combine experimental (XPS, ARPES) and theoretical (ab initio) methods to analyze the electronic properties and chemical states of atoms and defects in the substitutional position in TI that can be achieved using the free melt crystallization method of the sample growth. Doping introduced change in the position of Dirac cone is shown and discussed.

O 65.2   Wed 18:00   P2/EG

Green's functions formulation of Floquet topological invariants — •Marcus Meschede, Helena Drüeke, and Dieter Bauer — University of Rostock

Floquet topological insulators (FTIs) allow for topological protection through their time evolution as opposed to static topological insulators, which are only protected by their band topology. FTIs have become ubiquitous in the pursuit of realizing new phases of matter. In general, the momentum-dependent quasi-energy spectrum of single-particle time evolution operators or, equivalently, Floquet Hamiltonians is used to classify the band topology. In the presence of many-particle interactions, this single-particle picture breaks down. In order to overcome this issue, topological invariants of static systems have been formulated through their single-particle Green's functions. [1,2] We expand on this work by calculating Floquet topological invariants through their Floquet Green's function. As there is much experimental work on realizing FTIs, we hope to provide another tool to determine the topological properties of these systems through their bulk spectral function.

Interaction-Induced Directional Transport on Driven Coupled Chains — •Helena Drüeke and Dieter Bauer — Universität Rostock

We examine whether interaction between particles may introduce (topologically protected) directional transport in a driven two-particle quantum system. As a simple example, we consider two one-dimensional chains of equal length, each with one particle. The two particles interact but stay on their respective chain. The particles move alternatingly and without a preferred direction.

Without interaction between the particles, they each diffuse along their chains. Interaction between them suppresses this diffusion. With the proper timing of their alternating movement, the particles form a bound doublon state. Depending on their starting positions, this doublon either remains stationary or moves along the chain. The motion of the doublon consists of alternating, leapfrogging motion of the two particles.

O 65.4 Wed 18:00 P2/EG

Near-field investigation of topologically protected edge states in plasmonic waveguide arrays — •Hans-Joachim Schill, Anna Sidorenko, and Stefan Linden — Department of Physics, University of Bonn, Germany

Light propagation along evanescently coupled waveguide arrays resembles mathematically the dynamics of a lattice Schrödinger equation and is, therefore, ideally suited for simulating condensed matter lattice systems. Here, we report on near-field measurements with scattering-type scanning near-field optical microscopy (s-SNOM) in transmission mode combined with leakage radiation microscopy to investigate topological effects in coupled arrays of dielectric loaded surface plasmon polariton waveguides (DLSPPWs). Specifically, we implement the Su-Schrieffer-Heeger (SSH) model by fabricating arrays of DLLSPPWs with alternating weak and strong couplings. The interface between two topologically distinct domains of the SSH model is known to host a topologically protected edge state. The combination of far- and near-field imaging allows us to investigate the global intensity evolution of the lattice as well as the local amplitude and phase distribution of the edge state.

O 65.5 Wed 18:00 P2/EG

Orbital Protection of a Weyl Nodal line — •Tim Figgemeier[1,3], Maximilian Ünzelmann[1,3], Philipp Eck[2,3], Jakub Schusser[1,3], Jennifer Neu[4,5], Theo Siegrist[4,6], Domenico Di Sante[7], Giorgio Sangiovanni[2,3], Hendrik

Bentmann[1,3,8], and Friedrich Reinert[1,3] — [1]EP VII, Universität Würzburg, Germany — [2]ITPA, Universität Würzburg, Germany — [3]Würzburg-Dresden Cluster of Excellence, ct.qmat — [4]NHMFL, Tallahassee, FL, US — [5]Nuclear Nonproliferation Division, ORNL, Oak Ridge, Tennessee, US — [6]FAMU-FSU, Tallahassee, FL, US — [7]Center for Computational Quantum Physics, Flatiron Institute, New York, US — [8]NTNU, Trondheim, Norway

We present a combined soft X-ray angle-resolved photoelectron spectroscopy (SX-ARPES) and density functional theory study on TaAs and NbP. The two compounds are usually known as paradigmatic non-magnetic Weyl semimetals. Here, however, we show that they further host twofold spin-degenerate nodal lines located at the center of a one-dimensional vortex line of Orbital Angular Momentum (OAM). These momentum space vortices can be tracked experimentally by using k_z-resolved dichroic SX-ARPES. The OAM vortex line protects the spin degeneracy against spin-orbit coupling and imparts high topological robustness to the nodal line. In order to investigate the impact of SOC on the degeneracy experimentally, we compare TaAs with NbP, which differ from each other by having a different magnitude of atomic SOC strength.

O 65.6 Wed 18:00 P2/EG

Towards $higher-order$ topological corner states in quantum spin Hall insulating heterostructures — •Markus Feld[1,2], Philipp Eck[1,2], and Giorgio Sangiovanni[1,2] — [1]ITPA, Universität Würzburg, Germany — [2]Würzburg-Dresden Cluster of Excellence, ct.qmat

Real-space obstruction in $\mathbb{Z}_2$ trivial systems is under current investigation as it promotes quantized electronic bulk multipoles. In two dimensions it can stabilize a $higher-order$ topological insulator (HOTI) with insulating edges and zero energy in-gap corner states. However the recent analysis for the triangular quantum spin Hall insulator (QSHI) indenene has extended the concept of real-space obstruction to $\nu = 1$ phases [1].

We show that this is in contrast to the well established large-gap QSHI bismuthene [2], where the Wannier functions center on the atomic lattice sites. Here we present an *ab initio* based study, where we address the edges and corners of obstructed and non-obstructed interfaces by considering heterostructures of indenene and bismuthene.

Atomically Precise Synthesis and Characterization of Heptauthrene with Triplet Ground State — Xuelei Su[1], Can Li[2], •Qingyang Du[1], Kun Tao[3], Shiyong Wang[2], and Ping Yu[1] — [1]School of Physical Science and Technology, ShanghaiTech University, 201210 Shanghai, China — [2]Key Laboratory of Artificial Structures and Quantum Control (Ministry of Education), Shenyang National Laboratory for Materials Science, School of Physics and Astronomy and Tsung-Dao Lee Institute, Shanghai Jiao Tong University, Shanghai 200240, China — [3]Key Lab for Magnetism and Magnetic Materials of Ministry of Education, Lanzhou University, 730000 LanZhou, China

Heptauthrene, one of the most well-known structures, is a benzene-fused bisphenalenyls in mirror symmetry with triplet ground state. However, it is difficult to synthesize heptauthrene without any substituents due to its high activity. Owing to the development of on-surface synthesis, it is possible to obtain highly active species with properly-designed precursors. Here, we combined in-solution and on-surface synthesis to achieve unsubstituted heptauthrene, whose chemical structure can be characterized with bond-resolved atomic force microscopy. Its triplet ground state is clearly confirmed by the Kondo resonance around zero bias in dI/dV spectra. The response of this Kondo peak to external magnetic field is also detected to verify the high-spin state. We also engineered its spin-state through hydrogen atom addition or dissociation by tip manipulation. Our work provides access to phenalenyl-based structures with high-spin ground states, potentially useful in constructing spin networks.

O 66.2 Wed 18:00 P2/EG

Novel image interpretation methods for high-resolution STM — •Lauri Kurki[1], Niko Oinonen[1], Ondrej Krejci[1], and Adam S. Foster[1,2] — [1]Department of Applied Physics, Aalto University, 00076, Espoo, Finland — [2]WPI Nano Life Science Institute, Kanazawa University, Kakuma-machi, Kanazawa 920-1192, Japan

Scanning tunnelling microscopy (STM) functionalized with a CO molecule on the probe apex is a method capable of capturing sub-molecular level detail of the electronic and physical structure of a sample[1]. However, the produced images are often difficult to interpret due to the convoluted nature of the signal. We

propose image interpretation tools to extract physical and electronic information directly from STM images using machine learning.

In recent years, there has been rapid development in image analysis methods using machine learning, with particular impact in medical imaging. These concepts have been proven effective also in SPM in general and in particular for extracting physical features from atomic force microscopy (AFM) images[2]. We build upon these models and show that we can extract atomic positions and electrostatics directly from STM images. We further explore how the accuracy of these predictions varies with the use of a simultaneous AFM signal and ultimately establish the limits of the approach in an experimental context.

Distance dependence of s- and p-wave contributions in CO-tip STM — •Leonard-Alexander Lieske, Fabian Paschke, Florian Albrecht, and Leo Gross — IBM Research Europe - Zürich, Säumerstrasse 4, 8803 Rüschlikon, Switzerland

Funtionalized tips are frequently used in high-resolution AFM, particularly CO terminated tips, to facilitate atomic resolution [1]. CO functionalized tips can also enhance contrast in STM measurements of ionic resonances, mapping orbital densities [2,3]. For CO tips both *s*- and *p*-wave character of the tip contribute to the contrast [3,4,5]. Here, we study the contributions of *s*- and *p*-wave character of CO tips as a function of tip height, bias voltage and tunneling current.

Atomic-scale imaging of individual cyclic oligosaccharides with non-contact atomic force microscopy — •Márkó Grabarics[1,3], Benjamin Mallada Faes[2,3], Alejandro Jiménez-Martín[2], Pavel Jelínek[2], Bruno de la Torre[2], and Stephan Rauschenbach[1] — [1]University of Oxford, Department of Chemistry, United Kingdom — [2]Institute of Physics of Czech Academy of Sciences, Czech Republic — [3]These authors contributed equally.

Carbohydrates, also referred to as saccharides, are a major class of biopolymers that are essential to all known living organisms. While important in a range of biological processes, the structural complexity of carbohydrates poses a challenge to conventional analytical techinques, which often fail to provide unambiguous structural assignment.

We aim to overcome this challenge by imaging single, surface-adsorbed carbohydrate molecules using high-resolution SPM. For these proof-of-concept experiments, β-cyclodextrin was chosen as model compound, a cyclic oligosaccharide consisting of seven glucose units linked together via α-1,4-glycosidic linkages. Incompatible with thermal evaporation, the molecules were deposited in ultrahigh vacuum onto close-packed noble metal surfaces using electrospray deposition. STM and non-contact AFM with CO-functionalized tips revealed two distinct adsorption geometries, with the individual glucose units clearly resolved within the macrocycles.

Our results demonstrate the potential of high-resolution SPM for the structural characterization of carbohydrates, opening up novel ways for the analysis of this important class of biomolecules.

O 66.5   Wed 18:00   P2/EG

observation and definition of lipid raft in live MCF-7 cell by AFM — •Hsiang-Ling Chuang[1], Yu-Chen Fa[2], Chun-Hsien Chen[1], Lli-Chen Wu[3], and Ja-An Ho[1,2] — [1]department of chemistry, National Taiwan University, Taiwan 10617. — [2]department of biochemical science and technology, National Taiwan University, Taiwan 10617. — [3]department of applied chemistry, National Chi Nan University, Nantou, Taiwan 54561.

Lipid rafts are composed of cholesterol, sphingolipid, and proteins. Previous studies indicated that resveratrol and fibrinogen can bind to the receptor on alpha-v beta-3 integrin. Through the protein-lipid or protein-protein interactions, drug-bound integrins will aggregate into larger raft blocks with unbound integrins. Due to the limitation of optical microscopy and complicated sample preparation, the techniques on lipid rafts observation have shortages of real-time and original state information. In this study, we explore the application of in-situ atomic force microscope (AFM) for the observation of lipid rafts on the cell surface and the response upon the administration of chemicals in real time. We obtained AFM images of morphology and stiffness of live breast cancer cells (MCF-7) in phosphate buffered saline (PBS), resveratrol and fibrinogen solutions to identify the location, drifting and aggregation of lipid rafts. Via cross-comparison of AFM images, the regions are higher and stiffer than the surrounding cell membranes resemble the characteristics of lipid rafts. The developed method may be applicable to identify the location of lipid rafts in real-time and allow us to elucidate complex biological systems at the molecular level.

O 66.6   Wed 18:00   P2/EG

Balanced trolling quartz-based sensor with high quality factor used for atomic force microscopy in the liquid — Rui Lin, •Yingzi Li, Jianqiang Qian, and Peng Cheng — School of Physics, Beihang University, Beijing, China

Quartz tuning fork (QTF) has been widely used in atomic force microscopy (AFM) due to its self-sensing property, high quality factor, and high frequency stability. However, owing to the bulky structure and exposed surface electrode arrangement of QTF, the application of quartz-based AFM sensor in the liquid imaging is limited. One way to solve this problem is to coat the QTF with an insulating layer and immerse it into the liquid. However, it would result in a sharp drop of the quality factor and lead to reduction of force detection sensitivity. Here, a high quality factor AFM sensor based on balanced trolling QTF is proposed. Both prongs of the QTF are glued with same tips to make sure high symmetry of QTF, while only one tip is immersed in the liquid. In this configuration, the hydrodynamic interaction can be reduced so that the quartz-based sensor can maintain a high quality factor, which will improve the sensitivity of force detection in the liquid. A theoretical model is presented to analyze the sensing performance of the balanced trolling quartz-based sensor in the liquid. Then, the sensing performance of the sensor is estimated through experimental tests. Finally, the proposed sensor is applied in AFM imaging on different samples in the liquid. The results validate the high quality of the proposed balanced trolling quartz-based sensor and its feasibility of liquid imaging of AFM.

O 66.7   Wed 18:00   P2/EG

AFM characterization of surface metal oxides with an O-terminated copper tip — •Philipp Wiesener, Bertram Schulze-Lammers, Harald Fuchs, and Harry Mönig — Westfälische Wilhelms-Universität, Münster, Germany

Previously we investigated the performance of various tip terminations, namely Cu-, Xe-, CO-, and O-terminated Cu-tips (CuOx-tips), on the Cu(110)O(2x1) surface with non contact AFM. A direct comparison of the imaging and force-spectroscopy capabilities by these different tip terminations shows, that only for the CuOx-tip a significantly selective force interaction between metal and oxygen atoms can be observerd.

In this work we want to generalize the idea of chemical selective imaging by analyzing a broad spectrum of metal oxide systems with CuOx-tips. We perform constant height measurements over an extendend range of tip sample distances and analyze surfaces that posses varying relative heights of metal and oxygen atoms to probe possible effects on the chemical selectivity. For an additional contrast analysis we investigate various defects of the metal oxide surfaces and complement our site-selective microscopy with force-spectroscopy measuerements on the observerd metal and oxygen atoms.

The performed measurements can be seen as a first step of developing CuOx-tip AFM imaging as an efficient tool for the surface characterization of metal oxide materials. Subsequently, we want to extend our methodology to more complex surface- and bulk metal oxide systems and relate them with complementary DFT calulations and AFM simulations.

O 66.8   Wed 18:00   P2/EG

On-Surface Synthesis of C144 Hexagonal Coronoid with Zigzag Edges — •Xujie Zhu, Yanan Liu, Weiwen Pu, Fang-Zi Liu, Zhijie Xue, Zhaoru Sun, Kaking Yan, and Ping Yu — School of Physical Science and Technology, ShanghaiTech University, 201210 Shanghai, China

Coronoids as polycyclic aromatic macrocycles enclosing a cavity and they can be also regarded as nanoporous graphene molecules whose electronic properties are critically dependent on the size and topology of their outer and inner peripheries. However, because of their synthetic and characteristic challenges, the extended hexagonal coronoids with zigzag outer edges have not been reported yet. Here, we report the on-surface synthesis of C144 hexagonal coronoid with outer zigzag edges on a designed precursor undergoing hierarchical Ullmann coupling and cyclodehydrogenation on the Au(111) surface. The chemical and electronic structure is unambiguously characterized by bond-resolved non-contact atomic force microscopy and scanning tunneling spectroscopy measurements. In combination with the density functional theory calculations, the result is shown that the HOMO-LUMO energy gap oscillates with the size of the central cavity. Moreover, the values of the harmonic oscillator model of aromaticity suggest that the molecular structure is ideally represented by Clars model. Our results provide approaches toward realizing a hexagonal coronoid with zigzag edges, potentially inspiring fabrication of hexagonal zigzag coronoids with multiple radical characers in the future.

O 66.9   Wed 18:00   P2/EG

Setup of a quartz needle sensor-based nc-AFM/STM operating at millikelvin temperatures — •Sven Just[1,2], Taner Esat[1,2], Denis Krylov[1,2], Peter Coenen[1,2,3], Vasily Cherepanov[1,2,3], Bert Voigtländer[1,2,3], Stefan Tautz[1,2], and Ruslan Temirov[1,2,4] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Jülich, Germany — [2]Jülich Aachen Research Alliance (JARA), Fundamentals of Future Information Technology — [3]mProbes GmbH, 52428 Jülich, Germany — [4]Institute of Physics II, University of Cologne, 50937 Cologne, Germany

A non-contact (nc) atomic force microscope (AFM) is developed for operation in ultra-high vacuum at a base temperature of 300 mK. The AFM is based on an ultra-compact quartz needle sensor oscillating at 1 MHz with a 7.5 μm thick tungsten tip glued to one end of the needle allowing for simultaneous operation of AFM and STM [1]. Nanopositioners with resistive readout and a scanner with a large low-temperature scan range of 30×30 μm^2 are used. Additionally, HF wiring for an antenna and a capillary for supply of gases, both close to the junction, are provided. The AFM setup is mounted on a removable insert (mK-stick) for usage in an existing millikelvin system based on adiabatic demagnetization refrigeration (ADR) [2]. Due to the modularity of the mK-sticks a quick exchange is possible without any need for warming up the LHe cryostat.

While offering high resolution atomic and electronic structure, scanning probe microscopy techniques have found greater challenges in providing reliable electrostatic characterization on the same scale. In this work, we offer electrostatic discovery atomic force microscopy, a machine learning based method which provides immediate maps of the electrostatic potential directly from atomic force

microscopy images with functionalized tips. We apply this to characterize the electrostatic properties of a variety of molecular systems and compare directly to reference simulations, demonstrating good agreement. This approach offers reliable atomic scale electrostatic maps on any system with minimal computational overhead.

O 66.11	Wed 18:00	P2/EG
Building up atomically-precise topological heterostructures in one-dimensional conjugated polymers — •Alejandro Jiménez-Martín[1,2,3], Shayan Edaltmanesh[1,2], Benjamin Mallada[1,2], Héctor González-Herrero[4], David Ecija[5], Pavel Jelínek[1,2], and Bruno de la Torre[1,2] — [1]Czech Advanced Technology and Research Institute (CATRIN), Palacký University, Olomouc, Czech Republic — [2]Czech Academy of Sciences, Prague, Czech Republic — [3]Czech Technical University, Prague, Czech Republic — [4]Universidad Autónoma, Madrid, Spain — [5]IMDEA Nanoscience, Madrid, Spain

The discovery of topological phases in acene-based π-conjugated polymers has been one of the most exciting developments in the field of on-surface synthesis [1]. We recently demonstrated that the topological phase transition can be precisely controlled by the length of the polymer [2], where topologically protected zero-mode states forms at the boundary between two interfaces.

In this contribution, we use such new design criteria for engineering the quantum phase to place edge-gap states at specific sites within a single polymer. We investigate the electronic properties and level of hybridization in close enough topological states depending on their separation by Scanning Tunneling Microscopy and non-contact Atomic Force Microscopy. The results presented here could serve as a blueprint for creating topologically protected quantum spin chains.

Fermi-level pinning at InP(001):H surfaces — •Rachele Sciotto, Isaac Azahel Ruiz Alvarado, and Wolf Gero Schmidt — Lehrstuhl für Theoretische Materialphysik, Universität Paderborn, 33095 Paderborn, Germany

Stable InP(001):H surfaces are characterized by fully occupied and empty surface states close to the bulk valence and conduction band edges, respectively [1]. However, photoemission shows a surface Fermi level pinning at midgap energy [2]. In order to resolve that apparent discrepancy, we perform density-functional calculations. Ab initio thermodynamics is used to determine the density of surface defects as a function of temperature and hydrogen pressure. The influence of spin polarization and charging on the electronic properties of the surface defects is studied in detail. It is found that in particular P dangling bonds resulting from H desorption give rise partially filled midgap electronic states that are suitable to explain the experimental findings.

Dielectric anisotropy of heteroepitaxial GaP/AlP films grown on Si(001) from first-principles calculations — •Max Grossmann and Erich Runge — Technische Universität Ilmenau, Ilmenau, Deutschland

Low-defect III-V semiconductor films grown on Si(001) create new opportunities for cost-effective high-performance photovoltaic and optoelectronic devices. The recent work of Nandy et al. [1] shows a route how to drastically reduce the defect concentration of such structures through a thin GaP/AlP buffer layer. The growth of the latter is best monitored via reflection anisotropy spectroscopy (RAS). The theoretical characterization of RAS spectra is therefore vital for the monitoring of semiconductor growth processes as well as the understanding and improvement thereof. For these reasons we analyse the dielectric anisotropy for the case of a GaP/AlP/Si(001) heterostructure through first-principles calculations and compare them to the RAS measurements of Ref. [1]. Hannappel, A Route to Obtaining Low-Defect III/V Epilayers on Si(100) Utilizing MOCVD, Crystal Growth & Design 21, 5603-5613 (2021), 10.1021/acs.cgd.1c00410

O 67.3	Wed 18:00	P2/EG
Photoemission study of a Te Kagome adatom lattice on Pt(111) — •Nicolai Taufertshöfer[1,2], Begmuhammet Geldiyev[1,2], Maximilian Ünzelmann[1,2], Andreas Raabgrund[3], Tilman Kisslinger[3], Lutz Hammer[3], M. Alexander Schneider[3], Hendrik Bentmann[4], and Friedrich Reinert[1,2] — [1]Experimentelle Physik VII, JMU Würzburg — [2]Würzburg-Dresden Cluster of Excellence ct.qmat — [3]Lehrstuhl für Festkörperphysik, FAU Erlangen-Nürnberg — [4]Center for Quantum Spintronics (QuSpin), NTNU Trondheim

Kagome lattices can host a variety of exotic phenomena such as flat bands, topological Dirac physics, or unconventional superconductivity [1]. In this contribution, we investigate the electronic structure of a Pt(111)-(3x3)-Te structure. This phase corresponds to a Kagome adlayer on a strongly reconstructed Pt(111) surface as determined by quantitative LEED-IV and STM. Utilizing angle-resolved photoemission spectroscopy, we find a Fermi surface with a rich structure stemming from a complex manifold of bulk and surface electronic states. Intending to unravel the influence of the Kagome lattice on the surface electronic band structure, we will carefully analyse and discuss our photoemission data. Particular attention will be on the nature of a band located in the close vicinity of the Fermi level at the center of the surface Brillouin zone.

Spin asymmetries in photoemission from PtTe$_2$. — •Muthu Prasath Thirugnanasambandam Masilamani[1], Jakub Schusser[1], Mohammed Qahosh[2], Gustav Bihlmayer[3], Lukasz Plucinski[2], and Friedrich Reinert[1] — [1]Experimentelle Physik VII and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Würzburg, Germany — [2]Peter Grünberg Institut (PGI-6), Forschungszentrum Jülich GmbH, Jülich, Germany — [3]Peter Grünberg Institut (PGI-1) and Institute for Advanced Simulation (IAS-1), Forschungszentrum Jülich and JARA, Jülich, Germany

In our recent work [1], we addressed the occurrence of spin-resolved photoemission signal asymmetries in the Weyl type-II semimetal candidate WTe$_2$. Here, we aim to understand the asymmetric spin texture of electrons photoemitted from surface and bulk states and its relation to the initial state of type-II Dirac semimetal PtTe$_2$ with photon energy of hν = 21.22 eV at room temperature and at 50K. Our spin- and angle-resolved photoemission data were augmented by the one-step model of the photoemission within the spin-polarized relativistic Korringa-Kohn-Rostoker (SPR-KKR) Green's function method of the Munich band structure software package. In order to extract information about the different contributions to the resulting spectral weight and spin polarization, the matrix-element used in our one-step model of photoemission calculations includes all experimental parameters such as photon energy, light polarization and geometry configurations.

O 67.5	Wed 18:00	P2/EG
Quasiparticle lifetime and formation of electronic states at Tellurium–metal interfaces — •Begmuhammet Geldiyev[1,3], Maximilian Ünzelmann[1,3], Philipp Eck[2,3], Domenico Di Sante[2,3], Giorgio Sangiovanni[2,3], Thomas Fauster[4], Hendrik Bentmann[1,3], and Friedrich Reinert[1,3] — [1]Experimentelle Physik 7, Universität Würzburg — [2]Theoretische Physik 1, Universität Würzburg — [3]Würzburg-Dresden Cluster of Excellence ct.qmat — [4]Lst. f. Festkörperphysik, Universität Erlangen-Nürnberg

Properties of interfaces between a device material and metallic contacts can decisively influence the resulting device performance. In particular, the formation of electronic interface states (IS) with short lifetimes could speed up the charge carrier injection [1]. In this contribution, we will discuss the formation of IS at Te – noble metal interfaces, i.e., particularly in a suitable model system AgTe / Ag(111) [2]. Utilizing one- and two-photon photoemission, we find that hybridizations between Te-p_z orbitals with substrate bulk and surface states determine the interface electronic structure. Whilst the AgTe valence band states are located almost completely within the AgTe layer, the wave function of the unoccupied state γ, lying 530 meV above E_F within the projected bulk band gap, has a sizable overlap with the substrate states. Evidence is provided by a rather short lifetime τ = 31 $\pm$ 3 fs of γ as well as by light-polarization-dependent measurements revealing the orbital character of the occupied and unoccupied states.

Accelerating plane-wave-based *ab initio* molecular dynamics by optimization of Fast-Fourier transforms for modern HPC architectures — •Christian Ritterhoff, Tobias Klöffel, Sagarmoy Mandal, and Bernd Meyer — Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg, Germany

The most important advantage of plane-wave basis sets is that wave functions can be transformed efficiently from reciprocal to real space and back by using the Fast-Fourier transform (FFT) algorithm. This allows to evaluate the kinetic

and potential energy in reciprocal and real space, respectively, where both operators are diagonal. This reduces the computational cost for applying the Hamilton operator from N^2 to $N \log N$. However, the scalability of current FFT libraries is rather limited on today's HPC systems, which offer large numbers of compute nodes, each of them with many cores. Here we present our optimization of the FFTX library of the Quantum Espresso software package. Data distribution and communication patterns have been revised to make optimal use of combined MPI and OpenMP parallelization. Scalability is further increased by combining FFTs into batches and by introducing overlapping computation and communication. We implemented the revised FFTX library in our optimized version of the CPMD code [1], and we demonstrate the achieved acceleration by a series of benchmark simulations.

Comparison of machine learning strategies in the high-throughput exploration of ABO_2 **delafossites** — •Armin Sahinovic, Benjamin Geisler, and Rossitza Pentcheva — Fakultät für Physik, Universität Duisburg-Essen

The advent of machine learning introduced new techniques to considerably expedite materials discovery. This raises a fundamental question about how they balance interpretability versus accuracy. We address this aspect by comparing ensemble-based active learning (AL) of neural networks (NN) [1] and the sure independence screening and sparsifying operator (SISSO) [2] for the prediction of formation energies and lattice parameters in ABO_2 delafossite oxides. To this end, we generate a consistent dataset from first principles. Element embedding is found to be superior to scalar input strategies, e.g., atomic properties. In conjunction with AL, the NNs reach DFT accuracy, allowing for a significant acceleration of high-throughput materials screening. In contrast, the precision of the physically interpretable SISSO descriptors is limited by the high data complexity. We combine ABO_2 infinite-layer, ABO_3 perovskite [1] and the delafossite data to extend the unsupervised AL into the structural space, thereby enhancing the sample efficiency in the spirit of transfer learning. Finally, we compile a phase diagram that compares the relative stability of the three distinct oxide materials classes.

Spin-polarized very-low-energy electron diffraction from spin-orbit- and/or exchange-influenced targets — •Christoph Angrick[1], Christian Thiede[1], Andre Reimann[1], Annika Henriksen[1], Nicole Mutzke[1], Moritz Ewert[2,3], Lars Buss[2,3], Jens Falta[3], Jan Ingo Flege[2], and Markus Donath[1] — [1]University of Münster, Germany — [2]BTU Cottbus-Senftenberg, Germany — [3]University of Bremen, Germany

Exchange (XC) or spin-orbit (SOC) interaction cause electron scattering from surfaces to be spin dependent. The resulting spin filtering of the scattered electron beam can be used in spin-polarization analyzers. These analyzers are implemented in, for instance, photoemission setups to obtain spin resolution. Therefore, for promising targets, electron reflectivity and resulting spin asymmetry of very-low-energy electrons are measured for a wide range of incident electron energies and angles. By this, the investigated target is put to a test regarding the usability as a scattering target in a spin-polarization analyzer.

Here, several results of SOC- as well as XC-influenced targets are presented.

The results of the SOC-influenced targets Au(111), single-layer MoS_2/Au(111) and W(110) [1] are compared with the results of the XC-influenced target Fe(001)-p(1x1)O [2]. Additionally, the influence of SOC interaction in the case of the XC-influenced target is investigated. The spin asymmetry caused by SOC is found to be one order of magnitude smaller than the spin asymmetry caused by XC.

Exploring electronic structural properties of Copper(Cu) via Auger Photoelectron Coincidence Spectroscopy — •Swarnshikha Sinha[1,2], Danilo Kühn[1], and Alexander Föhlisch[1,2] — [1]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Albert-Einstein-Strasse 15, 12489 Berlin, Germany — [2]Universtät Potsdam, Institut für Physik und Astronomie

The electronic structure of the 3d transition metals are immensely influenced by many electron effects. Photoemission spectroscopy (PES) and Auger electron spectroscopy (AES) can help to learn about screening processes in core excited states and electron correlations in two-hole final states, respectively.

However, in Cu 3p photoemission and MVV Auger decay, the final state holes are located in the same main shell as the initial vacancy, leading to strong lifetime broadening in the spectra. APECS, can help in reducing lifetime broadening and revealing overlapping spectral features. [1] A comparative study of three different copper surfaces (111,110 and 100) was conducted using APECS, at the CO-ESCA station, UE52 PGM beamline at BESSYII [2].Our results confirm a strong energy sharing between the Photo and Auger electrons [3]and substantial differences in the screening of the final states, leading to different asymmetry of the atomic multiplet peaks in the two-hole spectra of the three Cu surfaces.

Improved convergence of the density response function by an incomplete-basis correction — •Jörn Stöhler[1,2], Markus Betzinger[1], Stefan Blügel[1], and Christoph Friedrich[1] — [1]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, Germany — [2]RWTH Aachen University, Germany

The polarizability (or density response function) is a central quantity in many electronic structure methods, e.g., the GW approach, the random-phase-approximation (RPA) total-energy method, the optimized effective potential method, the Bethe-Salpeter approach, Coulomb-hole screened-exchange (COH-SEX). In time-dependent perturbation theory, the polarizability can be expressed as a sum over unoccupied states. However, the resulting sum-over-states expression converges very slowly with respect to the number of bands or the basis-set size, in particular, in systems containing localized d- and f-states. Here, we discuss a method, called incomplete-basis-set correction [1,2], which augments the sum-over-states expression with a numerical solution of the radial Sternheimer equation in the atomic (muffin-tin) spheres. The method is implemented in the Spex code within the FLAPW approach. The resulting polarizability shows a considerably improved convergence behavior with respect to the basis set and the number of unoccupied states.

Sub-nanometer depth profiling of native transition metal oxide layers within single XPS spectra — •Martin Wortmann, Dominik Graulich, Natalie Frese, and Timo Kuschel — Bielefeld University, Bielefeld, Germany

Many transition metals form a thin oxide layer of only few nanometers upon exposure to the atmosphere, which affects their interfacial properties. Such native oxide layers are commonly analyzed using photoemission spectroscopy (PES) and X-ray photoelectron spectroscopy (XPS) in particular. The most common method to obtain compositional depth profiles in PES is based on gradual surface ablation by ion sputtering. However, it is known to affect the microstructure of the surface, compromising depth-resolution and compositional accuracy. Other methods such as angular-resolved, energy-resolved, or hard X-ray PES are associated with considerable experimental effort or demands on sample texture. Here we propose a simple and accessible approach for sub-nanometer depth profiling of native metal oxide layers within single lab-XPS spectra. Heavy transition metals usually have multiple orbital energies within the energy range of a lab-XPS giving rise to peak regions at various binding energies. The signal contributions

of oxidized and elemental metals can be distinguished by peak deconvolution. The kinetic energy of the photoelectron determines its inelastic mean free path (IMFP) length, which is a measure for the depth from which information is obtained. Different binding energies can thus be assigned to different values for IMFP, so that an oxide concentration profile can be inferred from a single XPS spectrum.

Ab-initio investigations of the order of K^+ ions on cleaved muscovite mica — •Andrea Conti, Giada Franceschi, Michael Schmid, Ulrike Diebold, and Florian Mittendorfer — Institute of Applied Physics, TU Wien, Wiedner Hauptstrasse 8-10/134, 1040 Vienna, Austria

Model systems based on single crystals can help to provide a better understanding of the chemistry and the catalytic activity of a given oxide surface. In this work, we present DFT calculations on the surface of muscovite mica, a common phyllosilicate whose structure consists of alternating layers of aluminosilicates and K^+ ions. This material easily splits into thin K-terminated sheets, yet the atomistic order of the surface K^+ ions has been, until recently, unknown

[Franceschi *et al.*, *submitted* (2022)]. Calculations, using the "Vienna Ab-initio Simulation Package" (VASP) and the metaGGA (r^2SCAN) exchange-correlation functional, indicate a close correlation between the distribution of the surface K^+ ions and the arrangements of the subsurface Al^{3+} ions: the K^+ ions preferentially occupy the Al-rich rings. In addition, the calculated diffusion barriers suggest that the K^+ ions are mobile enough at room temperature to jump to more favorable sites. AFM simulations, using the Probe Particle Model, are in good agreement with the experimental images.

O 68.3   Wed 18:00   P2/EG

Vanadium and iron intermixing in honeycomb oxides on Pt(111) and Ru(0001) — •Piotr Wemhoff[1], Claudine Noguera[2], Jacek Goniakowski[2], and Niklas Nilius[1] — [1]Carl von Ossietzky University, Institute of Physics, D-26111 Oldenburg, Germany — [2]CNRS-Sorbonne University, UMR 7588, INSP, F-75005 Paris, France

Whereas V and Fe are immiscible in bulk-type perovskite oxides, mixed oxide honeycomb layers can be prepared on Pt(111) and Ru(0001) surfaces. Their atomic composition is accessible from bias-dependent STM topographic images, as the Fe ions develop a protruding contrast with respect to V when tunneling into their 3d(z2) orbitals at elevated bias. On Pt(111), up to 50% iron can be incorporated into a V2O3 host oxide, whereby the Fe runs through a series of distinct configurations evolving from isolated ions to pairs in 3rd neighbor positions, short chains of 2nd neighbor Fe and finally ordered (2x2) V/Fe islands separated by domain boundaries. The observed phase behavior can be traced back to attractive Fe-V and repulsive Fe-Fe pair interactions, which have been identified by DFT calculations and enable perfect reproduction of the experimental patterns by means of Monte-Carlo simulations. In contrast, a V/Fe self-organization scheme becomes active on Ru(0001) that only allows for one unique cation arrangement in the honeycomb oxide. DFT finds a layer of interfacial oxygen between Ru(0001) and the oxide film to be responsible for this rigid structural composition.

O 68.4   Wed 18:00   P2/EG

Atomic View on the (111) Surface of a Cu2O Single Crystal: Reconstruction, Electronic Properties and Band Bending Effects — Alexander Gloystein, Jack Creed, and •Niklas Nilius — Carl von Ossietzky University, Institute of Physics, D-26111 Oldenburg, Germany

The nature of the (sqrt3xsqrt3)R30° reconstruction of the Cu2O(111) surface has been heavily debated for almost 30 years. This work demonstrates that the nano-pyramidal reconstruction model that was recently developed for Cu2O(111) thin films is valid also for bulk samples. Well-prepared crystals develop a robust (sqrt3xsqrt3)R30° superstructure in electron diffraction, while atomically resolved STM images display extended arrays of trifold symmetric protrusions with 10.5 Å periodicity. Both findings are in perfect agreement with the nano-pyramidal model, in which Cu4O units attach to every third Cu-O six-ring of a Cu-depleted (111) surface. STM conductance spectra reveal the p-type character of the oxide with the valence-band top pinned to the Fermi level. From band-bending effects in the tip electric field, an induced carrier concentration of 6x10^17 cm-3 is determined for the (sqrt3xsqrt3)R30° phase, increasing to 4x10^18 cm-3 on the few (1x1) patches covered with a Cu-poor minority phase. This difference reflects the close interplay between atomic structure, electronic properties and local screening response for a given surface termination.

The Surface Chemistry of Hydrated Lime - Wave Optics tested on a Model System — •Nils Schewe[1], Thomas Mayerhöfer[2], Hicham Idriss[1], and Christoph Wöll[1] — [1]Institute of Functional Interfaces (IFG), Karlsruhe Institute of Technology (KIT), Hermann-von-Helmholtz-Platz 1, Eggenstein-Leopoldshafen, 76344, Germany — [2]Institut für Physikalische Chemie, Friedrich-Schiller-Universität Jena, Jena, 07745, Germany

We report on the results of a combined experimental and theoretical study of the interaction of sulfur dioxide with a calcium hydroxide single crystal surface. Our investigation of this model system for flue gas desulfurization and concrete corrosion was carried out on the Ca(OH)2 (001) surface under ultra-high-vacuum conditions. Combining polarization resolved UHV infrared reflection absorption spectroscopy (IRRAS) with calculations based on wave optical considerations, we were able to demonstrate the adsorption behavior and mode of SO2 on this surface. We show, that the preferred angle of adsorption is 23 ° below 65 K. Heating does not lead to reaction, but fully desorbs the formed adsorbate after crystallization between 80 - 100 K. Additionally, we were able to obtain the first low energy electron diffraction (LEED) pattern of an alkaline earth metal hydroxide by using UHV exfoliation for cleaning.

Understanding the mechanism of Li-mediated nitrogen reduction reaction — •Yuanyuan Zhou and Jens K. Nørskov — Department of Physics, Technical University of Denmark, Kongens Lyngby, Denmark

Green ammonia production is a key environmental goal. As a crucial step towards this goal, a direct electrocatalytic N_2 reduction (eNRR) by protons and electrons emerges as a highly desirable alternative. However, all pragmatic attempts to develop such an electrochemical route have so far been hindered by invariably low selectivities and large overpotentials. The most reliable method presently is the lithium-mediated eNRR (LiNR) in non-aqueous electrolytes.[J. Choi *et al.* Nat. Commun. 11, 1-10 (2020)] Despite significant progress made to achieve high FE and current density [K. Li *et al.* Science 374, 1593-1597 (2021), S. Li *et al.* Joule, 6, 2083-2101 (2022)], the mechanism of LiNR is yet not fully understood due to so many intricate processes involved ranging from the atomic scale to the macroscopic scale. Moreover, most Li-NRR studies have the limitations of using a sacrificial solvent as proton donors and difficulties in scaling up production in batch reactors. The talk will, address the long-term stability and high activity of PtAu in the HOR process by suppressing the unwanted THF oxidation and improving the tolerance towards CO-poison. Futhermore, the crucial step for achieving an improved understanding the dynamic change of the solid-electrolyte interphase in different LiNR reaction conditions and the effect on the performance.

When qualitative do not imply quantitative differences: Analyzing the oxygen reduction reaction using first-principles kinetic Monte Carlo simulations. — •Elia Zonta[1], Younes Hassani Abdollahi[1,2], Karsten Reuter[1], and Sebastian Matera[1,2] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Institute for Mathematics, Freie Universitaet Berlin, Germany, Germany

The oxygen reduction reaction (ORR) is one of the major bottlenecks for the efficiency of fuel cell devices. We implemented a first-principles kinetic Monte Carlo model for this reaction on Pt(111) using a mechanism from literature [1]. This model possesses two reaction pathways contributing to the electrochemical current density. Disabling one of these pathways results in an identical simulated Tafel plot for this reduced model, as compared to the original model with both pathways being active. One might conclude that the turned off pathway is effectively inactive also in the original model and, especially, has no impact on the qualitative kinetics. However, a detailed analysis reveals that both models lead to very different surface coverages and, particularly, exhibit different rate-determining steps. Thus, these qualitative microkinetic differences do not lead to any quantitative differences in the macrokinetic behavior.

Electric Double Layer effect on outer-sphere benzyl halides electro-reduction mechanism — •Aleksandr Kramarenko[1], Felix Studt[1], and Evgeny Pidko[2] — [1]Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]TU Delft, Delft, The Netherlands

Electrocatalytic CO2 fixation is one of the most efficient methods of carbon dioxide conversion, which can be carried out at room temperature and pressure. Thus, the fixation of carbon dioxide with electrochemically activated benzyl halides is an environmentally friendly and ambitious method for the synthesis of the most important carboxylic acid derivatives, which are invaluable for pharmaceuticals and fuel production. For these types of processes, electrocatalysis is a key technology, where electrified interfaces are the main object of study and where the electrochemical potential determines the stability of adsorbed particles and the structure of the electric double layer (EDL) on the electrode surface. Therefore, it is important to gain insight into the electrode-electrolyte interface and the rate-determining reaction steps in order to improve electrode material selectivity and product yields. The combination of first principles and molecular dynamics simulations gives us a good understanding at the molecular level of charged interface phenomena and allows us to study elementary chemical processes in detail, which sheds light on how to improve electrocatalytic reactivity.

O 69.4   Wed 18:00   P2/EG

Atomistic electric double layer modeling of water/metal interfaces from AIMD and continuum approaches — •Sung Sakong and Axel Gross — Ulm University, Ulm, Germany

Electrochemical interfaces are typically associated with forming an electric double layer (EDL) whose theoretical modeling requires an appropriate description

of the polarization of the electrode and the electrolyte. In principle, ab initio molecular dynamics (AIMD) simulations are the natural choice as they reliably treat the competing water-water and water-metal interactions and explicitly consider the electronic degrees of freedom [1]. However, this approach is computationally still very demanding and only allows simulations of relatively small canonical ensembles for limited simulation times. Thus, there is a need for computationally less demanding but still reliable approaches to model the EDL. By comparing EDL properties calculated from a continuum method based on a grand canonical scheme [2] with ab initio atomistic approaches [3], we will provide an outlook on possible future directions in the EDL modeling [4].

Water/InP(001) from Density Functional Theory — •Isaac Azahel Ruiz Alvarado and Wolf Gero Schmidt — Lehrstuhl für Theoretische Materialphysik, Universität Paderborn, Paderborn, Germany

Water adsorption on the In-rich and P-rich InP(001) surface is studied by density functional theory [1]. Single water molecules attach to three-fold coordinated surface In atoms on In-rich surfaces. Dissociative water adsorption is energetically favorable, but hindered by an energy barrier that decreases with increasing water coverage. The oxygen and hydrogen evolution reactions on InP are characterized by overpotentials of the order of 1.7-1.8 and 0.2-0.3 eV, respectively. The In-rich InP surface band edges lie above the redox potential for oxygen and favors hydrogen evolution. Water adsorption is less favorable on P-rich surfaces and characterized by weak physisorption due to charge accumulation between the water O atom and second-layer In surface atoms.

O 69.6   Wed 18:00   P2/EG

CO_2 Electroreduction Reactions at Gold and Copper Electrodes in Ionic Liquids — •Björn Ratschmeier, Gina Ross, and Björn Braunschweig — University Münster, Institute of Physical Chemistry, Münster, Germany

Room-temperature ionic liquids (RTIL) can play a major role in CO_2 reduction reactions in mitigation of existing problems of aqueous electrolytes, such as high overpotentials and product selectivity. In this context, we have studied the influence of Au(111), Cu(111) single crystals, as well as Cu enriched Au(111) electrodes prepared by Cu underpotential deposition with Cu coverages of 1/3, 2/3 and 3/3, in 1-butyl-3-methylimidazolium trifluorosulfonylimide [BMIM][NTf$_2$] for CO_2RR. For Au and Cu enriched Au electrodes we observed high selectivity for H_2 and CO formation, with onset potentials at around -1.0 V vs SHE and a H_2/CO syngas ratio between 0.2-0.4, whereas for Cu only H_2 and traces of CO were detected until 1.5 V. By increasing the degrees of coverage of Cu on Au, we were able to modulate the syngas ratio to an optimum ratio of about 1.8 for a monolayer of Cu on Au(111), which approaches the ideal ratio of 2 for Fischer-Tropsch synthesis of hydrocarbons.

Exploring charge transfer at electrified interfaces via *ab initio* thermopotentiostat molecular dynamics — •Florian Deissenbeck[1], Mira Todorova[1], Christoph Freysoldt[1], Jörg Neugebauer[1], and Stefan Wippermann[1,2] — [1]Max-Planck-Institut für Eisenforschung, Düsseldorf — [2]Philipps-Universität Marburg

Developing accurate simulation techniques to explore and predict structural properties and chemical reactions at electrified liquid/solid interfaces will be critical to surmount materials-related challenges in the context of energy conversion and storage. Exciting progress in recent years allows us now to realistically describe electric fields at charged surfaces from first principles. Building on these techniques, we recently introduced a "thermopotentiostat": a novel approach to control the electrode potential in molecular dynamics (MD) simulations [1]. We demonstrate how to implement the thermopotentiostat into density-functional codes [2]. Using ab initio thermopotentiostat MD simulations, we explore the splitting of liquid water and charge transfer reactions at electrified Si and Ge surfaces.

Density functional calculations of diffusion paths of methyl thiolate on c(2x2)Cl- and Br-covered Cu(100) surfaces — •Falk Wendorff and Eckhard Pehlke — Institut für Theoretische Physik und Astrophysik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany

The surface dynamics of methyl thiolate on Cu(100) surfaces has been studied with video-STM in an electrochemical environment by Yang et al. [1]. Here we present density functional calculations for the diffusion paths and diffusion energy barriers using PWscf and PWneb from the Quantum ESPRESSO package

[2]. The diffusion path of CH_3S_{ad} substitutionally adsorbed on the c(2x2)Cl- or Br-Cu(100) surface without further halogen vacancies has been inspired by the 'rotation' diffusion path of S_{ad} on these surfaces [3]. Additional vacancies in the halogen adlayer enable further diffusion paths of CH_3S_{ad} with significantly lower energy barriers. In case of the Cl coadsorbate the barrier decreases from 1.2 eV to 0.7 eV and in case of Br from 1.6 eV to 0.8 eV. The dipole moment change between the adsorption position and the transition state is negative, which is consistent with the experimental observations by Yang et al. that a more positive sample potential leads to a higher energy barrier [1,4].

Growth and structure formation of [EMIm][OTf] on Au(111) — Jonas Hauner[1], •Hanna Bühlmeyer[1], Simon Trzeciak[2], Julien Steffen[3], Dirk Zahn[2], Andreas Görling[3], and Jörg Libuda[1] — [1]Interface Research and Catalysis, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstraße 3, 91058 Erlangen, Germany — [2]Computer Chemistry Center, Department of Chemistry and Pharmacy, Friedrich-Alexander-Universität Erlangen-Nürnberg, Nägelsbachstraße 25, 91052 Erlangen, Germany — [3]Chair of Theoretical Chemistry, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstraße 3, 91058 Erlangen, Germany

The growth mechanisms of ultrathin ionic liquid (IL) films have recently received considerable attention. We report on *in situ* studies of 1-ethyl-3-methylimidazolium trifluoromethanesulfonate ([EMIm][OTf]) on Au(111). The IL thin films were prepared by physical vapor deposition and investigated by scanning tunneling microscopy (STM). We carried out measurements at various sample temperatures and coverages, and identified three different surface structures. At low coverage, [EMIm][OTf] tends to exhibit a 2D-glass structure growing close to gold terraces and the elbows of the well-known herringbone structure of Au(111). Oblique and hexagonal structures of the IL are visible at higher coverage. With temperature-dependent measurements, possible phase transitions and melting points of [EMIm][OTf] were investigated. Small glasslike islands of IL melt at 190 - 200 K resulting in a mobile phase of 2D liquid/gas. Islands with highly ordered structures are stable up to 300 K.

In situ surface X-ray diffraction studies of Pt(110) — •Finn Schröter[1], Jan Ole Fehrs[1], Timo Fuchs[1], Jakub Drnec[2], Marta Mirolo[2], David Harrington[3], and Olaf Magnussen[1] — [1]Christian-Albrechts Universität zu Kiel — [2]European Synchrotron Radiation Facility — [3]University of Victoria

The surface oxidation of platinum is an important process in the degradation of platinum electrocatalysts in PEM fuel cells, limiting their lifetime. Its atomic-scale mechanism has been addressed in extensive studies by structure-sensitive in situ techniques. However, these studies up to now have been restricted to room temperature, whereas real fuel cells operate at elevated temperatures of 60°C or higher. We here present first temperature-dependent of the surface oxidation of Pt(111) electrodes in perchlorate solution by in situ high-energy surface X-ray diffraction (HESXRD) The measurements were performed at the ID31 beamline of the European Synchrotron Radiation Facility using photon energies of 70 keV. The kinetics of oxidation-induced extraction of Pt atoms out of the surface was quantitatively determined and correlated with the electrochemical charge transfer measured simultaneously in the experiments. The work was funded by the Deutsche Forschungsgemeinschaft via grant 418603497 and the BMBF via project 05K19FK3.

The self-assembly process of helical molecules — Thi N. Ha Nguyen[1], F. Günther[2], K. Preis[1], •J. Kelling[1], C. Tegenkamp[1], and S. Gemming[1] — [1]Institut für Physik, TU Chemnitz, Chemnitz — [2]Instituto de Fisica de Sao Carlos, Universidade de S\~{a}o Paulo, Sao Carlos, Brazil; Instituto de Geocincias e Ciencias Exatas, Universidade Estadual Paulista, Rio Claro, Brazil

Helical polyalanine (PA) molecules gathered a lot of interest as the propagation of electrons along the helical backbone structure comes along with spin polarization. Via liquid and solid scanning tunneling microscopy (STM) we studied the ordering of physisorbed and chemisorbed PA molecules on HOPG and Au surfaces. While enantiopure PA molecules adsorb in a hexagonally close-packed structure, we found heterochiral dimers with a rectangular unit cell for DL-PA. Despite the steric hindrance, the packing density of the DL-PA heterophase is increased by 25% compared to the enantiopure PA structure. Apparently, this is achieved by shifting D- and L-PA along their helical axis. Moreover, the alpha-helix structure of the PA molecules seems to be preserved; thus, electrostatic forces indeed play an important role for the formation and stabilization of the helical structure. In parallel, the interactions between PA homo- and heterochiral pairs were analyzed by van-der-Waals-corrected DFT-based tight binding calculations. Denser packing geometries can be reached by heterochiral PA pairs.

Second, coarse-grained classical potentials were derived from the DFTB data, and the different PA phases seen in STM were also successfully obtained from Monte-Carlo simulations.

DFT calculation of the S_{ad} diffusion energy barriers on Ag(100) in the presence of Br coadsorbates — •SÖNKE BUTTENSCHÖN and ECKHARD PEHLKE — Institut für Theoretische Physik und Astrophysik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany

Coadsorbed halides are known to affect the adatom diffusion on metal surfaces [1]. As a prerequisite for theoretical modelling of the S_{ad} diffusion on Ag(100) as a function of Br coverage, we have calculated the effect of single and multiple Br coadsorbates on the S_{ad} adsorption energy as well as on the energy at the transition geometry along the S_{ad} diffusion path for various Br coadsorbate configurations with Br coverages up to 0.25. The density functional total-energy calculations have been carried through with PWscf and PWneb from the Quantum ESPRESSO package [2]. The dipole moment of S_{ad} is negative. It is larger in magnitude at the transition state (TS) than at the adsorption position. Averaged over the considered S-Br configurations the absolute value of the S_{ad} dipole moment has a tendency to decrease with Br coverage in qualitative agreement with a depolarization model. After similar averaging, for the TS configurations the superposition of individual S_{TS}-Br pair interaction energies tends to overestimate the actual S_{TS}-Br interaction. Funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation), project 504552981.

Correlation between electrostatic and hydration forces on silica and gibbsite surfaces: An Atomic Force Microscopy Study — •IGOR SIRETANU, ARAM KLAASSEN, and FRIEDER MUGELE — Physics of Complex Fluids Group, MESA+ Institute, Faculty of Science and Technology, University of Twente, PO Box 217, 7500 AE Enschede, The Netherlands

The balance between hydration and Derjaguin Landau Verwey Overbeek forces at solid-liquid interfaces controls many processes, such as colloidal stability, elec- trochemistry and ion adsorption. Yet, the hydration forces origin and their relation to the surface charge density controlling the continuum scale electrostatic forces are poorly understood. We argue that these two types of forces are largely independent of each other. Here we performed AFM using intermediate-sized tips that enable the simultaneous detection of DLVO and oscillatory hydration forces at the interface between gibbsite:silica-aqueous electrolyte interfaces. We extract surface charge densities from forces using DLVO theory in combination with a charge regulation boundary conditions for variable pHs and salt concentrations. We simultaneously observe both DLVO and oscillatory hydration forces for an individual crystalline gibbsite particle and the amorphous silica for all fluid compositions. While the diffuse layer charge varies with pH as expected, the oscillatory hydration forces are largely independent of pH and salt concentration, supporting our hypothesis that both forces indeed have a very different origin. We rationalize this based on the distribution of OH groups available for H-bonding on the two distinct surfaces.

The interfacial (electronic) structure of InP(001) in contact with electrolytes studied via computational Reflection Anisotropy Spectroscopy — •VIBHAV YADAV[1], MARGOT GUIDAT[1,2], MARIO LÖW[2], JONGMIN KIM[1,2], HOLGER EUCHNER[1], and MATTHIAS M. MAY[1,2] — [1]Institute of Physical and Theoretical Chemistry, University of Tübingen — [2]Institute of Theoretical Chemistry, University of Ulm, Germany

Controlling the electrochemical interface of III-V semiconductors is of great relevance for hydrogen production in Photoelectrochemical water splitting devices. Under operating conditions InP surfaces in contact with the electrolyte can undergo polymerization or dissolution, with the possible formation of In-O-In as charge recombination centers [1,2]. In this work, we vary the oxygen adatom coverage on In-rich and P-rich InP(001) surfaces using Density-functional Theory. Furthermore, we show that combining computational and experimental Reflection Anisotropy Spectroscopy has the potential to provide a better understanding of InP surfaces and their (electronic) structure under applied potentials.

Phase correction and stability of a Mach-Zehnder interferometer for 2D electronic spectroscopy — •SIMON DURST, SANCHAYEETA JANA, CHRISTOPH SCHNUPFHAGN, and MARKUS LIPPITZ — University of Bayreuth

Fluorescence detected 2D electronic spectroscopy (F-2DES) allows the measurement of ultrafast electron dynamics in complex systems, while disentangling this spectral information from energetically similar phenomena, such as molecular vibration.

The technique requires an excitation signal of four time-delayed laser pulses, which we create via a four-arm Mach-Zehnder interferometer. This interferometer receives a single pulse as an input, and, through the use of delay stages and acusto-optical modulators, outputs a desired pulse train with frequency-modulated phase profiles, used for lock-in detection.

When exciting a sample with this pulse train, special attention must be given to the phase relation between the individual pulses. A mismatch or instability in their spectral phase leads to an excitation with pulses of different lengths or unknown delays and will overall worsen the performance of the setup.

Therefore, this poster highlights the techniques and instruments we use to characterize and compensate the relative phase between the different interferometer arms: GVD correction using a spatial light modulator, a prism compressor setup and interferometric delay scans.

In-Situ TEM Study of Structural and Optical Changes by Laser-Induced Grain-Growth — •JAKOB HAGEN, MURAT SIVIS, and CLAUS ROPERS — Max-Planck-Institute for Multidisciplinary Sciences, Göttingen, Germany

Resonantly excited surface-plasmons (SP) can be exploited in various scientific fields [1] and have thus sparked widespread attention. One major characteristic of these collective free-electron oscillations is the ability to localize and enhance electromagnetic fields beyond the diffraction limit [2]. Here, we created Aluminum nanodiscs by electron beam lithography (EBL), which are polycrystalline in nature. In general, single-crystalline structures are preferred because high optical quality can be obtained due to the absence of propagation-damping grain boundaries [3]. Using annealing in an ultrafast transmission electron microscope (TEM) with a pulsed laser source, a grain-growth process could be driven where the boundary migration was observed frame by frame. Upon illumination, the number of grains reduced drastically, leading to almost perfect mono-crystals while preserving the shape. In addition, optical characterization of SPs by photon-induced near-field electron microscopy (PINEM) [4] was carried out before and after annealing. Our approach fuses the precise, nanometric positioning from EBL with the benefits of mono-crystalline plasmonics [5].

Gold nanoparticles as scannable plasmonic light source for STM enabled electroluminescence — •CINJA S. MÜLLER, BERK ZENGIN, ALEŠ CAHLÍK, and FABIAN D. NATTERER — Department of Physics, University of Zurich, Winterthurerstrasse 190, CH-8057, Switzerland

The preparation of high quantum yield tips for electroluminescence includes the use of plasmonic metals, by either making tips from wires of coinage metals or coating of tungsten (or Pt/Ir) tips by violent indentation into Au or Ag crystals. While the former appears as the most logical choice, tips made from ductile coinage metals tend to be mechanically unstable. The plunging of tungsten tips into metal substrates, on the other hand, is rather crude and irreproducible. Here, we attempt to use concepts from both extremes by attaching gold nanoparticles (AuNP) onto the apex of tungsten or Pt/Ir tips. We drop-cast commercially available colloidal AuNP onto a graphite substrate from which the AuNP may be transferred to the STM tip by gentle contact. We describe our setup and characterize the electroluminescence using a fiber-coupled single photon counter.

Neuromorphic plasmonic computing - Surface plasmon polariton neurons — •MARIO F. PFEIFFER[1], TOBIAS EUL[1], EVA PRINZ[1], BENJAMIN STADTMÜLLER[1,2], and MARTIN AESCHLIMANN[1] — [1]Department of Physics and Research Center OPTIMAS, University of Kaiserslautern, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, Germany

Today, the classical electronic computer architecture is the limiting factor for faster, and energy efficient data processing. In combination with the rapidly increasing use of artificial intelligence in science and industry, additional ap-

proaches for a suitable hardware architecture are necessary. For this reason, neuromorphic photonics emerged as a novel research field for new classes of information processing devices that incorporate photonically integrated neural networks [1].

The hybrid nature of surface plasmon polaritons (SPPs) combines photonic advantages such as high bandwidth and speed with strong electronic interactions. These properties have the potential to further advance the development of new hardware. Here we present a concept for building an artificial neuron based on SPP interactions. We have designed initial building blocks of the neuron based on finite-difference time-domain simulations of the plasmonic response. Finally, we imaged this response using a photoemission electron microscope.

Optical writing of switchable mid-infrared surface phonon polariton resonators with the plasmonic phase-change material In$_3$SbTe$_2$ — •Luis Schüler, Lukas Conrads, Konstantin Georg Wirth, Matthias Wuttig, and Thomas Taubner — I. Institute of Physics (IA), RWTH Aachen University

Chalcogenide-based phase-change materials (PCMs) are prime candidates for active nanophotonics. They can be reversibly switched between an amorphous and a crystalline state, which exhibit a strong contrast in optical and electrical properties [1]. Therefore, PCMs can be used, for example, to tune surface phonon polariton (SPhP) resonances in the infrared [2]. The recently introduced PCM In$_3$SbTe$_2$ (IST) possesses a crystalline phase which is metallic in the entire infrared range. It allows for direct writing of arbitrary resonant structures in a dielectric surrounding [3], which could also confine SPhPs in cavities of subwavelength size. However, an investigation of different confined modes in those cavities with IST has not been performed yet. Here, we investigate IST on a SiC substrate. By laser-induced phase switching, we define various SPhP resonator structures, such as circular cavities, and measure their resonant behavior with optical near- and far-field methods. This study is a first step towards rapid prototyping of switchable SPhP resonators of arbitrary shape that could be employed, for example, in chemical sensing and active metasurfaces.

Enhanced Second Harmonic Generation from Silver Nanoantennas — •Fabian Scheidler, Johanna Klos, Jessica Meier, Luka Zurak, and Bert Hecht — Nano-Optics and Biophotonics Group, Experimental Physics 5, University of Würzburg, Am Hubland, 97074 Würzburg, Germany

Plasmonic gold nanostructures allow to achieve large field enhancement in nanoscale volumes and are therefore appealing to boost nonlinear processes such as second harmonic generation (SHG). Especially intense near-field hot spots emerge in the gaps of symmetric dimer antennas, yet strong SH sources created in the gap region oscillate out-of-phase and thus destructively interfere in the farfield [1]. Introducing local asymmetry by careful design of the antenna gap geometry allows to mitigate the so-called silencing effect and leads to enhanced SHG [2].

In the ultraviolet-visible spectral range, however, the SH efficiency for gold nanoantennas is limited due to high damping below 500 nm. Here we present silver nanoantennas fabricated from epitaxial grown single-crystalline microplatelets to boost SHG below 500 nm, where silver shows significantly less absorption losses compared to gold. The antenna design is optimised for SHG taking into account the linear scattering response with a resonance at the SH.

A room temperature tunable scanning fiber Fabry-Pérot cavity microscope — •Lars Denzer, Paul Steinmann, and Stefan Linden — Physikalisches Institut, Universität Bonn, Nussallee 12, 53115 Bonn, Germany

Since the technological advancements in the fabrication of ultra-smooth concave fiber surfaces, fiber-based Fabry-Pérot cavities (FFPCs) are a field of ongoing research. Many applications emerged, ranging from light-matter coupling utilizing very small mode volumes over cavity-enhanced sensing, to cavity mi-

croscopy. Here, we report on the construction and test of a tunable scanning fiber Fabry-Pérot cavity microscope operating at room temperature. To this end, we fabricated a concave metallic mirror on the facet of an optical fiber. Using a focused CO2 laser beam, we achieve an ultra-smooth Gaussian depression at the fiber facet. Afterwards, the fiber is gold-coated in an evaporation chamber. Coarse tuning of the cavity is possible by the use of a 3D-piezo stage and the cavity length is fine-tuned by a shear piezo. Laterally scanning the cavity enables a mapping of the sample surface. As a first test, we investigate the coupling of a MoSe2 monolayer to the cavity field.

Near-field scanning optical microscopy of topologically protected excitons in molecular aggregates — Sidhartha Nayak, Christopher W. Wächtler, and •Alexander Eisfeld — MPIPKS, Dresden, Germany

Delocalized excitonic eigenstates of molecular aggregates are responsible for the energy transfer from an incoming radiation into the aggregate. Static disorder, which can arise from an imperfect environment of each molecule, reduces the exciton transport and large disorders can even localize the exciton. It has been shown theoretically that a two-dimensional periodic array of tilted and interacting molecules in a homogeneous magnetic field shows topologically protected edge states [1]. With a scattering scanning near-field optical microscope setup, one can not only record position dependent absorption spectra [2] but also reconstruct the wavefunctions from these specta [3]. We study theoretically the near field spectra of the aforementioned 2D aggregates in which the molecules experience a disordered environment because of the probing metallic tip. Due to the topological protection, the edge states are robust even in the presence of the metallic nanoparticle, such that the spectrum shows clear signatures of these states.

Nanoantenna Conjugated Graphene Photodetectors — •Abhinav Raina, Mo Lu, Max Reimer, Vasilii Osipov, Klaus Meerholz, and Klas Lindfors — Department für Chemie, Universität zu Köln, 50939, Köln, Germany

Optical communications is a technology that utilizes light for the wireless transduction of signals. Over the past few decades, the rapid development of nanoscale fabrication techniques has allowed for a significant improvement in the control over the transduction of optical signals. For example, optical nanoantennas have been used in steerable wireless links.[1] In an effort to detect the signals in optical nanoantenna links as an electrical signal, we couple nanoantenna arrays with a graphene photodetector. Such a device would act as a demonstration of tunable, on-chip, wireless transmission and detection of optical signals.

Surface dynamics under reaction conditions — •Edvin Lundgren — Department of Synchrotron Radiation Research, Institute of Physics, Lund university, Box 118, SE-221 00 Lund, Sweden

Catalysis is an important process and is widely applied on an industrial scale for many applications in either gas or in liquid phase. Industrial catalysts are complex materials, and consequently the gas/liquid-surface interaction between simplified single crystal surfaces and molecules in controlled environments has

been studied for decades. We have in recent years explored the possibilities to perform experiments at conditions closer to those of a technical catalyst, at elevated pressures and in an electrolyte. In this contribution, recent results using in situ/operando techniques [1-5] will be presented. Armed with structural knowledge from ultra-high vacuum experiments, the dynamics of the gas or electrolyte induced structures and phases can be observed in real time. The strength and

weaknesses of the experimental techniques will be discussed.

Imaging electrons in 1D: correlated states within MoS_2 mirror twin boundaries — •Wouter Jolie — II. Physikalisches Institut, Universität zu Köln, Germany

Electrons are prone to strong correlations when confined into one-dimensional (1D) cavities. An ideal experimental testbed for the observation of correlated electronic behavior is found in mirror twin boundaries (MTBs) of the two-dimensional material MoS_2. These MTBs function as structurally perfect 1D cavities, are only weakly coupled to the environment and accessible to spatially resolved spectroscopic investigations using scanning tunneling microscopy.

In my talk I will show that the confined quasiparticles within finite MoS_2 MTBs transform into spin and charge modes as described by the Tomonaga Luttinger theory of strongly interacting 1D electrons [1]. In addition, a Kondo resonance, delocalized over the entire length of the MTB, emerges when the highest occupied mode is half filled [2]. The unique construction of our Kondo system enables us to directly measure the energies of both the Kondo resonance and the half filled confined level, as well as their correlated beating along the boundary. Lastly, I will outline how to alter the electronic system in MTBs through giant Fermi level shifts [3] and atomic manipulation.

Interface-engineered quantum states in van der Waals heterostructures — •Felix Lüpke — Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany — Jülich Aachen Research Alliance (JARA), Fundamentals of Future Information Technology, 52425 Jülich, Germany

The assembly of van der Waals (vdW) materials into heterostructures enables the engineering of exotic quantum states by interface effects such as moiré and proximity. Scanning tunneling microscopy (STM) has become an important tool to study the properties of such heterostructure, because it gives direct access to the resulting structural and electronic properties. While the possibilities to combine different vdW materials in Lego-like fashion are virtually infinite, the fabrication of samples with atomically clean surfaces, as required for STM, was typically limited to air-stable or epitaxially grown samples, which drastically diminishes the engineering capabilities. To address this problem, we have developed a novel dry-transfer flip fabrication technique, which allows the preparation and STM study of heterostructures with atomically clean surfaces and interfaces and without exposure to air. In my talk, I will summarize our developments in heterostructure fabrication and will show results of proximity-induced superconductivity in topological insulator WTe_2, interlayer interactions in twisted bilayer WTe_2, phonon gap supported tunneling and interfacial electric fields in Fe_3GeTe_2 heterostructures, and quantum dot lattices in $NbSe_2$ heterostructures.

O 72.3 Thu 11:30 CHE 89

Electronic States and Polarons on Polar Surfaces — •Michele Reticcioli[1], Florian Ellinger[1], Martin Setvin[2], and Cesare Franchini[1,3] — [1]University of Vienna (Austria) — [2]Charles University, Prague (Czech Republic) — [3]University of Bologna (Italy)

Polar surfaces of oxides exhibit an internal electric field and intrinsic excess charge that might be exploited for a wide range of applications, such as catalysis or electron-hole separation for solar light harvesting. However, there is very limited fundamental understanding of the processes induced by the surface polarity. In our study we attempt to shed some light on the nature of the electric

field and the interplay with surface charge. Our density functional theory calculations and scanning-probe microscopy measurements on $KTaO_3(001)$ show spontaneous localization of the excess charge in the form of electron and hole polarons. In the absence of external perturbations, the internal electrostatic potential keeps the electron-hole polaron pairs spatially separated. We also show that the electronic properties of the surface can be tuned by adsorbing molecules and metal atoms. Finally, we apply these concepts to more debated cases, such as the $SrTiO_3(001)$ surface, where the polarity is too weak to produce a large charge separation. We believe that our findings contribute to deepen the interpretation of polar surfaces of oxides and ionic compounds in general.

O 72.4 Thu 12:00 CHE 89

Submolecular-scale control of phototautomerization — •Anna Rosławska[1], Katharina Kaiser[1], Michelangelo Romeo[1], Fabrice Scheurer[1], Stéphane Berciaud[1], Tomáš Neuman[2], and Guillaume Schull[1] — [1]Université de Strasbourg, CNRS, IPCMS, UMR 7504, 67000 Strasbourg, France — [2]Institut des Sciences Moléculaires d'Orsay (ISMO), UMR 8214, CNRS, Université Paris-Saclay, 91405 Orsay Cedex, France.

Photochemistry plays a central role in fundamental natural and artificial reactions such as photosynthesis, photocatalysis, or phototautomerization. Here, we demonstrate that using a tunable light source focused on a scanning tunneling microscope (STM) tip we drive and control the rate of a free-base phthalocyanine (H_2Pc) phototautomerization with sub-molecular precision, providing a path to pilot the intrinsic reactivity of the molecule with an external controllable stimulus. In addition, we probe the excited state of the molecule, which drives the tautomerization, by recording tip-enhanced photoluminescence (TEPL) spectra and maps where varying patterns for non-resonant and resonant excitation conditions are observed. These TEPL maps reflect different atomic-scale coupling between the localized plasmonic fields and the transition dipole moment of the molecule influenced by the hydrogen switching process.

O 72.5 Thu 12:30 CHE 89

Single-molecule synthesis by scanning probe manipulation of intra- and inter-molecular reactions — •Qigang Zhong[1,2], Artur Mardyukov[2,3], Ephrath Solel[2,3], Alexander Ihle[1,2], Daniel Ebeling[1,2], Peter R. Schreiner[2,3], and André Schirmeisen[1,2] — [1]Institute of Applied Physics, Justus Liebig University Giessen (JLU), Germany — [2]Center for Materials Research, JLU, Germany — [3]Institute of Organic Chemistry, JLU, Germany

Single-molecule synthesis by scanning probe manipulation has emerged as a powerful tool not only to visualize, but also to generate and couple highly reactive molecules, which often are not accessible by traditional synthetic methods. As an example of precise "intra-molecular surgery", we demonstrate the on-surface synthesis of the structurally elusive cyclotriphosphazene (P3N3) based on STM tip-induced sextuple dechlorination of a sub-nanometer P3N3Cl6 precursor molecule on a Cu(111) surface [1]. Real-space atomic-level imaging of P3N3 reveals its planar D3h-symmetric ring structure. This method is further expanded to the inter-molecular level to construct covalent organic nanostructures molecule-by-molecule [2]. We have achieved unprecedented control over the whole reaction process including activation, lateral transfer and inter-molecular coupling of halogenated precursors on an inert NaCl surface. Our work presents strategies for synthesizing elusive molecules as well as covalent nanoarchitectures, studying structural modifications and revealing pathways of on-surface reactions.

O 73: Metal Substrates: Adsorption and Reaction of Small Molecules II

Time: Thursday 10:30–12:30   Location: CHE 91

O 73.1   Thu 10:30   CHE 91

Benchmarking machine-learned interatomic potentials for reactive surface dynamics at metal surfaces: accuracy vs speed — •Wojciech Stark[1], Julia Westermayr[1], Cas van der Oord[2], Lingjun Zhu[3], Bin Jiang[3], Gabor Csanyi[2], and Reinhard Maurer[1] — [1]University of Warwick, UK — [2]University of Cambridge, UK — [3]University of Science and Technology of China, China

Machine-learned interatomic potentials (MLIP) have become widely used tools to accelerate ab initio molecular dynamics simulations in materials science. Many promising MLIPs emerged recently, ranging from simple linear models to deep neural networks (DNN), differing in stability, accuracy, and inference time. Reactive scattering dynamics are highly sensitive to potential corrugation and low reaction probabilities require extensive ensemble averaging. Therefore, MLIPs need to combine smooth and accurate landscapes with extremely efficient inference. In this study, we compare different families of MLIPs, from atomic cluster expansion (ACE), message-passing based Neural Network SchNet and embedded atom neural networks (EANN), to equivariant neural networks such as PaiNN and MACE on the example of reactive molecular hydrogen scattering on copper. We compare these diverse methods by measuring accuracy and inference performance directly on dynamical observables. This provides a detailed picture of MLIP accuracy, speed, and learning rate that goes beyond simple train/test error analysis.

O 73.2   Thu 10:45   CHE 91

Electrooxidation of 1-cyclohexyl ethanol on Pt single crystal electrodes — •Lukáš Fusek[1,2], Maria Minichová[3], Valentín Briega-Martos[3], Lukas Fromm[1], Evanie Franz[1], Juntao Yang[1], Andreas Görling[1], Serhiy Cherevko[3], Peter Wasserchied[1,3], Olaf Brummel[1], and Jörg Libuda[1] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Charles University, Prague, Czech Republic — [3]Helmholtz-Institut Erlangen-Nürnberg, Germany

Isopropanol can be used as a liquid organic hydrogen carrier (LOHC), which is compatible with direct alcohol fuel cells.1 However, it has a limited hydrogen storage capacity. 1-Cyclohexyl-ethanol is a potential LOHC with an increased hydrogen storage capacity with two different functionalities, the alcohol (2 H+) and the cyclohexyl functionality (6 H+). In this study, we investigated the electrooxidation of 0.02 M 1-cyclohexyl ethanol on Pt(hkl) electrodes in 0.1 M HClO4 using cyclic voltammetry and electrochemical infrared reflection absorption spectroscopy. We demonstrate that it is possible to oxidize electrochemically 1-cyclohexyl-ethanol to acetophenone. Additionally, we observed 1-cyclohexylethanone and decomposition products. The latter poison the Pt surface, limiting the electrocatalytic activity. The possibility to dehydrogenate electrochemically not only the alcohol but also the cyclohexyl functionality may enable us to increase the hydrogen storage capacity of fuel cell compatible LOHCs substantially, reaching values that are comparable to conventional LOHCs.

O 73.3   Thu 11:00   CHE 91

Ab initio-based chemisorption and thermodynamic stability of atomic H and O on Pt-Ir alloy surfaces — •Tobias Wittemann, Thorsten Klüner, and Halil Ibrahim Sözen — Institute of Chemistry, Carl-von-Ossietzky University of Oldenburg, 26129 Oldenburg, Germany

Electric vehicles powered by proton-exchange membrane (PEM) fuel cells are a CO_2 emission-free alternative to conventional fossil fuel vehicles. In this study, we report density functional theory (DFT) investigations of binary Pt-Ir surfaces, which are a promising candidate for bifunctional anode catalysts in PEM fuel cells that could enable higher long-term durability of the anode catalyst. The chemisorption behaviour of atomic H and O on bimetallic $Pt_3Ir(111)$ and PtIr(111) surfaces was investigated for different coverages and compared with the monometallic Pt(111) and Ir(111) surfaces. We found that in both cases the chemisorption on the alloys becomes more stable with increasing number of Ir atoms at the adsorption site. Using the *ab initio* thermodynamics approach, we calculated phase diagrams for the chemisorption of atomic H and O species on these metal surfaces in order to transfer our findings to finite temperature and pressure conditions prevailing in real PEMFCs. Our theoretical results can provide a fundamental understanding for subsequent studies of the hydrogen oxidation reaction (HOR) and oxygen evolution reaction (OER) on Pt-Ir alloy surfaces and are thus crucial for the rational development of new anode catalyst materials.

O 73.4   Thu 11:15   CHE 91

Approaching electrochemical interfaces by computational spectroscopy — •Holger Euchner[1], Jongmin Kim[1,2], Margot Guidat[1], Mario Löw[2], and Matthias M. May[1,2] — [1]Institute of Physical and Theoretical Chemistry, Universität Tübingen, 72076 Tübingen, Germany — [2]Institute of Theoretical Chemistry, Universität Ulm, 89081 Ulm, Germany

Understanding interfacial processes on the atomistic scale is essential for improving and tailoring the performance of electrochemical devices. Unfortunately, due to limited experimental access to the electrochemical interface such understanding is difficult to obtain. Applying reflection anisotropy spectroscopy (RAS), an operando optical high resolution technique, to electrochemical interfaces can help to overcome this issue. However, the information contained in experimental RAS spectra needs to be interpreted by comparison with those of computational model systems. In this work, we present computationally determined spectra for different metal electrode surfaces and analyze the impact of adsorbants on the resulting RAS signal. For this purpose, the surface dielectric function is determined by applying the random phase approximation. Finally, the obtained spectra are compared to available experimental data, showing the potential power of this approach.

O 73.5   Thu 11:30   CHE 91

Atomistic Insights at Au(111) / Deep Eutectic Solvents Interface using in situ STM — •Yannick Mattausch[1], Areeg Abdelrahman[1], Maren-Kathrin Heubach[1], Ludwig A. Kibler[1], and Timo Jacob[1,2,3] — [1]Institute of Electrochemistry, Ulm University, Ulm, Germany. — [2]Helmholtz-Institute-Ulm (HIU), Ulm, Germany. — [3]Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany.

Deep eutectic solvents (DESs) have outstanding electrochemical characteristics such as high electrochemical stability and conductivity.[1][2] Nonetheless, the interactions between the metal electrode surface and DESs besides their electrochemical behavior, like the electrolyte / Au(111) interface structure are still poorly understood. Recently, the electrochemical behavior and adsorption structures of Au(111) in Ethylenglycole / Cholinchloride (2:1) have been studied, including an ordered chloride structure at 0.1 V *vs.* Pt and the potential induced surface reconstruction of Au(111).[3] Here, we go a step further by changing the electrolyte composition and studying its influence on the electrochemical behavior as well as the dynamics at the electrode-electrolyte interface at an atomistic level. To reach this aim, *in situ* scanning tunneling microscopy (STM) is employed to observe morphological changes at the electrode surface in real time and space.

O 73.6   Thu 11:45   CHE 91

2D chiral crystallization and thermally-induced on-surface polymerization of 2,3-dicarbonitrile-tetrahelicene on Ag(111) surface — •Aleksandra Cebrat[1,3], Christian Wäckerlin[1], Kevin Martin[2], Manfred Parschau[1], Narcis Avarvari[2], and Karl-Heinz Ernst[1,3] — [1]Empa, Swiss Federal Laboratories for Materials Science and Technology, Überlandstrasse 129, 8600 Dübendorf, Switzerland — [2]Laboratoire Moltech-Anjou, CNRS-Université d'Angers, 49045 Angers, France — [3]Department of Chemistry, University of Zurich, 8057 Zürich, Switzerland

The controlled on-surface polymerization using templates like metal surface and non-planar molecules can lead to synthesis of variable phthalocyanines and organic semiconducting polycyanine open-chains. Here, we report the initial results on the 2D chiral crystallization of racemic mixture of 2,3-dicarbonitrile-tetrahelicene on Ag(111) and its thermally-induced surface polymerization. Deposition of racemic diCN[4]H up to 0.9ML coverage on Ag(111) kept at 300 K leads to formation of islands of honeycomb domains built of M- and P-enantiomers. Deposition of rac-diCN[4]H on 330K up to 0.9ML leads to aggregation of molecules into long molecular lines and denser phase of unbalanced domains with either enantiomers present in excess. Subsequent annealing to 420 K leads to partial desorption of molecular lines and formation of single tetramers built from different stereoisomeric subunits. The formation of polymerized species was confirmed ToF-SIMS. Finally, we performed LT-STM lateral manipulation of the tetramers units to affirm the nature of bonds as covalent.

O 73.7   Thu 12:00   CHE 91

Interaction of chlorine with lithium and magnesium anodes in Cl-ion batteries — •Kanchan Sarkar[1] and Axel Gross[1,2] — [1]Institute of Theoretical Chemistry, Ulm University, 89069 Ulm, Germany — [2]Helmholtz Institute Ulm (HIU), Electrochemical Energy Storage, 89069 Ulm, Germany

We present the results of first-principles electronic structure calculations based on density functional theory addressing the adsorption of chlorine and the formation of a surface chloride on Li(001) and Mg(0001). This process is relevant for chloride-ion batteries in which lithium and magnesium are used as anode materials, but it is also of fundamental interest, as halide adsorption on metal electrodes is an important process in electrochemistry. We discuss the adsorption properties and determine the stable adsorption structures, both with respect

to the free chlorine molecule but also as a function of the electrode potential. We will also address the process of chloride formation on the surface.

O 73.8 Thu 12:15 CHE 91
Bromine on Rh(111) - A combined XPS and LEED study — •Eva Marie Freiberger[1], Natalie J. Waleska[1], Anton Harrer[1], Felix Hemauer[1], Valentin Schwaab[1], Hans-Peter Steinrück[1], and Christian Papp[1,2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [2]Freie Universität Berlin, Berlin, Germany

The adsorption of halogens on metals is a fundamental question in surface science. Detailed knowledge in this regard is of interest for any processes on surfaces, in which halogens are involved as a reactant or by-product. This plays a role, for example, in electrochemistry, when the electrolyte adsorbs at the elec-

trodes, or in on-surface synthesis, which often relies on coupling reactions with halogens as the leaving group, leading to their accumulation on the surface.

We investigated the adsorption and thermal evolution of elemental bromine on the Rh(111) single-crystal surface by synchrotron radiation-based high-resolution X-ray photoelectron spectroscopy (XPS), temperature-programmed XPS, and low energy electron diffraction (LEED). The adsorption of bromine on Rh(111) held at 170 K was followed in situ by XPS, revealing a coverage-dependent shift in the Br 3d spectra. Using LEED as a complementary method, we propose that the observed shift is caused by different bromine superstructures on Rh(111): a ($\sqrt{3}$ x $\sqrt{3}$)R30° structure for lower coverages and a compression structure for saturation coverage. Subsequent heating shows a quite high temperature stability of bromine on Rh(111) up to 925 K, indicating covalent bonding.

O 74: 2D Materials IV: Heterostructures (joint session O/CPP)

Time: Thursday 10:30–12:45									Location: GER 37

O 74.1 Thu 10:30 GER 37
In-situ growth characterization of 2D heterostructures: MoSe$_2$ on intercalated graphene/Ru(0001) — •Lars Buss[1], Nicolas Braud[2], Moritz Ewert[1], Matteo Jugovac[3], Tevfik Onur Mentes[3], Andrea Locatelli[3], Jens Falta[2], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, BTU Cottbus-Senftenberg, Cottbus, Germany — [2]Institute for Solid State Physics, University of Bremen, Bremen, Germany — [3]Elettra-Sincrotrone Trieste S.C.p.A, Bazovizza, Trieste, Italy

Despite the great fundamental interest in 2D heterostructures, most of the investigated 2D heterostructures were realized by mechanical exfoliation or chemical vapor deposition in the millibar range, preventing true in-situ characterization of the growth process. Here, we have investigated the growth of MoSe$_2$ on single-layer graphene on Ru(0001) via real-time in-situ low-energy electron microscopy and micro-diffraction. After preparation of the graphene by standard procedures from an ethylene precursor, MoSe$_2$ has been prepared via co-deposition of Mo and Se. Prior Se intercalation of the graphene appears to enhance the subsequent growth of MoSe$_2$ on the graphene. At elevated temperatures, rotational ordering of the MoSe$_2$ is facilitated by the strongly enhanced mobility of single-domain MoSe$_2$ islands that align with the high symmetry orientations of the underlying graphene, indicating a non-negligible interaction between the two van-der-Waals materials. Micro-spot angle-resolved photoemission proves the monolayer nature of the as-grown MoSe$_2$ as well as the free-standing character of the Se-intercalated graphene underneath.

O 74.2 Thu 10:45 GER 37
Designer quantum states in metal-organic frameworks — •Orlando J Silveira[1], Linghao Yan[1], Shawulienu Kezilebieke[2], Benjamin Alldritt[1], Viliam Vano[1], Ondřej Krejčí[1], Jose Lado[1], Adam S Foster[1,3], and Peter Liljeroth[1] — [1]Department of Applied Physics, Aalto University, Espoo, Finland — [2]University of Jyväskylä, FI-40014 University of Jyväskylä, Finland — [3]Kanazawa University, Kakuma-machi, Kanazawa 920-1192, Japan

Vertical heterostructures have emerged as a promising path to the design of quantum materials with exotic properties. Here, we show that this concept can be also extended to a family of 2D kagome metal-organic frameworks (MOFs) of the family M$_2$DCA$_3$, with M= Cu and Ni. The two MOFs have been fabricated either on a graphene/Ir(111) surface or the superconducting substrate NbSe$_2$, and the structural and electronic properties of different phases of both 2D MOFs + substrates were studied through density functional theory (DFT) calculations. Results show that the Cu$_2$DCA$_3$ MOF is effectively decoupled from the Ir(111) metallic substrate by the graphene layer, which is important to reveal the topological properties of this family of MOF. Moreover, this study extends the synthesis and electronic tunability of 2D MOFs beyond the metal surfaces to superconducting substrates, which are needed for the development of emerging quantum materials. We show that the Ni$_3$DCA$_2$ MOF has a spin density around the Ni atom when synthesized on the NbSe$_2$ substrate due to charge transfer, and this makes a perfect platform to realize topological superconductivity.

O 74.3 Thu 11:00 GER 37
Phonon gap supported tunneling and Faraday screening through graphene — •Tobias Wichmann[1,2,3], Keda Jin[1,2,4], Jose Martinez Castro[1,4], Honey Boban[5], Lukasz Plucinski[5], Markus Ternes[1,2,4], F. Stefan Tautz[1,2,3], and Felix Lüpke[1,2] — [1]Peter-Grünberg-Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Jülich Aachen Research Alliance (JARA) - 52425 Jülich, Fundamentals of Future Information Technology, Germany — [3]Institut für Experimentalphysik IV A, RWTH Aachen, 52074 Aachen, Germany — [4]Institut für Experimentalphysik II B, RWTH Aachen, 52074 Aachen, Germany — [5]Peter-Grünberg-Institut (PGI-6), Forschungszentrum Jülich, 52425 Jülich, Germany

Encapsulation of van der Waals materials has proven a vital technique to protect them from degradation and contamination. Usually, metallic encapsulation

layers mask the properties of the underlying material when studied in scanning tunneling microscopy. Utilizing the inelastic tunneling phonon gap of graphene, however, enables the unfettered investigation of low energy phenomena (e.g. Kondo effect, Majoranas, etc.) by scanning tunneling spectroscopy, while maintaining the advantages of encapsulated samples. Furthermore, we find that the conductive nature of the graphene encapsulation layer screens the sample from tip-induced electric fields, exemplified by our low-temperature STM examination of encapsulated Fe3GeTe2.

O 74.4 Thu 11:15 GER 37
Fermi level tuning of a MnBi$_2$Te$_4$ monolayer — •Marco Dittmar[1], Philipp Kagerer[1], Celso I. Fornari[1], Simon Müller[1], Sergio L. Morelhão[2], Hendrik Bentmann[1], and Friedrich Reinert[1] — [1]Exp. Physik VII and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Germany — [2]Instituto de Física, Universidade de São Paulo, Brazil

By breaking time reversal symmetry, introducing magnetic order to topological insulators leads to the opening of a 2D surface state gap at the Dirac point. As a second crucial parameter, tuning the position of the Fermi level inside this gap, enables the observation of exciting new phenomena, such as the quantum anomalous Hall effect (QAHE).

Here, we focus on the intrinsic ferromagnetic monolayer of MnBi$_2$Te$_4$, acting as a magnetic extension of the topological insulator Bi$_2$Te$_3$ [1]. We tune the Fermi level position in this compound by preparing a single layer of MnBi$_2$Te$_4$ on top of the topologically non-trivial p-n-junction of Sb$_2$Te$_3$ and Bi$_2$Te$_3$ grown by molecular beam epitaxy (MBE) [2]. We will present a study containing structural characterization of the heterostructures by X-ray diffraction and atomic force microscopy, while the electronic structure is assessed by X-ray and angle resolved photoemission spectroscopy.

O 74.5 Thu 11:30 GER 37
1D Topological Superconductivity in a van der Waals heterostructure probed by Abrikosov vortices — •Jose Martinez-Castro[1,2], Tobias Wichmann[1,3], Tomáš Samuely[4], Keda Jin[1,2], Oleksander Onufriienko[4], F. Stefan Tautz[1,3,5], Markus Ternes[1,2,3], and Felix Lüpke[1] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Institut für Experimentalphysik II B, RWTH Aachen, 52074 Aachen, Germany. — [3]Jülich Aachen Research Alliance, Fundamentals of Future Information Technology, 52425 Jülich, Germany — [4]Centre of Low Temperature Physics, Faculty of Science, P. J. Safarik University & Institute of Experimental Physics, Slovak Academy of Sciences, Kosice, Slovakia — [5]Institut für Experimentalphysik IV A, RWTH Aachen, 52074 Aachen, Germany

The 2D topological insulator monolayer (ML) WTe$_2$ is characterized by an insulating interior surrounded by helical 1D edge states. When this material is brought into proximity to the s-wave superconductor NbSe$_2$, the spectroscopic features of the helical edge state remain intact while showing a proximity-induced superconducting gap [1]. However, so far there has been no direct evidence that the observed edge superconductivity is of different nature than that observed away from the edge. Here, by inducing Abrikosov vortices at the boundary between ML WTe$_2$ and NbSe$_2$, we show that the induced superconductivity in the helical edge is robust against magnetic fields, a strong indication of 1D topological superconductivity.
[1] Lüpke et al., Nat. Phys. 16, 526 (2020)

O 74.6 Thu 11:45 GER 37
Density functional theory studies of Anthracene on MoS$_2$ — •Gérald Kämmerer and Peter Kratzer — Faculty of Physics, University of Duisburg-Essen

Thin layers of MoS$_2$ are attractive as transparent contacts on organic semiconductors, e.g., oligoacene. As a model for molecules with a delocalized system of

π-bonds, we investigate the physisorption of a monolayer of anthracene ($C_{14}H_{10}$) on a MoS_2 single layer using density functional theory. The calculations were carried out with the FHI-Aims code with different functionals. Van der Waals interactions are described by a pairwise potential of the Tkatchenko-Scheffler type or by a many-body dispersion technique. We determine structural properties and can identify the relative position of the molecular HOMO and LUMO (Π and Π^*) orbital concerning the band edges of MoS_2. These results can help find the type of band alignment between MoS_2 and an anthracene molecular crystal, as well as the binding energy of the molecule on the surface. The financial support by DFG within CRC 1242 (*Project B 02*) and computation time on the MagnitUDE supercomputer system are gratefully acknowledged.

O 74.7 Thu 12:00 GER 37
Lateral heterostructures of graphene and h-BN with atomic lattice coherence and tunable rotational order — •Haojie Guo[1], Ane Garro-Hernandorena[1], Antonio J. Martínez-Galera[2,3], and José M. Gómez-Rodríguez[1,3,4] — [1]Departamento de Física de la Materia Condensada, Universidad Autónoma de Madrid, E-28049 Madrid, Spain — [2]Departamento de Física de Materiales, Universidad Autónoma de Madrid, E-28049 Madrid, Spain — [3]Instituto Nicolás Cabrera, Universidad Autónoma de Madrid, E-28049 Madrid, Spain — [4]Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, E-28049 Madrid, Spain

In-plane heterostructures of graphene and h-BN exhibit exceptional properties, which are sensitive to the structure of the alternating domains. However, achieving accurate control over their structural properties, while keeping a high perfection of the graphene-h-BN boundaries, still remains a challenge. Here, the growth of lateral heterostructures of graphene and h-BN on Rh(110) surfaces is reported. The choice of the 2D material, grown firstly, determines the structural properties of the whole heterostructure layer, allowing to have control over the rotational order of the domains. The atomic-scale observation of the boundaries demonstrates a perfect lateral matching. Lateral heterostructures floating over an oxygen layer have been successfully obtained, enabling to observe intervalley scattering processes in graphene regions. The high tuning capabilities of these heterostructures suggests their usage as testbeds for fundamental studies.

O 74.8 Thu 12:15 GER 37
Relaxation mechanisms for in-plane heterostructures of transition metal dichalcogenide monolayers — •Kai Mehlich[1], Francis H. Davis[3], Thais Chagas[1], Daniela Dombrowski[2], Daniel Weber[1], Catherine Grover[1], Arkady Krasheninnikov[3], and Carsten Busse[1] — [1]Derpartment Physik, Universität Siegen, Walter-Flex-Str. 3, 57072 Siegen — [2]Institut für Materialphysik, WWU Münster, Wilhelm-Klemm-Str. 10, 48149 Münster — [3]Ion Beam Centre, Helmoltz-Zentrum Dresden Rossendorf, Bautzner Landstraße 400, 01328 Dresden

We use sequential epitaxial growth to synthesise in-plane heterostructures of MoS_2 and TaS_2 monolayers on Au(111). Even though the two materials have significantly different lattice constants, STM-measurements show that coherent interconnection of the two materials can be achieved. Defects at the interface such as dislocations are absent. We find this for all interfaces, independent of orientation or the widths of the joined materials. This is at variance with DFT-calculations where we find that the formation of dislocations is energetically favoured, at least until a critical width of the heterostructures. Our growth process can thus lead to a metastable, defect-free interface.

O 74.9 Thu 12:30 GER 37
Predicting the Gas Sensing Performance of 2D Materials — •Udo Schwingenschlögl, Vasudeo Babar, Hakkim Vovusha, and Altynbek Murat — King Abdullah University of Science and Technology (KAUST), Physical Science and Engineering Division (PSE), Thuwal 23955-6900, Saudi Arabia

We study the potential of material simulations based on first-principles methods to predict gas sensing properties of 2D materials. This emerging class of materials is of particular interest to gas sensing applications due to high surface-to-volume ratios and chemical stability. We discuss results of electron transport calculations within the Landauer-Büttiker formalism and compare the conclusions to analyses in terms of the adsorption energy. Journal References: ACS Appl. Nano Mater. 2, 6076 (2019); J. Phys. Condens. Matter 32, 355602 (2020)

O 75: Focus Session: Ultrafast Dynamics in Nanostructures I

In nanostructures, the response of electrons and atoms to external stimuli often differs significantly from that of their bulk counterparts due to spatial confinement and greatly increased surface-to-volume ratios. Whereas pump-probe techniques provide real time access to the dynamics of nanostructures in excited states, investigating the response of single nanostructures and probing their dynamics locally requires ultrafast imaging techniques that provide simultaneously a high spatial and temporal resolution.

Several ultrafast nanoscale imaging methodologies have made a tremendous progress in recent years. Crucial instrumental developments have enabled time-resolved variants of scanning probe techniques, such as ultrafast scanning near-field optical microscopy and ultrafast scanning tunneling microscopy. Furthermore, bright sources for femtosecond electron as well as extreme ultraviolet and x-ray pulses now allow for the ultrafast far-field probing with nanometer resolution.

To highlight these recent developments, this focus session brings together researchers interested in ultrafast nanoscale science and in the development of ultrafast high-resolution imaging approaches.

Time: Thursday 10:30–13:15　　　　　　　　　　　　　　　　　　　　　　　　　　Location: GER 38

Topical Talk O 75.1 Thu 10:30 GER 38
Ultrafast nano-imaging: probing quantum dynamics in space and time — •Markus Raschke — Department of Physics and JILA, University of Colorado, Boulder, USA

Understanding and ultimately controlling the properties of matter, from molecular to quantum systems, requires imaging the elementary excitations on their natural time and length scales. To achieve this goal, we developed scanning probe microscopy with ultrafast and shaped laser pulse excitation for multiscale spatiotemporal optical nano-imaging. In corresponding ultrafast movies we resolve the fundamental quantum dynamics from the few-femtosecond coherent to the thermal transport regime. I will discuss specific examples visualizing in space and time the nanoscale heterogeneity in competing structural and electronic dynamic processes that define the performance in perovskite photovoltaics or energy dissipation in 2D heterostructures. I will extend the discussion to new forms of photon-matter hybrid states that emerge from confining light on the nano- to atomic scale, with imaging in tip-enhanced strong coupling of single emitters, to new regimes of nonlocal and quantum nonlinear nano-optics.

O 75.2 Thu 11:00 GER 38
Towards a nanoscale ultrafast optical oscilloscope — •Abbas Chimeh, Sam Nochowitz, Tom Jehle, Juanmei Duan, Sven Stephan, and Christoph Lienau — Universität Oldenburg

Measuring the ultrafast time response on the nanoscale gives insights into the complex structure and dynamics of nanomaterials. A variety of all-optical and electron-based spectroscopy techniques are currently under development to probe such ultrafast dynamics [1].

Here, we propose and demonstrate a broadband, interferometric scattering-type scanning near-field optical spectroscopy technique to measure ultrafast response function on the nanoscale. The idea is to mix the weak optical near field that is scattered out from the gap of a laser-illuminated tip-sample junction with a broadband reference pulse in a single spatial mode. From the resulting phase-stable spectral interferogram, we can directly retrieve the linear optical response function of the coupled tip-sample system and, thus, the time structure of re-emitted electric field with sub-cycle precision. By recording scattering spectra at a rate much higher than typical tip-sample modulation frequencies, we can separate the near-field response from unmodulated signal backgrounds and directly probe the time structure of optical near-fields on the nanoscale. We demonstrate the technique by probing local light scattering from single TMDC monolayers.

Our technique provides a general approach for measuring the response functions of nanostructures in the visible and near-infrared spectral range with femtosecond temporal and nanometer spatial resolution.

Ultrafast electron dynamics in semiconductor nanowires — •Jan Vogelsang[1,2], Lukas Wittenbecher[1], Cord L. Arnold[1], Anne L'Huillier[1], and Anders Mikkelsen[1] — [1]Department of Physics, Lund University, 221 00 Lund, Sweden — [2]present address: Institut für Physik, Universität Oldenburg, 26129 Oldenburg, Germany

The dynamics and, in particular, the transport of charge carriers in semiconductor nanostructures after optical excitation are influenced by different processes whose interaction is not yet fully understood. Here, we employ ultrashort laser pulses in combination with a photoemission electron microscope (PEEM) to spatiotemporally resolve these processes. We observe the radial transport of charge carriers in semiconductor nanowires after impulsive optical excitation and investigate the influence of electron-hole scattering on the relaxation times of hot electrons. We conclude with a glimpse on an attosecond streaking experiment in a PEEM promising an even higher temporal resolution.

SPP induced coherent electronic excitations investigated by Time- and Angle-Resolved Plasmoemission-Spectroscopy on Cs/Au(111) — •Alexander Neuhaus, Pascal Dreher, David Janoschka, Michael Horn-von Hoegen, and Frank-J. Meyer zu Heringdorf — Faculty of Physics, University of Duisburg-Essen, 47048 Duisburg, Germany

Non-perturbative interactions of intense light fields with the electronic band structure in a solid can result in transient electronic properties. The experimental conditions required to realize the necessary field strength can be realized in nano-optical systems, as these can be designed to provide tremendous enhancements of the local field amplitude. Ultimately, observing the non-equilibrium electron dynamics in such systems requires a combination of precise control over the local driving field, state resolution, and spatial selectivity. Here, we explore electron emission from nano-focused femtosecond surface plasmon polariton (SPP) pulses, providing us with deep-subwavelength spatial selectivity. Two-dimensional time- and angle-resolved photoelectron spectroscopy using a birefringent delay line provides us with direct access to the coherent and incoherent dynamics of the electronic excitations with attosecond precision. The technique is applied to the system Cs/Au(111), where we observe SPP induced coherent electronic excitations of the first image potential state.

Lightwave-driven scanning tunneling microscopy and spectroscopy at the atomic scale — •Vedran Jelic[1], Spencer E. Ammerman[1], Yajing Wei[1], Vivian N. Breslin[1], Mohammed Hassan[1], Nathan Everett[1], Sheng Lee[1], Stephanie Adams[1], Trevor Hickle[1], Kaedon Cleland-Host[1], Qiang Sun[2], Carlo A. Pignedoli[2], Pascal Ruffieux[2], Roman Fasel[2,3], and Tyler L. Cocker[1] — [1]Department of Physics and Astronomy, Michigan State University, East Lansing, MI 48824, USA — [2]Empa Swiss Federal Laboratories for Materials Science and Technology, 8600 Dübendorf, Switzerland — [3]Department of Chemistry, Biochemistry and Pharmaceutical Sciences, University of Bern, 3012 Bern, Switzerland

Lightwave-driven scanning tunneling microscopy is a new technique for studying atomic-scale surfaces that exhibit sub-picosecond dynamics. By coupling free-space-propagating single-cycle terahertz pulses to an atomically sharp metal tip, lightwave-driven microscopy can achieve simultaneous sub-angstrom and sub-picosecond spatio-temporal resolution. We utilize terahertz scanning tunneling microscopy (THz-STM) to investigate seven-atom-wide graphene nanoribbons on an Au(111) surface and unveil highly localized wavefunctions that are inaccessible with conventional STM. Three-dimensional tomographic THz-STM imaging of the electron densities reveals a faster spatial decay of the valance band compared to the conduction band. Additionally, an algorithm is introduced for extracting the underlying differential conductance from THz-STS measurements in both steady-state and pump-probe scenarios.

O 75.6   Thu 12:15   GER 38

Probing hot electron dynamics in a metal nanotip with THz-STM — •Vivien Sleziona[1], Faruk Krecinic[1], Natalia Martín Sabanés[1,2], Fabian Schulz[1,3], Takashi Kumagai[1,4], Martin Wolf[1], and Melanie Müller[1] — [1]Fritz-Haber-Institute, Berlin — [2]IMDEA Nanoscience, 28049 Madrid, Spain — [3]CIC NanoGUNE, San Sebastian, Spain — [4]Institute of Molecular Science, 444-8585 Okazaki, Japan

In metal nanostructures, such as the tip of a scanning tunneling microscope (STM), the excitation and dynamics of hot electrons can differ significantly from their behavior in bulk solids. However, how exactly the electrons in an STM tip respond to femtosecond (fs) laser excitation is still poorly understood, although this is important for optimizing and understanding fs-laser-excited STM oper-

ation. Here we use a THz-gated STM to study the ultrafast dynamics of photoexcited electrons in a tungsten STM tip [1]. Specifically, we investigate the role of thermalized hot electrons for the generation of ultrafast photocurrents and tunneling in STM. Knowledge of the THz voltage transient combined with simulation of the electron dynamics inside the confined volume of the STM tip allows us to extract the electronic temperature and its ultrafast decay. We evaluate the relevance for fs laser-excited STM and discuss how the tip geometry affects electronic heating on ultrafast time scales. [1] N. Martín Sabanés et al., ACS Nano 16, 9, 14479-14489 (2022)

O 75.7   Thu 12:30   GER 38

Spin current control by hybrid pulses — •Jyoti Krishna[1], Sangeeta Sharma[2], Julen Ibañez-Azpiroz[1,3], and Sam Shallcross[2] — [1]Centro de Fisica de Materiales (CSIC-UPV/EHU), 20018, San Sebastian, Spain — [2]Max-Born-Institut für Nichtlineare Optik und Kurzzeitspektroskopie, Max-Born-Straße 2A,12489 Berlin — [3]Ikerbasque Foundation, 48013 Bilbao, Spain

Spin and valley indices represent the key quantum labels of quasiparticles in a wide class of two dimensional materials, and control over these degrees of freedom, the creation of valley and spin states as well as the generation of pure spin and valley currents, remains a central challenge in these fields. Here we show that hybrid femtoscond laser pulses combining optical frequency circularly polarized pulse and a terahertz frequency linearly polarized pulse, a so-called "hencomb" pulse, can generate currents, whose magnitude and direction can be precisely controlled by the THz envelope. We explore this effect both in bilayer graphene and the dichalocogenide WSe_2, finding control over substantial currents that are nearly 100% pure valley and spin currents respectively. Employing a Wannier tight-binding method we then explore the creation of coherent photocurrents in the 2d magnets CrI_3 and FGT, generalizing the role of the THz and optical pulses to "momentum guiding" and "excitation" components of hybrid laser pulses.

O 75.8   Thu 12:45   GER 38

Mode-selective ballistic pathway to a metastable electronic phase — •Hannes Böckmann[1,2], Jan Gerrit Horstmann[3], Felix Kurtz[1,2], Abdus Samad Razzaq[4], Stefan Wippermann[4], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen 37077, Germany — [2]4th Physical Institute, Solids and Nanostructures, University of Göttingen — [3]Department of Materials, ETH Zurich, Zurich — [4]Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf

Exploiting vibrational excitation for the dynamic control of material properties is an attractive goal with wide-ranging technological potential. Most metal-to-insulator transitions are mediated by few structural modes and are, thus, ideal candidates for selective driving toward a desired electronic phase. Such targeted navigation within a generally multi-dimensional potential energy landscape requires microscopic insight into the non-equilibrium pathway. However, the exact role of coherent inertial motion across the transition state has remained elusive. Here, we demonstrate mode-selective control over the metal-to-insulator phase transition of atomic indium wires on the Si(111) surface, monitored by ultrafast low-energy electron diffraction. We use tailored pulse sequences and spectrally selective excitation to individually enhance or suppress key phonon modes and thereby steer the collective atomic motion within the potential energy surface underlying the structural transformation. Our work illustrates that coherent excitation of collective modes via exciton-phonon interactions evades entropic barriers and enables the dynamic control of functionality.

O 75.9   Thu 13:00   GER 38

Nanoscale coherent phonon excitation via plasmon-matter interaction in ultrathin ZnO films — •H. Wiedenhaupt[1], S. Liu[1,2], L. Parra López[1], A. Hammud[1], I. Hamada[3], F. Schulz[1,4], M. Wolf[1], T. Kumagai[1,2], and M. Müller[1] — [1]Fritz Haber Institute, Berlin, Germany — [2]Institute for Molecular Science, Okazaki 444-8585, Japan — [3]Hunan University, Hunan 410082, P. R. China — [4]CIC NanoGUNE, San Sebastian, Spain

In crystalline nanostructures, nanoscale variations of the lattice and/or electronic structure can alter their microscopic response and its interaction with light. Using light-coupled scanning tunneling microscopy (STM) with plasmonic junctions, we demonstrated recently that the local electronic structure of ultrathin ZnO on Ag(111) can strongly affect light-matter interaction on the nanoscale. Specifically, resonant laser excitation of these films seems crucial for tip-enhanced Raman spectroscopy (TERS) [1] and for the nanoscale excitation and observation of coherent phonon dynamics [2]. CPs are excited by femtosecond excitation of localized surface plasmons (LSP), and modulate the femtosecond photocurrent in the STM on ultrafast time scales. To better understand the optical excitation mechanism in these films, we measure plasmon-enhanced STM-induced luminescence, which allows us to correlate the local electronic structure of the films with their light coupling efficiency on the nanoscale. [1] S. Liu, Nano Lett. 19, 5725 (2019), [2] S. Liu et al., Sci. Adv. 8, eabq5682 (2022)

Continuous-wave multiphoton-induced electron transfer in a biased tunnel junction driven by intense plasmonic fields — Chenfang Lin[1], •Melanie Müller[1,2], Faruk Krecinic[1], Hiroko Yoshino[1], Adnan Hammud[1], Anlian Pan[2], Martin Wolf[1], and Takashi Kumagai[3] — [1]Fritz Haber Institute, Faradayweg 4-6, Berlin — [2]Hunan University, Hunan 410082, China — [3]Institute for Molecular Science, Okazaki 444-8585, Japan

Understanding photoinduced tunneling processes in the presence of intense plasmonic fields is of crucial importance for the design of plasmon-induced hot carrier technology and optical rectennas. However, in contrast to femtosecond laser excitation, the observation of multiphoton-induced electron transfer and the understanding of the role of hot carriers under intense continuous-wave (cw) illumination remains scarce. Here we exploit the strong spatial confinement of light inside the plasmonic gap of a scanning tunneling microscope (STM) to drive photocurrents with cw optical fields at local peak intensities up to 10^9 W/cm^2 at low incident power. We find that the photoinduced tunneling current scales nonlinear (linear) with laser intensity at low (high) STM bias. To yield insight into the photoinduced tunneling process we analyze the photocurrent-voltage dependence for different laser wavelength and powers. We discuss two possible origins of the multiphoton-induced electron transfer, namely transport of photoexcited hot electrons and photon-assisted quantum tunneling into light-dressed states.

O 76.2 Thu 10:45 WIL A317

Atomically resolved optical spectroscopy and microscopy in a scanning-tunneling microscope: Theory and experiment — •Tomas Neuman[1,2], Anna Roslawska[1], Benjamin Doppagne[1], Andrei G. Borissov[2], Michelangelo Romeo[1], Fabrice Scheurer[1], Javier Aizpurua[3], and Guillaume Schull[1] — [1]Universite de Strasbourg, CNRS, IPCMS, UMR 7504, F-67000, Strasbourg, France — [2]Institut des sciences Moleculaires d'Orsey (ISMO), UMR 8214, CNRS, Universite Paris-Saclay, 91405 Orsay Cedex, France — [3]Center for Materials Physics and DIPC, Paseo Manuel de Lardizabal 5, Donostia-San Sebastian 20018, Spain

We present a joint theoretical and experimental study of the optical properties of individual small organic molecules excited electrically by the plasmonic tip of a STM. We investigate how these properties vary as a function of the tip position with atomic-scale resolution. We show that the variation of the spectral position and width of the electroluminescence emission line of the molecular exciton can be linked with the DC Stark effect (induced by the static voltage across the tip-substrate gap) and the plasmonic Purcell effect due to the plasmonic response of the tip, respectively. We interpret the spectral line shift map as an image of the difference between the excited- and ground-state electron densities of the molecule, and the tip-position-dependent map of the excitonic line-width variation as an image of the transition electron density. In contrast, the map of light intensity emitted by the molecule reveals the information about the electronic mechanism leading to the tip-mediated generation of the exciton.

O 76.3 Thu 11:00 WIL A317

Modeling of molecular systems probed by near-field spectroscopy — •Sofia Canola, Jiří Doležal, Rodrigo Ferreira, and Martin Švec — Institute of Physics, Czech Academy of Sciences, Praha, Czech Republic

Spectroscopy coupled to scanning-probe microscopy is a powerful tool to analyze molecular properties at a single molecule level with submolecular resolution. In this technique, some intrinsic limitations and selection rules of conventional spectroscopy are overcome. This aspect, together with the high resolution of the signal and the precise control over the sample, allow to obtain information otherwise not accessible, such as for example the structural arrangement of the molecule, the electronic structure of its ground or excited molecular electronic state, its charging state or its response to stimuli. To fully unpack and rationalize the information, a theoretical interpretative framework must accompany the experimental findings. A crucial aspect is the ability to describe the molecular spectroscopic response in the near-field while including all the relevant aspects of the setup. High-level quantum-chemical calculations are needed, capable of reliably modeling the molecular system in its complexity and providing the appropriate response function. In this contribution, we present the results from the application of this technique to small conjugated molecules, with particular focus on the modeling aspects and the interesting molecular properties that become accessible when experiments and theory complement.

O 76.4 Thu 11:15 WIL A317

Plasmon-Induced Molecular Switching of PTCDA on Si(111) Studied by STM-TERS — •Youngwook Park[1], Adnan Hammud[1], Martin Wolf[1], Takashi Kumagai[2], and Akitoshi Shiotari[1] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Institute for Molecular Science, Okazaki, Japan

We studied a unique plasmon-induced molecular motion of perylenetetracarboxylic dianhydride (PTCDA) single molecules on the Si(111)-7x7 surface by means of the atomic point contact (APC) tip-enhanced Raman spectroscopy (TERS) with a low temperature scanning tunneling microscope (STM) under an ultrahigh vacuum condition. In our APC-TERS scheme, a silver tip approaches close to the surface until the tip makes an atomic point contact with its counterpart. It was reported by our previous study that at the point contact with Si(111) the TERS signal was significantly enhanced. The PTCDA on the Si(111), fixed on the surface by four oxygen-silicon bonds, showed a distinctive APC-TERS pattern where the Raman intensity was dramatically enhanced at a certain gap distance during the tip approach, and then was attenuated at shorter tip-molecule distances. At the TERS "sweet spot", the STM current rapidly switched between two states, implying a fluctuative motion of PTCDA molecule between the tip and the surface. On the contrary to PTCDA, perylenetetracarboxylic diimide (PTCDI) did not show such TERS "sweet spot" nor STM current switching. We believe this unique system could provide a better understanding on the plasmon-molecule interaction, as well as their implication on the enhancement mechanism in TERS.

O 76.5 Thu 11:30 WIL A317

Photoluminescence mapping of an anionic molecule — •Jiří Doležal, Rodrigo Ferreira, Amandeep Sagwal, Petr Kahan, and Martin Švec — Institute of Physics, Czech Academy of Sciences; Cukrovarnická 10/112, CZ16200 Praha 6, Czech Republic

Only recently, the photoluminescence (PL) of a single molecule has been attained [1,2] with sub-nm resolution in a scanning tunneling microscope (STM). However, only a fluorescent peak from a neutral phthalocyanine has been observed. The observation of fluorescence from a charged molecule is still elusive, likely due to the plasmon-mediated excitation mechanism which is fundamentally different from the electroluminescence (EL) process where a charged exciton can be created via electron/hole tunneling into dication/dianion [3,4].

Here, we present STM-PL maps of PTCDA anion adsorbed on 3ML/NaCl. The anionic charge state of the adsorbed molecule [5] enables its direct excitation by a laser-induced gap plasmon. We show STM-PL photon maps of an individual molecule and small molecular clusters qualitatively comparable to STM-EL maps [5], but independent of the tunneling current. This brings a major advantage over electroluminescence as the current is a scaling factor in the photon map intensity and its elimination [5-7] creates unwanted artefacts.

A Setup for Fluorescence-Detected Two-Dimensional Electronic Spectroscopy of Single Molecules — •Sanchayeeta Jana, Simon Durst, Lucas Ludwig, and Markus Lippitz — Chair for Experimental Physics III, University of Bayreuth, Bayreuth, Germany

Fluorescence-Detected Two-Dimensional Electronic Spectroscopy is a recent ultrafast technique that yields information about the coupling between the states of a system. At the same time, fluorescence-detected single molecule spectroscopy is a well-established technique since more than 30 years. By combining these two techniques one should be able to measure 2d spectra of single molecules to get new insight in molecular dynamics on ultrashort time scales.

Here we present our work towards this goal. We use four phase-modulated ultrafast pulses to excite the molecule with the help of a high NA objective. The fluorescence is registered by single-photon detectors and demodulated at several mixing frequencies to get the rephasing and non-rephasing signals. The novelty of our technique is that we can measure Fluorescence Correlation Spectroscopy (FCS) and Time-Correlated Single Photon Counting (TCSPC) simultaneously to monitor the number of molecules in our excitation focus and the fluorescence lifetime.

In this work we illustrate our experimental technique and discuss 2d spectra measured on a molecular sample at low concentration.

O 76.7 Thu 12:00 WIL A317

Luminescence from Cu$_2$O films and bulk crystals in the STM — Alexander Gloystein, Mina Soltanmohammadi, and •Niklas Nilius — Carl von Ossietzky Universität, Institut für Physik, D-26111 Oldenburg, Germany

STM luminescence spectroscopy is employed to compare the optical response of bulk Cu$_2$O(111) and 1-10 nm thick Cu$_2$O/Au(111) films. Although both systems share similar structural and electronic properties and expose the same thermodynamically preferred $(\sqrt{3} \times \sqrt{3})$R30° reconstruction, their luminescence exhibits pronounced differences. The spectra of bulk Cu$_2$O are dominated by the

recombination of free and defect-bound excitons, whereas a unique plasmonic response is detected for the oxide films. The latter arises from the electromagnetic coupling between STM tip and gold support, while the Cu_2O ad-layer exclusively controls the inelastic tunneling rates, i.e., the intensity, but not the spectral signature of the emission. Only upon tunneling into the Cu_2O band gap, a luminescence channel mediated by O vacancies is identified in the oxide film. The talk addresses the question why the unique exciton response of Cu_2O is covered by plasmon excitations even in films as thick as 10 nm.

O 76.8   Thu 12:15   WIL A317

Hot-carrier transfer across a nanoparticle-molecule junction: The importance of orbital hybridization and level alignment — •Jakub Fojt[1], Tuomas Rossi[2], Mikael Kuisma[3], and Paul Erhart[1] — [1]Department of Physics, Chalmers University of Technology, Gothenburg, Sweden — [2]Department of Applied Physics, Aalto University, Aalto, Finland — [3]Department of Physics, Technical University of Denmark, Kongens Lyngby, Denmark

While direct hot-carrier transfer can increase photocatalytic activity, it is difficult to discern experimentally and competes with several other mechanisms. To shed light on these aspects, here, we model from first-principles hot-carrier generation across the interface between plasmonic nanoparticles and a CO molecule. The hot-electron transfer probability depends nonmonotonically on the nanoparticle-molecule distance and can be effective at long distances, even before a strong chemical bond can form; hot-hole transfer on the other hand is limited to shorter distances. These observations can be explained by the energetic alignment between molecular and nanoparticle states as well as the excitation frequency. The hybridization of the molecular orbitals is the key predictor

for hot-carrier transfer in these systems, emphasizing the necessity of ground state hybridization for accurate predictions. Finally, we show a nontrivial dependence of the hot-carrier distribution on the excitation energy, which could be exploited when optimizing photocatalytic systems.

O 76.9   Thu 12:30   WIL A317

Disentangling the Orientations of Spectrally Overlapping Transition Dipoles in Dense Dye Layers — •Christoph Schnupfhagn[1], Thorsten Schumacher[1], Paul Markus[2], Georg Papastavrou[2], Olha Aftenieva[3], Tobias A. F. König[3], Volodymyr Dudko[4], Marian Matejdes[4], Josef Breu[4], and Markus Lippitz[1] — [1]Experimental Physics III, University of Bayreuth — [2]Physical Chemistry II, University of Bayreuth — [3]Leibniz-Institut für Polymerforschung Dresden e.V. — [4]Inorganic Chemistry I, University of Bayreuth

The transition dipole orientations of dye assemblies in heterostructures have a crucial impact on the efficiency of novel optoelectronic devices such as organic thin-film transistors and light-emitting diodes. These devices are frequently based on heterojunctions and tandem structures featuring multiple optical transitions. Precise knowledge of preferred orientations, spatial order, and spatial variations is highly relevant. We present a fast and universal large-area screening method to determine the transition dipole orientations in dye assemblies with diffraction-limited spatial resolution. Moreover, our hyperspectral imaging approach disentangles the orientations of different chromophores. As a demonstration, we apply our technique to dye monolayers with two optical transitions sandwiched between two ultrathin silicate nanosheets. A comprehensive model for dipole orientation distributions in monolayers reveals a long-range orientational order and a strong correlation between the two transitions.

Time: Thursday 10:30–12:45   Location: REC C 213

O 77.1   Thu 10:30   REC C 213

How cold is the junction of a millikelvin scanning tunnelling microscope? — Taner Esat[1,2], Xiaosheng Yang[1,2], Farhad Mustafayev[1,2], Helmut Soltner[3], Stefan Tautz[1,2,4], and •Ruslan Temirov[1,5] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany — [2]Jülich Aachen Research Alliance (JARA), Jülich, Germany — [3]Zentralinstitut für Engineering, Elektronik und Analytik (ZEA-1), Forschungszentrum Jülich, Germany — [4]Experimentalphysik IV A, RWTH Aachen University, Aachen, Germany — [5]University of Cologne, Institute of Physics II, Cologne, Germany

We employ a millikelvin scanning tunnelling microscope (STM) cooled to millikelvin temperatures by an adiabatic demagnetization refrigerator (ADR) to perform scanning tunnelling spectroscopy (STS) on an atomically clean surface of Al(100) in a superconducting state using normal-metal and superconducting STM tips. Varying the ADR temperatures between 30 mK and 1.2 K, we show that the temperature of the STM junction T is decoupled from the temperature of the surrounding environment T_{env}. Simulating the Josephson current with the $P(E)$ theory, we determine that $T_{env} \approx 1.5$ K, while fitting of the superconducting gap yields the lowest $T \approx 77$ mK.

O 77.2   Thu 10:45   REC C 213

Ultrahigh Vacuum Scanning Tunneling Microscopy with z Resolution of 2 pm at 1.3 K using Combined Pulse Tube and Joule-Thomson Cooling — •Marcus Esser[1], Marc Frömming[1], Marco Pratzer[1], Michael Krzyzowski[2], and Markus Morgenstern[1] — [1]2.Physikalische Institut B, RWTH Aachen University, Aachen, Germany — [2]CryoVac GmbH & Co KG, Troisdorf, Germany

The cooling of scanning tunneling microscopes with liquid helium by bath or flux cryostats suffers from He losses that get increasingly expensive. However, alternative closed cycle systems based on pulse tube refrigerators can induce additional mechanical noise into the tunneling contact due to mechanical vibrations in the μm range and acoustic emissions. We will present an STM system that reaches temperatures of 1.3 K and a z resolution of 2 pm (feedback loop off) with the help of a pulse tube cooler and a Joule-Thomson stage. The challenge is to provide a good thermal coupling as well as an good vibration damping. For this purpose, a new concept with multiple decoupling stages including negative stiffness isolation, detached coaxially guided shields for the different temperature stages and an optimized conical microscope design made out of Shapal Hi M-soft has been realized. Numerical calculations of transfer functions are compared with measurements on test setups using accelerometers as well as the tunneling contact of the STM. Eventual measurements on Au(111) showed atomic resolution and mechanical vibrations below 2 pm. The ongoing work to optimize spectroscopic resolution will be reported.

O 77.3   Thu 11:00   REC C 213

Development of a closed-cycle dilution refrigerator scanning tunneling microscope — •Mate Stark[1], Daria Sostina[2], Wantong Huang[1], Paul Greule[1], Christoph Sürgers[1], Philip Willke[1], and Wolfgang Wernsdorfer[1] — [1]Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Institute of Quantum Materials and Technologies (IQMT), Karlsruhe Institute of Technology, Karlsruhe, Germany

Throughout the last decades, scanning probe techniques, such as scanning tunneling microscopy (STM), have been successfully paving the way to discover and understand physics on the atomic scale. However, recent developments in studying single atoms' electronic and magnetic properties have shown experimental limitations. For instance, the combination of electron spin resonance (ESR) with STM has shown short spin relaxation time T_1 and phase coherence time T_2 on single atoms, among others limited by thermally excited electrons [Willke et al., Sci. Adv. 4(2), 1543 (2018)].

Here, we present the implementation of a compact closed-cycle dilution refrigerator (DR) reaching milli-Kelvin temperatures, which we combine with a commercial STM under ultra-high vacuum (UHV) conditions. This combination enables a fast cool down, shows a low vibrational level, and requires a minimum of everyday maintenance. We demonstrate the functionality of the DR-STM by performing ESR measurements on individual magnetic molecules.

O 77.4   Thu 11:15   REC C 213

Machine learning: radical technique or plus ça change? The case for automated scanning probe microscopy — •Dylan Barker, Adam Sweetman, and Phil Blowey — University of Leeds

Atomic resolution scanning probe microscopy (SPM) provides a critical tool for studying the chemical and electronic structure of surfaces at the single atom scale, however, practically these techniques require a large amount of experimental time to manually prepare the scanning probe tip in-situ, usually via controlled indents into the surface. This apparently simple, but time-consuming process, is potentially an ideal candidate for automation using machine learning and computer vision techniques. Previous attempts to automate the classification of probe tips from topographical images have been made using machine learning methods [1-2], however using prior knowledge of the system in question we find it is also possible to classify the tip state using computationally simple image analysis methods such as Fourier ring correlation and cross-correlation. In this work I will present a comparison between "deterministic" image analysis methods and machine learning approaches for tip state classification. I will also address the known issue of small sample sizes for training ML techniques for SPM image classification, via an automated (scripted) data generation approach.

O 77.5   Thu 11:30   REC C 213

Artificial Intelligence finds the optimal STM manipulation parameters of unknown molecules — •Bernhard Ramsauer[1], Grant J. Simpson[2], Leonhard Grill[2], and Oliver T. Hofmann[1] — [1]Institute of Solid State Physics, NAWI Graz, Graz University of Technology, Petersgasse 16, 8010 Graz, Austria — [2]Department of Physical Chemistry, Institute of Chemistry, NAWI Graz, University Graz, Heinrichstraße 28, 8010 Graz, Austria

Scanning probe microscopy gives us the possibility to precisely control the position and orientation of single molecules and unlocks the possibility of nanofabrication of novel structures with enhanced properties. However, interaction processes at the nanoscale are stochastic processes, and because their motion itself is often unintuitive and hard to predict, inducing controlled movements is not trivial at all.

In this study we present how a reinforcement learning algorithm identifies optimal manipulation parameters (i.e., the bias voltage, height, and lateral position of the STM tip relative to the molecule) for any unknown molecule to allow for precise control of its movement.

Leaving all the manipulation parameters open for investigation requires a method to exclude manipulation parameter that pick-up or destroy the molecule. Furthermore, already learned information is used to infer prior knowledge to similar manipulation parameters (e.g.: to infer knowledge at the same bias voltage to adjacent tip positions).

This allows for autonomous control of initially unknown molecules with high sub-nanometer precision that set the basis to construct molecular nanostructures from the bottom up.

O 77.6   Thu 11:45   REC C 213

Field-emission resonances at exceptional large voltages: Consequences for determining work functions — •Anika Schlenhoff[1], Gerassimos C. Kokkorakis[2], and John P. Xanthakis[2] — [1]Institute of Physics, University of Münster, Germany — [2]Electrical and Computer Engineering Department, National Technical University of Athens, Greece

In a scanning tunneling microscopy (STM) setup, a series of unoccupied electronic states evolve in the vacuum gap between the probe tip and the surface. Due to limited bias voltage ranges, so far only a small number (typically 4 - 8) of these so-called field-emission resonances (FERs) have been detected. Here, we report a combined experimental and theoretical study of FERs over an exceptional range of energy and number, typically tens of an eV and over thirty in order n [1]. Unlike commonly assumed, the triangular potential well is not found to be a good approximation for the high-n states. Although the spectroscopy mode assures a constant electric field at the tip apex, this leads only for the intermediate FERs (approx. $2 < n < 6$) to reside in a linear potential between the tip and the surface. At higher tip-sample distances d and bias voltages $U(d)$, the quantum well is no longer triangular but attains a curvature, which is d-dependent. Each high-n state resides in its own well that can be well-approximated by a polynomial of second order. Hence, the range of U_n to be analyzed in terms of spectroscopic positions needs to be chosen with great care when deducing surface work functions.

Phase compensation for ultrafast dynamic measurements of atomic spins — •Nicolaj Betz[1], Max Hänze[1,2], Gregory McMurtrie[1], Susanne Baumann[1], and Sebastian Loth[1,2] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — [2]Max Planck Institute for Solid State Research, Stuttgart, Germany

Understanding spin dynamics is vital for a wide range of applications , such as qubit manipulation. However, in many cases, especially for single atoms on surfaces, even stroboscopic measurement techniques, like pump-probe or pulsed electron spin resonance, do not provide enough time resolution to resolve the dynamics of the individual (atomic) spins. Such measurements are generally limited by the attenuation and distortion of the sharp pulses, that inevitably occurs due to imperfections in the instrumental setup. The attenuation in the frequency domain can be measured and compensated for [M. Herve, et al. Appl. Phys. Lett. 107, 093101, 2015]. However, such a compensation only has limited impact on the distortion. Here, we introduce a new technique, that enables the measurement of the phase shift between individual frequencies directly in the tunnel junction of a scanning tunneling microscope (STM). Using these phase shifts it is now possible to fully compensate arbitrary pulses and manipulate atomic spins with picosecond time resolution. Phase information also provides additional insights into stochastic resonance, an effect we recently utilized as an alternative way to measure spin dynamics [M. Hänze, et al. Sci. Adv. 7, 33, 2021], even of multiple spin states.

Simultaneous Measurement of Quasiparticle Interference and Decay Length Using Parallel Spectroscopy with the Scanning Tunneling Microscope — •Berk Zengin, Danyang Liu, Aleš Cahlík, Kevin Hauser, and Fabian D. Natterer — University of Zurich, Department of Physics, Winterthurerstrasse 190, 8057 Zurich, Switzerland

Developments in signal processing unlock the possibility to perform significantly faster spectroscopic measurements with a Scanning Tunneling Microscope by utilizing the harmonics created by non-linearities in the current-voltage characteristics. Having the capability to perform spectroscopy on the order of few milliseconds to measure the local density states(LDOS), we can afford to additionally vary the tip sample distance during QPI mapping, providing spatially and energy resolved decay length information. Our work shows how LDOS and decay length mapping can yield valuable insight into the electronic structure and dispersion relation of surface electrons.

Unveiling interference of Yu-Shiba-Rusinov states with novel multi-functionalized STM probe — •Artem Odobesko, Felix Friedrich, and Mathias Bode — Physikalisches Institut, Universität Würzburg, 97074, Würzburg, Germany

Scattering of superconducting pairs by magnetic impurities on superconducting surface results into pairs of sharp ingap resonances, known as Yu-Shiba-Rusinov states. By analogue with interference of quasiparticles scattered by defects in normal metals, these excitations form periodic charge density texture around magnetic impurity. Typically, STM is equipped with a superconducting (SC) probe to increase the energy resolution bypassing thermal broadening to detect these states. However, with such STM probe it almost unattainable to observe the spatial oscillatory behavior of YSR wave function due to a very fast spatial attenuation away from the impurity (with decay ~ 1/r). In this work, we attach a CO molecule to a SC-probe to maximize simultaneously both spatial and energy resolution. We examine the LDOS distribution of YSR states around the magnetic Fe dimer on Nb(110). The last leads to hybridization of YSR states, which can be interpreted as symmetric and antisymmetric combinations of YSR excitation of an individual Fe impurity. Using such CO-SC-probe we are able to map both symmetric and antisymmetric oscillatory interference patterns of hybridized YSR states in vicinity of Fe dimer. Compared to measurements made with CO-free probe, we demonstrate an exceptional spatial sensitivity combined with high energy resolution with a new multi-functionalized probe.

Data-centric heterogeneous catalysis: identifying rules and materials genes of alkane selective oxidation — •Lucas Foppa[1], Frederik Rüther[2], Michael Geske[2], Gregor Koch[3], Frank Girgsdies[3], Pierre Kube[3], Spencer J. Carey[3], Michael Hävecker[4], Olaf Timpe[3], Andrey Tarasov[3], Matthias Scheffler[1], Frank Rosowski[2], Robert Schlögl[3,4], and Annette Trunschke[3] — [1]The NOMAD Lab. at the FHI of the MPG and IRIS-Adlershof of HU Berlin — [2]BasCat Lab. at TU Berlin — [3]FHI of the MPG — [4]Max Planck Institute for Chemical Energy Conversion

Artificial Intelligence (AI) can accelerate materials design by identifying the key parameters correlated with the performance. However, widely used AI methods require big data, and only the smallest part of catalysis-research data meets the quality requirement for data-efficient AI. We use rigorous experimental procedures[1] to measure 55 physicochemical parameters as well as the reactivity of 12 catalysts towards ethane, propane, and *n*-butane oxidation. By applying the sure-independence-screening-and-sparsifying-operator approach to the so-

obtained data set, we identify nonlinear property-function relationships depending on several key parameters and reflecting the intricate interplay of processes governing selective oxidation.[2,3]

Adaptive Experimental Designs for the Unsupervised Exploration of Reaction Kinetic Phase Diagrams — •Frederic Felsen, Karsten Reuter, and Christoph Scheurer — Fritz-Haber-Institut der MPG, Berlin, Germany

In heterogeneous catalysis the interplay of various elementary processes taking place at the catalytic interface gives rise to complex kinetic phase diagrams [1]. Characteristic for such phase diagrams are regimes of smooth kinetic behavior separated by phase transitions going along with drastic changes in effective kinetics. Generally it is difficult to reconstruct the kinetic regime topology of a given

process without a detailed understanding of the underlying reaction mechanism. Here, we tackle this issue by approximating the reaction kinetics using statistically robust effective rate laws [2]. Locally fingerprinting the apparent behavior of a chemical reaction, we can generate point-wise regime labels as a basis for estimates of the position of the phase transitions. In order to achieve this in a data efficient way, we propose an iterative adaptive design algorithm, bridging between the classical theory of experimental design [3] and modern statistical learning and optimization. Using a microkinetic model, we illustrate the potential of this approach by investigating the kinetic phase diagram of CO oxidation over RuO_2.

Machine-learning Gaussian Approximation Potentials to discover RuO_2 surface reconstructions — •Yonghyuk Lee, Jakob Timmermann, Christoph Scheurer, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin, Germany

Machine-learning Gaussian Approximation Potentials (GAPs) have recently evolved into a powerful class of surrogate models for computationally demanding first-principles calculations. Combined with structure exploration techniques, they enable us to examine the potential energy surface of interest with a hitherto unforeseen combination of physical accuracy and computational efficiency and to achieve global surface structure determination (SSD) for increasingly complex systems. This can be exploited, e.g., to discover novel surface motifs, which are critical in understanding the dynamics of heterogeneous catalysts under operating conditions. In our preceding study on IrO_2, this methodology was extended by a general and data-efficient active-learning framework that allows for the on-the-fly generation of GAPs via the actual surface exploration process. During the iterative GAP refinement for RuO_2, we have now identified plenty of unknown low-energy reconstructions of RuO_2 low index facets. Intriguingly, by extending the searching space to larger surface unit cells, we discovered $c(2 \times 2)$ reconstructions of $RuO_2(100)$, which provide solutions to longstanding questions in heterogeneous catalysis and experiments.

Exploration of IrO2 electrocatalyst deactivation via machine learning potentials — •Hao Wan, Hendrik Heenen, Simon Wengert, Christoph Scheurer, and Karsten Reuter — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany

IrO2 catalysts are one of the best performing oxygen evolution reaction (OER) catalysts in terms of both catalytic activity and stability under harsh acidic conditions. Yet, they still suffer from deactivation under long term OER conditions due to possible changes in surface compositions and morphology. To shed light into these deactivation processes, characterization of the microscopic structure and composition of IrO2 interfaces is necessary. The involved phase space, however, is vast and its exploration requires extensive sampling and automatic (surface) structure searches which are unfeasible via Density Functional Theory (DFT) calculations. Enabling the intensive computations, machine learning interatomic potentials (MLIP) retain DFT accuracy to within a few meV per atom while reducing the computational cost by up to three orders of magnitude.

In this contribution, we present a reliable MLIP based on Gaussian approximation potentials to investigate IrO2 deactivation. Stable and metastable IrO2 surfaces at various surface oxidation states have been extensively sampled using parallel tempering. Relevant surfaces are suggested by evaluating their relative stability compared to rutile-IrO2(110), while considering electrochemical conditions. OER activity from these surfaces can be estimated using established reaction descriptors which will help unravel likely deactivation mechanisms.

O 78.5   Thu 11:30   TRE Phy

Machine Learning Driven Molecular Dynamics Simulation of the M1 Selective Oxidation Catalysts — •Kyeonghyeon Nam[1], Yonghyuk Lee[1], Liudmyla Masliuk[2], Thomas Lunkenbein[2], Annette Trunschke[2], Christoph Scheurer[1], and Karsten Reuter[1] — [1]Theory, Fritz-Haber-Institut der MPG — [2]Inorganic Chem. Dept., Fritz-Haber-Institut der MPG, Berlin, Germany

The activity and selectivity of realistic heterogeneous catalysts can be altered noticeably by small changes in a multitude of factors such as bulk composition, dopants, defects, reaction conditions, etc. Their effects are furthermore interrelated in non-trivial ways. As an important first step to rationally disentangle them, we here aim to understand their influences on the evolution of local atomic-scale structural motifs presented by the catalyst. Specifically, we do this for the M1 structural modification of $(Mo,V)O_x$ and $(Mo,V,Te,Nb)O_x$ as an active catalyst for oxidative dehydrogenation of ethane to ethylene. The large primitive cell of the M1 catalyst challenges a detailed study of all surface terminations by means of predictive-quality first-principles calculations. To this end, we deconstruct the primitive cell into 'rod-like structures' of surface motifs with

various oxygen content. A machine-learned Gaussian Approximation Potential (GAP), trained against this structural library, faithfully reproduces experimental data from electron microscopy [1]. MD simulations of M1 catalyst hk0 prismatic faces with the iteratively improved GAP help to rationalize the influence of vanadium and niobium doping on the active surface structure.

O 78.6   Thu 11:45   TRE Phy

Studing of rate-limiting steps on CO_2 reduction on ZnO/Cu(111) — •Sina Dortaj[1,2] and Sebastian Matera[1,2] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Institute for Mathematics, Freie Universität, Berlin, Germany

To simulate the chemical kinetics of heterogeneous catalysts, the kinetic Monte Carlo (kMC) method is a common choice as it allows estimating turnover frequencies and coverages with a tunable accuracy. This advantage comes at much higher computational costs compared to classical kinetic approaches, in addition to stochastic noise on the simulation results. Thus, local sensitivity analysis to determine the rate-limiting step becomes cumbersome. Additionally, rate constants often carry some sizeable uncertainty due to the intrinsic approximations in quantum chemical methods or the noise in experimental data used to determine reaction barriers that make the use of just local methods obscure. We address both problems, high costs, and parameter uncertainties, by a novel global sensitivity analysis based on the Cramér von Mises distance and a Quasi-Monte Carlo sampling of the space of rate constants. While applicable to any model, our approach is particularly suited for the use of kMC and other Monte Carlo models. We demonstrate the approach on the CO_2 reduction on ZnO/Cu(111) catalysts identifying the key atomic scale factors controlling activity and selectivity.

O 78.7   Thu 12:00   TRE Phy

Identifying materials genes describing selectivity of catalytic CO_2 hydrogenation: an AI approach with theoretical and experimental data — •Ray Miyazaki[1], Kendra Belthle[2], Harun Tüysüz[2], Lucas Foppa[1], and Matthias Scheffler[1] — [1]The NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft and IRIS-Adlershof of the Humboldt-Universität zu Berlin, Germany — [2]Max-Planck-Institut für Kohlenforschung, Germany

Investigating CO_2 hydrogenation by heterogeneous catalysis that mimics hydrothermal vents leads to a deeper understanding of the origin of organic molecules at the early earth [1]. We focus on cobalt nanoparticles supported on M-SiO$_2$ where hetero atoms (e.g., Ti or Al) are incorporated into SiO_2. However, heterogeneous catalysis is governed by an intricate interplay among multi-scale processes. Thus, it is rather difficult, if not impossible, to identify the key physical parameters correlated with the catalytic performance (*materials genes*) directly by theoretical or experimental approaches. In this study, materials properties obtained from density functional theory calculations and experiments, such as adsorption energy of CO_2 and measured pore volume, are used to model the experimental selectivity of each organic molecule (e.g., CH_3OH, CH_4) by the sure-independence screening and sparsifying operator (SISSO) AI approach [2]. In order to accelerate catalyst design, we also investigate the accuracy of the models using input parameter sets with the different acquisition cost.

O 78.8   Thu 12:15   TRE Phy

Structural and Electronic Properties of Iron Nanoparticles onto Well-Defined Ceria Thin Films — •Lesia Piliai[1], Mykhailo Vorokhta[1], Peter Matvija[1], Tomáš Skála[1,2], Ivan Khalakhan[1], and Iva Matolínová[1] — [1]Charles University, Prague, Czech Republic — [2]Elettra-Sincrotrone, Elettra-Sincrotrone, Italy

The interaction of iron with ceria using model Fe/ceria systems consisting of Fe nanoparticles vapor deposited on well-ordered CeOx(x=1,5;2) thin films grown on Cu(111) has been investigated by X-ray photoelectron spectroscopy (XPS), synchrotron radiation photoemission spectroscopy (SRPES), and scanning tunneling microscopy (STM). The Fe atoms are oxidized to Fe3+ and Fe2+ species upon deposition on CeO2 at 300 K at the cost of the reduction of Ce4+ to Ce3+. With increasing the Fe coverage, the concentration of Ce3+ increases monotonically. The notable growth of Fe2+ species was observed upon deposition on CeO2 at 300 K, but Fe3+ species remain predominant in Fe/CeOx systems. Our studies demonstrate that in comparison with other transition metals, Fe remains oxidized on ceria even at higher coverage and exhibits a small particle size, likely arising from strong metal*support interactions. Combining the SRPES and STM data suggests that annealing to higher temperatures leads to the formation of an iron-ceria solid solution. These results illustrate that Fe modifies both the electronic and structural properties of ceria depending on external conditions.

O 78.9   Thu 12:30   TRE Phy

In situ characterization of cerium oxide on Au(111) under reducing and oxidizing conditions by low-energy electron microscopy — •RUDI TSCHAMMER[1], LARS BUSS[1,2], CARLOS MORALES[1], SANJAYA SENANAYAKE[3], JENS FALTA[2,4], and JAN INGO FLEGE[1] — [1]Applied Physics and Semiconductor Spectroscopy, BTU Cottbus-Senftenberg, Cottbus, Germany — [2]Institute of Solid State Physics, University of Bremen, Bremen, Germany — [3]Chemistry Division, Brookhaven National Laboratory, Upton, NY 11973, USA — [4]MAPEX Center for Materials and Processes, University of Bremen, Bremen, Germany

The development of novel catalysts for a variety of applications is a key challenge for modern catalysis. Inverse metal oxide catalysts consisting of oxide nanoparticles dispersed on a metal support have recently attracted much attention, showing higher activity and selectivity compared to traditional catalytic systems, harnessing synergistic effects attributed to the so-called metal-support interaction. To gain further insights, we deposited cerium oxide nanoparticles on Au(111) and studied this system by low-energy electron microscopy (LEEM) and low-energy electron diffraction (LEED). The prepared samples demonstrate a distinct correlation between the deposition temperature and the structural order of the nanoparticles. This has been expanded upon by exploring the changes induced by reduction with H_2 and reoxidation with O_2 or CO_2, again exhibiting a connection between structural order and activity, while also showing the influence of the oxide-metal interaction on the stability of cerium oxide under reducing conditions.

O 79: Focus Session: Frontiers of Electronic-Structure Theory VI (joint session O/HL)

Nailing down charge-density-wave phase-transition temperatures with downfolding approaches — •ARNE SCHOBERT[1], JAN BERGES[2], MICHAEL SENTEF[3], ERIK VAN LOON[4], SERGEY BRENER[1], MARIANA ROSSI[3], and TIM WEHLING[1] — [1]University of Hamburg, Germany — [2]University of Bremen, Germany — [3]MPSD, Hamburg, Germany — [4]Lund University, Sweden

The coupled dynamics of electrons and nuclei is an extremely complex problem of relevance to multiple branches of sciences. *Ab initio* molecular dynamics (AIMD) simulations are often challenging — especially in large systems, on long time scales, in non-equilibrium or in presence of strong correlation. We can overcome these problems by mapping the full *ab initio* density functional theory (DFT) Hamiltonian onto a low-energy lattice model through downfolding. Three different downfolding strategies based on constraining, unscreening and combinations thereof are compared. The best performing model, which properly accounts for anharmonicity, is combined with path integral molecular dynamics (PIMD). This allows us to nail down the transition temperatures of charge-density waves — for instance in 1H-TaS_2.

O 79.2   Thu 10:45   TRE Ma

Structural and electronic properties of the $Ba_8Au_xGe_{46-x}$ clathrate: an ab-initio study with cluster expansion — •PETER WEBER, SANTIAGO RIGAMONTI, and CLAUDIA DRAXL — Humboldt-Universität zu Berlin, Berlin, Germany

Intermetallic clathrate materials are promising candidates for high-efficiency thermoelectric applications as they can reach very low thermal conductivity. These materials possess a cage-like structure containing guest atoms. Their electronic properties can be tailored by exploiting the idea of the phonon-glass–electron-crystal which allows for reaching a large figure of merit. We study the compound $Ba_8Au_xGe_{46-x}$ ($0 \leq x \leq 8$), which has raised interest due to its glass-like thermal conductivity [1]. Using the Zintl concept, a semiconducting state is expected to occur at the charge-balanced composition corresponding to x=5.33. This composition requires a supercell of at least 3 unit cells (162 atoms) which makes a direct *ab initio* study challenging. We tackle this problem by using the cluster expansion method combined with density-functional theory calculations. In this way, we are able to find the atomic ground-state configurations, together with various properties at different temperatures and gold content. These include lattice constants, bond lengths, site occupancies, as well as band gaps and band structures which are compared with available experimental data.

Topical Talk   O 79.3   Thu 11:00   TRE Ma

New Opportunities for First Principles Simulations of Thousands of Atoms Using Linear Scaling Density Functional Theory — •LAURA RATCLIFF — University of Bristol, Bristol, United Kingdom

Density-functional theory (DFT) is routinely used to simulate a wide variety of materials and properties, however, standard implementations are cubic scaling with the number of atoms, limiting the system sizes which can be treated. This motivated the development of alternative implementations of DFT, which exploit the nearsightedness principle by using a localised description of the system, leading to algorithms with linear scaling (LS) cost which can treat large systems containing tens of thousands of atoms. One approach, which is implemented in the wavelet-based BigDFT code, uses localised orbitals, also known as support functions, which are optimised to reflect their local chemical environment, and thus constitute an accurate minimal basis set. Beyond reduced computational cost, the localised support function description also facilitates additional developments, such as the ability to automate a fragment-based description. In this talk we will present the formalism behind LS-BigDFT, including some examples of the new types of systems and analyses which are opened up by the ability to treat such large systems. We will also describe recent developments in PyBigDFT, a python-based interface which aims to simplify the usage of LS-BigDFT for complex systems and workflows.

Fully Anharmonic Electronic Transport Coefficients from Temperature-dependent Spectral Functions — •JINGKAI QUAN, MATTHIAS SCHEFFLER, and CHRISTIAN CARBOGNO — The NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft and IRIS-Adlershof of the Humboldt-Universität zu Berlin

The combination of *ab initio* molecular dynamics (aiMD) and band-structure unfolding techniques provides a non-perturbative route to obtain temperature-dependent spectral functions. [1] In contrast to commonly employed perturbative approaches [2], this technique accounts for all orders of anharmonic and vibronic couplings. Building on this non-perturbative formalisms, we here present an approach to obtain electronic transport coefficient such as the electrical conductivity using Kubo's formulation of the fluctuation-dissipation theorem. By this means, all relevant quantities, including electron lifetimes, are obtained from the unfolded, self-consistent wave functions computed during the aiMD runs. We critically benchmark the approach against existing perturbative data for harmonic systems, carefully analyzing to which extent short- and long-range couplings are captured with increasing supercell size. Furthermore, we demonstrate the advantages of the proposed approach for strongly anharmonic systems, for which perturbative approaches become unreliable.

Accurate prediction of vibrational spectra for solid state systems from ab initio molecular dynamics — •EKIN ESME BAS, THOMAS HEINE, and DOROTHEA GOLZE — Chair of Theoretical Chemistry, Technische Universität Dresden, 01062 Dresden, Germany

We present a highly accurate computational method to calculate vibrational spectra for solid state materials, primarily for covalent-organic frameworks (COFs). IR and Raman spectra are important tools that are frequently used for material characterization. However, the experimental spectra are often difficult to interpret without aid from theory. The computation of IR and Raman spectra is usually based on the harmonic approximation where molecular vibrations can be determined as normal modes from the second derivatives of the electronic energy with respect to the coordinates. Although this method is more straightforward and computationally less expensive, anharmonic modes cannot be captured. Thus, we employ an AIMD (ab initio molecular dynamics) based approach to include vibrational anharmonicities. Power, IR and Raman spectra can then be calculated via a Fourier transformation of the time correlation functions of velocities, dipole moments and polarizability tensors, respectively [1]. We discuss different approaches to compute dipole moments and polarizabilities. We present the power, IR and Raman spectra we calculated for COF-1, and we compare our AIMD based approach to the spectra obtained via harmonic approximation and experiment.

Anharmonic Fingerprints from THz Modes of Polyacene Crystals — •PAOLO LAZZARONI, SHUBHAM SHARMA, and MARIANA ROSSI — Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany

Organic molecular crystals exhibit strong lattice anharmonicity, especially in the collective motions that are governed by intermolecular interactions and lie in the low-frequency THz range [1]. Inspired by recent observations that the polarization-orientation (PO) Raman spectra can give exquisite insight into the anharmonic couplings between modes [2], we devise a first-principles framework that can reproduce, explain and give quantitative insight into the type and

strengths of mode coupling. This framework is based on machine-learned potentials and polarizability tensors trained on *ab initio* molecular dynamics trajectories [3]. We obtain results through the time-correlation formalism for PO Raman signals, retaining the full anharmonic nature of the potential, and perform a novel analysis of effective temperature-dependent mode couplings from our trajectories. A first-principles Newns-Anderson chemisorption function applied to ultrafast electron transfer — •Simiam Ghan[1], Elias Diesen[1], Christian Kunkel[1], Karsten Reuter[1], and Harald Oberhofer[2] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany. — [2]University of Bayreuth, Bayreuth, Germany

We offer a method to calculate the electronic couplings H_{ad} between an adsorbate and substrate in an ab-initio fashion. The couplings are acquired by projec-

tion of the Kohn-Sham Hamiltonian onto a diabatic basis[1]. By averaging over the Brillouin Zone, it becomes possible to calculate a convergent chemisorption function of Newns and Anderson[2], which gives the energetic broadening of an adsorbate frontier orbital upon adsorption. This broadening corresponds to the experimentally-observable lifetime of an electron in the state, which we confirm for the case of core-excited $Ar^*(2p_{3/2}^{-1}4s)$ atoms on a number of transition metal surfaces[3].

We find that the (tunneling) model captures and elucidates aspects of energy-dependence, spin, phase cancellation and k-space in the electron transfer process, in particular suggesting a significant role played by the surface d-bands. Given the prevalence of electronic couplings - and the chemisorption function - in theoretical models, we discuss potential for further applications.

Energy and momentum distribution of surface plasmon-induced hot carriers — •Christopher Weiss[1], Michael Hartelt[1], Pavel N. Terekhin[1], Tobias Eul[1], Anna-Katharina Mahro[1], Benjamin Frisch[1], Eva Prinz[1], Baerbel Rethfeld[1], Benjamin Stadtmüller[1,2], and Martin Aeschlimann[1] — [1]Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, Germany

Are the spectroscopic properties of plasmon- and photon-induced hot carriers fundamentally different? Electrons excited at the bulk plasmon resonance, for example, exhibit a distinct spectroscopic signature [1]. However, bulk plasmons are rather unsuited for technological applications compared to surface plasmons.

To answer the initial question for surface plasmons, we separate the energy and momentum distributions of surface plasmon polariton (SPP)-induced hot electrons from those of photoexcited electrons in a two-color time-resolved photoemission electron microscopy experiment.

In our experiment, these SPP-induced hot electrons show only small momenta parallel to the surface and a narrow energy distribution close to the Fermi energy [2]. This result clearly distinguishes them spectroscopically from their photoinduced counterparts.

Lorentz Microscopy of Optical Fields — •John H. Gaida[1,2], Hugo Lourenço-Martins[1,2], Sergey V. Yalunin[1,2], Armin Feist[1,2], Murat Sivis[1,2], Thorsten Hohage[3], F. Javier García de Abajo[4,5], and Claus Ropers[1,2] — [1]MPI for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Germany — [3]Institute of Numerical and Applied Mathematics, University of Göttingen, Germany — [4]ICFO-Institut de Ciencies Fotoniques, Castelldefels (Barcelona), Spain — [5]ICREA-Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain

In electron microscopy, detailed insights into nanoscale optical properties of materials are gained by spontaneous inelastic scattering leading to electron-energy loss and cathodoluminescence. Photon-induced near-field electron microscopy (PINEM) allows for mode- and polarization-selective imaging based on stimulated scattering in the presence of external sample excitation. Through this process a spatial phase profile inherited from the optical fields is imprinted onto the wave function of the probing electrons. Here, we introduce Lorentz-PINEM for the full-field, non-invasive imaging of complex optical near fields at high spatial resolution. We use energy-filtered defocus phase-contrast imaging and iterative phase retrieval to reconstruct the phase distribution of interfering surface-bound modes on a plasmonic nanotip. Our approach is universally applicable to retrieve the spatial phase of nanoscale fields and topological modes.

Topological Plasmonics and Plasmonic Twistronics: Skyrmions, Merons, Quasicrystals, and Sykrmion Bags — •Harald Giessen[1], Bettina Frank[1], Pascal Dreher[2], David Janoschka[2], Frank Meyer zu Heringdorf[2], Julian Schwab[1], Tim Davis[1,4], Kobi Cohen[3], Shai Tsesses[3], and Guy Bartal[3] — [1]4. Physikalisches Institut, Universität Stuttgart, Germany — [2]CENIDE, University of Duisburg-Essen — [3]Technion, Haifa, Israel — [4]University of Melbourne, Australia

We present ultrafast vectorial electric field measurements of plasmonic skyrmions, merons, quasicrystalline structures, and skyrmion bags. 10 nm spa-

tial resolution, sub-fs temporal resolution, and vectorial properties of the surface plasmon field on single crystalline, atomically flat gold surfaces are presented. Our techniques combine ultrafast vector PEEM and interferometric s-SNOM. Our tailored model systems reveal a rich set of topological phenomena, reaching even into 4-dimensional topology.

O 80.4   Thu 16:00   CHE 89

Direct imaging of photonic band-edge states in golden-angle Vogel spirals using photoemission electron microscopy — Martin Aeschlimann[1], Felix Fenner[2], Tobias Brixner[3], Benjamin Frisch[1], Patrick Folge[4], Michael Hartelt[1], •Matthias Hensen[3], Thomas H. Loeber[5], Walter Pfeiffer[2], Sebastian Pres[3], and Bernd Stannowski[6] — [1]Fachbereich Physik and Research Center OPTIMAS, TU Kaiserslautern, 67663 Kaiserslautern, Germany — [2]Fakultät für Physik, Universität Bielefeld, 33615 Bielefeld, Germany — [3]Institut für Physikalische und Theoretische Chemie, Universität Würzburg, 97074 Würzburg, Germany — [4]Angewandte Physik, Universität Paderborn, 33098 Paderborn, Germany — [5]Nano-Structuring-Center, 67663 Kaiserslautern, Germany — [6]5PVcomB, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, 12489 Berlin, Germany

Golden-angle Vogel spirals, as deterministic aperiodic structures, support isotropic photonic band gaps and have interesting applications. Especially localized modes, such as band-edge states, are essential for tailored light–matter interaction. Here we report imaging of such modes using photoemission electron microscopy (PEEM). Tunable ultrashort light pulses excite them in golden-angle Vogel spirals that were fabricated by focused-ion-beam (FIB) milling of an a-Si:H layer. The local near-field leads to electron emission which is detected spatially resolved. The demonstration of FIB-textured a-Si:H as photonic material and the ability of PEEM mode imaging offers means to spatiotemporally resolve mode dynamics and to perform nanospectroscopy.

O 80.5   Thu 16:15   CHE 89

Short-range plasmonic skyrmions — •Bettina Frank[1], Simon Mangold[1], Harald Giessen[1], Pascal Dreher[2], Frank Meyer zu Heringdorf[2], and Stefan Kaiser[1] — [1]4. Physikalisches Institut, Universität Stuttgart, Germany — [2]CENIDE, University of Duisburg-Essen

We utilize ultrathin, atomically flat, single crystalline gold flakes which compress the plasmon wavelength to lambda_air/7. Using hexagonal boundaries that are carved with focused gold ions, we demonstrate plasmonic skyrmions, both using PEEM as well as s-SNOM. The electromagnetic field is structured on a 140 nm scale, which offers opportunities for topological light-matter interaction on a deep subwavelength scale.

O 80.6   Thu 16:30   CHE 89

Phase-resolved mapping of plasmonic resonances at nanostructures — •Tim Dauwe[1,2], Hugo Lourenco-Martins[1,2], Murat Sivis[1,2], Jakob Hagen[1,2], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, 37077 Göttingen, Germany — [2]IV. Physical Institute, University of Göttingen, 37077 Göttingen, Germany

In this contribution, we study resonant plasmonic nanostructures by a combination of inelastic electron-light scattering techniques. We investigate metallic nanorods using electron-energy loss spectroscopy (EELS) and photon-induced near-field electron microscopy (PINEM), elucidating spectrally-dependent mode profiles and symmetries using spontaneous and stimulated interactions. We explore multicolor excitation and nonlinear wave mixing as contrast mechanisms accessing spatial phase profiles and local nonlinear response.

O 80.7 Thu 16:45 CHE 89

Shortcut to Self-Consistent Light-Matter Interaction and Realistic Spectra from First Principles — •CHRISTIAN SCHÄFER[1,2] and GÖRAN JOHANSSON[1] — [1]Department of Microtechnology and Nanoscience, MC2, Chalmers University of Technology, 412 96 Göteborg, Sweden — [2]Department of Physics, Chalmers University of Technology, 412 96 Göteborg, Sweden

Nanoplasmonic and optical cavity environments provide a novel handle to nonintrusively control materials and chemistry. We introduce here a simple approach to how an electromagnetic environment can be efficiently embedded into state-of-the-art electronic structure methods, taking the form of radiation-reaction forces [1]. We demonstrate that this self-consistently provides access to various optical effects and provides an efficient path to connect vastly different system scales [2]. As an example, we illustrate its seamless integration into time-dependent density-functional theory and its application to polaritonic chemistry with virtually no additional cost, presenting a convenient shortcut to self-consistent light-matter interactions.

[1] C. Schäfer and G. Johansson, PRL 128, 156402 (2022).
[2] C. Schäfer, J. Phys. Chem. Lett. 2022, 13, 6905-6911.

O 80.8 Thu 17:00 CHE 89

Microscopic description of the optical response in metal nanoparticles — •JONAS GRUMM, ROBERT SALZWEDEL, MALTE SELIG, and ANDREAS KNORR — Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Berlin, Germany

The optical response of metal nanoparticles is dominated by the formation of collective electronic resonances, so-called localized plasmons.

Here, we present a microscopic approach to their temporal dynamics based on the self-consistent treatment of the microscopic Boltzmann transport equations and the macroscopic Maxwell's equations for the electromagnetic fields. The corresponding numerical simulations describe the formation, propagation and thermalization dynamics of plasmons via the coupled electron-phonon dynamics in the self-consisting solved optical field. The formalism allows nonlinear optical processes to be included in the description.

O 81: Oxide and Insulator Surfaces I: Adsorption and Reaction of Small Molecules

Time: Thursday 15:00–18:00   Location: CHE 91

O 81.1 Thu 15:00 CHE 91

Adsorption of phosphonic acids on Fe_3O_4 (001) surfaces - a DFT study — WERNFRIED MAYR-SCHMÖLZER, JOHANN FLEISCHHAKER, SOMAK BANERJEE, KAI SELLSCHOPP, and •GREGOR VONBUN-FELDBAUER — Institute of Advanced Ceramics, TU Hamburg, Germany

The usage of magnetite nanoparticles is interesting for diverse applications from catalysis to hybrid materials. In organic-inorganic hybrids, organic linker molecules are used to allow for the self-assembly of functionalized nanoparticles. The impact of linkers with different functional groups on the, e.g., mechanical properties of assembled materials is not fully clear yet. Here, we present results from investigating the adsorption of small phosphonic acids on the magnetite (001) surface using density functional theory calculations to shed light on this essential interface. For the surface a distorted bulk truncated termination and the sub-surface cation vacancy reconstruction model are used. The adsorption configuration space is sampled and configurations as input for DFT calculations are selected using unsupervised machine learning approaches. Structural, energetic, electronic, and vibrational results are presented and compared to carboxylic acids. Potentials for multi-scale modeling approaches are sketched.

O 81.2 Thu 15:15 CHE 91

Predicting platinum adatom geometries on hematite for single-atom catalysis — •FLORIAN BUCHNER, RALF WANZENBÖCK, JESÚS CARRETE, and GEORG K. H. MADSEN — Institute of Materials Chemistry, TU Wien, 1060 Vienna, Austria

In single-atom catalysis, where isolated adatoms anchored on a support are used as catalysts, performance is highly sensitive to the charge state and coordination of the adatoms. This offers new avenues to design and tune catalysts. But to do so efficiently, a detailed understanding of the potential energy surface (PES) of the adatom-substrate system is needed.

In this theoretical study, we present an application of an evolutionary algorithm, the covariance matrix adaptation evolution strategy (CMA-ES) [M. Arrigoni et al., npj Comput Mater 7, 1–13 (2021)], to the prediction of Pt adatom configurations on the $(1\bar{1}02)$ surface of hematite (α-Fe_2O_3).

We find a rich PES that is not only governed by the large-scale adatom geometry but also reflects competing electron localization between the Pt and substrate Fe atoms, giving rise to sets of geometrically almost identical structures whose energies nonetheless span an appreciable range. We further discuss the effect of substrate doping on this localization and argue that a combination of different experimental methods and theory is required to understand observed adatom geometries.

O 81.3 Thu 15:30 CHE 91

Growth and adsorption studies of magnetite nanoparticles on Al2O3 — •MOHAMMAD EBRAHIM HAJI NAGHI TEHRANI[1,2], MARCUS CREUTZBURG[1], HESHMAT NOEI[1], and ANDREAS STIERLE[1,2] — [1]Deutsches Elektronen-Synchrotron (DESY), D-22603 Hamburg, Germany — [2]Fachbereich Physik Universität Hamburg, Jungiusstrasse 9, 20355 Hamburg, Germany

Magnetite (Fe3O4) is an important transition metal oxide with diverse applications in catalysis, data storage and biomedical imaging. In this study, we grow model catalyst magnetite nanoparticles on Al2O3(0001) surface under UHV conditions and at different temperatures: 150, 300, 500, and 700°C. Grazing incidence X-ray diffraction (GIXRD) and microscopy techniques were assisted in defining the facet and morphology of the developed nanoparticles, respectively. GIXRD outcomes indicated the formation of 111 oriented nanoparticles. Fourier transmission infrared reflection-absorption spectroscopy (FTIRRAS) was performed to study the adsorption of formic acid on magnetite/Al2O3 samples. The results demonstrate different types of adsorption and dissociation of formic acid. The results of this study can be applied as a paradigm in order to provide insight into the fundamental surface science of the next generation of the hierarchical organic-linked magnetite.

O 81.4 Thu 15:45 CHE 91

$Fe_3O_4(111)$: surface structure and CO adsorption — •JOHANNA HÜTNER[1], FLORIAN KRAUSHOFER[1], MATTHIAS MEIER[1,2], ZDENEK JAKUB[3], CESARE FRANCHINI[2,4], MICHAEL SCHMID[1], ULRIKE DIEBOLD[1], GARETH S. PARKINSON[1], and JAN BALAJKA[1] — [1]Institute of Applied Physics, TU Wien, Austria — [2]Computational Materials Physics, University of Vienna, Austria — [3]CEITEC, Brno University of Technology, Czech Republic — [4]Department of Physics and Astronomy, Università di Bologna, Italy

The surface structure of $Fe_3O_4(111)$ has been the subject of an ongoing debate. The most stable termination, over a wide range of oxygen chemical potentials, has a layer of tetrahedrally coordinated iron atoms (Fe_{tet1}). We present AFM data that show an almost perfect grid of Fe_{tet1} atoms. In filled states STM images, iron atoms exhibit varying contrast, suggesting electronic structure variations among the cation sites. We study the adsorption of CO as a probe molecule on the $Fe_3O_4(111)$ surface with noncontact AFM. The data show that CO adsorbs on top of Fe_{tet1} atoms at all coverages. We identify coverage-dependent adsorption structures with varying CO–CO spacings. We propose that the apparent CO–CO repulsion is a substrate-mediated effect that could be explained by charge redistribution in the surface. The CO ordering on a defect-free $Fe_3O_4(111)$ surface is consistent with previously measured temperature programmed desorption data. Our findings contribute to the understanding of the electronic structure of the $Fe_3O_4(111)$ surface and will be a requisite for modeling the adsorption of more complex molecules.

O 81.5 Thu 16:00 CHE 91

Reactivity and Influence of Catalytic Support Materials - a combined in situ and operando Infrared Study of CeO2 — •ERIC SAUTER[1], LACHLAN CAULFIELD[1], ALEXEI NEFEDOV[1], FLORIAN MAURER[2], DARIA GASHNIKOVINA[2], JAN-DIRK GRUNWALDT[2], and CHRISTOPH WÖLL[1] — [1]Institute of Functional Interfaces (IFG), Karlsruhe Institute of Technology (KIT), Hermann-von-Helmholtz-Platz 1, 76344 Eggenstein-Leopoldshafen, Germany — [2]Institute for Chemical Technology and Polymer Chemistry (ITCP), Karlsruhe Institute of Technology (KIT), Engesserstraße 20, 76131 Karlsruhe, Germany

For most catalytic reactions the morphology, oxidation state and support were found to have a strong influence on the catalytic activity. Investigation of the most active sites, the support material and its behavior under model as well as realistic conditions is a prerequisite for a comprehensive understanding of catalytic processes. With Infrared Spectroscopy the surface composition and interaction with water, as well as carbon monoxide, can be investigated. The combination of low temperature, UHV gas adsorption as well as operando DRIFTS was used to characterize CeO2 as catalytic support material. The adsorption of CO on single crystals was used as reference for the interpretation of more complicated spectra like powders or nanoparticles. The interactions with water have shown the high reactivity of the cerium oxide surface, which at the end leads to hydroxyl termination. With the use of in situ and operando Infrared spectroscopy the behavior of catalysts and their support material can be investigated, under realistic reaction conditions, into more detail.

O 81.6 Thu 16:15 CHE 91

Reduction of ceria with carbon monoxide - A high resolution, operando DRIFTS study — •Lachlan Caulfield, Eric Sauter, and Christoph Wöll — Institute of Functional Interfaces (IFG), Karlsruhe Institute of Technology (KIT), Hermann-von-Helmholtz-Platz 1, Eggenstein-Leopoldshafen, 76344, Germany

In the last decades, ceria-based systems have seen an increase in popularity, due to its unique redox behavior and catalytic characteristics. Ceria powders are widely used in exhaust catalysts as well as other catalytic cycles, in particular due to the cheap and simple preparation methods. To gain a better understanding of the chemical and structural behavior of ceria nanoparticles and their interaction with gaseous molecules, an operando DRIFTS study was carried out. Following the complete oxidation of the powder samples, they were introduced in a carbon monoxide atmosphere at room temperature. By tuning the pressure of carbon monoxide gas as well as the reaction temperature inside the catalytic cell it was possible to observe the reduction and structural changes of ceria, induced by the presence of carbon monoxide. Using operando DRIFTS with carbon monoxide as a reducing agent as well as a probe molecule, the chemical and structural changes of ceria can be easily investigated.

O 81.7 Thu 16:30 CHE 91

Tailoring photolytic reaction products by application of a low interacting rare gas decoupling layer — •Inga Langguth[1], Julien Rowen[2], Wolfram Sander[2], and Karina Morgenstern[1] — [1]Chair of Physical Chemistry I, Ruhr-Universität Bochum, Germany — [2]Chair of Organic Chemistry II, Ruhr-Universität Bochum, Germany

While carbene molecules are known to be highly reactive and short living reactants in gas phase, they are passivated on metal surfaces upon chemisorption. Thin solid rare gas films on coinage metal surfaces are a novel type of decoupling layer applicable for STM investigations. Thus, it is taken advantage of the low interacting chemical environment of xenon (Xe) monolayer on Ag(110) in order to investigate the photolytic reactions of classical carbenes. The reaction products of the carbene coupling formed on the Xe layer adsorbed on the metal are straightforwardly accessed by subsequent Xe desorption. Vast structural differences reveal that the reaction products formed on the Xe substantially differ from the species formed under the same conditions on the metal surface. Both reaction products are compared, revealing the tool function of the non-ionic, low interacting rare gas decoupling layer for tailoring reaction pathways.

O 81.8 Thu 16:45 CHE 91

Methanol and water compete for the same adsorption sites on In$_2$O$_3$(111) — Chiara Wagner[1], Andreas Ziegler[2], Michael Schmid[1], Bernd Meyer[2], Ulrike Diebold[1], and •Margareta Wagner[1] — [1]Institute of Applied Physics, TU Wien, Austria — [2]Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg, Germany

Indium oxide, a transparent conductive oxide, has been discovered to be a highly selective catalyst for methanol synthesis by CO$_2$ hydrogenation. The large surface unit cell of In$_2$O$_3$(111) exhibits a variety of Lewis acid and base sites for methanol and water adsorption. We compare the adsorption of both molecules under UHV conditions by employing AFM, STM, XPS, and TPD, together with DFT calculations. For medium coverages up to 9 molecules per surface unit cell we find a similar behavior: Initially, at room temperature, both molecules dissociate and protonate the most reactive O sites of the unit cell. When both molecules are dosed consecutively, methanol readily replaces water, while water is less efficient to substitute methanol. Below 300 K, both methanol and water adsorb molecularly in less-favored regions of the unit cell, still occupying the same sites and thus forming the same structural motifs. However, at coverages beyond 9 molecules per unit cell significant difference are found due to the ability of water to form and receive two hydrogen bonds instead of only one in the case of methanol.

O 81.9 Thu 17:00 CHE 91

How the (2x1) Reconstruction of Calcite (10.4) dominates the Desorption Kinetics of Water and Ethanol — •Tobias Dickbreder[1], Dirk Lautner[2], Antonia Köhler[1], Lea Klausfering[1], Ralf Bechstein[1], and Angelika Kühnle[1] — [1]Physical Chemistry I, Bielefeld University, 33615 Bielefeld, Germany. — [2]Institute of Physical Chemistry, Johannes Gutenberg University Mainz, Duesbergweg 10-14, 55099 Mainz, Germany.

Calcite, the most abundant carbonate mineral in the Earth's crust, plays a dominate role in a variety of environmental processes. Upon cleavage, calcite exposes the (10.4) cleavage plane with a rectangular unit cell. Interestingly, several experiments have been presented that suggest a (2x1) surface reconstruction. However, clear experimental evidence and a theoretical confirmation were long missing. Recently, an atomic force microscopy study provided convincing experimental indication for a (2x1) reconstruction at 5 K. Nevertheless, it remained unclear how the (2x1) reconstruction effects the surface properties of calcite.

Here, we present temperature-programmed desorption (TPD) curves of water and ethanol desorbing from calcite (10.4) around room temperature. Our experiments can be excellently described by a kinetic model considering two different adsorption positions, as would be present in case of a (2x1) reconstruction. This finding applies to the desorption of water and ethanol, suggesting that the effect is not molecule specific, but characteristic for the calcite cleavage plane. Our results, thus, demonstrate that the (2x1) reconstruction has significant impact on the interfacial properties of calcite.

O 81.10 Thu 17:15 CHE 91

Identification of Intermediates in the Reaction Pathway of SO2 on the CaO surface: From Physisorption to Sulfite to Sulfate — •Nils Schewe[1], Farahnaz Maleki[2], Giovanni Di Liberto[2], Hicham Idriss[1], Gianfranco Pacchioni[2], and Christoph Wöll[1] — [1]Institute of Functional Interfaces (IFG), Karlsruhe Institute of Technology (KIT), Hermann-von-Helmholtz-Platz 1, Eggenstein-Leopoldshafen, 76344, Germany — [2]Department of Materials Science, University of Milano-Bicocca, 20125 Milano, Italy

We report on the results of a combined experimental and theoretical study of the interaction of sulfur dioxide with a calcium oxide single crystal surface. Our investigation of this model system for flue gas desulfurization was carried out on the CaO (001) surface under ultra-high-vacuum conditions. Combining UHV infrared reflection absorption spectroscopy (IRRAS) with x-ray photo electron spectroscopy (XPS) and ab initio density functional theory (DFT) calculations, we were able to identify a three-step reaction path way. After the physisorption of SO2 at temperatures below 70 K on the ubiquitously hydroxylated surface, increasing the temperature leads to insertion of the SO2 into surface hydroxyl groups. Around 110 K the first insertion leads to a surface hydrogen-sulfite, which evolves into a surface hydrogen-sulfate with the second insertion into another OH-group above 160 K. The surface state was confirmed by DFT, where the predicted IR vibrational frequencies align with the experimentally observed ones.

O 81.11 Thu 17:30 CHE 91

Interaction and structural behavior of thymidine on polycrystalline cerium oxide films — •Sascha Mehl[1], Anastasiia Deineko[2], Viacheslav Kalinovych[2], Tomáš Skála[2], Iva Matolinová[2], Vladimír Matolín[2], Kevin C. Prince[1], and Nataliya Tsud[2] — [1]Elettra-Sincrotrone Trieste S.C.p.A., in Area Science Park, Strada Statale 14, km 163.5, Basovizza (Trieste), 34149, Italy — [2]Charles University, Faculty of Mathematics and Physics, Department of Surface and Plasma Science, V Holešovičkách 2, Prague, 18000, Czech Republic

Thymidine (dT) is a nucleoside and therefore important for the contribution to in-depth studies of cerium oxide as a potential sensing material applicable for analytes such as DNA. This topic contributes to a survey which embraces from simple nucleobases to more complex DNA components as probe molecules on a wide array of different CeO2 films. Consequently, bridging the material gap and deposition of dT from aqueous solution on compact CeO2 allows us to get closer towards more realistic conditions. The goals of the present study were the elucidation of the electronic structure of the biomolecule-cerium oxide interface, as well as the adsorption geometry and thermal stability of the nucleoside. Adsorption studies were carried out by using SRPES, RPES and NEXAFS techniques. A noteworthy result was the successful deposition of dT from solution and in gas phase without decomposition, which was never previously reported in the literature. The analysis of the experimental data revealed that dT molecules anchor on CeO2 film via two carbonyl oxygen atoms and an amino group.

O 81.12 Thu 17:45 CHE 91

Modeling Bio-MOFs for Anesthetic Xenon Recovery: The Role of Noncovalent Host-Guest Interactions — •Yeliz Gurdal — Lehrstuhl für Theoretische Chemie II, Ruhr-Universität Bochum, 44780 Bochum, Germany — Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, 44780 Bochum, Germany — Department of Bioengineering, Adana Alparslan Türkeş Science and Technology University, 01250 Adana, Türkiye

Taking advantage of metal organic frameworks (MOFs) for anesthetic Xe recovery has been a recent topic studied rarely in the literature. In this work, Xe recovery performances of 43 biological MOFs (Bio-MOFs) consisting of biocompatible cations and linkers have been studied by means of Grand Canonical Monte Carlo, Density Functional Theory, and Molecular Dynamics simulations. Results reveal that Xe-host interactions are maximized mainly due to noncovalent interactions of Xe, such as charge-induced dipole and aerogen-π interactions. Polarized Xe atoms in the vicinity of cations/anions as well as π systems suggest enhanced guest-host interactions. The results of this work depict examples of superficially studied aerogen interactions playing an important role in selective adsorption of Xe in porous materials. This study has received funding from the TUBITAK under the 1002 Short Term R&D Funding Program (grant agreement No: 120Z160).

O 82: Graphene I: Adsorption, Intercalation and Doping

Time: Thursday 15:00–17:15   Location: GER 37

O 82.1   Thu 15:00   GER 37

Graphene quantum dot nanoarray in a van der Waals heterostructure — •Keda Jin[1,2,3], Junting Zhao[1,2,3], Tobias Wichmann[1,3,4], F. Stefan Tautz[1,3,4], Jose Martinez-Castro[1,3], Markus Ternes[1,2,3], and Felix Lüpke[1,3] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany. — [2]Institut für Experimentalphysik II B, RWTH Aachen, 52074 Aachen, Germany. — [3]Jülich Aachen Research Alliance (JARA), Fundamentals of Future Information Technology, 52425 Jülich, Germany. — [4]Institut für Experimentalphysik IV A, RWTH Aachen, 52074 Aachen, Germany.

Graphene quantum dots (GQDs) are promising candidates for spin qubits because of their long spin coherence and short switching time. Although isolated GQDs have been created in van der Waals (vdW) heterostructures, the fabrication of GQD nanoarrays is still an ongoing challenge. Here, we realize a regular two-dimensional array of GQDs in a vdW heterostructure composed of graphene on a single layer of $1T$-$NbSe_2$ on top of $2H$-$NbSe_2$ (Gr/$1T$/$2H$-$NbSe_2$) by combining mechanically assembled vdW heterostructures and nanoscale phase engineering. Using scanning tunneling microscopy (STM) and non-contact atomic force microscopy (nc-AFM), we demonstrate that the $1T$-$NbSe_2$ phase periodically dopes the graphene layer, which in response exhibits quantized charge states that can be manipulated by the local electric field of the tip. Our findings show a possible route for the creation of a highly dense GQD nanoarray with a potential application in the quantum technologies.

O 82.2   Thu 15:15   GER 37

Sn-induced superstructures at the EG/SiC(0001) interface and their influence on EG — •Zamin Mamiyev, Chitran Ghosal, and Christoph Tegenkamp — Institut für Physik, Technische Universität Chemnitz

Intercalating chemical elements into the buffer layer/SiC(0001) interface is a promising approach to delaminate a single carbon layer forming extended epitaxial graphene (EG) layers with new properties. In this regard, Sn is an interesting candidate because the triangular monolayer structure on SiC(0001) was shown to exhibit a Mott state [1].

By means of low energy electron diffraction we studied recently in detail the intercalation of Sn below the buffer layer grown before on SiC(0001) and found 1×1 and $(\sqrt{3}\times\sqrt{3})$ Sn induced phases depending on details of the annealing procedure [2]. As deduced from transport but also local spectroscopy, the former is metallic while the latter reveals a band gap opening. In addition, we found a $(\sqrt{3}\times\sqrt{3})R30°$ interference pattern with respect to the EG lattice. This so-called broken Kekulé order forms due to the breaking of the bond order in EG and often found in the vicinity of buckled Sn(1×1) subsurface clusters opening the channel for K,K' scattering in EG. The electronic structure and, in particular, the formation of a Mott gap will be investigated by electron energy loss spectroscopy.

O 82.3   Thu 15:30   GER 37

Stabilizing high-overlap organic crystals by n-doped graphene — •Fabio Calcinelli and Oliver Hofmann — Graz University of Technology, Graz, Austria

Organic thin-films are known for their tuneable properties, which are strongly dependent on the polymorph the films assume. Traditional ab-initio studies of thin films geometries remain computationally prohibitive, due to the immense number of possible configurations, and this results in the need for structure-property relationships to help in the design of materials with certain target properties.

In this contribution, we examine the correlation between the energy of polymorphs and their interlayer LUMO-LUMO overlap for benzoquinone on n-doped graphene. Employing smart-data machine learning, we use a small number of DFT calculations to predict the energy and the LUMO-LUMO overlap for a large sample of polymorphs. We assess the impact of the n-doping of the substrate on this overlap/stability relationship by performing the energy and overlap evaluation for different intensities of n-doping.

We find that, for low dopant concentrations, there exists no relationship between interlayer overlap and stability, while for high dopant concentrations, it appears that polymorphs with high LUMO-LUMO overlap are predominant in the stability ranking. We explain this different behavior as the consequence of charge transfer from the substrate to the first molecular layer producing different LUMO occupations for different dopant concentrations, resulting in a stabilizing effect of high LUMO-LUMO overlap for high concentrations only.

O 82.4   Thu 15:45   GER 37

Theoretical studies of nitrogen-doped corrugated graphene on metal supports — •Ivan Abilio[1] and Krisztián Palotás[1,2] — [1]Wigner Research Center for Physics, Budapest, Hungary — [2]ELKH-SZTE Reaction Kinetics and Surface Chemistry Research Group, Szeged, Hungary

For maximizing the usability of N-doped graphene materials, the microscopic understanding of their structures (graphitic, pyridinic, pyrrolic, etc) and electronic properties at the atomic scale is crucial. Motivated by this, density functional theory calculations of N-doping configurations in corrugated graphene single layers on Ir(111) and Ru(0001) substrates were performed. Taking systematically selected N-doped graphene defect configurations, their energetic preference is found to be correlated with their atomic structure. Scanning tunneling microscopy simulations with different tip models [1] were performed, and a great variety of STM image contrasts showed a good agreement with experimental STM images. The negatively charged N atoms embedded into the corrugated graphene layer suggest single atom catalytic potential for these structures.

O 82.5   Thu 16:00   GER 37

Formation model of AlF₃ intercalated aggregates on HOPG surfaces for rechargeable battery applications — •Sindy Rodríguez Sotelo[1,2], Adriana Candia[1], Igor Stanković[3], Mario Passeggi Jr.[1,2], and Gustavo Ruano[4] — [1]IFIS, CONICET-UNL, Santa Fe, Argentina — [2]FIQ, UNL, Santa Fe, Argentina — [3]Scientific Computing Laboratory, Center for the Study of Complex Systems, IPB, Belgrade, Serbia — [4]CAB, CNEA, Bariloche, Argentina

Rechargeable batteries based on ion intercalation are currently of great interest, with lithium being the most studied and with the best performance. However, the limited reserves of this material and its scarce distribution in the world have led to the research for new alternatives. In our recent work, we studied the intercalation of AlF_3 in HOPG as a new possibility to use this molecule in rechargeable batteries and to understand its role when used as a solvent component [1,2]. Based on our recent reports, in this work we theoretically and experimentally characterize the dynamics of the AlF_3 interlayers, to discuss the possibility of decoupling the first graphene layers from the HOPG under ultra-high vacuum conditions. We show experimental measurements performed by STM, XPS and AES, also proposing a model to glimpse the growth and behavior of AlF_3 in the surface layers of the HOPG substrate, to provide clarity regarding the formation of the AlF_3/HOPG interface. We complement the analysis with calculations in the formalism of DFT and molecular dynamics (MD). **References** [1] A.E. Candia *et al.* Carbon, 186 (2022) 724. [2] Rodríguez *et al.* Phys. Chem. O 82.6   Thu 16:15   GER 37

Atomic and electronic structure of intercalated Pb layers in proximity to epitaxial graphene — •Chitran Ghosal, Markus Gruschwitz, Julian Koch, and Christoph Tegenkamp — Institut für Physik, TU Chemnitz, Chemnitz, Germany

Selective intercalation into the buffer layer/SiC(0001) interface can realize atomically sharp interface layers near epitaxial graphene that resemble novel 2D heterosystems. High-Z elements are interesting candidates, not only because they are expected to host Dirac fermions, but also because spin effects are expected in graphene.

Intercalation of Pb leads to the formation of different phases, which we have studied in detail using scanning tunneling microscopy. As recently shown, intercalated Pb bilayers form nanostripes under graphene and show fingerprints of plumbene. These Pb layers are rotated with respect to graphene, which breaks the sublattice symmetry and is associated with an electronic gap in graphene [1]. Hexagonally arranged bubble-like structures with an average size of 2.3 nm were also found. Scanning tunneling spectroscopy (STS) again revealed the formation of mini-gaps in the 2D heterosystem. Spatially resolved mapping of the electronic structure also clearly showed the existence of a network of edge states around the edges of the bubbles.

Tailoring permanent carrier density in epitaxial graphene by F4-TCNQ molecular doping for quantum Hall resistance standards — •Yefei Yin, Atasi Chatterjee, Davood Momeni, Mattias Kruskopf, Martin Götz, Stefan Wundrack, Frank Hohls, Klaus Pierz, and Hans Werner Schumacher — Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany

A prerequisite for the development of graphene electronics is the reliable control of its carrier density. Since epi-graphene on SiC already exhibits a high electron density of up 10^{13} cm^{-2}, the goal is a controlled reduction towards the charge-neutrality point. This was achieved by molecular doping with the ac-

ceptor F4-TCNQ doping stacks deposited on graphene. By precise adjustment of the dopant concentration and controlling the initial carrier density of the un-doped graphene, we can tune the carrier density in a wide range from intrinsic n- to the p-type. Precision measurements of the quantum Hall resistance show a quantization accuracy of 10^{-9} which underlines the high quality and suitability of this doping method for electronic device application in metrology. [1] Our data show a correlation between the electron density and the onset of the i = 2 quantum Hall plateau which gives a valuable criterion for evaluating graphene-based resistance standards since the *classical* relation (n = ieB/h) to determine the centre of the quantum Hall plateau is not valid in epi-graphene. The results are discussed in the charge transfer model. [1] Y.Yin et al., Adv. Physics Res. 2022, DOI: 10.1002/apxr.202200015.

O 82.8   Thu 16:45   GER 37

Transport properties of intercalated epitaxial graphene — •Markus Gruschwitz, Zamin Mamiyev, Chitran Ghosal, Susanne Wolff, Thomas Seyller, and Christoph Tegenkamp — Institut für Physik, TU Chemnitz, Chemnitz, Germany

Large-scale growth and electronic manipulation of graphene are of great interest for nanoelectronics applications. The former is already realized by epitaxial growth and intercalation of buffer layers on SiC(0001). Electronic properties such as doping level and gap opening of the decoupled graphene layer strongly depend on the element and the structure of the interface. In this study we investigated Sn, Bi and In intercalated graphene by means of nanoscopic transport, supplemented by STM, LEED and PES. Depending on the film thickness and temperature, (1x1) phases can be formed with all three elements, accompanied by the formation of free-standing graphene. The fully intercalated phases show metallic conductivity behavior (σ_{Sn}=0.63 mS/□, σ_{Bi}=0.74 mS/□). The slightly lower conductivity of 10% compared to clean MLG is most likely due to interface scattering rather than different doping levels of the EG. Further heating allows the forma-

tion of $\sqrt{3}$-structures for all intercalants. Thereby, the conductivities drop by 2-3 orders of magnitude, accompanied by an increase of the anisotropy with respect to SiC step structure. This is indicative of inhomogeneous desorption especially around the step edges. The detailed analysis with the variable range hopping model yield localization lengths that correlate with the size of intercalated areas.

O 82.9   Thu 17:00   GER 37

Magnetotransport and structural properties of Bi(110) islands on epitaxial graphene — •Julian Koch[1], Sergii Sologub[1,2], Chitran Ghosal[1], and Christoph Tegenkamp[1] — [1]Institut für Physik, TU Chemnitz, Reichenhainerstr. 70, 09126 Chemnitz — [2]Institute of Physics, NAS of Ukraine, Nauki avenue 46, 03028 Kyiv

Magnetotransport measurements at 10 K using a 4 T magnet were performed on Bi islands on monolayer graphene/SiC with average thickness up to 3.6 bilayers (BL). They are supported by structural investigations using SPA-LEED and STM, which reveal that Bi predominately grows as needle-like islands with a (110) termination.

The analysis of the magneto and Hall conductivity gives the electron concentration and the mobility. The electron concentration slightly decreases with $4 \cdot 10^{11}$ cm^{-2}BL^{-1} from an initial value of $1.4 \cdot 10^{13}$ cm^{-2} for the clean surface. The mobility decreases from 2100 cm^{2}V^{-1}s^{-1} to a minimal value of 1630 cm^{2}V^{-1}s^{-1} at 2.4 BL. Moreover, the electron electron interaction contribution to the magneto conductivity, which is almost negligible for the clean surface, strongly increases linearly with approximately 0.44 mS/BL. At 3.6 BL it is equal to approximately half the Drude conductivity at zero field.

The weak localization (WL) of the clean surface gradually transitions to weak anti-localization (WAL) with increasing Bi coverage. This is associated with a decrease of the dephasing length of the scattered electrons, which is correlated with the average distance of the islands obtained from STM measurements.

O 83: Focus Session: Ultrafast Dynamics in Nanostructures II

Time: Thursday 15:00–17:30   Location: GER 38

Topical Talk   O 83.1   Thu 15:00   GER 38

Imaging ultrafast electron dynamics in isolated nanoparticles — •Daniela Rupp — LFKP, ETH Zurich, Switzerland

Atomic clusters and nanodroplets are used as ideal model systems over all wavelength regimes for exploring the ultrafast physical processes underlying the formation and evolution of highly excited matter. Via single-pulse single-particle coherent diffractive imaging (CDI) with the intense femtosecond pulses from short-wavelength free electron lasers (X-FELs), it became possible to study single specimen in free flight.

In CDI, the elastically scattered light forms an interference pattern that encodes the particle's structure, allowing to investigate the morphology of fragile and short-lived specimen. Also light-induced dynamics after pulsed laser excitation can be visualized by time-resolved CDI. Even changes in the electronic properties were found to be imprinted in the CDI patterns, but their time-evolution could not be investigated with typical pulse durations of 100 femtoseconds.

We recently showed that, under favorable conditions, single helium nanodroplets can be also imaged with an intense HHG source, providing much shorter pulses. In time-resolved experiments, a moderately intense near-infrared (NIR) laser pulse, too weak to ionize helium nanodroplets, dramatically changed their scattering response in the extreme ultraviolet (XUV) regime. The ability to switch the optical properties of nanoscale matter within less than a femtosecond, and observe this temporally and spatially resolved, promise to impact a broad field of science from non-linear XUV optics to ultrafast material science.

O 83.2   Thu 15:30   GER 38

Sub-picosend Elastic Response of a supported Pd Nanoparticle Ensemble studied by Time-resolved X-ray Diffraction — Simon Chung[1], Thorben Eggert[2], •Vedran Vonk[1], Nastasia Mukharamova[1], Sebastian Matera[2], Roman Shayduk[3], Johannes Moeller[3], Nils Schewe[4], Eric Sauter[4], Christoph Schreuer[4], Anders Madsen[3], Karsten Reuter[2], and Andreas Stierle[1] — [1]CXNS - Centre for X-ray and Nanoscience, Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]Theory Department, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6t, Berlin, 10587, Germany. — [3]European X-Ray Free-Electron Laser Facility GmbH, Holzkoppel 4, Schenefeld, 22869, Germany. — [4]Institute of Functional Interfaces (IFG), Karlsruher Institut fur Technologie (KIT), Hermann-von-Helmholtz-Platz 1, Eggenstein-Leopoldshafen, 76344, Germany.

We report on the results of a combined experimental and theoretical study of the structural response of a Pd nanoparticle ensemble upon fs-laser excitation. Time-resolved X-ray diffraction experiments, having a time resolution of approx. 100 fs, were performed at end-station MID of the European X-ray Free-Electron Laser (XFEL). Molecular dynamics simulations were done taking explicitly into

account the particle size distribution, as determined from SEM. The results are interepreted in terms of the dephasing of size-dependent elastic modes and picosecond energy dissipation of the nanoparticle ensemble towards the MgO single crystal support. An overview will be given about the experimental details, data analysis and molecular dynamics simulations.

O 83.3   Thu 15:45   GER 38

Description of High Garmonic Generation in Quantum Dots using a Tight-Binding approach — •Martin Thümmler[1], Alexander Croy[1], Stefanie Gräfe[1], and Ulf Peschel[2] — [1]Institute of Physical Chemistry, University of Jena — [2]Institute of Condensed Matter Theory and Optics, University of Jena

Recently, high harmonic generation (HHG) was experimentally observed in quantum dots showing striking differences compared to HHG in molecules and bulk materials. At the same time, the available theoretical tools (like semiconductor Bloch-equations and real-time density-functional theory (DFT)) have proven to be insufficient to describe the size dependence of the nonlinear response of these nanostructures. Here, we present a computationally feasible, real-space tight-binding method to account for the description of inter- and intraband harmonics, and ionization effects, while all model parameters are derived from DFT calculations. Inspired by recent experiments, we present first simulation results of HHG in 3D CdSe quantum dots for linear and elliptic polarization of the driving laser.

O 83.4   Thu 16:00   GER 38

Imaging of femtosecond spin dynamics at the nanoscale — •Sergey Zayko[1,4], Hung-Tzu Chang[1], Ofer Kfir[2], Timo Schmidt[3], Jakob Hagen[1], Michael Heigl[3], Murat Sivis[1,4], Manfred Albrecht[3], and Claus Ropers[1,4] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]School of Electrical Engineering, Tel Aviv University, Tel Aviv, Israel — [3]Experimental Physics IV, Institute for Physics, University of Augsburg, Germany — [4]IV Physical Institute, Solids and Nanostructures, Georg-August University

Femtosecond pulse durations combined with broad extreme-UV spectrum inherent to high harmonic generation (HHG) grant spectroscopic access to various material properties and phenomena including charge, spin and lattice dynamics. Here, we extend the applicability of HHG sources to direct real-space imaging of ultrafast processes. Specifically, we map femtosecond spin dynamics induces by optical excitations ferro- and ferrimagnetic materials. Our results demonstrate the first implementation of HHG radiation for element specific imaging as well as the first real-space imaging of femtosecond dynamics. Moreover, the achieved spatio-temporal resolution (down to 13.5 nm spatial and 15 fs temporal) is more than an order of magnitude higher than any magneto-optical imaging scheme reported so far, which would facilitate deeper fundamental understanding and, in

particular, support application-oriented studies. Notably, the developed imaging scheme is directly applicable to a broad range of phenomena including transient absorption and structural phase transitions.

Topical Talk   O 83.5   Thu 16:15   GER 38

Ultrafast coherent manipulation of free electrons via quantum interaction with shaped optical fields — •Giovanni Maria Vanacore — Department of Materials Science, University of Milano-Bicocca, Via Cozzi 55, 20126 Milano

The interaction between light and electrons can be exploited for generating radiation, or for controlling electron beams for dynamical investigation of materials, enabling new applications in quantum technologies and microscopy. In this contribution, I will describe an innovative method for coherent and versatile longitudinal/transverse manipulation of a free-electron wave function. Using appropriately shaped light fields in space and time, I will demonstrate how to modulate the energy, linear and orbital angular momenta, as well as spatial and temporal distributions of the electron wave function. The experiments have been performed in an ultrafast-TEM, where a pulsed electron beam was made to interact with shaped optical field generated via a spatial light modulator. The energy-momentum exchange resulting from such interaction was directly mapped via momentum-resolved ultrafast electron energy-loss spectroscopy. Our approach for arbitrary longitudinal/transverse electron modulation at the sub-fs timescale would pave the way to achieve unprecedented insights into non-equilibrium phenomena in advanced quantum materials, playing a decisive role in the rational design and engineering of future photonics and electronics application.

Funding source: SMART-electron project that has received funding from the EU Horizon 2020 Programme under GA No 964591.

O 83.6   Thu 16:45   GER 38

Structural Dynamics in Nanostructured Systems Probed by Ultrafast Transmission Electron Microscopy — •Nora Bach[1], Armin Feist[2], Marcel Möller[2], Claus Ropers[2], and Sascha Schäfer[1] — [1]Institute of Physics, University of Oldenburg, Germany — [2]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany

One successful approach to investigate ultrafast nanoscale structural dynamics and to disentangle different excitation mechanisms in spatially inhomogeneous systems is based on local diffractive probing with nano-focused femtosecond electron pulses in an ultrafast transmission electron microscope (UTEM). Employing the Göttingen UTEM [1,2] in ultrafast convergent electron beam diffraction (U-CBED) mode [3], we study local dynamics in a multi-component model system consisting of a metal/semiconductor hybrid structure. Ultrashort optical excitation of a platinum stripe on a silicon membrane results in the generation of a multi-modal distortion wave propagating through the membrane. Pronounced lattice distortions are quantitatively tracked by U-CBED, and experimental results are reproduced by numerical simulations demonstrating that a superposition of Lamb waves at resonance frequencies of the bilayer structure [4] governs the evolution of the displacement inhomogeneity within the depth of the membrane.

O 83.7   Thu 17:00   GER 38

Controlling and shaping the electron recoil and energy transfer via nearfield geometry — •Fatemeh Chahshouri[1] and Nahid Talebi[1,2] — [1]Institute of Experimental and Applied Physics, Kiel University, 24098 Kiel, Germany — [2]Kiel, Nano, Surface, and Interface Science, KiNSIS, Kiel University, 24098 Kiel, Germany

Inelastic interaction of free-electrons with optical near fields has recently attracted attention for manipulating and shaping free-electron wave packets. Understanding the nature and the dependence of the inelastic cross section on the polarization of the optical near-field modes of the nanostructures is important for both fundamental studies and the development of new applications in this field. Here, we investigate the effect of the laser-field polarization and nanostructures asymmetric geometry on shaping free-electrons and controlling the energy transfer mechanisms, but also tailoring the electron recoil. We show that, an oblique incident electric field improves the coupling efficiency for coherent control of the longitudinal and transversal phase modulation of an electron wave packet. We also demonstrate the possibility of tailoring the shape of the localized plasmons by incorporating specific arrangements of nanorods to enhance or hamper the transversal and longitudinal recoils of free-electrons. Our findings open up a route towards the spatial characterization of plasmonic near-fields for the coherent manipulation and control of slow electron beams for creating desired shapes of electron wave packets.

O 83.8   Thu 17:15   GER 38

Light-induced hexatic state in a layered quantum material — •Till Domröse[1], Thomas Danz[1], Sophie F. Schaible[2], Kai Rossnagel[3,4], Sergey V. Yalunin[1], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Germany — [3]Institute of Experimental and Applied Physics, Kiel University, Germany — [4]Ruprecht Haensel Laboratory, DESY, Hamburg, Germany

Ultrafast transmission electron microscopy (UTEM) is a powerful technique for resolving non-equilibrium dynamics on the nanoscale, employing a stroboscopic laser pump/electron probe approach [1]. Here, we harness the high-coherence electron source of the Göttingen UTEM [2] in the investigation of a structural phase transition between two charge-density wave (CDW) phases in a layered material [3]. A three-dimensional reconstruction of the nascent CDW order by means of ultrafast tilt-series nanobeam diffraction allows us to identify a transient hexatic state in the early stages of the phase formation. As the optical excitation induces a loss of interlayer correlations, this two-dimensional intermediate is characterized by a high density of topological defects suppressing the translational symmetry, while the orientational order is weakly preserved. On longer timescales, defect recombination and the establishment of the equilibrium stacking sequence lead to the formation of the long-range ordered high-temperature CDW phase.

O 84: Focus Session: Making Experimental Data F.A.I.R. − New Concepts for Research Data Management I (joint session O/TT)

Data have been identified as major resource of the 21st century, unlocking great potential if refined and processed in the right way. In scientific research, particularly modern data science concepts like machine learning or neural networks enable novel types of data analysis with often strong predictive power. This Focus Session aims at providing a framwork for presenting and discussing novel concepts, tools and platforms for managing experimental research data related to surface science and solid-state physics. In particular, in light of the German NFDI initiative, where several consortia are actively working on tackling the imminent challenges of research data management in experimental solid-state physics, this Focus Session will offer an ideal environment for exchange among researchers, and bringing these novel developments into the labs. The intended topics include the description of experimental data and meta data generation workflows, meta data schemas and file formats, electronic lab notebooks, novel tools for handling and analyzing scientific research data, as well as sharing and searching platforms according to F.A.I.R. principles.

Organizers: Martin Aeschlimann (TU Kaiserslautern), Laurenz Rettig (FHI Berlin) and Heiko Weber (U Erlangen)

Time: Thursday 15:00–18:30   Location: WIL A317

Topical Talk   O 84.1   Thu 15:00   WIL A317

Introducing a FAIR research data management infrastructure for experimental condensed matter physics data — •Christoph Koch — Humboldt-Universität zu Berlin, Department of Physics & IRIS Adlershof, Berlin, Germany

Digitization and an increase in complexity and price of experimental materials characterization techniques, an increase in accuracy and system size of computational solid state physics (or computational materials science), and the maturation of machine learning tools to extract patterns from large amounts of very

diverse (annotated) data promise an acceleration of materials development by synergistically combining research data from many sources. While some labs start to upload their (raw) research data to data repositories, this is only a first but not sufficient step in leveraging the above-mentioned potential, since such repositories are typically either specific to a very particular technique or agnostic to the content of the data being uploaded. In both cases the research data cannot easily, and definitely not without significant human effort, be compared to and integrated with experimental data from other sources, or numerical predictions. In this talk I will report on recent progress of the FAIRmat NFDI consortium in extending the novel materials discovery laboratory (NOMAD), the world's largest data base for ab-initio computational materials data, to ingest experimental research data on the synthesis and characterization of materials in a machine-accessible manner, i.e. annotated with well-defined and interoperable metadata, achieved by establishing links between related (experimental and computational) quantities.

O 84.2   Thu 15:30   WIL A317

Introducing an electronic laboratory notebook in a collaborative research center — •Sebastian T. Weber[1], Aneta Daxinger[1], Philipp Pirro[1], Marek Smaga[1], Christiane Ziegler[1], Mathias Kläui[2], Georg von Freymann[1], Baerbel Rethfeld[1], and Martin Aeschlimann[1] — [1]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau — [2]Institute of Physics, Johannes Gutenberg University Mainz

The basis of a FAIR data management is a well-described and detailed documentation of every single step of the experiment and data analysis. In recent decades, however, the focus has shifted from analog measuring instruments and analytical calculations to computer-based experiments and simulations. This has lead to a large increase in the numbers of measurements and observed quantities and therefore in the amount of data generated. Consequently, traditional paper lab notebooks have reached their limits. Electronic lab notebooks (ELNs) are better suited for storing, indexing, searching and retrieving a large amount of entries. In particular, the automated filling-in of meta data can lead to a reduction in the workload of the scientists in the long term.

We present the lessons learned on challenges and advantages with the introduction of a joint electronic lab notebook within our collaborative research center CRC/TRR173 *Spin+X*. We report on our experiences in the daily work of the scientists and in education in student labs.

O 84.3   Thu 15:45   WIL A317

An efficient workflow for processing single event dataframes. — •Steinn Ýmir Ágústsson[1], M. Zain Sohail[2,3], David Doblas Jiménez[4], Dmytro Kutnyakhov[3], and Laurenz Rettig[5] — [1]Aarhus University, DK — [2]RWTH, Aachen — [3]DESY, Hamburg — [4]Eu-XFEL, Schenefeld — [5]FHI, Berlin

Single event resolved data streams measured by delay-line-detectors allow to correlate each measured photoelectron with the state of the experimental apparatus. This allows corrections and calibrations to be applied on a shot-to-shot basis and a flexible investigation of correlations between various measurement parameters.

We are developing an open-source python package[1], where highly optimized dataframe management and binning methods enable leveraging the full potential of event-resolved data structures. The flexible design of the pipeline allows processing any event-resolved data stream.

With momentum microscopy as the primary target application, we developed axis calibration and artifact correction methods designed to be agnostic to the experimental apparatus. These methods are tested on data generated by microscopes at FELs (HEXTOF@FLASH) as well as at HHG sources (FHI), but are easily exended to other end-stations using similar detection techniques.

Our aim is to provide tools for the community which will reduce the development time for each end station, as well as an open and accessible data processing pipeline, built around the FAIR data principles.

O 84.4   Thu 16:00   WIL A317

FAIR Data Infrastructure for Computation: Advanced many-body methods. — •José M. Pizarro[1], Nathan Daelman[1], Joseph F. Rudzinski[1,2], Luca M. Ghiringhelli[1], Roser Valentí[3], Silvana Botti[4], and Claudia Draxl[1] — [1]Institut für Physik und IRIS-Adlershof, Humboldt-Universität zu Berlin — [2]Max-Planck-Institut für Polymer Forschung, Mainz — [3]Institut für Theoretische Physik, Goethe University Frankfurt am Main — [4]Institut für Festkörpertheorie und Optik, Friedrich-Schiller-Universität Jena

Big-data analyses and machine-learning approaches have recently emerged as a new paradigm to study and predict properties of materials. In order to perform these analyses, materials data have to be structured in a FAIR (findable, accessible, interoperable, and reusable) format [1]. While most of the current databases deal with density-functional-theory (DFT) calculations, there is a clear need for developing FAIR-data schema for methodologies going beyond DFT. Methods such as the *GW* approximation, dynamical mean-field theory, and time-dependent DFT allow to calculate excited- and many-body-states properties beyond DFT, thus having a direct quantitative comparison with experiments. In this talk, we will introduce the achievements and challenges undertaken within

the FAIRmat consortium towards fully structuring the (meta)data of all these techniques. We demonstrate how users can analyze the data and compare with angle-resolved photoemission spectroscopy.

O 84.5   Thu 16:15   WIL A317

Electronic Laboratory Notebooks for FAIR Data Management; Evaluation and Recommendations for Solutions at Research Infrastructures — •Philipp Jordt[1], Wiebke Lohstroh[2], and Bridget Murphy[1] — [1]IEAP, Kiel University, Germany — [2]MLZ, Technische Universität München, Germany

Electronic Laboratory Notebooks (ELN) are the digital counterpart to the classical handwritten paper notebook and play a vital role in the implementation of FAIR data standards. Modern ELN solutions range from simple note taking applications to integrated tools, combining documentation, inventory management, progress tracking and more. Nowadays, ELNs are becoming more prominent in research laboratories around the world, replacing paper notebooks. This evaluation of basic needs was carried out in the context of the DAPHNE4NFDI consortia. Of special interest is the view on ELNs for combined use at large scale facilities and in the home laboratory. Thus, the requirements regarding implementation, deployment, authentication, etc., may differ from those for single or laboratory use at universities. An overview of different concepts and existing solutions is given. Multiple ELNs have been evaluated during test runs at large scale facilities and a survey on existing solutions was held. From these results, a list of ELN specifications is presented, ranging from useful to necessary. These insights may serve as a guideline for evaluating or implementing ELNs in the future.

O 84.6   Thu 16:30   WIL A317

Ontology for Experimental Data — •Sandor Brockhauser — Center for Materials Science Data, Humboldt-Universität zu Berlin, Germany

Ontology is the scientific field of formal knowledge representation. This field contributes to Data Science and helps Experimentalist to properly annotate their data and metadata on a FAIR way. During the last decades several different ways have been developed in the field of Ontology for describing knowledge as a set of information and their relationships. These include Information mapping, Concept maps, Topic maps, Mind maps, Knowledge graphs, BORO (Business Objects Reference Ontology), RDF (Resource Description Framework), OWL (Web Ontology Language), ORO (Object-Role Modeling), UML (Unified Modeling Language), ISO 15926 (standard for data sharing), OLOG (mathematical framework for knowledge representation), GELLISH (ontology language for data storage and communication), etc. For describing experimental facts, we suggest using an ontology in OWL which is derived from the NeXus community standard. It represents all the concepts developed for explaining experiments and experimental data, just like the relationships between them. Such representation allows connecting the concepts defined in NeXus also to other ontologies. Additionally, any data management systems, like NOMAD which accepts experiment data provided in the NeXus standard, can immediately link the data and metadata to the ontology and make them interoperable.

Open Research Data for Photons and Neutrons: Applications in surface scattering and machine learning — •Linus Pithan — Universität Tübingen, Institut für Angewandte Physik - DAPHNE4NFDI

Open (F.A.I.R.) research data is becoming a key ingredient for data driven machine learning (ML) applications that requires access to existing data of preceding experiments - which goes well beyond data collected in the context of one's own experiments which one might keep in a secret drawer. We will discuss current possibilities as well as future opportunities and challenges with special emphasis on surface scattering. Embedded in the DAPHNE4NFDI (DAta from PHoton and Neutron Experiments) consortium we present efforts on how data catalogs may serve as backbone for F.A.I.R. datasets provided by synchrotron and neutron sources or through community efforts. Besides suitable metadata collection also the harmonization of data- and metadata formats are issues still to be tackled especially for systematic access to fully analyzed, experimental datasets (e.g. by adopting NeXus community conventions). After a broader overview and shining light on the SciCat meta-data catalog system,[1] we discuss as application examples efforts in the field of reflectometry (XRR, NR) [2,3] and X-Ray scattering and diffraction (WAXS, GIWAXS and XPCS).[1,4]

NOMAD OASIS as a Tool for Electron and Atom Probe Microscopists — •Markus Kühbach — Department of Physics, Humboldt-Universität zu Berlin, Germany

Embracing the FAIR principles for sharing data and knowing how to work with different tools in research data management systems is becoming an invaluable skill in a scientist's daily life. Embracing such systems of tools, one of which is offered with NOMAD OASIS, allows you to start organizing your research data locally. Learning such tools will train you to understand what schemes and electronic lab notebooks are and how the data and metadata are processed by these tools. Example implementations of specific workflows can give you ideas where to start from and how to customize these tools for the needs of your own research and colleagues. Thereby, you can provide feedback which supports the evolution and improvement of the research data management system.

NOMAD OASIS offers you many examples which show now also how data and metadata of specific experiments can be parsed into a standardized representation. These examples teach users through detailing how data can be entered, viewed, and organized with customizable schemes in NOMAD. Furthermore, the examples suggest strategies for how the information in NOMAD can be accessed for generic or domain-specific data analytics tools.

In my talk, I will go through one or two of these examples specific to electron microscopy (orientation imaging microscopy or spectroscopy).

O 84.9   Thu 17:45   WIL A317

FAIR Data Infrastructure for Computation: Introducing the parsers for Quantum Monte Carlo and ALF — •Jonas Schwab[1], José M. Pizarro[2], Jefferson Stafusa E. Portela[1], Luca M. Ghiringhelli[2], and Fakher F. Assaad[1] — [1]Institut für Theoretische Physik und Astrophysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany — [2]Institut für Physik und IRIS-Adlershof, Humboldt-Universität zu Berlin

DFT calculations lead to low-energy effective models. A modern example would be Kitaev types spin Hamiltonains for $RuCl_3$. Once the model is specified, many different many-body calculations can be carried out. Here, we will concentrate on the ALF [1] implementation of the auxiliary field quantum Monte Carlo algorithm that can deal with general models that includes the ones produced by DFT calculations. Being a Monte Carlo method, the ALF library produces stochastic time series. We will discuss how to implement this workflow in the NOMAD Repository & Archive (https://nomad-lab.eu) and concentrate on a FAIR metadata scheme. The first challenges are to define the models in a searchable way as well as standards for the Monte Carlo time series. In this talk we will discuss the present state of this project for the special case of the ALF-library and how users can exploit the benefits of the NOMAD repository to find, compare and resuse our QMC data.

O 84.10   Thu 18:00   WIL A317

CAMELS - A Configurable Instrument Control Software for FAIR Data — •Alexander Fuchs[1,3], Johannes Lehmeyer[1,3], Michael Krieger[1,3], Heiko B. Weber[1,3], Patrick Oppermann[2,3], and Heinz Junkes[2,3] — [1]Lehrstuhl für Angewandte Physik, Friedrich-Alexander-Universität Erlangen-Nürnberg, — [2]Fritz-Haber-Institut der Max-Planck-Gesellschaft (FHI), Berlin — [3]FAIRmat, Humboldt-Universität zu Berlin, Berlin, Germany

We are developing a configurable measurement software (CAMELS), targeted towards the requirements of experimental solid-state physics. Here many experiments utilize a multitude of measurement devices used in dynamically changing setups. CAMELS [1] will allow to define instrument control and measurement protocols using a graphical user interface (GUI). This provides a low entry threshold enabling the creation of new measurement protocols without programming knowledge or a deeper understanding of device communication. The GUI generates python code that interfaces with instruments and allows users to modify the code for specific applications and implementations of arbitrary devices if necessary. Even large-scale, distributed systems can be implemented. CAMELS is well suited to generate FAIR-compliant output data. Nexus standards, immediate NOMAD integration and hence a FAIRmat compliant data pipeline can be readily implemented. [1] https://github.com/FAU-LAP/CAMELS

OpenSemanticLab: Usecase Device Repository — •Matthias A. Popp and Simon Stier — Fraunhofer ISC, Neunerplatz 2, 97082 Würzburg, Germany

Fully automated experiments provide benefits regarding precision, repeatability, as well as data quality and therefore gain more and more popularity. However, setting them up can be time consuming, especially when computer interface information has to be manually transferred from device manuals to software.

In order to implement FAIR principles precise descriptions of measurement setups and instrumentation are necessary. Currently, this results in extra workload for experimental scientists.

With our framework OpenSemanticLab, we address this shortcoming by providing a central metadata repository for scientific instruments. The ontology-based repository meets both human (GUI) and machine requirements (APIs). A device ontology helps finding and classifying devices. In an associated Python package, abstract device drivers and concrete device metadata can be combined into executable workflows. Overall, this approach not only strengthens the transparency of research according to FAIR principles, but also significantly reduces the implementation effort for complex setups.

O 85: Electronic Structure of Surfaces II

Electronic structure of transition metal oxide surfaces from coincident electron spectroscopy — •Danilo Kühn[1], Swarnshikha Sinha[1,2], Artur Born[1,2], Fredrik O. L. Johansson[3], Ruslan Ovsyannikov[1], Nils Mårtensson[3], and Alexander Föhlisch[1,2] — [1]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Albert-Einstein-Strasse 15, 12489 Berlin, Germany — [2]Institut für Physik und Astronomie, Universität Potsdam, Karl-Liebknecht-Strasse 24-25, 14476 Potsdam, Germany — [3]Department of Physics and Astronomy, Uppsala University, P.O. Box 256, 751 05, Uppsala, Sweden

Transition metal oxides are a much studied class of materials with a wide range of applications, e.g. solar cells, batteries, magnetic storage devices, sensors or pigments. Varying charge localizations in the s,p and d valence shells and coupling between subsystems invoke complex electronic, magnetic and optical phases as high Tc superconductivity. Here, results from the new COESCA station for coincident electron spectroscopy at the BESSY II synchrotron will be presented [Leitner, T. et al. J. El. Spec. 250, 147075 (2021)]. Combining the high transmission and energy resolution of ARTOF time-of-flight spectrometers with the tailored time structure of BESSY II, Auger- Photoelectron coincidence spectroscopy (APECS) is possible with unprecedented information rate in the soft x-ray regime. Exploiting enhanced chemical selectivity and surface sensitivity, we gain insight into the excitation-decay dynamics and electron correlation effects in Ni, Cu and their oxides [Born, A. et al. Sci Rep 11, 16596 (2021)]

Black Phosphorus and the Free-Electron Final-State Assumption in Photoemission Spectroscopy — •Charlotte Sanders[1], Klara Volckaert[2], Deepnarayan Biswas[3], Marco Bianchi[2], Philip Hofmann[2], and Irene Aguilera[4] — [1]Central Laser Facility, STFC Rutherford Appleton Lab, Research Complex @ Harwell, OX11 0QX, UK — [2]Dept. of Physics and Astronomy, Interdisciplinary Nanoscience Center, Aarhus University, 8000 Aarhus-C, DK — [3]Diamond Light Source, Division of Science, Didcot, OX11 0DE, UK —

[4]Institute for Theoretical Physics, University of Amsterdam, Science Park 904, 1098 XH, Amsterdam, NL

In the photoemission process, the in-plane component (k_x, k_y) of the electron wave vector is conserved; but the k_z component is not, due to breaking of out-of-plane symmetry at the surface. This fact complicates analysis of photoemission spectra from k_z-dispersing states.

Bulk black phosphorus has a k_z-dispersing state that has been the subject of several studies wherein photoemission intensity close to the Fermi level resists interpretation on the basis of simple free-electron-like final-state assumptions. Experimental spectra have been interpreted in terms of surface resonances, or of complexities in the final state that go beyond the free-electron assumption. Here we present experimental and theoretical results concerning the latter interpretation; and, we consider the fundamental meaning of the free-electron-like final-state.

O 85.3   Thu 15:30   REC C 213

Direct observation of antiferromagnetic parity violation in the electronic structure of Mn_2Au — •Yaryna Lytvynenko[1,2], Olena Fedchenko[1], Libor Šmejkal[1,3], Michael Kallmayer[4], Katerina Medjanik[1], Sergey Babenkov[1], Dmitry Vasilyev[1], Mathias Kläui[1], Jure Demsar[1], Gerd Schönhense[1], Martin Jourdan[1], Jairo Sinova[1,3], and Hans-Joachim Elmers[1] — [1]Institute of Physics, JGU Mainz — [2]Institute of Magnetism of the NAS and MES of Ukraine — [3]Institute of Physics Academy of Sciences of the Czech Republic — [4]Surface Concept GmbH

Using time-of-flight momentum microscopy with a sub-μm spatial resolution (sub-μ-ToFMM), allowing for momentum-resolved photoemission on individual antiferromagnetic domains, we observe an asymmetry in the electronic band structure, $E(k) \neq E(-k)$, in Mn_2Au. This broken band structure parity originates from the combined time and parity symmetry, PT, of the antiferromagnetic order of the Mn moments, in connection with spin-orbit coupling [1,2]. The spin-orbit interaction couples the broken parity to the Néel order parameter direction. We

demonstrate a novel tool to image the Néel vector direction by combining spatially resolved momentum microscopy with ab-initio calculations that correlate the broken parity with the Néel vector [3].

O 85.4   Thu 15:45   REC C 213

Impact of atomic defects in the electronic states of FeSe$_{1-x}$S$_x$ superconducting crystals — •Yanina Fasano[1,2], Jazmin Aragon Sanchez[1], Maria Lourdes Amigo[1], Esteban Gayone[1], and Gladys Nieva[1] — [1]Instituto Balseiro and Centro Atomico Bariloche, UnCuyo-CNEA, Argentina — [2]Leibniz Institute for Solid State and Materials Research, Dresden, Germany

The electronic properties of Fe-based superconductors are drastically affected by deformations on their crystal structure introduced by doping and pressure. Here we study single crystals of FeSe$_{1-x}$S$_x$ and reveal that local crystal deformations such as atomic-scale defects impact the spectral shape of the electronic core level states of the material. By means of scanning tunneling microscopy we image S-doping induced defects as well as diluted dumbbell defects associated with Fe vacancies. We have access to the electronic structure of the samples by means of x-ray photoemission spectroscopy (XPS) and show that the spectral shape of the Se core levels can only be adequately described by considering a principal plus a minor component of the electronic states. We find this result for both pure and S-doped samples, irrespective that in the latter case the material presents extra crystal defects associated to doping with S atoms. We argue that the second component in our XPS spectra is associated with the ubiquitous dumbbell defects in FeSe that are known to entail a significant modification of the electronic clouds of surrounding atoms.

O 85.5   Thu 16:00   REC C 213

Double Photoemission Spectroscopy of C$_{60}$ on SrTiO$_3$(001) with Laser VUV radiation — •Kathrin Plass[1], Robin Kamrla[1], Frank O. Schumann[2], and Wolf Widdra[1] — [1]Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany — [2]Max Planck Institute of Microstructure Physics, Halle (Saale), Germany

Via photoelectron spectroscopy, important insights into the electronic structure of solids were obtained. However, correlation effects can only be addressed indirectly. With double photoemission spectroscopy (DPE), such phenomena can be observed directly by detecting pairs of correlated photoelectrons emitted upon absorption of a single photon [1]. C$_{60}$ is classified as a strongly correlated material with a highly structured valence band spectrum. Moreover, theory predicts the possibility of plasmon-mediated pair emission in C$_{60}$ [2]. In this contribution we present DPE data for C$_{60}$ thin films on SrTiO$_3$(001), obtained by a laboratory high-order harmonic (HHG) light source, operating at an energy range from 14 to 40 eV and MHz repetition rates [3]. We analyze the 2D energy maps and compare the data to the SPE spectrum. In addition, we discuss plasmon-mediated DPE in fullerenes.

O 85.6   Thu 16:15   REC C 213

Electronic structure at the "interface" of spin-orbit and exchange interaction: Ultrathin ferromagnetic films on W(110) — •Pascal Jona Grenz[1], Peter Krüger[1], Marcel Holtmann[1], Koji Miyamoto[2], Shiv Kumar[2], Taichi Okuda[2], and Markus Donath[1] — [1]WWU, Münster, Germany — [2]HISOR, Hiroshima, Japan

Ultrathin ferromagnetic layers on W(110) provide a suitable platform for investigating spin phenomena originating from the interplay of spin-orbit coupling (SOC) and exchange interaction (XC). First, we focus on the influence of ferromagnetic adlayers on the SOC-induced topologically non-trivial surface state (TSS) hosted by the W(110) surface [1,2]. Our systematic angle-resolved photoemission study of thin Ni, Co, and Fe films and their influence on the TSS will be presented and discussed in view of conflicting literature results [3]. Second, the unoccupied electronic structure of thin Ni films on W(110) is surveyed by spin- and angle-resolved inverse photoemission. By carefully choosing the Ni film's thickness, we tune the relative strength of SOC and XC. In such a way, SOC induces a degeneracy of Ni-related exchange-split states. Based on density functional theory, the strong interplay of SOC and XC is traced back to the hybridization of W and Ni states.

Circular dichroism in angle-resolved photoemission from core-level emission of W(110) — •Trung Phuc Vo[1], Olena Tkach[2,3], Katerina Medjanik[2], Olena Fedchenko[2], Hans-Joachim Elmers[2], Gerd Schönhense[2], and Ján Minár[1] — [1]New Technologies - Research Centre, University of West Bohemia,

301 00 Pilsen, Czech Republic — [2]Institut für Physik, Johannes Gutenberg-Universität Mainz, Staudingerweg 7, D-55128 Mainz, Germany — [3]Sumy State University, Rymski-Korsakov 2, 40007 Sumy, Ukraine

Angle-resolved photoemission spectroscopy (ARPES) is a driving experimental technique for examining the electronic structure of quantum materials. There is another technique called X-ray photoelectron diffraction (XPD) which is considered to be the same thing as ARPES from an elementary point of see, specifically the angular distribution of photoelectrons emitted from a crystal surface. Nevertheless, the angular distribution of emitted electrons represents the momentum of initial states in ARPES meanwhile it reveals the interference of photoelectron waves from final states in XPD. At high photon energies, photoelectron diffraction (PED) effects are found in ARPES measurements beside other obstacles (e.g. non-negligible phonon scattering). Here, to disentangle these diffraction influences, we present a PED implement for SPRKKR package which makes use of multiple scattering theory and one-step model in photemission process. For the sake of applications, we have calculated the circular dichroism in angular distributions (CDAD) associated with of 4f and 3d states from W(110). Photoelectrons are excited by hard X-rays (6000 eV).

O 85.8   Thu 16:45   REC C 213

Automatic Quantification of Transitional Metal X-ray Photoelectron Spectra using Convolutional Neural Networks — •Lukas Pielsticker, Walid Hetaba, and Mark Greiner — Max Planck Institute for Chemical Energy Conversion, Mülheim an der Ruhr, Germany

In X-ray photoelectron spectroscopy (XPS), quantitative analysis of the nature and composition of surface chemical species is typically performed manually through empirical curve fitting by expert spectroscopists. However, recent advancements in the ease-of-use and reliability of XPS instruments have led to ever more (novice) users creating increasingly large data sets that are becoming harder to analyze by hand. Reflecting this development, more automated analysis techniques are desirable to aid these users with the analysis of big XPS datasets. Here we show that by training convolutional neural networks (CNN) on artificially generated XP spectra with known quantifications (i.e., for each spectrum, the concentration of each chemical species is known), it is possible to obtain models for auto-quantification of transition metal XP spectra. CNNs are shown to be capable of quantitatively determining the presence of metallic and oxide phases, achieving competitive accuracy as more conventional data analysis methods. The proposed networks are flexible enough to accommodate spectra containing multiple chemical elements and measured with different experimental settings. The use of dropout variational inference for the determination of quantification uncertainty is discussed.

Revisiting the Strongly Correlated Si-terminated 3C-SiC(100)-p(2×1) Surface with Density- and Wave Function-Based Methods — •Niklas Thoben and Thorsten Klüner — Carl von Ossietzky Universität, Oldenburg, Germany

Silicon carbide is an environmentally friendly, abundant and chemically stable wide band gap semiconductor. From the numerous known polytypes, cubic silicon carbide (3C-SiC) shows the lowest band gap with 2.36 eV, which straddles the water redox potentials and thus making this material a possible candidate for photoelectrochemical water splitting [1]. 3C-SiC is generally obtained as thin films on Si(100) substrates [2], resulting in the 3C-SiC(100) surface being the most common surface. In the Si-terminated case, this surface can exhibit a p(2×1) reconstruction with symmetric Si-dimers [3]. In literature, this system has almost exclusively been described by periodic closed shell density functional theory (DFT) even though the symmetric dimers should be strongly correlated and thus show open shell and multi-configurational character to a certain extent. Consequentially, in this contribution we apply spin-polarized periodic hybrid DFT and multi-configurational wave function-based methods on the 3C-SiC(100)-p(2×1) surface.

Coulomb potential truncation in hybrid calculations — •Kristians Kacars and Andris Gulans — University of Latvia

Solving Poisson's equation is a fundamentally important part of electronic structure calculations. The long-range character of the Coulomb potential makes this task non-trivial in a range of applications. It leads to diverging Fock exchange and spurious interactions of periodic images of low-dimensional systems in supercell calculations. We address this problem in the context of linearized augmented plane waves(LAPW), considering two different approaches to extending Weinert's method. In the first of them, we employ a wavelet-based Poisson equation solver from the *psolver* library. In the second one, we use Coulomb potential truncation schemes. Both approaches are implemented and tested in the LAPW code `exciting`. We apply and compare these methods for bulk materials and low-dimensional systems in calculations with local and hybrid functionals.

Ultra-fast machine learning potentials for hydrogen under pressure — •Thomas Bischoff[1], Bastian Jäckl[1], and Matthias Rupp[1,2] — [1]Department of Computer and Information Science, University of Konstanz, Germany — [2]Materials Research and Technology Department, Luxembourg Institute of Science and Technology (LIST), Luxembourg

Hydrogen exhibits remarkably complex behavior at high pressures. Its rich phase space with multiple solid and liquid polymorphs is the subject of controversial scientific debate [1,2].

We apply ultra-fast potentials (UFPs) to model hydrogen under pressure. UFPs are recent robust interpretable machine-learning potentials that enable ac-

curate simulations of large atomistic systems over long time scales [3].

We examine the accuracy of UFPs for training data from density functional theory and quantum Monte Carlo calculations. We also demonstrate the physical interpretability of UFPs for reference configurations composed of atomic and molecular hydrogen. With the obtained machine-learning potential, we investigate solid-liquid and liquid-liquid phase transitions for an extensive part of the phase diagram of dense hydrogen.

Enter the Void: Cavity Formation at Metal-Water Interfaces — •Thorben Eggert[1,2], Nicolas G. Hörmann[1], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]Technical University of Munich, Munich, Germany

Cavity formation is an important concept when rationalizing the solvation of ions. However, most studies only analyze cavities in bulk liquids, omitting that their properties may change dramatically at solid-liquid interfaces.

Here, we study cavities at interfaces, particularly their free energy of formation based on classical molecular dynamics simulations. Specifically, we use a particle insertion approach, as well as thermodynamical integration via the Multistate Bennett Acceptance Ratio. We demonstrate that cavity formation at interfaces depends on the substrate material, which can be rationalized by the strength of the substrate-water interaction. Furthermore, we observe deviations from the bulk behavior in the second solvation layer, which underlines the importance of the substrate-specific interfacial water structure. Finally, we validate our findings with *ab initio* molecular dynamics simulations.

These results allow a quantification of the competitive nature of adsorption processes at solid-liquid interfaces. Ultimately, they could improve implicit solvation models, which typically neglect substrate-specificity.

first-principles molecular dynamics simulations of electrified Pt(111)/H2O interfaces — •Lang Li[1,2], Nicolas Hörmann[1], and Karsten Reuter[1] — [1]Fritz haber institut of Max planck socirty — [2]Humboldt-Universität zu Berlin

Metal-water interfaces play a fundamental role in electrochemistry. An accurate understanding of their properties is required in any attempt to describe electrochemical phenomena such as electrocatalytic reactions or charge transfer processes.

In this work, we benchmark the description of electrified Pt(111)/water interfaces based on first-principles molecular dynamics simulations at applied potential conditions using density functional theory. We apply the potential by introducing excess electrons that are counterbalanced by partially charged hydrogen atoms. This method is tested with a variety of slab setups and cell sizes.

We analyze in detail the structure of the interface as well as the obtained capacitance vs. potential curves and compare these with published theoretical and experimental results [1]. Our results highlight the response of interfacial water to an applied potential and its importance for understanding the hump in the capacitance, observed at high electrolyte concentrations [2].

Novel concepts to simulate electrified liquid/solid interfaces from first principles — Florian Deissenbeck[1], Christoph Freysoldt[1], Mira Todorova[1], Jörg Neugebauer[1], and •Stefan Wippermann[1,2] — [1]Max-Planck-Institut für Eisenforschung — [2]Philipps-Universität Marburg

Ab initio techniques have revolutionized the way how theory can help practitioners to discover and design new materials, and explore critical mechanisms. Achieving an atomistic understanding of electrochemical processes is imperative to realize disruptive innovations, e.g. power-to-X devices, supercapacitors, metal-air batteries, new concepts in sustainable metallurgy. A well known example, how novel concepts can impact our ability to perform such studies is the introduction of temperature control into *ab initio* simulations. The analogous technique to model electrochemical systems - potential control - is just emerging.

We recently introduced a "thermopotentiostat": a novel approach to control the electrode potential in molecular dynamics (MD) simulations [1], that can be straightforwardly implemented into any density-functional code [2]. Here, we provide a perspective on the key concepts of simulating electrified liquid/solid interfaces via *ab initio* MD at controlled electrode potential. To highlight the op-

portunities provided by these developments we discuss the dielectric response and splitting of liquid water in contact with electrified semiconductor surfaces.

Entropic contributions to the stability of electrochemically adsorbed anion layers on Au(111), a microcalorimetric study — •Marco Schönig and Rolf Schuster — Karlsruhe Institute of Technology, Germany

The understanding of the solid/electrolyte interface is detrimental for rationalizing of electrochemical processes. In this contribution we use electrochemical microcalorimetry to study the entropy of formation of the interface for anion $(Cl^-, Br^-, I^-, SO_4^{2-})$ adsorption on Au(111) [1]. The entropy of formation of the interface provides information on the structure, order and composition of this interface, which are often used as descriptors in electrochemical processes. The specific adsorption of anions on Au(111) is an important model system, since the nearly ideal polarizability of the gold surface over a large potential window allows to study the formation of surface adlayers up to high surface coverages. We found a negative reaction entropy during the adsorption process, with a distinct minimum around two thirds of the maximum coverage. Additionally, we observed that the course of the reaction entropy vs. potential changes with the employed cation (Li^+, K^+, Cs^+) in solution. We will discuss contributions of the solvent and the electrolyte to the entropy of formation of the interface and provide statistical mechanics models to describe the measured data. We found that it was imperative to include repulsive interactions between the adsorbates to account for the experimental results. [1] M. Schoenig and R. Schuster Phys. Chem. Chem. Phys., 2022, Accepted Manuscript

Impact of confined water on solvation and adsorption/desorption energetics of charged ions at the electrified interface — •Zhenyu Wang, Mira Todorova, and Jörg Neugebauer — Department of Computational Materials Design, Max-Planck-Institut für Eisenforschung, Max-Planck-Str.-1, D-40237, Düsseldorf, Germany

Understanding processes at electrified solid/liquid interfaces is crucial for many systems and a wide range of applications in the electrochemical industry, catalytic sciences and biological engineering. Using a prototypical model system of a single ion in water confined between two charged electrodes, we perform nanosecond-scale atomistic molecular dynamics simulations to study the dielectric behavior of chemically pure water as well as the solvation of ions in the presence of an electric field. For weak electric fields, we find that the screening charge density of water is proportional to the external electric intensity, in agreement with classical polarization theory. Probing the interface structure by the single Na+/Cl- ion we investigate the formation and evolution of the ion's solvation shell as a function of the electrode-ion distance. Comparing potential profiles from Na+/Cl- calculations for different charge states and positions, we elucidate the role of screening and solvation shell size on reorganization energies and the transmission barrier of the ions close to the interface.

Dynamics of the Iridium-Oxide/Water Interface from Machine Learning Potential Simulations — •Nikhil Bapat, Simon Wengert, Hendrik H. Heenen, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin, Germany

The interaction of liquid water with a solid substrate at an electrified solid/liquid interface plays a crucial role in the activity and stability for electrocatalysts such as IrO_2. It is therefore important to obtain detailed insights about the underlying processes on these interfaces. Here, resolving the dynamical evolution at the atomic scale requires highly accurate yet efficient models that overcome the length and time scale restrictions imposed by traditional *ab initio* molecular dynamics simulations. To that end, we use the Gaussian approximation potential framework to construct a machine-learned model trained on density-functional

theory data for the $IrO_2(110)$/water interface. The established training protocol uses an automated and iterative procedure to ensure that the training data covers the *a priori* unknown geometric and compositional motifs of the evolving working interface.

The model is then used to run reactive molecular dynamics simulations with varying surface compositions. Crucial for electrolysis, the reduced computational cost allows to efficiently explore the diverse configuration space of adsorbed intermediates in the oxygen evolution reaction. Furthermore, we investigate the mobility of water in dependence of the underlying surface composition in which, long-range effects are reflected in a strong variation of water mobility as a function of distance to the surface.

First-principles study of electrochemical effects in Si/SiOx-water interfaces — •Kamila Savvidi[1] and Robert H. Meissner[1,2] — [1]Institute of Polymer and Composites, Hamburg University of Technology, Hamburg, Germany — [2]Institute of Surface Science, Helmholtz-Zentrum Hereon, Geesthacht, Germany

Nanoporous silicon is a prominent candidate for application in energy storage devices as silicon can be conductive under certain conditions. Computer simulations offer an understanding of the electrified semiconductor/water interfaces on the atomistic level; essential for the efficient design and optimization of these devices. We use *ab-initio* molecular dynamics (AIMD) to study the capacitive properties of Si/water interface in the presence of an electrostatic potential. A doped Ne crystal is used as counter electrode to a SiO_x slab and to a hydrogenated Si(100) slab to apply a constant bias potential while explicit water molecules constitute the electrolyte solution.[1] Differential capacitance is estimated by the time-averaged atomic charge fluctuations for each system. To obtain more information about the influence of individual electrode atoms to the differential capacitance, the charge fluctuations of each atom are used to calculate a charge-charge covariance matrix $\mathbf{K}_{qq}^{-}$. [2] Results are compared to the simulation of a single electrode with water on either side in an electric field.

Thermodynamic Cyclic Voltammograms from First Principles — •Nicolas Bergmann, Nicolas G. Hörmann, and Karsten Reuter — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany

Cyclic voltammograms (CVs) are a central experimental tool for assessing the structure and activity of electrochemical interfaces. Computationally, a predictive-quality modeling of CVs is challenging due to the entangled need to accurately account for the interactions and reactive chemistry at the liquid electrolyte/solid electrode interface as well as for the applied potential [1]. For sufficiently small scan rates, thermodynamic approaches help to meet these challenges.

Here, we compare different options to derive thermodynamic CVs consistently and at low computational cost, using the well-studied model system of Ag(100) in a Br-containing electrolyte as a test case. We present our generalized ansatz to derive continuous expressions within a mean-field (MF) model, using non-parametric Gaussian process regression. We also shine light on the inherent

accuracy limitations of MF theory, by comparing it to CVs from grand-canonical lattice Monte Carlo simulations. Finally, we show how augmenting traditional zero-field calculations (computational hydrogen electrode, CHE) with capacitive double layer energetics (CHE+DL) [1] within an implicit solvent model influences the theoretical results.

Electrodeposition and Electrochemical Characterization of Thin Nickel Overlayers on Au(111) — •Markus Wittmann, Ludwig A. Kibler, and Timo Jacob — Ulm University, Institute of Electrochemistry, 89069 Ulm, Germany

Nickel is widely used in energy storage and conversion, *e.g.* nickel–iron, nickel–cadmium, and nickel–metal hydride batteries. The behavior of nickel electrodes has been investigated extensively. However, a detailed understanding of adsorption and absorption processes on the atomic level is still missing. In particular, the distinction between surface and bulk atoms, as well as adsorbed hydrogen during electrooxidation is difficult.[1,2] Here we report on the electrochemical fabrication of thin nickel overlayers on Au(111) and their electrochemical characterization. Stable nickel overlayers have been electrochemically deposited onto Au(111) from a 1 mM $NiSO_4$ solution and subsequently characterized by cyclic voltammetry in a 10 mM KOH solution. The current density–potential curves of nickel overlayers on an Au(111) single crystal in comparison with the behavior of Au(111) and Ni(111) in 10 mM KOH help separating surface and bulk contributions of nickel electrooxidation. This is especially relevant for small deposits with a high surface-to-bulk ratio. In addition, relations between the structure of the nickel electrodeposit and its electrochemical behavior are addressed.

Cu Underpotential Deposition on Au(111) in Presence of Carboxylic Acids — •Sebastian Fackler, Markus Wittmann, Ludwig A. Kibler, and Timo Jacob — Ulm University, Institute of Electrochemistry, 89069 Ulm, Germany

The underpotential deposition (UPD) of foreign metals on different host metals has been extensively studied, especially for Cu on Au(111).[1] Apart from the nature of the metals, the nature and concentration of anions in the solution govern the initial stages of the deposition process. The influence is usually explained with respect to non-specific and specific adsorbing anions, with the ability of the latter to stabilize sub-monolayers of the deposited metal on the host metal by co-adsorption on top of well-ordered superstructures.[1]

Similarities and differences of the Cu UPD on Au(111) with short-chained carboxylic acids in comparison with known inorganic anions were systematically investigated by cyclic voltammetry and current transients. Despite the non-specifically adsorbing nature of perchlorate ions, the present study demonstrates that perchlorate can influence the Cu deposition in presence of specifically adsorbing acetate ions. Similarly, it has been found by in-situ STM studies that the presence of perchlorate influences the adsorption structure of strongly adsorbing formate on Au(111).[2]

O 87: Focus Session: Scanning Probe Microscopy with Quartz Sensors III

Time: Thursday 15:00–17:30   Location: TRE Ma

Topical Talk   O 87.1   Thu 15:00   TRE Ma

Quartz-sensor detection for single-electron tunneling spectroscopy — •Jascha Repp — Department of Physics, University of Regensburg, 93040 Regensburg, Germany

We exploit the high sensitivity of qPlus-based [1] atomic force microscopy (AFM) to perform scanning tunneling microscopy (STM) and spectroscopy on molecules in absence of any conductance of the underlying substrate. Thereby, we gain access to out-of-equilibrium charge states that are out of reach for conventional STM [2]. Extending this technique by electronic pump-probe spectroscopy [3], we measured the triplet lifetime of an individual pentacene molecule on an insulating surface [4] and lifetime quenching by nearby oxygen molecules. Combined with radio-frequency magnetic-field driving we introduce AFM-based electron spin resonance and spin manipulation showing long spin coherence in single molecules.

O 87.2   Thu 15:30   TRE Ma

molecular diffusion studied by multidimensional cantilever-based UHV AFM — •Zuned Ahmed[1,2], Hao Liu[1,2], Manfred Parschau[1], and Hans Josef Hug[1,2] — [1]Empa (Swiss Federal Laboratories for Materials Science and Technology), Dübendorf , Switzerland — [2]University of Basel, Switzerland

Scanning probe microscopy permits a characterization of the diffusion of atoms or molecules on surfaces, which is governed by diffusion energy barrier and entropy difference between ground and excited states. With our home-built, cantilever based UHV, low temperature scanning force microscope [1], we studied the diffusion of benzene-based molecules with flexible and rigid hydrocarbon chains, namely,1,3,5-Triethylbenzene (TEB) and 1,3,5-Trimethylbenzene (TMB), respectively, measured at temperatures between 6.38 and 10.68 K on Cu (111). An Arrhenius analysis revealed that the molecule with the flexible hydrocarbon arms (TEB) showed an enhanced diffusion rate which we can attribute to its higher configurational entropy of its ethyl chains. Moreover, we used multidimensional AFM to map the vertical and lateral forces required to manipulate both molecules. Compatible with the lower diffusion energy barrier of the TEB molecule, the force required to manipulate the TEB was much smaller than that of the TMB molecule. In addition, the measured flexural and torsional frequency shift data permitted a detailed analysis of the manipulation process.

O 87.3 Thu 15:45 TRE Ma

Flexible Superlubricity Unveiled in Snake-Like motion of Individual Chains — •Guilherme Vilhena[1,2], Rémy Pawlak[1], Philipp D'Astolfo[1], Xunshan Liu[3], Enrico Gnecco[4], Marcin Kisiel[1], Thilo Glatzel[1], Rúben Pérez[2], Robert Häner[3], Silvio Decurtins[3], Alexis Baratoff[1], Giacomo Prampolini[5], Shi-Xia Liu[3], and Ernst Meyer[1] — [1]University of Basel, Switzerland — [2]Universidad Autónoma de Madrid, Spain — [3]University of Bern, Switzerland — [4]Jagiellonian University, Poland — [5]Consiglio Nazionale delle Ricerche, Italy

A combination of low-temperature atomic force microcopy and molecular dynamic simulations demonstrates that soft designer molecules realize a sidewinding motion when dragged over a gold surface. Exploiting their longitudinal flexibility, pyrenylene chains are indeed able to lower diffusion energy barriers via on-surface directional locking and molecular strain. The resulting ultralow friction reaches values on the order of tens of pN reported so far only for rigid chains sliding on an incommensurate surface. Therefore, we demonstrate how molecular flexibility can be harnessed to realize complex nanomotion while retaining a superlubric character. This is in contrast with the paradigm guiding the design of most superlubric nanocontacts (mismatched rigid contacting surfaces).

O 87.4 Thu 16:00 TRE Ma

Machine learning for high-resolution AFM image interpretation — •Niko Oinonen[1], Lauri Kurki[1], Chen Xu[1], Shuning Cai[1], Markus Aapro[1], Alexander Ilin[2], Peter Liljeroth[1], and Adam Foster[1,3] — [1]Department of Applied Physics, Aalto University, Finland — [2]Department of Computer Science, Aalto University, Finland — [3]WPI Nano Life Science Institute (WPI-NanoLSI), Kanazawa University, Japan

State-of-the-art non-contact atomic force microscopy (AFM) setups operating in vacuum at low temperatures are able to resolve features on the scale of individual atoms in molecules [1]. However, the process of interpreting the resulting AFM images is often a very challenging task even for highly trained experts in the field. We are working towards greater interpretability and greater automation of the processing of AFM images using machine learning methods. We have introduced an approach based on convolutional neural networks for discovering the atomic structure and electrostatic properties of samples directly from AFM images via image descriptors that characterize the sample [2]. Our recent work refines the geometry prediction task by predicting the molecule graph of the sample using a model based on graph neural networks [3]. The current challenge is in generalizing from simulated training data to experimental test data, where we find that the choice of the training data becomes very important.

Topical Talk O 87.5 Thu 16:15 TRE Ma

Application of atomic force microscopy with quartz sensors to quantum states in graphene and related twisted heterostructures — •Joseph Stroscio — National Institute of Standards and Technology, Gaithersburg, MD, USA.

Atomic force microscopy (AFM) with quartz sensors pioneered by Franz Giessibl has opened many applications in quantum nanoscience where AFM measurements can be made simultaneously and conveniently with scanning tunneling microscopy measurements (STM). In this presentation I will review our work using combined AFM/STM measurements to give a microscopic view of the quantum states in single layer graphene and in twisted graphene heterostructures. In single layer graphene, electrostatic pn junction boundaries provide a convenient geometry for the examination of quantum Hall edge states with microscopic probes. For a graphene Hall bar device defined and tunable by dual gates, we carry out simultaneous AFM, STM, and electrical transport measurements in the system which we developed for detailed measurements of two-dimensional devices in-operando at mK temperatures and in magnetic fields up to 15 T. The AFM, operated in the Kelvin probe force microscopy (KPFM) mode, detects the chemical potential transitions when Landau levels are being filled or emptied as a function of back gate potential with the same fidelity as the scanning tunneling spectroscopy measurements. With KPFM we can map the dispersion of the Landau levels across the quantum Hall edge boundary as a function of density and spatial position.

O 87.6 Thu 16:45 TRE Ma

On the origin and elimination of cross coupling between excitation and tunneling current in scanning probe experiments that utilize the qPlus sensor — •Michael Schelchshorn — Institute of Experimental and Applied Physics, University of Regensburg, Universitätsstraße 31, 93053 Regensburg

The qPlus sensor is a stiff quartz cantilever that facilitates high-resolution combined STM/AFM [1]. Both a tunneling current and the deflection signal resulting from the forces at the tip are measured simultaneously; however, unwanted cross coupling between the tunneling current signal and the excitation of the sensor oscillation can occur. At one bias polarity, this cross coupling acts as an excitation of the oscillation, in the opposite bias it appears as a damping.

This unwanted effect has been observed since the early years of combined STM/AFM experiments using qPlus sensors, but was difficult to explain. Here, we present a new theory that explains this phenomenon, supported by experiments and supplemented by verified measures on how to prevent or at least minimize cross talk. [2]

O 87.7 Thu 17:00 TRE Ma

Fe adsorbates and their effect on the surfaces of topological insulators TlBiSe$_2$ and Bi$_2$Se$_3$ — •Adrian Weindl, Christoph Setescak, Emma Grasser, Alexander Liebig, and Franz J. Giessibl — University of Regensburg, Regensburg, Germany

Can one tailor the properties of the topological surface state (TSS) of topological insulators (TIs) by magnetic doping of the TI material? Here, we study the effect of magnetic adatoms on TI surfaces by combined scanning tunneling microscopy (STM) and atomic force microscopy (AFM). Two archetypical TIs, Bi$_2$Se$_3$ and TlBiSe$_2$, are analyzed, which both have relatively large band gaps with their Dirac points well isolated and far from bulk states. Magnetic impurities, in this case single Fe adatoms, and their influence on the local density of states (LDOS) of the two TIs are investigated by scanning tunneling spectroscopy. We detect resonances in the LDOS for both surfaces that arise due to the scattering of electrons in the TSS at these impurities. The position and shape of these resonances are a function of the exact adsorption position of the adatoms, which can be determined by atomically-resolved AFM measurements. In addition, we detect a relaxation of surface atoms due to the presence of Fe adatoms on Bi$_2$Se$_3$. The charge state of the Fe adatoms is determined by Kelvin probe force spectroscopy.

O 87.8 Thu 17:15 TRE Ma

The (2x1) reconstruction of calcite(104) — Jonas Heggemann[1], Yashasvi Ranawat[2], Ondřej Krejčí[2], Adam S. Foster[2], and •Philipp Rahe[1] — [1]Fachbereich Physik, Universität Osnabrück, Barbarastraße 7, 49076 Osnabrück, Germany — [2]Department of Applied Physics, Aalto University, Helsinki FI-00076, Finland

Calcite is an abundant material in the Earth's crust, a central constituent of biominerals in living organisms [1], and currently investigated as a capture material for CO2 [2]. Despite intensive studies, however, there is still serious ambiguity regarding the properties of this surface due to conflictive conclusions for the so-called row-pairing [3] and (2x1) reconstruction [4].

Here, we use a combination of non-contact atomic force microcopy (NC-AFM) with CO-functionalized tips at 5K, density functional theory with state-of-the-art dispersion corrections, and NC-AFM image simulations to clarify the microscopic geometry of calcite(104). A (2x1) reconstruction and a glide plane symmetry is consistently found in the NC-AFM data and DFT results. Most importantly, we identify two different adsorption positions for CO molecules within the (2x1) unit cell. These findings are most critical for future studies where processes on calcite(104)-(2x1) are influenced by the surface geometry.

Molecular Surfaces With a Twist: Magnetochiral Asymmetries and Topological Self-Assembly — •Karl-Heinz Ernst — Empa, Swiss Federal Laboratories for Materials Science and Technology, Dübendorf (Switzerland) — Nanosurf Laboratory, Institute of Physics, The Czech Academy of Sciences, Prague (Czech Republic) — Department of Chemistry University of Zurich, Zurich (Switzerland)

Surfaces functionalized with helically shaped aromatic hydrocarbons, so-called helicenes, are of interest for chiroptical electronic devices or for electron spin filtering. After a general introduction into the topic we will report a unique transmission of chirality from single polyaromatic hydrocarbons into two-dimensional self-assembled monolayers on a silver surface. A helicene with relatively high molecular flexibility allows adaptation of handedness during crystal growth which is governed rather by entropy than by enthalpy. The layer is dominated by motifs, such as nodes of different topology, i.e., two-armed and three-armed spirals, and by enantiospecific lateral offset of oligomeric triangles. To our knowledge such chiral self-assembly phenomenon has been neither reported previously nor has such aperiodic tiling of the plane been previously described by geometers. Moreover, we will report spin-selective electron transport phenomena and enantioselective magnetochiral interactions of helicenes with ferromagnetic surfaces by means of photoelectron spectroscopy, spin-polarized low-energy electron microscopy and spin-polarized scanning tunneling microscopy.

O 91: Plasmonics and Nanooptics V: Waveguides and Antennas

O 91.1 Fri 10:30 CHE 89
Intermediate-field coupling of single epitaxial quantum dots to plasmonic nanowires — •Michael Seidel[1], Yuhui Yang[2], Saimon Covre Da Silva[3], Thorsten Schumacher[1], Armando Rastelli[3], Stephan Reitzenstein[2], and Markus Lippitz[1] — [1]Experimental Physics III, University of Bayreuth, Germany — [2]Institute of Solid State Physics, TU Berlin, Germany — [3]Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, Austria

Integrated plasmonic nanocircuits are highly promising building blocks for future quantum optical applications. In combination with self-assembled epitaxially grown GaAs quantum dots as stable, bright and narrow-band single-photon sources, ultra-compact nanocircuits operating below the diffraction limit can be designed [1]. A crucial aspect is the coupling of the quantum dot emission into plasmonic waveguide modes. Typically, quantum emitters are placed in the optical near-field of a waveguide, imposing high demands on controlled nanofabrication. Furthermore, plasmonic waveguiding is drastically attenuated near high-index dielectrics due to radiative losses. We overcome these challenges by introducing a 100nm thick dieletric spacer layer, which effectively increases the propagation length and preserves acceptable coupling efficiency, resulting in a robust coupling scheme which is difficult to achieve in the near-field. We characterize the nanostructure by low-temperature photoluminescence and cathodoluminescence imaging and find good agreement to numerical simulations.

O 91.2 Fri 10:45 CHE 89
How to obtain modes in optical fibers — •Sergei Gladyshev, Adria Canos Valero, and Thomas Weiss — Institute of Physics, University of Graz, Universitätsplatz 5, 8010 Graz, Austria

Nowadays, new and complex types of optical fibers such as bandgap photonic crystal fibers and antiresonant fibers are actively studied. To understand the physical mechanisms in such fibers, numerical modeling is of great importance. However, numerical calculations for these fibers are extremely challenging. We present an efficient numerical method for obtaining fiber modes in these systems. More specifically, we adapt the contour integral method, a method for solving nonlinear eigenvalues problems, to derive the propagation constant and the electromagnetic near fields of several modes simultaneously.

O 91.3 Fri 11:00 CHE 89
Directional transport in plasmonic waveguide arrays in the presence of disorder — •Anna Sidorenko and Stefan Linden — Physikalisches Institut, Friedrich-Wilhelms-Universität Bonn, Kreuzbergweg 24, 53115-Bonn, Germany

Evanescently coupled waveguides provide a convenient platform for the simulation of various quantum phenomena whose experimental realization in analogous condensed matter systems is otherwise difficult. The basis for this is the mathematical equivalence of the coupled mode theory equations and the discrete Schrödinger equation in the tight-binding approximation. Here we present a comparative study of the robustness of directional transport in presence of disorder in two periodically driven waveguides systems - ratchets [1] and fast Thouless pumps [2]. Directional transport in a ratchet requires fine-tuning of the driving parameters. In contrast, directional transport in Thouless pumping is a topological effect that exists for a range of driving frequencies considering the closed cycle in parameter space. We analyze the effect of topological protection on directional transport by introducing identical disorder distributions to both systems.

Spatially resolved nonlinear plasmonics — •Johannes Schust, Florian Mangold, Niklas Metz, Mario Hentschel, Bettina Frank, and Harald Giessen — 4th Physics Institute, Research Center SCoPE, and IQST, University of Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany

Nonlinear optical plasmonics investigates plasmonic nanoantenna fields with the help of nonlinear spectroscopy. Here we introduce nonlinear spatially resolved spectroscopy (NSRS) which is capable of imaging the k-space as well as spatially resolved single antennas while it is still possible to carry out spectroscopy.

These additional abilities give us the possibility to spatially resolve the THG signal of gold nanoantenna arrays and investigate the homogeneity of the antenna field. Furthermore, we are able to spatially resolve the THG emission centers of the third-order mode and observe their response to tuning the wavelength over the resonance.

In addition, we discovered that by increasing the laser intensity, certain antennas in our array became exceptionally bright. By correlating our spatially resolved nonlinear image with structural SEM data, we can prove that these bright antennas have deformed into a peanut shape. Thus our NSRS setup enables the investigation of the nonlinear self-enhancement process of nanoantennas under intense laser heating.

O 91.5 Fri 11:30 CHE 89
Spatio-spectral metrics in electron energy loss spectroscopy as a tool to resolve nearly degenerate plasmon modes — Michal Horák, Andrea Konečná, Tomáš Šikola, and •Vlastimil Křápek — Brno University of Technology, Czechia

Electron energy loss spectroscopy (EELS) is utilized to characterize localized surface plasmon modes supported by plasmonic antennas (PAs) with excellent spatial resolution, including studies of hybridized modes in dimer PAs [1,2,3]. However, the spectral resolution of EELS is often insufficient to resolve the hybridized modes for weakly coupled dimers.

Here we address this issue for a case study of the dimer PA composed of two gold discs. We analyze four nearly degenerate hybridized dipole modes. With a traditional approach, the modes cannot be experimentally identified with EELS. Therefore, we propose several metrics that employ the spatial and spectral sensitivity of EELS simultaneously. We apply the metrics to experimental EELS data, demonstrating their ability to resolve three of the above-mentioned modes (with

transverse bonding and antibonding modes still unresolved), identify them unequivocally, and determine their energies. In this respect, the spatio-spectral metrics increase the information extracted from EELS applied to PAs.

From Static to Dynamic Modulation of Second Harmonic Generation from Plasmonic Hotspots — •Jessica Meier[1], Luka Zurak[1], Andrea Locatelli[2], Thorsten Feichtner[1], René Kullock[1], and Bert Hecht[1] — [1]Nano-Optics and Biophotonics Group, Experimental Physics 5, University of Würzburg, Am Hubland, 97074 Würzburg, Germany — [2]Department of Information Engineering, University of Brescia, Italy

Plasmonic dimer antennas feature strong intensity enhancement squeezed into nanoscale gaps, which makes them highly attractive for boosting nonlinear processes, such as multiphoton excitation and harmonic generation [1]. Such phenomena, alongside large field enhancement, often require control over the field symmetry in the gap, which is challenging considering the nanometer length scales. Here, by means of strongly enhanced second harmonic (SH) generation, we demonstrate unprecedented control over the field distribution by systematically introducing geometrical asymmetry. We use focused helium ion beam milling of mono-crystalline gold to realize asymmetric-gap dimer antennas in which an ultra sharp tip with 3 nm apex faces a flat counterpart [2]. By tuning the tip opening angle, we systematically vary the field asymmetry, which in turn modulates the release of SH radiation to the far-field. We further extend the concept of inducing local field asymmetry to reversible tuning of the SH signal from a single antenna by applying an external voltage.

O 91.7 **Fri 12:00** **CHE 89**

Laser Printing of Plasmonic Dimers on Optical Fiber Tips for Fiber-based SERS — •Paul Vosshage, Francis Schuknecht, and Theobald Lohmüller — Chair for Photonics and Optoelectronics, Nano-Institute Munich, Department of Physics, LMU Munich, Königinstraße 10, 80539 Munich, Germany

Raman Spectroscopy through optical fibers offers great flexibility for conducting measurements both in situ and in vivo, but shows limitations due to the weak Raman scattering cross-sections of most molecules and a considerable background introduced by the fiber material itself. However, a strong signal amplification can be obtained via surface enhanced Raman scattering (SERS) by introducing plasmonic hot-spots on the optical fiber tip.

Here, we demonstrate a single-step approach to pattern plasmonic dimer antennas directly onto glass fibers by optical means. A focused laser beam is used to transform a gold nanorod into two nanospheres of equal size via heating. Simultaneously, optical forces are harnessed to print the two spheres onto the fiber tip as a strongly coupled dimer. The resulting plasmonic dimers feature nm-sized gaps, which provide a strong electromagnetic field enhancement required for fiber-based SERS.

O 91.8 **Fri 12:15** **CHE 89**

Reconfiguring magnetic resonances with plasmonic and dielectric phase-change materials — Lukas Conrads, Andreas Hessler, Sebastian Meyer, Konstantin Wirth, Matthias Wuttig, Dimitry Chigrin, and •Thomas Taubner — I. Institute of Physics (IA), RWTH Aachen University

For miniaturized active nanophotonic components, resonance tuning of nanoantennas is a key ingredient. Phase-change materials (PCMs) have been established as prime candidates for non-volatile resonance tuning based on a change in refractive index [1]. Currently, a novel material class of switchable infrared plasmonic PCMs, like In_3SbTe_2 (IST), is emerging. Since IST can be locally optically switched between dielectric (amorphous phase) and metallic (crystalline phase) states in the whole infrared range, it becomes possible to directly change the geometry and size of nanoantennas to tune their infrared resonances [2]. Here, crystalline IST split-ring resonators (SRRs) are directly optically written and reconfigured in their arm size to continuously tune their magnetic dipole resonances over a range of 2.4 μm without changing their electric dipole resonances. Furthermore, electric and magnetic dipole resonances of aluminum SRRs covered by the conventional PCM $Ge_3Sb_2Te_6$ can be individually tuned by addressing the hotspots locally [3]. Our concepts are well-suited for rapid prototyping, speeding up workflows for engineering ultrathin, tunable, plasmonic devices for infrared nanophotonics, telecommunications or (bio)sensing.

Nanoantenna Electro-Optical-Transducer Utilizing Monolayer WSe₂ — •Patrick Pertsch, René Kullock, Monika Emmerling, Romana Ganser, and Bert Hecht — NanoOptics & Biophotonics Group, Experimental Physics 5, University of Würzburg, Am Hubland, 97074 Würzburg, Germany

Using light for the communication on computer chips could decrease the power consumption and increase the data bandwidth [1]. To this end, transition-metal-dichalcogenides (TMD), and especially monolayers thereof, are a very promising material class, because they can be used in electronic computing [2] as well as in optical applications [3].

To achieve high integration densities of logical elements, the transducers between electronic and optical signals should be of the same size as the nanoscale transistors used in modern electronics. But so far the photodetectors and emitters based on TMDs are usually much larger.

By combining TMDs with plasmonic nanostructures, the size of the optical elements can be decreased due to the large absorption cross section afforded by the plasmonic nanoantennas. In this work, we demonstrate single plasmonic nanoantennas on monolayer WSe₂ acting as optically-active material. This combination allows to emit and detect light by using only one single nanoscale device.

Growth of ultrathin silica films on Pt(111) and Rh(111): Influence of intermixing with the support — •Florian Kraushofer[1], Matthias Krinninger[1], Nils Refvik[2], Friedrich Esch[1], and Barbara Lechner[1] — [1]TU Munich, Germany — [2]University of Alberta, Canada

Silica is a widely used catalyst support material for clusters and nanoparticles. Understanding the relationship between these clusters and the support is challenging, however, because SiO_2 is insulating, and in most applications not crystalline, which limits the use of diffraction-based experimental techniques. Several previous studies have investigated ultrathin, quasi-2D silica films on a variety of metal supports [1], which can then be measured by scanning tunneling microscopy (STM). Previous work on Pt(111) did not result in closed films, which was attributed to lattice mismatch [2]. We show that closed films can in fact be grown on Pt(111) when silica is deposited in excess, likely due to formation of a platinum silicide layer with a slightly expanded lattice constant at the interface. We also report results of film growth on Rh(111), which is a near-perfect match to the lattice constant of freestanding SiO_2 films as calculated by theory. However, no high-quality films were achieved, which we attribute to a different balance of the formation energies for silicide and oxide.

Growth of single-phase honeycomb Ti₂O₃ on Pd(111) — •Rajesh Chirala, Stefan Förster, and Wolf Widdra — Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, 06120 Halle, Germany

Transition metal oxides are known to form honeycomb (HC) structures when grown on metal substrates. The oxide-substrate interaction strength defines the substrate-dependent HC lattice parameter. On Au(111), the Ti_2O_3 HC forms a (2×2) superstructure corresponding to lattice parameter of 5.77 Å [1]. On the contrary, Pt(111) has HC relaxing to a lattice parameter of 5.95 Å [2].

Here we study the growth of a Ti_2O_3 HC structure on Pd(111) from the initial stages up to monolayer coverages. The HC is grown by consecutive steps of room-temperature Ti deposition and annealing at 875 K in 7×10⁻⁹ mbar of O_2. Whilst the smallest HC patches grow with a lattice parameter of 5.8 Å with a rotation of 26° against the < $1\bar{1}2$ > direction of Pd(111), they relax to a lattice parameter of 5.95 Å at higher coverage. Due to this relaxation, the HC lattice coincides with the Pd(111) at a rotation of 30°. The implications of this HC structure as template for the growth of dodecagonal oxide quasicrystal will be discussed [3].

O 92.3 Fri 11:00 CHE 91

Magnetite homoepitaxy observed by X-ray intensity growth oscillations — •Steffen Tober[1,2,3], Marcus Creutzburg[1], Björn Arndt[1], Simon Chung[1], Leon Jacobse[1], Arno Jeromin[1], Vedran Vonk[1], and Andreas Stierle[1,2] — [1]Deutsches Elektronen-Synchrotron DESY, Centre for X-ray and Nanoscience, Hamburg — [2]Universität Hamburg, Fachbereich Physik — [3]Jülich Centre for Neutron Science (JCNS) and Peter Grünberg Institut (PGI), JARA-FIT, Forschungszentrum Jülich

Processes on the magnetite ($Fe_{3-\delta}O_4$) (001) surface like oxidative regrowth, (partial) lifting of the subsurface cation vacancy reconstruction and the element-specific incorporation of adatoms demonstrate the sensitive relation of oxygen pressure, cation transport and structure in the near-surface region of $Fe_{3-\delta}O_4$ influencing the performance of catalysts and devices [1,2,3]. We exemplarily studied the homoepitaxial growth of $Fe_{3-\delta}O_4$ (001) surface in dependence of the O_2 pressure and iron flux. X-ray intensity growth oscillations proved ordered growth of $Fe_{3-\delta}O_4$ for all probed conditions while atomic force microscopy revealed newly formed micrometre-sized surface structures exceeding the amount of deposited material [4]. Our results indicate the presence of multiple parallel processes during reactive $Fe_{3-\delta}O_4$ homoepitaxy suggesting similar processes to occur also in other applications of $Fe_{3-\delta}O_4$. O 92.4 Fri 11:15 CHE 91

The dependence of structure on thickness of NiO(100) films on Ag(100) studied by IV-LEED — •Jan Lachnitt[1], Shuvankar Das[2], Krishnakumar S. R. Menon[2], Suman Mandal[3], and Jan I. Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Cottbus, Germany — [2]Surface Physics & Material Science Division, Saha Institute of Nuclear Physics, Kolkata, India — [3]Department of Physics, Sabang Sajanikanta Mahavidyalaya, Paschim Medinipur, India

Ultrathin NiO films have prospective applications especially in heterogeneous catalysis, microelectronics, and spintronics and are thus an object of active research. The Ag(100) surface is the usual support for these films, as its cubic lattice parameter is only 2.2 % smaller than that of NiO, which enables pseudomorphic growth at very low thicknesses. We have studied the NiO(100) surface for three thicknesses of the oxide: 2 ML on Ag(100), 20 ML on the same substrate, and a bulk single crystal. We have used intensity-voltage low-energy electron diffraction (IV-LEED) in combination with X-ray photoelectron spectroscopy (XPS) and density-functional theory (DFT) calculations. We focus on differences among the three thicknesses, mainly in terms of lattice parameters and surface defects, and our study deepens existing knowledge of the growth of ultrathin NiO films. The IV-LEED calculations have been carried out using the AQuaLEED package, which will also be briefly presented.

O 92.5 Fri 11:30 CHE 91

LEED I(V) with ViPErLEED: Overview and Applications — •Alexander M. Imre[1], Florian Kraushofer[1,2], Florian Doerr[1], Tilman Kisslinger[3], Michael Schmid[1], Ulrike Diebold[1], Lutz Hammer[3], and Michele Riva[1] — [1]TU Wien, Vienna, Austria — [2]TU Munich, Munich, Germany — [3]FAU Erlangen-Nürnberg, Erlangen, Germany

LEED $I(V)$ is an extension to qualitative Low Energy Electron Diffraction (LEED) pattern analysis in which diffraction intensities are quantitatively studied as a function of incident electron energy. This yields structural information about the surface that can be difficult to obtain otherwise. Regrettably, LEED $I(V)$ has been underutilized by the surface science community over the last decades.

Our group has developed the Vienna Package for TensErLEED (ViPErLEED); a suite of hardware and software aiming to drastically reduce the barrier of entry for the technique. The three core parts of ViPErLEED are: (1) electronics that enable upgrading existing LEED setups for LEED $I(V)$, (2) a spot tracker for easy $I(V)$ curve extraction, and (3) a Python package for LEED $I(V)$ analysis based on the TensErLEED package.

We present a quick overview of ViPErLEED and give insight into current developments. We then show LEED $I(V)$ results obtained and analyzed using ViPErLEED for the α-Fe_2O_3(012)-(1 × 1) and (2 × 1) surfaces. While a bulk-truncation is confirmed for α-Fe_2O_3(012)-(1×1), current structural models cannot explain the (2 × 1) termination.

O 92.6 Fri 11:45 CHE 91

Reduction by H2 exposure at room temperature of ceria ultrathin films grown by atomic layer deposition — •Carlos Morales, Yuliia Kosto, Rudi Tschammer, Karsten Henkel, and Jan Ingo Flege — Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Konrad-Zuse-Strasse 1, D-03046 Cottbus, Germany

Atomic layer deposition (ALD) exhibits a high potential for integration as a scalable process in microelectronics, allowing well-controlled layer-by-layer deposition and conformal growth on 3D structures. Yet, the ALD technique is also well known to lead to amorphous and defective, non-stoichiometric films, potentially resulting in modified materials properties that, in the case of ultra-thin deposits, can also be affected by film/substrate interaction. Interestingly, initial in situ X-ray photoemission spectroscopy (XPS) measurements of ceria ALD-deposits on Al2O3/Si, sapphire, and SiO2 substrates confirm a Ce3+/Ce4+ mixture dependent on the substrate interaction, deposit thickness, and morphology. Using near-ambient pressure XPS, we have significantly reduced ultrathin (< 10 nm) ceria films grown by ALD by exposing them to different O2/H2 partial pressures at moderate temperatures (< 525K). Notably, the total amount of reduction to Ce3+ is found to depend on the deposit thickness and initial ceria/substrate interaction. Furthermore, the intrinsic defects related to the ALD method seem to play a critical role in the reversible reduction at room temperature.

O 92.7 Fri 12:00 CHE 91

Role of orientation and oxyhydroxide formation on the OER activity of LaNiO₃ surfaces — •Achim Füngerlings[1], Marcus Wohlgemuth[2], Marcel Risch[3], Felix Gunkel[2], Christoph Bäumer[2,4], and Rossitza Pentcheva[1] — [1]Department of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [2]Peter Gruenberg Institute and JARA-FIT, Forschungszentrum JuelichGmbH, Juelich, Germany — [3]Nachwuchsgruppe Gestaltung des Sauerstoffentwicklungsmechanismus, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Berlin, Germany — [4]MESA+ Institute for Nanotechnology, Faculty of Science and Technology,University of Twente, Enschede, Netherlands

We present a combined experimental and theoretical study of the influence of surface orientation and transformation on the OER activity of Ni-terminated (001), (110) and (111) oriented $LaNiO_3$ films, epitaxially grown on $SrTiO_3$ substrates via pulsed laser deposition and characterized by AFM and XRD, as well as Hall measurements of the electrical conductivity. Cyclic voltammetry shows the lowest overpotential for (111) and the highest for (001), and gives indication for the formation of a surface oxyhydroxide(-like) skin layer, supported by EXAFS measurements. Based on density functional theory calculations with an on site Hubbard U, we explored different models for the transformed surfaces and find a strong sensitivity of the OER activity on interlayer H concentration and number of oxyhydroxide layers with distinct behavior of the two surface orientations.

O 92.8 Fri 12:15 CHE 91

Electron-phonon coupling for the 2D electron gas at EuO/KTaO₃(001) studied by HREELS — •Hannes Herrmann, Anne Oelschäger, and Wolf Widdra — Martin-Luther-Universität Halle-Wittenberg, Institute of Physics, 06120 Halle, Germany

Recent studies at the $KTaO_3$(111) surface revealed a 2D electron gas (2DEG) with much higher charge carrier density than in $SrTiO_3$-based heterostructures [1]. Similar 2DEGs with lower charge carrier densities could be obtained on the (011) and (001) surfaces [2].

In this work, we study surface plasmon polaritons (SPP) and their coupling to a 2DEG with high-resolution electron energy loss spectroscopy (HREELS). By evaporating Eu on top of $KTaO_3$(001), a 2DEG is initiated resulting in a pronounced asymmetric SPP line shape and extreme broadening compared to the phonons of the clean surface. The line shape will be analysed in terms of a strong coupling of the SPP with the 2DEG. The response can be described by a two-layer model with a 2D Drude-like response with frequency-dependent electronic mobility on top of a bulk-like $KTaO_3$.

O 92.9 Fri 12:30 CHE 91

2D electron gas and interdiffusion processes at the EuO/SrTiO₃(001) interface — •Anne Oelschläger, Hannes Herrmann, Stefan Förster, and Wolf Widdra — Martin-Luther-Universität Halle-Wittenberg, Institute of Physics, 06120 Halle, Germany

The deposition of metallic europium (Eu) on $SrTiO_3$(001) (STO) creates a two-dimensional electron gas (2DEG) and concomitant Ti^{3+}-O_2-vacancy complexes [1]. Here we study this interface by HREELS, XPS, and LEED. The phonon spectra are dominated by the dipole-active surface phonon polaritons of STO. They show a prominent broadening in the presence of the 2DEG due to strong electron-phonon coupling.

Upon annealing to 1020 K, the Ti^{3+} related photoemission lines as well as the phonon broadening vanish. We assign these changes to diffusion of oxygen from the bulk to the EuO/STO interface. Finally, the intensity ratio of Sr3p and Ti2p core levels indicates a diffusion of Ti to the europium oxide (EuO) layer, i.e. formation of $EuTiO_3$.

O 92.10 Fri 12:45 CHE 91

Surface Structures of La$_{0.8}$Sr$_{0.2}$MnO$_3$(001): from Commensurate to Quasicrystal Phases — •Erik Rheinfrank[1], Michael Brunthaler[1], Giada Franceschi[1], Peter Matvija[2], Michael Schmid[1], Ulrike Diebold[1], and Michele Riva[1] — [1]Institute of Applied Physics, TU Wien, Austria — [2]Faculty of Mathematics and Physics,Department of Surface and Plasma Science, Charles University, Prague, Czech Republic

Lanthanum-strontium manganate (La$_{0.8}$Sr$_{0.2}$MnO$_3$, LSMO) is a perovskite oxide used as a cathode material in solid oxide fuel cells, which convert chemical energy to electrical energy. To gain deeper insights into the reaction mechanisms,

it is important to understand the structure of the surface at the atomic scale. To this end, we grow atomically flat single-crystalline LSMO(001) thin films on Nb-doped SrTiO$_3$ (STO) substrates via pulsed laser deposition (PLD). The as-grown films have a B-site (Mn) rich surface that can be transformed into an A-site (La/Sr) rich structure by Ar$^+$ sputtering and subsequent annealing. The B-site rich surface is recovered by depositing Mn from a MnO target. In low-energy electron diffraction (LEED), the Mn-rich surface shows a 4-fold symmetric structure that is best explained by a set of four basis vectors. This is reminiscent of quasicrystals. Scanning tunneling microscopy reveals a non-periodic structure with a Fourier transform consistent with the LEED pattern.

Energy dissipation on magic angle twisted bilayer graphene — •Marcin Kisiel, Alexina Ollier, Urs Gysin, and Ernst Meyer — Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel, Switzerland

Understanding nanoscale energy dissipation is nowadays among few priorities particularly in quantum systems. While traditional Joule dissipation omnipresent in today's electronic devices is well understood, the energy loss of the strongly interacting electron systems remains largely unexplored. Twisted bilayer graphene (tBLG) is a host of interaction-driven correlated insulating phases, when the relative rotation is close to the magic angle (1.08deg). Here, we report on low temperature (5K) nanomechanical energy dissipation of tBLG measured by sharp tip of the pendulum atomic force microscope (pAFM). Ultrasensitive cantilever tip acting as an oscillating gate over the quantum device shows dissipation peaks attributed to different fractional filling of the flat energy bands. pAFM provides exquisite spatial resolution and thus allows to determine the twist angle distribution of tBLG. Strikingly it does it without literally touching the sample surface. Application of magnetic fields provoked strong oscillations of the dissipation signal at 3/4 band filling, which we identified as familiar to Aharonov-Bohm oscillations. The work demonstrates that nano-mechanical energy dissipation provides a rich source of information on the dissipative nature of the correlated electronic system of tBLG, with implications for coupling a mechanical oscillator to the quantum devices.

O 93.2 Fri 10:45 GER 37

Raman features of graphene and weyl semimetals beyond the standard nonadiabatic theory — •Nina Girotto and Dino Novko — Institute of Physics, Zagreb, Croatia

Although graphene has already been thoroughly studied with Raman spectroscopy, there still exists a disagreement about the broadening mechanisms of the E2g mode and its actual temperature dependence [Nano Lett. 10, 466 (2010)]. Along with the importance of the nonadiabatic effects in graphene, higher order electron-phonon scattering processes also significantly impact the phonon spectrum. Specifically, the electron-phonon-induced lifetime and energy renormalization of the electron-hole pair excitations bring additional temperature dependence in the electron-coupled phonon modes and their corresponding linewidths. The nonadiabatic theory relying on first principles calculations, developed in [Phys. Rev. B 98, 041112(R) (2018)], is here successfully applied to graphene in various doping regimes and to Weyl semimetals, which contain a 3-dimensional analog of Dirac points in the electron band structure and are, therefore, excellent candidates for achieving a nonadiabatic regime.

O 93.3 Fri 11:00 GER 37

Near-field optical investigation of tetralayer graphene reveals ABCB stacking — •Konstantin G. Wirth[1], Jonas B. Hauck[2], Alexander Rothstein[3], Christoph Stampfer[3], Dante M. Kennes[2], Lutz Waldecker[3], and Thomas Taubner[1] — [1]I. Institute of Physics (IA), RWTH Aachen University — [2]Institute for Theory of Statistical Physics, RWTH Aachen University — [3]2nd Institute of Physics, RWTH Aachen University

The crystallographic structure of few-layer graphene (FLG) greatly influences its electronic and optical properties. Local probing of the stacking order is usually done by optical measurements, such as infrared absorption [1] or Raman spectroscopy, which work for non-contacted and encapsulated samples but are limited in lateral resolution by diffraction to a few micrometer. Here, we directly probe the electronic properties of tetralayer graphene (4LG) with amplitude and phase-resolved near-field spectroscopy with a broadly tunable laser source over the energy range from 0.28 to 0.56 eV. We differentiate between rhombohedral and Bernal stacking sequences and reveal domains of the previously elusive third stacking order of 4LG, namely ABCB[2], by addressing distinctive interband contributions in optical conductivity. These results establish near-field spectroscopy at the interband transitions as a semi-quantitative tool, enabling the recognition and characterization of FLG domains.

O 93.4 Fri 11:15 GER 37

Image potential states as local probes for graphene magnetism — •Maciej Bazarnik[1,2,3], Roland Wiesendanger[3], and Anika Schlenhoff[1] — [1]Institute of Physics, University of Münster, Germany — [2]Institute of Physics, Poznan University of Technology, Poland — [3]Department of Physics, University of Hamburg, Germany

Image-potential states (IPSs) evolving in front of polarizable surfaces are known to serve as quantum sensors for various properties, including surface magnetization and interfacial coupling at buried interfaces. Using a spin-polarized scanning tunneling microscopy (SP-STM) setup, the spin-polarized IPS can be probed locally. In hybrid systems such as iron (Fe) -intercalated graphene (Gr) on Ir(111), Fe is known to grow pseudomorphically on the Ir substrate in a monolayer thickness limit. In contrast, the Gr overlayer exhibits a substantial buckling within the moiré unit cell, resulting in a laterally varying hybridization to the Fe. As a result, the monolayer Gr exhibits a laterally varying spin-polarization within the moiré unit cell.

Here, we present resonant tunneling studies on Fe-intercalated Gr, showing a much stronger contrast between the fcc and hcp parts of the moiré unit cell compared to conventional STM images on this system. Moreover, our SP-STM studies show that the IPSs are sensitive to the interlayer coupling of Gr to the underlying ferromagnet. The resulting local IPS spin-polarization can be used to probe the atomic-scale magnetism within the moiré unit cell of the ferromagnet graphene hybrid system.

O 93.5 Fri 11:30 GER 37

Quantitative measurement and first principle prediction of the adsorption structure of graphene on Cu(111) — •Matthew A. Stoodley[1,2], Benedikt P. Klein[1,2], Luke A. Rochford[2], Tien-Lin Lee[2], David A. Duncan[2], and Reinhard J. Maurer[1] — [1]University of Warwick, Coventry, United Kingdom — [2]Diamond Light Source, Didcot, United Kingdom

Copper is the dominant substrate for the industrial scale growth of graphene, and graphene-functionalised copper foils are regularly employed as electrodes and heterogeneous catalysts. Yet, little is known about the structure of the graphene-copper interface. We report a quantitative measurement of the adsorption height of graphene on Cu(111) using the x-ray standing waves technique. Using state-of-the-art dispersion-corrected density functional theory, we tested different structural models of graphene on copper. Quantitative agreement with experiment could only be achieved by accounting for the moiré superstructure of the graphene layer on the copper surface. We further investigate how lattice strain affects long-range dispersion interactions and therefore the adsorption height of graphene on Cu(111) as well as graphene bilayer interlayer distances. We use these results to assess the predictive capabilities of common dispersion-corrected density functional approximations. Exploration of the adsorption energy of aromatic molecules of varying size, from benzene to graphene enables us to explore size effects between the substrate and organic overlayer.

O 93.6 Fri 11:45 GER 37

Determining the stability and catalytic formation of graphene on liquid Cu using machine-learning potentials — •Hao Gao[1], Valentina Belova[2], Maciej Jankowski[2], Hendrik H. Heenen[1], Gilles Renaud[2], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]ESRF, Grenoble, France

The rapid, high-quality synthesis of graphene (Gr) on liquid Cu catalysts is microscopically still poorly understood. This is due to the difficult characterization of the Cu liquid surface. Especially in atomistic simulations, the large length and time scales necessary to reliably emulate the temporal evolution of the liquid are a major challenge. Corresponding molecular dynamics simulations require large simulation cells and need to span well into the nanosecond regime – an endeavor presently intractable via first-principles methods. In this work we use computationally efficient machine-learning potentials (MLPs) trained to density-functional theory (DFT) data in order to extrapolate the first-principles predictive power to the required scales. Detailed benchmarking confirms that

our MLP captures the involved physics well, accurately reproducing the experimentally determined Gr adsorption height. We apply the MLP to further obtain free energy barriers of possible rate-limiting steps which can be compared to the distinct reaction kinetics found experimentally. Our work draws a path for the use of reliably trained MLPs as a multiscale modeling technique to explore previously uncharted computational problems. In that we provide new insight into the domain of liquid metal catalysts which generally lack atomic-scale understanding.

O 93.7   Fri 12:00   GER 37

In-situ photoemission electron microscopy investigation of mono- and bilayer graphene growth on Ru(10$\bar{1}$0) — •Lukas Schewe, Cathy Sulaiman, Lars Buss, Moritz Ewert, and Jan Ingo Flege — Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg

Epitaxial graphene growth has often been studied on close-packed transition metal substrates, e. g., the Ru(0001) surface, which is a well-studied model system for strong graphene-support interaction. Here, we focus on a Ru surface with different symmetry, i. e., the Ru(10$\bar{1}$0) surface, to investigate the influence of the presumably modified graphene-substrate interaction on the growth of epitaxial monolayer and bilayer graphene (MLG, BLG) islands. The structural and chemical differences of the graphene on the two different surfaces are investigated by photoemission electron microscopy (PEEM), delivering information on both morphology and electronic structure. In-situ PEEM observation of graphene growth on the Ru(10$\bar{1}$0) substrate by ethylene decomposition reveals the growth characteristics of MLG and BLG, the latter showing second layer nucleation via surface segregation of carbon. Furthermore, depending on growth temperature and relative orientation of the growing islands and surface steps, different growth characteristics are observed, in contrast to previous studies of the

graphene/Ru(0001) system whereas similar electronic properties seem to prevail. Yet, when the MLG is decoupled from the Ru(10$\bar{1}$0) substrate via intercalation of oxygen a distinct shift in work function is identified, slightly different from the resulting shift on Ru(0001).

O 93.8   Fri 12:15   GER 37

Defective graphene by topological design — Benedikt P Klein[1,2], Matthew A Stoodley[1,2], Joel Deyerling[3], Michael Clarke[4], Luke A Rochford[1], Marc Walker[2], Raymundo Marcial Hernandez[5], Christian B Nielsen[5], Lars Sattler[6], Sebastian M Weber[6], Gerhard Hilt[6], Alexander Generalov[7], Alexei Preobrajenski[7], Leon BS Williams[1,8], Tien-Lin Lee[1], Alex Saywell[4], Willi Auwärter[3], Reinhard J Maurer[2], and •David A Duncan[1] — [1]Diamond Light Source, UK — [2]University of Warwick, UK — [3]Technische Universität München, Germany — [4]University of Nottingham, UK — [5]Queen Mary University of London, UK — [6]Carl von Ossietzky Universität Oldenburg, Germany — [7]MAX IV, Lund, Sweden — [8]University of Glasgow, UK

Defective graphene is a promising material for both applications in electronic devices and as substrates for modern catalysts. However, generating deliberate imperfection in graphene often relies on brute force methods, like ion sputtering. Herein, we demonstrate one-step bottom-up synthesis of defective graphene with incorporated 5- and 7-membered ring defects by using a polyaromatic feedstock that contains the same topology as the desired defect. Furthermore, the ratio of ideal to defective graphene could be controlled by the temperature used to grow the film. By a combination of X-ray standing waves, non-contact atomic force microscopy, X-ray photoelectron spectroscopy, near-edge X-ray absorption fine structure and density functional theory, we thoroughly characterise these networks and propose this method as a novel method of functionalising graphene.

O 94.1   Fri 10:30   GER 38

Multigap topology and non-Abelian braiding of phonons from first principles — •Bo Peng[1], Adrien Bouhon[1,2], Bartomeu Monserrat[1,3], and Robert-Jan Slager[1] — [1]TCM Group, Cavendish Laboratory, University of Cambridge, J. J. Thomson Avenue, Cambridge CB3 0HE, United Kingdom — [2]Nordic Institute for Theoretical Physics (Nordita), Stockholm University and KTH Royal Institute of Technology, Hannes Alfvéns väg 12, Stockholm SE-106 91, Sweden — [3]Department of Materials Science and Metallurgy, University of Cambridge, 27 Charles Babbage Road, Cambridge CB3 0FS, United Kingdom

Non-Abelian braiding of quasiparticles can encode information immune from environmental noise with the potential to realize topological quantum computation. Here we propose that phonons, a bosonic excitation of lattice vibrations, can carry non-Abelian charges in their band structures that can be braided using external stimuli. Taking some earthly abundant materials such as silicates [1] and aluminium oxide [2] as representative examples, we demonstrate that an external electric field or electrostatic doping can give rise to phonon band inversions that induce the redistribution of non-Abelian charges, leading to non-Abelian braiding of phonons. We show that phonons can be a primary platform to study non-Abelian braiding in the reciprocal space, and we expand the toolset to study such braiding processes.

O 94.2   Fri 10:45   GER 38

Electronic Structure of the Weak 3D Topological Insulator Bi$_{12}$Rh$_3$Ag$_6$I$_9$ — •Johannes Hessdörfer[1,2], Eduardo Carillo-Aravena[2,3], Armando Consiglio[2,4], Maximilian Ünzelmann[1], Michael Ruck[2,3], Domenico Di Sante[5], and Friedrich Reinert[1,2] — [1]Experimentelle Physik VII, Universität Würzburg, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, Germany — [3]Anorganische Chemie II, Technische Universität Dresden, Germany — [4]Theoretische Physik I, Universität Würzburg, Germany — [5]University of Bologna, Italy

Weak three-dimensional (3D) topological insulators (TI) can be considered as a stack of 2D TI separated by insulating spacer layers. The first experimentally observed weak TI is Bi$_{14}$Rh$_3$I$_9$ [1], in which the TI layers are Kagome nets formed by rhodium centered bismuth cubes. Importantly, a modification of the [Bi$_2$I$_8$]$^{2-}$ spacer layer, like e.g. by Ag-substitution, can change the coupling between the 2D-TI and with that decisively influences the topological properties. Here, we investigate Bi$_{12}$Rh$_3$Ag$_6$I$_9$ by means of angle-resolved photoemission experiments and density functional theory band structure calculations. In particular, we will discuss the influence of the modified spacer layer on the electronic structure and compare the results with Bi$_{14}$Rh$_3$I$_9$ and other compounds of this family.

Doping of coupled 1D topologically protected edge states on the (001) surface of the topological crystalline insulator (Pb,Sn)Se — •Florian Keller, Artem Odobesko, and Matthias Bode — Physikalisches Institut, Lehrstuhl für Experimentelle Physik II, Julius-Maximilians-Universität Würzburg, Würzburg, Germany

Topological crystalline insulators (TCI) are a class of materials with topological protected surface states protected by crystalline symmetry. One representative of this material class is (Pb,Sn)Se which exhibits Dirac fermions at the surface and topologically protected one-dimensional edge state at the step edges with a height equivalent to an odd number of atomic layers [1]. It was shown that the 1D edge states hybridize when two or more odd step edges are in close proximity [2]. The nature of this hybridization indicates that the quasiparticle edge mode is not an infinite quantum 1D state, but is either strongly localized or has a very short coherence length along the edge. One way to check this hypothesis is to increase the coherence length by shifting the Dirac energy close to the Fermi energy [3]. Here we present experiments where Fe adatoms are deposited onto p-doped PbSnSe, resulting in a downwards-bending of the surface band structure. The dependence of the correlation length of Dirac fermions is investigated by determining the edge state hybridization for pristine and doped (Pb,Sn)Se.

Pressure-driven tunable properties of the small-gap chalcopyrite topological quantum material ZnGeSb$_2$: A first-principles study — •Surasree Sadhukhan[1], Banasree Sadhukhan[2], and Sudipta Kanungo[1] — [1]Indian Institute of Technology Goa, 403401 Ponda, India — [2]KTH Royal Institute of Technology, Stockholm

Search for new topological quantum materials is the demand to achieve substantial growth topological phase of matter. In this search process, theoretical prediction is crucial besides the obvious experimental verification. The divination of topological properties in already well-known narrow gap semiconductors are flourishing in quantum material science. We revisited the semiconductor compound in the chalcopyrite series, some of which were potential topological materials. Using this density functional theory-based first-principles calculations, we report a strong topologically nontrivial phase in chalcopyrite ZnGeSb$_2$, which can act as a model system of strained HgTe. The estimates reveal the non-zero topological invariant (Z_2), Dirac cone crossing in the surface spectral functions with spin-momentum locked spin texture. We also report the tunable topological properties from nontrivial to trivial phases under moderate hydrostatic pressure within *7 GPa. A minor modification of a lattice parameter is enough to

achieve this topological phase transition easily accomplished in an experimental lab. We have incorporated the discontinuity in the tetragonal distortion of non-centrosymmetric ZnGeSb$_2$ to drive the topological quantum phase transition.

O 94.5 Fri 11:30 GER 38

Shift current in the Haldane model: analytic and numerical evaluation — •Javier Sivianes Castaño and Julen Ibañez Azpiroz — Centro de Física de Materiales, Universidad del País Vasco, 20018 San Sebastián, Spain

The shift current is a second order optical response which takes place in non-centrosymmetic crystals and is characterized by a DC photocurrent. As realized recently, the shift current is sensitive to the topology of materials [1]. In particular, DFT calculations have predicted a sign change when going through a topological phase transition (TPT) in the bulk crystals BiTeI and CsPbI$_3$ [2]. Here we analyse the shift current in the Haldane model, as a toy model that describes inversion symmetry breaking and features non-trivial topological phases. We derive a simple analytical expression that accounts for the sign change across the TPT by relating it to the inversion of the mass term, in agreement with Ref [3]. We complement our study by a numerical evaluation on a continuum version on the Haldane model [4]. In this description we study the quantitative importance of the off-diagonal matrix elements of the position operator that are commonly discarded in the tight-binding description.

The 2D Ferromagnetic Extension of a Topological Insulator — •Philipp Kagerer[1,2], Celso I. Fornari[1,2], Sebastian Buchberger[1,2], Begmuhammet Geldiyev[1,2], Teresa Tschirner[2,3], Louis Veyrat[2,3,4], Abdul V. Tcakaev[2,4], Martin Kamp[5], Sergio L. Morelhao[6], Vladimir Hinkov[2,4], Hendrik Bentmann[1,2], and Friedrich Reinert[1,2] — [1]Exp. Physik VII, Universität Würzburg — [2]Würzburg-Dresden Cluster of Excellence ct.qmat — [3]Leibnitz IFW Dresden — [4]Exp. Physik IV, Universität Würzburg — [5]Physikalisches Institut and RCCM, Universität Würzburg — [6]Instituto de Física, Universidade de São Paulo

3D topological insulators (TI) are known to have a topological non-trivial band structure protected by time reversal symmetry, which also guarantees the metallicity of the surface. Consequently, it is sufficient to break this symmetry only locally at the surface of the sample to gap out the topological surface state (TSS), leading to a variety of novel topological effects, e.g. an axion term in the electromagnetic response and quantized spin-selective edge channels. While most experimental approaches to date have aimed to introduce magnetism globally, we present the first experimental realisation of the *ferromagnetic extension* (1), a design directly interfacing a 3D TI with a two-dimensional non-trivial magnet. Utilizing a single septuple layer MnBi$_2$Te$_4$ on the prototypical TI Bi$_2$Te$_3$, we establish a stable 2D ferromagnetic ground state and introduce a sizeable magnetic exchange gap in the TSS (2).

Orbital angular momentum in indenene measured by circular dichroism in ARPES — •Jonas Erhardt, Cedric Schmitt, Simon Moser, and Ralph Claessen — Physikalisches Institut and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Würzburg D- 97074, Germany

Indenene, a monolayer of In atoms arranged in a triangular lattice on SiC(0001), has recently been identified as a quantum spin Hall insulator (QSHI) [1]. Its topological character is encoded in a characteristic energy staggering of its orbital angular momentum (OAM) polarized Dirac states [1]. This makes indenene an ideal test case for recent claims that circular dichroism in angle-resolved photoelectron spectroscopy (CD-ARPES) gives access to local Berry curvature signatures via the OAM [2]. However, a particular challenge of such experiments is the extraction of the intrinsic OAM-related CD signal, requiring

its distinction from final state effects and extrinsic contributions induced by experimental geometry.

In this talk, I will present a systematic photon energy dependent CD-ARPES study of indenene's Dirac states and use simple geometric considerations to disentangle experimental from OAM induced CD. The resulting OAM sequence confirms indenene to be a QSHI and thus establishes a new approach to experimentally identify the topological character of a 2D quantum material directly from its bulk states.

Transfer matrix analysis of non-Hermitian interfaces — •Jacob Fauman — Max Planck Institute for the Science of Light, Erlangen, Germany

Non-Hermitian systems exhibit unique features not present in Hermitian systems, including the so-called non-Hermitian skin effect in which the modes accumulate at the surface of the system. We analyze the interface between a non-Hermitian system and a Weyl semimetal analytically using the transfer matrix method. This approach is especially well-suited to the study of spatially inhomogeneous systems, and allows for analysis of the Fermi arcs at the interface. We also consider the effect of Hermitian and non-Hermitian spectral degeneracies on the interface modes.

O 94.9 Fri 12:30 GER 38

Spectroscopic signatures of non-trivial topology in Weyl semimetals — •Jakub Schusser[1], Hendrik Bentmann[2], Maximilian Ünzelmann[1], Tim Figgemeier[1], Chul-Hee Min[3], Simon K. Moser[4], Jennifer N. Neu[5], Theo Siegrist[6], and Friedrich Reinert[1] — [1]Exp. Physik VII and Würzburg-Dresden Cluster of Excellence ct.qmat, JMU Würzburg — [2]Center for Quantum Spintronics, NTNU Trondheim — [3]Department of Physics, CAU zu Kiel — [4]Exp. Physik IV and Würzburg-Dresden Cluster of Excellence ct.qmat, JMU Würzburg — [5]National High Magnetic Field Laboratory, Tallahassee, Florida — [6]Department of Chemical and Biomedical Engineering, FAMU-FSU College of Engineering, Tallahassee, Florida

By performing angle-resolved photoemission spectroscopy (ARPES) on bulk samples we show the spectroscopic manifestation of topological features and Weyl physics beyond the simple photointensity over a broad range of excitation energies from the vacuum ultraviolet to the soft X-Ray regime and compare the surface to the bulk band structure. Our experimental observations were complemented by state-of-the-art first principle photoemission calculations based on one-step model of photoemission. The determinant criterion confirms the arc character of the spoon features in the constant energy contour close to Fermi level in non-centrosymmetric TaP. We further show the drawbacks of the existing spectroscopic techniques used to determine whether the given material has non-zero Chern number and discuss an improved approach for identifying Fermi arcs by the means of differential ARPES measurements as well as the proper final state description.

O 94.10 Fri 12:45 GER 38

Extended Hatano-Nelson model, exceptional points and spectral symmetry — •Julius Gohsrich[1,2], Sharareh Sayyad[1], and Flore K. Kunst[1] — [1]Max Planck Institute for the Science of Light, Staudtstraße 2, 91058 Erlangen, Germany — [2]Department of Physics, Friedrich-Alexander Universität Erlangen-Nürnberg, Staudtstraße 7, 91058 Erlangen, Germany

Non-Hermitian systems attract a lot of attention in recent years as effective description of open quantum systems. A prominent example in this context is the Hatano-Nelson model. While historically the model has short-range non-reciprocal hoppings, long-range hopping has not been systematically studied. In this talk, I will present our results on the extended Hatano-Nelson model. Using analytical techniques, we demonstrate how the underlying physics of the original Hatano-Nelson model is enriched when longer-range hoppings are also included. I will discuss how the crucial elements of the Hatano-Nelson model, namely, the non-Hermitian skin effect and the exceptional points, are modified for the generalized model.

O 95: Focus Session: Making Experimental Data F.A.I.R. − New Concepts for Research Data Management II (joint session O/TT)

Time: Friday 9:30–12:45 Location: WIL A317

FAIRifying ARPES: a Route to Open Data & Data Analytics — •Ralph Ernstorfer[1,2], Tommaso Pincelli[1,2], Patrick R. Xian[2], Abeer Arora[2], Florian Dobener[3], Sandor Brockhauser[3], and Laurenz Rettig[2] — [1]TU Berlin, Germany — [2]FHI Berlin, Germany — [3]HU Berlin, Germany

While angle-resolved photoemission spectroscopy (ARPES) is the most direct probe of crystals' electronic structure, the globally collected ARPES data have not been merged into an open experimental electronic structure database in equivalence to well-established atomic structure databases. We discuss a data format based on NeXus [1] as a concept for unifying the data structure for all

types of photoemission experiments including time-, spin-, and time-resolved ARPES [2]. The aim is to immediately enable preprocessed data and metadata shareability according to FAIR data principles, employing existing public storage and archiving research data infrastructures such as Zenodo, OpenAIRE, and Nomad/FAIRmat. Ultimately, the multidimensional photoemission spectroscopy (MPES) format is designed to allow high-performance automated access, providing experimental databases for high-throughput material search [3]. References: [1] https://www.nexusformat.org/ [2] https://mpes.science/; https://fairmat-experimental.github.io/nexus-fairmat-proposal/ [3] R. P. Xian et al., Scientific Data 7, 442 (2020); R.P. Xian et al., Nat. Comp. Sci, in print, arXiv:2005.10210

O 95.2   Fri 10:00   WIL A317

A FAIR data infrastucture for photoemission experiments — •Marten Wiehn[1], Tobias Eul[1], Benjamin Stadtmüller[1,2], and Martin Aeschlimann[1] — [1]Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany

Recent trends toward data-driven, high-tech experimental research and the growing volumes of data associated with it show the increasing importance of comprehensive data acquisition and management. We present an automated workflow for well-described photoemission data from experiment to archive and publication. Utilizing a powerful experiment control software to capture essential metadata for each measurement enables the collection of FAIR-ready data (Findable, Accessible, Interoperable, Reusable). In addition, using an electronic lab notebook pushes our lab further toward a FAIR data infrastructure that supports researchers in their daily work.

O 95.3   Fri 10:15   WIL A317

Multi-Dimensional Photoemission Spectroscopy: a concept for FAIR photoemission data — •Florian Dobener[1], Tommaso Pincelli[2,3], Abeer Arora[2,4], Steinn Ymir Augustsson[5], Dmytro Kutnyakhov[6], Michael Hartelt[7], Laurenz Rettig[1], Martin Aeschlimann[2], Ralph Ernstorfer[7], and Sandor Brockhauser[2,3] — [1]Department of Physics, HU Berlin, Germany — [2]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — [3]Institut für Optik und Atomare Physik, TU Berlin, Germany — [4]FU Berlin, Fachbereich Physik, Berlin, Germany — [5]Institut für Physik, Johannes Gutenberg-Universität Mainz, Germany — [6]DESY, Hamburg, Germany — [7]Department of Physics and OPTIMAS, University of Kaiserslautern, Germany

The complexity and size of photoemission data is rapidly increasing as new technological breakthroughs have enabled multidimensional parallel acquisition. However, most of the community is currently using heterogeneous data formats and workflows. We propose a new data format based on NeXus, a hierarchically organized hdf5 structure. This multidimensional photoemission spectroscopy format is designed to allow high-performance automated access, enabling experimental databases for high-throughput material search. Our approach involves reaching out to the community using a website with extensive documentation of our proposed standard. As a demonstrator of the potential of our approach we present a workflow and data pipeline integrated into the NOMAD research data management solution, which provides powerful analysis and search functionalities.

O 95.4   Fri 10:30   WIL A317

Towards an Infrastructure for FAIR Synthesis Data — •Sebastian Brückner[1,2], Andrea Albino[1], Jose Marquez[1], Florian Dobener[1], Hampus Näsström[1], Markus Scheidgen[1], Claudia Draxl[1], and Martin Albrecht[2] — [1]HU Berlin, Zum Großen Windkanal 2, 12489 Berlin — [2]IKZ Berlin, Max-Born-Straße 2, 12489 Berlin

A data infrastructure based on the FAIR (findable, accessible, interoperable and reusable) principles promises a new way of sharing and exploring data by using highly efficient data analysis and artificial intelligence tools. This also applies to data related to sample synthesis. At present, most synthesis data are not structured comprehensively or not even stored digitally but in handwritten lab books. There hardly exists any data standards in synthesis, which is in contrast to data from characterization techniques. The FAIRmat project (https://FAIRmat-NFDI.eu) is building a FAIR data infrastructure for condensed-matter physics and the chemical physics of solids. In FAIRmat's Area A, we focus on synthesis data to make sample synthesis reproducible, accelerate the development of novel materials, and make characterization data of synthesized materials assessable. Here we summarize our ongoing work and progress including: providing a general data model for synthesis which is harmonized with data from measurements and theory (ontologies); implementation of our data model in use cases and electronic laboratory notebooks; developing tools for data acquisition and analysis; data governance guidelines to enable a sustainable change of research data management at the institute/university level.

O 95.5   Fri 10:45   WIL A317

FAIRifying Material Synthesis with the NOMAD Electronic Laboratory Notebook (ELN) — •Andrea Albino[1], Hampus Näsström[1], Florian Dobener[1], Jose Marquez Prieto[1], Lauri Himanen[1], David Sikter[1], Mohammad Nakhaee[1], Amir Golparvar[1], Sebastian Brückner[1], Martin Albrecht[2], Markus Scheidgen[1], and Claudia Draxl[1,3] — [1]Physics Department and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany — [2]Leibniz-Institut für Kristallzüchtung, Berlin, Germany. — [3]The NOMAD Laboratory at the Fritz Haber Institute of the Max Planck Society, Berlin, Germany.

Approaching the era of big data-driven materials science, one crucial step to collecting, describing, and sharing experimental data is the adoption of ELNs. The project FAIRmat (fairmat-nfdi.eu) is offering such tools by developing and operating the open-source software NOMAD. The NOMAD ELN aims at offering a secure environment to protect the integrity of both data and metadata, whilst also affording the flexibility to adopt new synthetic processes or changes to existing ones without recourse to further software development.

We find that to promote an early adoption, it is important to adapt to a single user's needs and workflows. An inductive approach, going from a particular set of experiments to a general description of the similarities recurring in each of them, led us to adopt a common data structure as a standard. The state-of-the-art ELN features for a synthetic process will be shown in the talk, highlighting the development of both data modeling and specific implementation solutions.

O 95.6   Fri 11:00   WIL A317

FAIR Data Infrastructure for Computation: Classical Simulations and Multiscale Modeling — •Joseph F. Rudzinski[1,2], José M. Pizarro[1], Nathan Daelman[1], Luca M. Ghiringhelli[1], Karsten Reuter[2], Kurt Kremer[2], Silvana Botti[4], and Claudia Draxl[1] — [1]Institut für Physik, Humboldt-Universität zu Berlin — [2]Max-Planck-Institut für Polymer Forschung, Mainz — [3]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin — [4]Institut für Festkörpertheorie und Optik, Friedrich-Schiller-Universität Jena

The emergence of the (big-)data-centric techniques as a fundamental paradigm of science calls for the development of infrastructure for ensuring FAIR—findable, accessible, interoperable, reusable—data management. The FAIRmat consortium aims to build extensive infrastructure for a wide variety of materials-science data, including soft matter simulations [1], by expanding upon the success of the NOMAD Laboratory—a repository for atomistic calculations in materials science [2]. Both the large volume and heterogeneous nature of classical molecular-dynamics simulation data presents a number of distinct challenges. In this talk, we present FAIRmat's progress in developing infrastructure for molecular-dynamics simulations, including metadata for molecular topologies and tools for workflow management. We will also discuss the need for standardization of metadata schemas and ontologies within the community, and planned collaborations with other open science initiatives and software developers.

Topical Talk   O 95.7   Fri 11:15   WIL A317

Electronic Lab Notebooks in Teaching and Implications on Science — •Michael Krieger — Lehrstuhl für Angewandte Physik, Department Physik, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU)

In our department, we have recently introduced Electronic Lab Notebooks (ELN) in the obligatory electronic lab course in the 4th semester of the physics curriculum. Immediate advantages for the students are obvious: all data, raw data and metadata including experiment description and experimental observations, are digitally stored at the same place. Moreover, student teams share and actively work in their group ELN with access at the university as well as at home, and script-based evaluations can be performed directly in the ELN.

The introduction of ELNs in teaching has also implications on science. Students carry their ELN experience and data competences into all research groups. There, however, modern research data management is much more complex. According to the FAIR principles, it requires structured, machine-readable data using open formats and vocabularies that meet community standards. The development of such standards is in many cases still to be done and is the core of the Nationale Forschungsdateninfrastruktur (NFDI). Here, ELNs in teaching provide a sandbox with short learning and innovation cycles for testing structured schemas. The experience helps to develop and establish sustainable and FAIR documentation of research workflows in science.

O 95.8   Fri 11:45   WIL A317

A step towards predicting synthesis conditions of metal-organic frameworks — •Dinga Wonanke[1], Thomas Heine[2], and Christof Wöll[1] — [1]Institut für Funktionelle Grenzflächen (IFG), Karlsruher , Germany — [2]Faculty of Chemistry and Food Chemistry,Dresden, Germany

The process of synthesising metal-organic frameworks (MOFs) falls under a branch of chemistry known as reticular chemistry. Here, well defined crystalline compounds are synthesised from a well thought out design principle by linking predefined building blocks under specific conditions. Although, this approach appears to be intuitive, the synthesis of any novel MOF still follows

the conventional approach that begins with a thorough literature survey to explore reagents, calculations of aliquots and finally a series of time consuming and stressful trial-and-error syntheses. Consequently, although millions of stable hypothetical MOFs with interesting properties have been predicted, only approximately 100 thousand crystal structures of MOFs currently exist in the Cambridge Structural Database (CSD). Indicating a significant bottleneck in the intelligent design of novel stable MOFs with targeted properties.

In this talk, we will present an overview of our journey to design a new machine learning algorithm for predicting the synthesis condition of existing and hypothetical MOFs. We will discuss our experiences and challenges in mining and curating the MOF subset in the CSD. Finally, we will present our new MOF database that maps every MOF to its experimental synthetic conditions.

O 95.9   Fri 12:00   WIL A317

Deep learning surface scattering data analysis for processing large synchrotron datasets — •Vladimir Starostin, Valentin Munteanu, Linus Pithan, Alexander Gerlach, Alexander Hinderhofer, and Frank Schreiber — Institute of Applied Physics, University of Tübingen, Germany

In situ real-time surface scattering experiments such as grazing-incidence wide-angle X-ray scattering (GIWAXS) produce large amounts of data, frequently exceeding the capabilities of traditional data processing methods. Here we demonstrate an automated pipeline for the analysis of GIWAXS images, based on a machine learning architecture for object detection, designed to conform to the specifics of the scattering data [1]. Our pipeline enables real-time GIWAXS analysis and is designed to be employed at synchrotron facilities. We also present FAIR data strategies and traceable data resources from the raw data to the corresponding scientific publication and vice versa [2] including intermediate processing steps.

We demonstrate our method on real-time tracking of lead halide perovskite structure crystallization processes, which are relevant for hybrid solar cell applications. However, our approach is equally suitable for other crystalline thin-film materials by design. In general, the solution substantially accelerates the analysis process of GIWAXS images, potentially boosting the speed of scientific discoveries in material science.

FAIR Data Infrastructure for Computation: Mapping out the Space of Density Functionals — •Nathan Daelman[1], Joseph F. Rudzinski[1,2], José M. Pizarro[1], Luca M. Ghiringhelli[1], Miguel A. L. Marques[3], Silvana

Botti[4], and Claudia Draxl[1] — [1]Institut für Physik and IRIS-Adlershof, Humboldt-Universität zu Berlin, Berlin — [2]Max-Planck-Institut für Polymer Forschung, Mainz — [3]Institut für Physik, Martin-Luther-University Halle-Wittenberg, Halle — [4]Friedrich Schiller Universität Jena, Jena

The NOMAD Laboratory [1] holds over 135 million computational results, the vast majority of which stem from density-functional theory (DFT). The platform provides adequate querying and data analytics tools (e.g., machine-learning modelling) for processing such Big Data. However, the exchange-correlation (xc) functional with which the data was generated, limits the analysis scope of most thermodynamic and kinetic properties. Here, we present a strategy rooted in semantics for extending method interoperability. We will showcase our map of the entire xc-functional space that, in the context of the FAIRmat consortium [2], is built to be widely accessible and facilitate findability. Lastly, we will discuss the integration of this xc-functionals map into the NOMAD data platform, as well as its publication in ontology format as an effort towards a community-wide vocabulary standard.

O 95.11   Fri 12:30   WIL A317

OpenSemanticLab: Towards Open Semantic Research — •Simon Stier and Matthias A. Popp — Fraunhofer ISC, Neunerplatz 2, 97082 Würzburg, Germany

In materials science, complex relationships exist between the properties of materials and their composition and processing. Therefore, digital transformation and acceleration in this domain represents a particularly important challenge. Although it is generally agreed that data must be linked by means of semantics and ontologies to form holistic data spaces, there is still a lack of suitable tools for integrating the necessary structures into the everyday work of scientists.

Fraunhofer ISC addresses this challenge with a broad-based strategy that closely links activities at all relevant levels. The goal hereby is the development towards Lab 4.0, the machine-readable documentation of scientific processes and the harmonization of data structures in accordance with international standards.

Core of the resulting OpenSource solution architecture is the central web data platform OpenSemanticLab [1] that links people (knowledge), machines (data) and algorithms (AI) equally. As an open system, this platform is easily adaptable even without programming knowledge and without losing the uniform structure. In this way, OpenSemanticLab enables us as scientists to contribute individually and yet in a standardized fashion to future digital materials research.

O 96: Solid-Liquid Interfaces III: Reactions and Electrochemistry II

Time: Friday 10:30–13:00   Location: TRE Phy

O 96.1   Fri 10:30   TRE Phy

First step of the oxygen reduction reaction on Au(111): A computational study of the electrified metal/water interface — •Elias Diesen, Alexandra M. Dudzinski, Hendrik H. Heenen, Vanessa J. Bukas, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin, Germany

While significant insight has been gained in recent years by first-principles simulations of electrochemical processes, crucial methodological challenges remain, especially for accurate determination of reaction energies under operando conditions. One open question is how to represent the constant electrode potential in simulations of an electrified water/metal interface, where the periodic simulation setup requires a constant charge in the simulation cell throughout the reaction. Here we compare different levels of treatment of the electrochemical interface: explicit *ab initio* molecular dynamics, an implicit solvent model, and a sawtooth-potential electric field in vacuum, for the case of O_2 adsorption on Au(111). We find that all methods agree qualitatively in predicting significantly enhanced O_2 binding at more reducing conditions. Important quantitative differences, however, are also presented and discussed. Umbrella sampling simulations shed light on the underlying free-energy landscape at varying potentials, while assessing the level of detail required in first-principles models of the electric double layer.

O 96.2   Fri 10:45   TRE Phy

Multiscale simulation of nanostructured electrocatalytic systems by coupling neural network surrogates and continuum models — •Younes Hassani Abdollahi[1,2], Jürgen Fuhrmann[3], and Sebastian Matera[1,2] — [1]Institut f. Mathematik, Freie Universität Berlin, Berlin, Germany — [2]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [3]Weierstraß-Institut f. Angewandte Analysis u. Stochastik, Berlin, Germany

The kinetic Monte Carlo method (kMC) is the physically most sound approach for addressing the kinetic interplay of elementary processes at electrocatalytic surfaces but also comes at high computational costs. Therefore, computation-

ally efficient surrogate models are highly desirable which allow the utilization of kMC simulation results in coarser scale simulations.

Using the oxygen reduction reaction on Pt(111) as a prototypical example, we investigate regression neural networks as surrogates to reproduce the stationary TOF as a function of all reaction conditions, i.e. electrostatic potential, concentrations, and temperature. We found that a relatively shallow network serves as an appropriate choice. This surrogate is then coupled to a conservative and thermodynamically consistent Finite Volume discretization of a nanofluidic model. The resulting hybrid mesoscale model will be employed to discuss the interplay of the nanostructure, transport, and kinetics.

O 96.3   Fri 11:00   TRE Phy

Modeling Transport Effects on Selectivity in Electrochemical CO_2 Reduction — •Hendrik H. Heenen[1,2], Georg Kastlunger[2], Vanessa J. Bukas[1], Karsten Reuter[1], and Karen Chan[2] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]Technical University of Denmark, Lyngby, Denmark

Product selectivity in the electrochemical CO_2 reduction reaction (eCO_2RR) is known to change considerably with non-obvious parameters such as catalyst morphology or reactor design. In this work we explore the proposition that these parameters are related to selectivity through transport mediated desorption and adsorption of key intermediates. The mesoscopic morphology of a catalyst can be characterized by a measurable loading or roughness which determines the so-called active surface area. This area may in turn determine the selectivity by controlling the fate of desorbing (closed shell) intermediates along the reaction path: either to re-adsorb and further react on the surface, or to entirely leave the catalyst surface and form an early not fully-reduced product. We specifically show this competition in the reaction toward acetate which we propose to be governed by a solution reaction. Combining *ab initio* energetics, microkinetic and transport modeling in a multi-scale approach, we predict complex selectivity toward acetate with almost quantitative agreement to experiment. Finally, we demonstrate that the same principle applies to other important intermediates in

the eCO_2RR. Mesoscopic transport thus provides an alternative or, at least, complementary explanation to changes in selectivity that are otherwise attributed to active sites changes, to doping, or to alloying.

O 96.4   Fri 11:15   TRE Phy

Kinetics of the initial step in Pt electrochemical oxidation — Jan Ole Fehrs[1], Timo Fuchs[1], •Olaf Magnussen[1], Chentian Yuan[2], David Harrington[2], Valentin Briega Martos[3], Serhiy Cherevko[3], and Jakub Drnec[4] — [1]Christian-Albrechts Universität zu Kiel — [2]University of Victoria — [3]Helmholtz Institute Erlangen-Nürnberg for Renewable Energy — [4]European Synchrotron Radiation Facility

A key event in electrochemical metal oxidation is extraction of a metal atom from its lattice site to a location in a growing oxide. The direct observation of this fundamental step is difficult for base metals that actively corrode, because of the difficulty of producing clean surfaces and the speed of the oxidation. However, use of noble metals allows preparation of clean surfaces that are well-defined on the atomic scale, and for which in situ methods can directly observe this extraction. Here we show by fast simultaneous electrochemical and high-energy surface X-ray diffraction measurements, performed at the ID31 beamline of the European Synchrotron Radiation Facility with a photon energy of 70 keV, that the initial extraction of Pt atoms from Pt(111) is a fast, potential-driven process whereas charge transfer for the related formation of adsorbed oxygen occurs on a slower time scale. Electrochemical oxidation is therefore inherently different from gas-phase thermal oxidation, where the extraction must be driven by the chemisorption of oxygen species on the surface.

The work was funded by the Deutsche Forschungsgemeinschaft via grant 418603497 and the BMBF via project 05K19FK3.

O 96.5   Fri 11:30   TRE Phy

CO oxidation on Pt layers on Ru(0001): A UHV-STM, DEMS, and SXRD study — •Albert K. Engstfeld[1], Lukas Forschner[1], Mario Löw[2], Zenonas Jusys[2], Joachim Bansmann[2], R. Jürgen Behm[2], and Jakub Drnec[3] — [1]Ulm University, Institute of Electrochemistry, D-89069 Ulm — [2]Ulm University, Institute of Surface Chemistry and Catalysis, D-89069 Ulm — [3]ESRF, F-38000 Grenoble

According to the Sabatier principle, the performance of an (electro)catalyst material is determined by the fine balance between the binding strength of the reactants, reaction intermediates, and products to the catalyst surface. By changing the structural properties of the substrate, the electronic structure and in turn, also the binding of the species can be modified to tune the performance of the catalyst material. However, also the electrode's stability plays a crucial role in assessing the catalyst's performance.

Here we present results on the CO (and MeOH) electrooxidation on Pt layers with different thicknesses deposited on Ru(0001) under UHV conditions. The structural properties are studied by means of STM under UHV conditions before and after the electrochemical measurements. The electrocatalytic properties are studied in a flow cell (in a DEMS configuration) attached to the UHV chamber. This approach allows for disentangling surface redox processes from catalytic processes. Additional SXRD measurements provide additional insights into the stability of the electrodes. In combination, we discuss the fine balance between surface reactivity and electrode stability.

O 96.6   Fri 11:45   TRE Phy

Electrochemical Roughening of Stepped Platinum Surfaces — •Francesc Valls Mascaró[1], Marc Koper[1], and Marcel Rost[2] — [1]Leiden Institute of Chemistry, Leiden University — [2]Huygens-Kamerlingh Onnes Laboratory, Leiden Institute of Physics, Leiden University

Platinum is the model catalyst to be used in electrochemical energy conversion devices due to its high activity. Nevertheless, its industrial applicability is limited, as it degradates during fuel cell operation. This has been extensively studied by Cyclic Voltammetry and Inductively Coupled Plasma Mass Spectrometry (ICP-MS) [1, 2]. It is well known that this degradation is linked to the nucleation and growth of platinum nanoislands on initially atomically flat terraces [3, 4, 5, 6]. However, there is no insight yet on the role of steps on this roughening process. In this work, we combine Cyclic Voltammetry and Electrochemical Scanning Tunneling Microscopy to study the stability of different stepped platinum surfaces upon oxidation-reduction cycling. Surprisingly, the electrochemical results indicate that neither 2D nor 3D (for Pt(533)) and no 3D (for Pt(553)) roughness develops, although we clearly observe island formation in the STM, and thus an increase in the step lengths and roughness.

Shaping the electrochemical interfaces of high-performance photoelectrodes by dedicated corrosion — •Matthias M. May[1,2], Erica A. Schmitt[1,2], Margot Guidat[1,2], Mario Löw[2], Anna-Lena Renz[1], Marco Flieg[1], Max Nusshör[1], Vibhav Yadav[1], Jongmin Kim[1], and Moritz Kölbach[1] — [1]Universität Tübingen, Institute of Physical and Theoretical Chemistry, Tübingen, Germany — [2]Universität Ulm, Institute of Theoretical Chemistry, Ulm, Germany

Photoelectrodes for highly efficient solar water splitting often involve III-V semiconductors, which exhibit only a limited stability under operating conditions due to (electro)chemical corrosion. Yet photoelectrochemical in situ functionalisation, which also involves dedicated corrosion, can effectively create an interphase that passivates the solid-liquid interface in a similar manner as solid-electrolyte interphases in batteries [1].

We show how this approach can be used to also electronically passivate III-V/Si dual junction photoelectrodes. A full understanding of the underlying photoelectrochemistry is, however, not yet achieved. To improve this understanding, we study the structural evolution of the interface in the electrolyte, using operando reflection anisotropy [2], improving the control of functionalisation and catalyst photoelectrodeposition.

Understanding the Interfacial Capacitance of 2D Materials in an Implicit Water Environment — •Hedda Oschinski[1,2], Karsten Reuter[1], and Nicolas G. Hörmann[1] — [1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — [2]Technical University of Munich, Munich, Germany

The interfacial capacitance (C) is a central quantity in electrochemistry. For metal electrodes, C is dominated by the double layer capacitance that derives from the potential drop in the solvent. However, the finite density of states (DOS) in semiconducting 2D electrodes alters the picture and leads to a vanishing C around the point of zero charge. This entails a challenge in describing the energy-potential relation and the connected field effects when considering adsorbates. To explore this challenge, we study the interfacial capacitance for 2D metal halides MX_2, using density-functional theory in a continuum solvent environment. We break down C into a DOS-filling-related quantum capacitance and the double layer capacitance. Our analysis demonstrates that such a separation into individual components is not straightforward. Nevertheless, the qualitative behavior of C can be rationalized, making this study a first step towards better understanding of 2D, in particular semiconducting, electrodes.

Initial Stages of Cathodic Corrosion of Au(111) in an Ionic Liquid — •Maren-Kathrin Heubach[1], Fabian M. Schuett[1], Areeg Abdelrahman[1], Ludwig A. Kibler[1], and Timo Jacob[1,2,3] — [1]Institute of Electrochemistry, Ulm University, Ulm, Germany. — [2]Helmholtz-Institute-Ulm (HIU), Ulm, Germany. — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany.

At potentials negative of 0 V vs. SHE, noble metal surfaces can be etched by a phenomenon called 'cathodic corrosion'.[1] For this process, absence of protons and presence of stabilising cations and adsorbed hydrogen at the electrode-electrolyte interface are required.[2] Even if the presence of water plays an important role,[3] in non-aqueous electrolytes such as ionic liquids, cathodic corrosion can take place as well.[4]

In this study, the cathodic corrosion of Au(111) in the hydrophobic ionic liquid N-methyl-N-propylpiperidinium bis(trifluoromethane-sulfonyl)imide ([MPPip][TFSI]) was studied by in situ scanning tunnelling microscopy. Hereby, the formation of equidistant holes at the so-called 'elbows' of the Au(111) herringbone reconstruction was observed. Additionally, it was found that the water content plays a crucial role in the corrosion potential and extent. The higher the water content, the less negative is the onset potential of the cathodic corrosion and the more pits are formed at this potential.

Parameters Determining Electrode Modification by High Voltage Electrolysis — •Lukas Forschner, Evelyn Artmann, Timo Jacob, and Albert K. Engstfeld — Institute of Electrochemistry, Ulm University, Ulm, Germany

Applying a sufficiently high voltage between two gas-evolving electrodes of different sizes in an aqueous electrolyte can lead to transition from normal electrolysis (NE) to Contact Glow Discharge Electrolysis (CGDE). Due to Joule heating, the electrolyte temperature increases significantly until enough solvent evaporates to form a stable gas sheath around the smaller electrode in which a plasma is ignited. Both in the NE and the CGDE region, the electrode surface can be altered significantly, e.g., by the formation of a Au oxide film[1] or nanoparticles.[2]

During high voltage electrolysis, there are several factors which could influence the restructuring of an electrode surface. First, to disentangle these processes, we measured the distribution of the electric potential in the electrolyte during NE using reversible hydrogen reference electrodes.[3] We found, supported by a COMSOL® model, that the potential distribution mainly depends on the electrolyte conductivity and the cell geometry. Furthermore, we show that the amount of Au oxide formed on a Au electrode during NE is more closely correlated to the current (density) than the voltage (usually provided in the literature).

qPlus-based Lateral Force Microscopy — •Alfred J. Weymouth — Universität Regensburg, Regensburg, Deutschland

Lateral force microscopy (LFM) is a branch of AFM in which a component of force perpendicular to the surface normal is measured. Long-range forces have no lateral component over a flat terrace, making LFM ideal to study short-range forces. We have established methods to extract force and potential energy from our observations, and applied these methods to study a number of systems including molecular bending. We have also studied the interaction at the side of a molecular adsorbate, and more recently shown that we can measure the energy dissipation as we pull a molecule at the tip over the surface.

Exploring in-plane interactions beside an adsorbed molecule — •Shinjae Nam[1], Elisabeth Riegel[1], Lukas Hörmann[2], Oliver T. Hofmann[2], Oliver Gretz[1], Alfred J. Weymouth[1], and Franz J. Giessibl[1] — [1]Institute of Experimental and Applied Physics, University of Regensburg, Germany — [2]Institute of Solid State Physics, Graz University of Technology, Austria

In-plane interactions between two molecules on a surface can be used to guide on-surface chemical reactions. Our implementation to study in-plane interactions is Lateral Force Microscopy (LFM), where the tip of an AFM is oscillated laterally to directly measure the lateral forces. We investigate the short-range interactions by approaching the side of an adsorbate with a CO-terminated tip. By obtaining 3D data sets at the sides of PTCDA and CO, we demonstrated the large influence of the metal dipole at the tip apex. While previous work has noted this for strongly polarized materials, including defects in ionic crystals [1] and hBN [2], we showed that the metal tip dipole above CO must be also accounted for when measuring closer to single molecules.

Real-space imaging σ-holes and π-holes: a source of electrostatically driven non-covalent interactions — Benjamin Mallada[1,2], Martin Ondracek[1], Aurelio Gallardo[1], •Bruno de la Torre[1,2], and Pavel Jelinek[1,2] — [1]Institute of Physics, Academy of Sciences of the Czech Republic,Prague, Czech Republic. — [2]Regional Centre of Advanced Technologies and Materials, Palacký University, Olomouc, Czech Republic

Noncovalent interactions between molecules play an important role in supramolecular chemistry, molecular biology, and materials science. For the rational design/tweaking of supramolecular systems, it is helpful to understand the forces that make these systems stick to one another.

In this contribution, I will focus on the real-space visualization of the σ-hole (1) and π-hole (2). By a set of Atomic Force Microscopy (AFM), Kelvin Probe Force Microscopy (KPFM), and Scanning Tunneling Microscopy experiments we discriminate the emergence of both σ-hole and π-hole on a single molecule with unprecedented submolecular resolution. Our findings are fully supported by an atomistic model obtained from DFT calculations which allow us to simulate both AFM and KPFM images. These results may potentially open a new way to characterize biological and chemical systems in which anisotropic charges play a decisive role.

Heteroatom-substituted and three-dimensional nanocarbon materials studied with low temperature STM and qPlus AFM — •Shigeki Kawai — National Institute for Materials Science, Tsukuba, Japan

Since the first systematic on-surface covalent coupling of bromo-substituted porphyrins,[1] on-surface chemical synthesis has attracted tremendous interest of researchers. Combining with bond-resolved scanning probe microscopy (SPM) with the qPlus sensor, [2] this field has been rapidly developed. In this contribution, I will present our recent studies on on-surface chemistry with high-resolution SPM operating at low temperature under ultra-high vacuum. We synthesized heteroatom doped [3] and three-dimensional graphene nanoribbons (GNRs) by coupling bromo substituted-propellane molecules on Au(111).[4] In the 3D-GNR, the C-Br bonds distant from the surface remained intact even after the reaction. The radical species were formed by tip-induced debromination and were also stabilized by either Br atom or fullerene molecule. We also developed new on-surface reaction, which can synthesize graphene nanoribbon and covalent organic frameworks with silabenzene units by coupling Si atom and Br-substituted molecule.[5]

Interaction between an artificial and a natural atom — •Fabian Stilp, Marco Weiss, and Franz Giessibl — Institute of Experimental and Applied Physics, University of Regensburg, Universitätsstraße 31, 93053 Regensburg

The surface state of Cu (111), a quasi-2-dimensional electron gas, is trapped to a small surface area of about 15 x 15 nm^2 by placing 48 CO-molecules in a circular shape on the surface via atomic manipulation. By doing so, one creates a quantum corral with discrete electronic states forming an artificial atom. This structure can be described reasonably well by an infinitely high circular potential well leading to corral states with Bessel-type radial functions and an angular momentum normal to the surface. To investigate the interaction between this artificial atom and a natural atom we bring Fe atoms and CO molecules inside the corral and measure the response of the corral states.

Thanks to the large corral diameter, one can study the structure of the wave functions within that artificial atom by AFM and STM showing an angular dependence of the corral states after placing the perturbations inside the corral. This change of the wave functions leads to an energy shift of a few meV. By investigating the change of the corral states due to the perturbation, one can draw conclusion about the interaction between this artificial atom and a natural atom. Here we expand the interpretation of the adatom acting repulsively on the corral states as stated by Stilp et al. [1].

Revelation of an inhomogeneous broadening effect in artificial quantum structures caused by electron-adsorbate scattering — •Marco Weiss, Fabian Stilp, and Franz Giessibl — Institute of Experimental and Applied Physics, University of Regensburg, Universitätsstraße 31, 93053 Regensburg

In 1993 Crommie et al. [1] arranged 48 Fe adatoms on a Cu(111) surface in a circle with a diameter of 14.26 nm. This quantum corral confines surface electrons in a circular potential well. Past investigations with scanning tunneling microscopy revealed energetically discrete eigenstates with radial Bessel functions. These studies on the Fe quantum corral showed unwanted movement of the corral walls during spectroscopic measurements because of the weak bonding of Fe on Cu(111) [1].

We used CO molecules to provide the corral with more stable walls. This permitted us to access a larger voltage window and allowed for a detailed line shape analysis of the corrals eigenenergy levels. Surprisingly, we discovered a dominant Gaussian broadening of the eigenstates.

We find that the spectral width is dependent on the size of the quantum structure. The introduction of a simple model linking the energy dependence of this inhomogeneous broadening with the single particle movement of surface state electrons has shown that the observed behaviour is compatible with an electronic lifetime limitation by interaction with the corral wall.

Benchmarking atomically defined probe tips for NC-AFM experiments — Damla Yesilpinar[1], Bertram Schulze Lammers[1], Alexander Timmer[1], Zhixin Hu[2], Wei Ji[3], Saeed Amirjalayer[1], Harald Fuchs[1], and •Harry Mönig[1] — [1]Westfälische Wilhelms-Universität, Münster, Germany — [2]Tianjin University, Tianjin, China — [3]Renmin University of China, Beijing, China
Controlling the identity of the tip-terminating atom or molecule in NC-AFM constitutes a milestone in surface science. We consolidate the interpretation of such studies by directly comparing the performance of four atomically defined tips: Cu-, Xe-, CO-, and O-terminated copper (CuOx-) tips. Besides their imaging performances on a metal oxide, we directly compared their capabilities in force mapping during the lateral manipulation of single adsorbed atoms. Expectedly, Cu-tips strongly react with the surface inhibiting stable imaging and picking up the atoms to be manipulated. The chemically inert Xe- and CO-tips, allow entering the repulsive force regime. However, their flexibility leads to dynamic tip bending and pronounced artefacts due to the strongly varying potential above the oxide. Furthermore, tip deflection prevents reaching sufficient threshold forces along manipulation trajectories with high energy barriers. In contrast, the combination of moderate chemical passivation and high stiffness of CuOx-tips turned out decisive for a distinct chemical-specific contrast. Moreover, this results also in a superior performance in the manipulation experiments where their high mechanical stability allows quantitative force measurements also along the trajectories with high energy barriers.

O 97.8 Fri 12:30 TRE Ma

Visualizing electrochemical interfaces with a qPlus sensor-based AFM/STM — •Andrea Auer, Bernhard Eder, and Franz Giessibl — Institute of Experimental and Applied Physics, University of Regensburg, Germany
Atomic force microscopy (AFM) that can be simultaneously performed with scanning tunneling microscopy (STM) modes using metallic tips attached to self-sensing quartz cantilevers (qPlus sensors) has advanced the field of surface science by allowing for unprecedented high spatial resolution under ultrahigh vacuum conditions. Applying a qPlus sensor, which offers simultaneous STM/AFM and seamless transitions in between, to the field of electrochemistry creates new possibilities to locally image both the 3D layering of the interfacial water and the lateral structure of the electrochemical double layer. In this work, a home-built AFM/STM instrument equipped with a qPlus sensor for operation under precise potential control in an electrochemical liquid cell is presented. The potential-dependent structural interface organization of the electrochemical double layer on both highly oriented pyrolytic graphite (HOPG) and Au(111) electrodes in acidic media is investigated by means of (simultaneous) AFM/STM imaging and force spectroscopy. We observe frequency shift oscillations as a function of the z-piezo distance, which correspond to the layering of the interfacial solvent molecules, where both the number of layers as well as their strength is highly dependent on the applied potential.

Surfaces go topological – third generation 2D quantum materials — •Ralph Claessen — Physikalisches Institut and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Germany
Metal atom-decorated semiconductor surfaces have long been studied as model systems for the formation of electrical contacts to semiconductor devices. More recently, atomic monolayers on semiconductors have come into focus as two-dimensional designer quantum materials. A case in point are two-dimensional topological insulators (2D-TIs) which host 1D metallic and spin-polarized edge states, giving rise to the quantum spin Hall (QSH) effect. Starting from the notion that a 2D honeycomb lattice favors a topologically non-trivial band structure, I will discuss several examples of such synthetic 2D-TIs, ranging from bismuthene (Bi/SiC(0001)) [1-3], whose large gap even allows the optical generation of excitons in a topological band structure [4], to indenene (In/SiC(0001)), a triangular 2D lattice of In atoms with emerging honeycomb physics and first example of a real-space obstructed QSH insulator [5, 6].

Bounded Confidence Revisited: What We Overlooked, Underestimated, and Got Wrong — •Rainer Hegselmann — Frankfurt School of Finance & Management, 60322 Frankfurt, Adickesallee 32-34

The talk will discuss the so called bounded confidence model (BC-model, for short). The model is very simple: Period by period, all agents average over all opinions that are not further away from their actual opinion than a given distance Epsilon, their *bound of confidence*.

The simplicity of the model is deceptive. Two decades ago, Ulrich Krause and me published an analysis of the model in which we overlooked completely a decisive feature of our model: For increasing values of Epsilon, our analysis back then suggests smooth transitions in the model*s behavior. But in fact, the transitions are wild, chaotic, and non-monotonic.

In my talk I will present a new type of approach in which everything we overlooked at the time becomes directly obvious and, in a sense, unmissable. Key component of the new approach is an algorithm that identifies, exactly and exhaustively, all bounds of confidence, that make a difference. We get a list that, then, allows direct checks for wild behavior exhaustive of all possible cases. That is a good news. But it is accompanied by a bad one: The algorithm that does the work, requires an absolutely exact fractional arithmetic with integers of arbitrary length. As a consequence, we have to pay a price in terms of computational speed.

Tutorial   SOE 1.2   Sun 16:45   HSZ 02
When intuition fails: the complex effects of assimilative and repulsive influence on opinion polarization — •Michael Maes[1], Andreas Flache[2], Shuo Liu[3], and Haoxiang Xia[3] — [1]Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]University of Groningen, Groningen, The Netherlands — [3]Dalian University of Technology, Dalian, China

There is a debate about whether personalized services of social-media platforms contribute to the rise of bipolarization of political opinions. On the one hand, it is argued that personalized services of online social networks generate filter bubbles limiting contact between users who disagree. This reduces opportunities for assimilative social influence between users from different camps and prevents opinion convergence. On the other hand, empirical research also indicated that exposing users to content from the opposite political spectrum can activate the counter-part of assimilative influence, repulsive influence. Fostering contact that leads to opinion assimilation and limiting contacts likely to induce repulsive interactions, it has been concluded, may therefore prevent bipolarization. We demonstrate that these conclusions fail to capture the complexity that assimilative and repulsive influence generate in social networks. Sometimes, more assimilative influence can actually lead to more and not less opinion bipolarization. Likewise, increasing the exposure of users to like-minded individuals sometimes intensifies opinion polarization.

Tutorial   SOE 1.3   Sun 17:30   HSZ 02
How growing connectivity and self-organization changes opinion dynamics — •Philipp Lorenz-Spreen — Center for Adaptive Rationality, Max Planck Institute for Human Development, Berlin, Germany

Information technology has made various aspects of our lives more dynamic and self-organized. Connections with others can be made across spatial and socio-demographic boundaries and undone with the click of a button. Since the famous six degrees of separation, networks seem much more connected; Facebook reports 3.5 degrees of separation on its friendship graph. Yet there have been repeated reports of segregated, homophilic network structures and related trends of increasing polarization on most online platforms. The mechanism that could resolve this apparent paradox may lie behind the question of whether we change our opinions according to our friends or whether we change our friends according to our opinions. We have recently proposed that an agent's opinion changes as a process of mutual reinforcement within clusters of shared attitudes and a coevolution of the associated network structure that dynamically adapts to changing opinions and follows a probability distribution governed by homophily. This combination helps explain the potential emergence of increasing polarization even as connectivity increases. Moreover, extending this model to multiple dimensions of topics can explain the empirical observation of increasing alignment of issues, where opinions become increasingly correlated within ideological clusters.

SOE 2: Invited Talk: Dynamics of Networks (joint session DY/SOE)

Time: Monday 12:30–13:00   Location: ZEU 250

See DY 8 for details of this session.

SOE 3: Award Session: Young Scientist Award for Socio- and Econophysics (YSA)

Time: Monday 15:00–17:00   Location: HSZ 03

Presentation of the Award to the Awardee

Prize Talk   SOE 3.1   Mon 15:10   HSZ 03
Initial Progress on the Science of Science — •Dashun Wang — Northwestern University

The increasing availability of large-scale datasets that trace the entirety of the scientific enterprise, have created an unprecedented opportunity to explore scientific production and reward. Parallel developments in data science, network science, and artificial intelligence offer us powerful tools and techniques to make sense of these millions of data points. Together, they tell a complex yet insightful story about how scientific careers unfold, how collaborations contribute to discovery, and how scientific progress emerges through a combination of multiple interconnected factors. These opportunities–and challenges that come with them–have fueled the emergence of a multidisciplinary community of scientists that are united by their goals of understanding science and innovation. These practitioners of the science of science use the scientific methods to study themselves, examine projects that work as well as those that fail, quantify the patterns that characterize discovery and invention, and offer lessons to improve science as a whole. In this talk, I will highlight some examples of research in this area, hoping to illustrate the promise of science of science as well as its limitations.

Presentation of the Award to the Awardee

Prize Talk   SOE 3.2   Mon 16:00   HSZ 03
Complexity science can address marginalization in society and algorithms — •Fariba Karimi — Technical university of Vienna — Complexity Science Hub Vienna

Structural marginality refers to structural conditions that push certain groups towards a network*s margins, limiting their access to resources. Despite its importance, there are minimal quantitative understanding of its manifestation in networks and are thus we are unequipped to answer several urgent societal questions. For example, what underlying structural mechanisms drive marginalization? How can marginalized groups improve their social positions? How do AI systems reinforce these effects? Do hard (mathematical) limits exist on actions that would alleviate structural inequalities? In this talk, I argue that tools in complexity science are instrumental in measuring structural marginalities that emerge in society and algorithms.

After the Award Session, there will be an informal get-together with beer and pretzels at the poster session

SOE 4: Poster

Identifying subdominant collective effects in a large motorway network —
•Shanshan Wang, Michael Schreckenberg, and Thomas Guhr — Faculty
of Physics, University of Duisburg-Essen, Duisburg, Germany

In a motorway network, correlations between parts or, more precisely, between
the sections of (different) motorways, are of considerable interest. Knowledge of
flows and velocities on individual motorways is not sufficient, rather, their cor-
relations determine or reflect, respectively, the functionality of and the dynamics
on the network. These correlations are time-dependent as the dynamics on the
network is highly non-stationary. Apart from the conceptual importance, corre-
lations are also indispensable to detect risks of failure in a traffic network. Here,
we proceed with revealing a certain hierarchy of correlations in traffic networks
that is due to the presence and to the extent of collectivity. In a previous study,
we focused on the collectivity motion present in the entire traffic network, i.e.
the collectivity of the system as a whole. Here, we manage to subtract this dom-
inant effect from the data and identify the subdominant collectivities which af-
fect different, large parts of the traffic network. To this end, we employ a spectral
analysis of the correlation matrix for the whole system. We thereby extract infor-
mation from the virtual network induced by the correlations and map it on the
true topology, i.e. on the real motorway network. The uncovered subdominant
collectivities provide a new characterization of the traffic network. We carry out
our study for the large motorway network of North Rhine-Westphalia (NRW),
Germany.

SOE 4.2   Mon 17:00   P2/OG2

Feasibility and goodness of bimodal on-demand public transportation. —
•Puneet Sharma, Knut Heidemann, Helge Heuer, Steffen Muehle, and
Stephan Herminghaus — Max Planck Institute for Dynamics and Self Orga-
nization, Goettingen

Decarbonization of passenger transport is essential for fighting climate emer-
gency. While modern cities offer various modes of transportation, considered
separately, none of them is both, sustainable and convenient. A taxi service
is convenient, in a sense, due to door-to-door service, but is inefficient since
it usually serves one customer only. Demand-responsive ridepooling (DRRP)
with minibuses is more efficient, but leads to undue competition with line ser-
vices (LS), which provide even better pooling but are less convenient due to fixed
routes and stops. A combination of both modes, DRRP and LS, may provide
an ideal solution but is challenging to organize. Here we introduce a model
for such bimodal on-demand transportation based on a square-grid geometry.
Our model quantifies under what circumstances bimodal public transportation
is feasible, both in terms of convenience and ecological footprint. Moreover, the
model yields estimates for how to operate (LS frequency, modal split) a bimodal
transportation system optimally. Perhaps surprisingly, we find that operating LS
at maximum capacity is not necessarily optimal. We also consider the intricate
interplay between LS operations and DRRP performance, i.e. detours, waiting
times, and occupancy, via simulations.

SOE 4.3   Mon 17:00   P2/OG2

**Just in time vs. all in sync: an analysis of two types of synchronization
in a minimal model of machine activity in industrial production based on
excitable dynamics on graphs** — •Sanghita Bose[1], Annick Lesne[2,3], Ju-
lia Arlinghaus[4], and Marc-Thorsten Hütt[1] — [1]Department of Life Sci-
ences and Chemistry, Jacobs University Bremen, Germany — [2]Institut de Géné-
tique Moléculaire de Montpellier, University of Montpellier, CNRS, F-34293,
Montpellier, France — [3]Sorbonne Université, CNRS, Laboratoire de Physique
Théorique de la Matière Condensée, LPTMC, F-75252, Paris, France — [4]Otto-
von-Guericke University Magdeburg, Universitätsplatz 2, 31904, Magdeburg,
Germany.

The notion of synchronization in logistics is distinct from that encountered in
the natural sciences, and in particular, in physics. In logistics, synchronization is
often associated with a 'just in time' paradigm in supply and production systems.
A perfect synchronization therefore is that the arrival (of goods at a warehouse
or parts at a machine) is a cue for a subsequent transportation or manufacturing
event. Globally, this type of synchronization can be envisioned as a wave of activ-
ity running through a distribution network or a production network. Here our
goal is a deeper theoretical understanding of these two types of synchronization,
the one from logistics and the one from physics, as well as their interplay in the
context of production systems. We employ a minimal model of propagating ex-
citations (representing machine activity) in a graph (representing a production
network).

SOE 4.4   Mon 17:00   P2/OG2

**Impact of interactions between layers on source localization in multilayer
networks** — Robert Paluch, Łukasz Gajewski, •Krzysztof Suchecki,
and Janusz Hołyst — Faculty of Physics, Warsaw University of Technology,
Koszykowa 75, Warsaw, 00-662, Poland

Nowadays, it is not uncommon to have to deal with dissemination on multilay-
ered networks, and often finding the source of said propagation can be a crucial
task. We examine the issue of locating the source of Susceptible-Infected spread-
ing process in a multilayer network using the Bayesian inference and the max-
imum likelihood method established for general networks and adapted here to
cover multilayer topology. We show how its accuracy depends on the network
and spreading parameters and find the existence of two parameter ranges with
different behavior. If the inter-network spreading rate is low, observations in
different layers interfere, lowering accuracy below that of relying on single-layer
observers only. If it is high, on the other hand, observations synergize, raising
accuracy above the level of a single-layer network of the same size and observer
density. We also show a heuristic method to determine the case in a system and
potentially improve accuracy by rejecting interfering observations.

SOE 4.5   Mon 17:00   P2/OG2

**Mean field approach for link coupling in Heider dynamics in bilayer net-
work** — •Krishnadas Mohandas and Janusz Hołyst — Warsaw University
of Technology, Poland

Structural balance was observed in many social groups with simultaneous
friendly and hostile relations. Frequently these interactions need to be described
by muticomponent attributes and different components can be coupled together.
In this study we consider a bilayer topology of Heider balance in a link multiplex,
a unique multiplex in which coupling not only exists between different agents
but also between corresponding links of the same agent. In social networks, for
instance, agents can belong to the family, professional and friends group, where
links in each layer could address either sports or politics. The dynamics of agents
differs inside and between the layers and the coupling coefficients between the
layers govern the strength of influence of one link-layer on another. Numerical
simulations and analytical calculations using heat-bath approach and mean-field
approximation demonstrate that the link polarization for both layers of a com-
plete signed network of N agents tends towards Heider balance below critical
temperature. The effect of such inter-layer coupling results in the increase of crit-
ical temperature with the strength of positive coupling. Periodical and chaotic
trajectories of mean polarisations of both components are observed for a range
of temperatures in the case of negative interlayer coupling.

SOE 4.6   Mon 17:00   P2/OG2

Counting Graphs and Molecules — •Rana Shojaei[1,2,3] and Thilo Gross[1,2,3]
— [1]Helmholtz Institute for Functional Marine Biodiversity at the University
of Oldenburg (HIFMB), Oldenburg, Germany — [2]Alfred Wegener Institute-
Helmholtz Centre for Marine and Polar Research, Bremerhaven, Germany —
[3]Carl von Ossietzky University- Institute for Chemistry and Biology of the Ma-
rine Environment (ICBM), Oldenburg, Germany

Counting the number of simple graphs that can be constructed between a given
number of unlabeled (indistinguishable) nodes is a long-standing challenge. We
consider this problem using Polya's counting theory. For illustration, we first
consider a related problem that has historically received much attention: count-
ing the number of chemical molecules with a given number of atoms. Indeed, it
was in the context of this problem that the term 'graph' was first coined. Applica-
tion of the same principles and procedure leads to a simple closed-form formula
for the number of simple graphs, however, the efficient evaluation of the formula
for large graphs remains an open problem.

SOE 4.7   Mon 17:00   P2/OG2

How random are team sports leagues? — Maciej Pawlik[1], Michał Boruta[2],
Robert Paluch[1], and •Janusz Hołyst[1] — [1]Faculty of Physics, Warsaw Uni-
versity of Technology, Warsaw, 00-662, Poland — [2]Faculty of Mathematics and
Information Science, Warsaw University of Technology, Warsaw, 00-662, Poland

To answer the title question, the historical ranking tables of four team sports
leagues (Premier League, Bundesliga, La Liga, Svenska Hockeyligan) are ana-
lyzed. We investigate the predictability level of a given league by calculating the
average absolute rank change $\overline{\rho}$ between two subsequent seasons of every team.
The data are applied to calibrate an agent-based model of team sports leagues
where every team possesses a certain strength equal to the sum of strengths of
all players that have been selected to the team from a draft list. The sign of the
difference between the strengths of two teams indicates the favorite of a given
game, and there is a determinism parameter $\beta \in (0, \infty)$ that controls the game
predictability. We use the model to simulate many seasons of various leagues
and to compute the average absolute rank change $\overline{\rho}$ of a given team between two
consecutive seasons. Plotting $\overline{\rho}$ as a function of β reveals a continuous transi-

tion between phases of luck– and skill–based sports. Comparing the results of our model with the ranking tables of selected professional leagues, we show that they operate close to the transition line but in the deterministic phase. This finding suggests that random factors and abilities of team players are of comparable importance, with an advantage of the latter.

SOE 4.8   Mon 17:00   P2/OG2

Simulating neutral biodiversity in large-scale networks — •JEFFREY KELLING[1,2], RICHA TRIPATHI[3], and JUSTIN M. CALABRESE[3] — [1]Helmholtz-Zentrum Dresen-Rossendorf, Dresden, Germany — [2]Chemnitz University of Technology, Chemnitz, Germany — [3]Center for Advanced Systems Understanding (CASUS), Helmholtz-Zentrum Dresen-Rossendorf, Görlitz, Germany

The neutral model of biodiversity describes a Markov process of death and replacement of neutral individuals constituting the species occupying an ecosystem. It predicts a number macroscopic ecosystem observables, including local and global abundances, and can serve as advanced null-hypothesis for more complex models. We present a massively parallel approach to simulating the neutral model which both enables simulations on large networks, to, e.g., capture fine details of real river networks, and efficiently produces averages results to enable comparisons with empirical data or other models at high statistical significance or accurately compute correlations or responses.

SOE 4.9   Mon 17:00   P2/OG2

A toy model for the rise and collapse of societies — •ALEXANDER JOCHIM and STEFAN BORNHOLDT — Institute for Theoretical Physics, University of Bremen

Societal collapse as in ancient Rome is rather common than an exception along history. Similar patterns can be observed along time and space, and modern societies are potentially as vulnerable. Relying on empirical data, recent work has introduced mathematical models for long term processes in society. Here we report on a simple, physics-inspired model that exhibits metastable states and phases of collapse or sustained prosperity

SOE 4.10   Mon 17:00   P2/OG2

The Verification Dilemma in computer security: a game-theoretic perspective — •JENS CHRISTIAN CLAUSSEN and AAD VAN MOORSEL — School of Computer Science, University of Birmingham, UK

Verification protocols, as the Proof-of-Work (PoW) in blockchains, are essential mechanisms to ensure security in distributed networks. The computational costs of verification can also be organized in a shared way through special users, called miners. It has been pointed out that a Verifier's Dilemma arises between verifying and non-verifying miners [1]. Here we analyze the verification problem from game theory, identifying it as a strategic dilemma similar to a public goods game.

SOE 4.11   Mon 17:00   P2/OG2

Investigating the Impacts of Regulatory Changes in Energy Systems with Explainable Artificial Intelligence — •SEBASTIAN PÜTZ[1], DIRK WITTHAUT[2,3], and BENJAMIN SCHÄFER[1] — [1]Institute for Au- tomation and Applied Informatics, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany — [2]IEK-STE Research Centre Jülich, Jülich, Germany — [3]University of Cologne, Cologne, Germany

The stable supply of electrical energy is essential for the functioning of our society. Therefore, the operation of the electrical power grid and its related markets is subject to strict regulations. As the external technical, economic or social influences on the power grid change permanently, e.g. due to the energy transition, these regulations must also be constantly adapted. It is important to find out whether the regulatory changes lead to the intended results or whether they entail undesired side effects. We investigate regulatory changes using a data-driven approach based on publicly available techno-economic data on European power grids and electricity markets. We employ explainable machine learning models to identify important dependencies and disentangle the interaction of individual features. Using additive Shapley explanations, we identify changes due to the introduction of the 'Mischpreisverfahren' in the German balancing energy market or the splitting of the German-Austrian bidding zone.

SOE 4.12   Mon 17:00   P2/OG2

Delay Dynamics in a Nonlinear Economic Model — •SÁNDOR KOVÁCS[1], SZILVIA GYÖRGY[1], JÚLIA TOMPA[2], and NOÉMI GYÚRÓ[2] — [1]Department of Numerical Analysis, Eötvös LorándUniversity, \\ Pázmány Péter sétány 1/C, H-1117 Budapest, Hungary\\ E-mail: alex@ludens.elte.hu — [2]Eötvös Loránd University, \\ Pázmány Péter sétány 1/C, H-1117 Budapest, Hungary

This talk is about the qualitative behavior of an economic model proposed by D. Meyer (cf. [1]). It is shown that under certain conditions on the parameters the system has uniformly bounded and no non-trivial periodic solutions. Subsequently, a possible equilibrium on the boundary of the positive phase space not discussed in [1] was founded and showed that if there is no interior equilibrium, then the equilibrium at the boundary will become unstable, whereas the equilibrium at the boundary will be stable. In order to have more realism, two types of delay will be introduced: an infinite distributed delay and a discrete delay. It is shown that contrary to the result in [1] the distributed delay does not change the stability of the equilibrium points. Finally, by introducing a discrete delay, it was showed that at a certain parameter value Hopf bifurcation takes place: periodic solutions arise. [1] Meyer, D. Equity and Efficiency in Regional Policy. Periodica Mathematica Hungarica Vol. 56 (1), 2008, 105*119.

SOE 4.13   Mon 17:00   P2/OG2

A model of public opinion with time-dependent media influence, audience attention and social influence. — •MICHAEL SCHNABEL[1] and DANIEL DIERMEIER[1,2] — [1]Vanderbilt University, Department of Political Sciences, Nashville, TN, USA — [2]Vanderbilt University, Owen School of Management, Nashville, TN, USA

We consider a simple model of binary opinions. Individuals form their opinions based on individual preferences, time-dependent media influence and the overall opinions in the population. In addition, we also incorporate a mechanism that is responsive to the salience of the media influence and can be used to account for variations in public attention. We explore how attention affects the opinion dynamics in the population as well as the equilibrium properties in a hypothetical quasi-static environment. Our model can account for populations with heterogeneous preferences and can also be used to examine the dynamics of opinion polarization within a population.

SOE 4.14   Mon 17:00   P2/OG2

Analysis of changes of opinions and social network structure of NetSense experiment participants — •BARTŁOMIEJ ZWOLIŃSKI and PIOTR GÓRSKI — Faculty of Physics, Warsaw University of Technology, Warsaw, 00-662 Poland

We study the interrelation between interactions and opinions by using data on Bluetooth contacts between college freshmen. We research evolution of social network structure and their opinions on eight topics within two-year period.

We find weak but significant correlation between students' vectors of opinions and their further interactions. Higher number of interactions had different impact on students' opinions depending on the period of the study, polarising them or leading to opinion alignment.

Throughout the experiment, we observed change of the students' contact network from overall community to smaller groups worse interconnected with each other.

SOE 5: Physics of Contagion Processes I (joint session SOE/DY)

Time: Tuesday 9:30–10:00   Location: ZEU 260

Invited Talk   SOE 5.1   Tue 9:30   ZEU 260

Digital Pandemiology – Is that physics? — •DIRK BROCKMANN — Humboldt University of Berlin, Berlin, Germany

Three years of COVID-19 lie behind us. Experts from various fields worked constantly on understanding, mitigating and making sense of the pandemic. Novel digital tools became an essential part and complemented traditional, epidemiological methods. I will report on research activities and digital projects we launched during the past years that delivered important insights and were helpful as real-time assessment tools during the pandemic. These include the Covid-19-mobility monitor and the Corona Data Donation Project in which more than 500,000 participants donated daily data collected by their smartwatch or wearable device. I will summarize the results we obtained from these technologies and discuss why physics, as a mindset, is helpful for understanding phenomena that unfold across the borders of traditional scientific disciplines.

SOE 6: Physics of Contagion Processes II (joint session SOE/DY)

Time: Tuesday 10:00–10:45   Location: ZEU 260

SOE 6.1   Tue 10:00   ZEU 260

Explosive Epidemics — •Georg Börner[1], Malte Schröder[1], Davide Scarselli[2], Nazmi Burak Budanur[2,3], Björn Hof[2], and Marc Timme[1,4,5] — [1]Chair for Network Dynamics, Center for Advancing Electronics Dresden (cfaed) and Institute of Theoretical Physics, Technische Universität Dresden, Dresden 01062, Germany — [2]Institute of Science and Technology Austria, Klosterneuburg, Austria — [3]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [4]Cluster of Excellence Physics of Life, Technische Universität Dresden, Dresden 01062 Germany — [5]Lakeside Labs, Lakeside B04b, 9020 Klagenfurt, Austria

Standard epidemic models exhibit one continuous, second order phase transition to macroscopic outbreaks. However, interventions to control outbreaks may fundamentally alter epidemic dynamics. We reveal how such interventions modify the type of phase transition. In particular, we uncover three distinct types of explosive phase transitions for epidemic dynamics with capacity-limited interventions. Depending on the capacity limit, interventions may (i) leave the standard second-order phase transition unchanged but consistently suppress the probability of large outbreaks, (ii) induce a first-order discontinuous transition to macroscopic outbreaks, or (iii) cause a secondary explosive yet continuous third-order transition. These insights highlight inherent limitations in predicting and containing epidemic outbreaks. More generally our study offers a cornerstone example of a third-order explosive phase transition in complex systems.

SOE 6.2   Tue 10:15   ZEU 260

Large-deviations of the SIR model under the influence of Lockdowns — Leo Patrick Mulholland[1], •Yannick Feld[2], and Alexander K. Hartmann[2] — [1]Queen's University Belfast, United Kingdom — [2]Institute of Physics, Carl von Ossietzky University, Oldenburg, Germany

Due to the high real-wold impact of diseases, the modelling of its dynamics has long since become an important aspect of various disciplines. Statistical physics is one of them as it gives us the tools investigate the fundamental processes through which a disease spreads throughout a population.

The transmission of a disease is affected by a lot of different factors. For example in response to the SARS-CoV 2 pandemic many governmental bodies imposed interventions to impede the spread of disease. One of the earliest non-pharmaceutical interventions (NPIs) that most countries used were lockdowns.

Motivated by that, we numerically [1] study the dynamics of the susceptible-infected-recovered (SIR) model with lockdowns on small-world networks by using a large-deviation approach, which was previously used to study the case of an unimpeded spread [2]. This allows us to obtain the probability density function of the cumulative fraction of infected nodes down to very small probabilities like 10^{-55}. The density exhibits remarkable discontinuties of the first derivative.

SOE 6.3   Tue 10:30   ZEU 260

Short messages spread wider in online social networks — Patryk A. Bojarski, •Krzysztof Suchecki, and Janusz A. Hołyst — Faculty of Physics, Warsaw University of Technology, Warsaw, 00-662 Poland

We explore the behavior of an online message spreading model, that includes mutable message content, user opinions and limited processing capacities. The model shows robust power-law distribution of the number of shares for different messages and that the tail of the distribution is composed almost entirely of very short messages. The possibility to modify message content by spreaders makes already popular, short messages even more popular if the users are selective about what content they spread, but not too much. The distribution of message variants is also a power-law, in agreement with real message spreading in Facebook. The behavior of the model is robust against model parameters and network topology variations and offers an explanation as to why services focused on short messages, such as Twitter, are popular.

SOE 7: Networks: From Topology to Dynamics I (joint session SOE/DY)

Time: Tuesday 11:00–12:15   Location: ZEU 260

SOE 7.1   Tue 11:00   ZEU 260

Modelling the perception of music in brain network dynamics — •Jakub Sawicki[1,2,3,4], Lenz Hartmann[5], Rolf Bader[5], and Eckehard Schöll[1,4,6] — [1]Potsdam Institute for Climate Impact Research — [2]Institut für Musikpädagogik, Universität der Künste Berlin — [3]Fachhochschule Nordwestschweiz FHNW, Basel, Switzerland — [4]Institut für Theoretische Physik, TU Berlin — [5]Institute of Systematic Musicology, University of Hamburg — [6]Bernstein Center for Computational Neuroscience Berlin

We analyze the influence of music in a network of FitzHugh-Nagumo oscillators with empirical structural connectivity measured in healthy human subjects [1]. We report an increase of coherence between the global dynamics in our network and the input signal induced by a specific music song. We show that the level of coherence depends crucially on the frequency band. We compare our results with experimental data, which also describe global neural synchronization between different brain regions in the gamma-band range and its increase just before transitions between different parts of the musical form (musical high-level events). The results also suggest a separation in musical form-related brain synchronization between high brain frequencies, associated with neocortical activity, and low frequencies in the range of dance movements, associated with interactivity between cortical and subcortical regions. [1] Sawicki, J., Hartmann, L., Bader, R., Schöll, E., Front. Netw. Physiol. 2, 910920 (2022).

SOE 7.2   Tue 11:15   ZEU 260

Order-disorder transition in the zero-temperature Ising model on random graphs — Armin Pournaki[1,2], Eckehard Olbrich[2], Sven Banisch[3], and •Konstantin Klemm[4] — [1]Laboratoire Lattice, CNRS & ENS-PSL, Paris — [2]Max Planck Institute for Mathematics in the Sciences, Leipzig — [3]Karlsruhe Institute for Technology — [4]IFISC (UIB-CSIC), Palma de Mallorca, Spain

The zero-temperature Ising model is known to reach a fully ordered ground state in sufficiently dense graphs. In sparse random graphs, the dynamics gets absorbed in disordered local minima at magnetization close to zero. Here we find that the non-equilibrium transition between the ordered and the disordered regime occurs at an average degree that slowly grows with the system size. The system shows bistability: the distribution of the absolute magnetization in the absorbing state reached is bimodal with peaks only at zero and unity. For fixed system size, the average time to absorption behaves non-monotonically as a function of average degree. The peak value of the average absorption time grows as a power law of system size. These findings have relevance for community detection, opinion dynamics and games on networks. Full manuscript available at https://arxiv.org/abs/2209.09325

SOE 7.3   Tue 11:30   ZEU 260

Analytical methods to stochastic binary-state dynamics on networks. — •Antonio Fernandez Peralta[1] and Raul Toral[2] — [1]Central European University, Vienna, Austria — [2]IFISC (Instituto de Física Interdisciplinar y Sistemas Complejos), Palma de Mallorca, Spain

Recently, there has been a lot of effort in the development of highly accurate mathematical descriptions of the dynamics of binary-state models defined on complex networks. There are two main approaches: (i) individual based-approaches where the variables are the state of each node, and (ii) compartmental approaches where nodes are aggregated based on some topological property such as, for example, the number of neighbors in the network. Except in a few cases where stochastic effects are taken into account at some extent, the approaches are usually followed by a deterministic description, neglecting the stochastic nature of the models defined by the individual transitions rates. Stochastic effects may become relevant even for extremely large system sizes, specially if the system is close to a critical point, or the network has high degree heterogeneity. Besides, there are some models where the deterministic approach does not provide the relevant information sought. For instance, the noisy-voter (Kirman) model, the contact process or the Threshold model, are examples of relevance in which the stochastic effects greatly dominate the dynamics. The main aim of this work is to give a general theoretical approach to binary-state models on complex networks that takes into account stochastic effects, going beyond incomplete deterministic approaches.

SOE 7.4   Tue 11:45   ZEU 260

Infinite sequence of explosive transitions in network robustness — •Laura Barth[1,2,3] and Thilo Gross[1,2,3] — [1]Helmholtz Institute for Functional Marine Biodiversity (HIFMB), Oldenburg, Germany — [2]Alfred-Wegener-Institute (AWI), Helmholtz Center for Polar and Marine Research, Bremerhaven, Germany — [3]Institute for Chemistry and Biology of the Marine Environment (ICBM), Carl-von-Ossietzky University, Oldenburg, Germany

Explosive transitions in networks have recently received much attention. Here we show that such transitions also appear in one of the most fundamental problems in network science if it is considered from a certain angle. This problem

is the fragmentation of networks under node or link removal, which has been studied extensively in the context of social networks. One key property in this context is v, the probability that a random link of a random node does not connect to the giant component. Now suppose we are constructing a random graph with a prescribed mean degree. How would we choose the degree distribution such that v is minimal after the attack? We show that the optimal degree distributions undergo an infinite sequence of discontinuous transitions as the size of the attack is changed.

SOE 7.5   Tue 12:00   ZEU 260

Information parity to measure the consonance of influence in complex networks — Aline Viol[1] and •Philipp Hövel[2] — [1]Scuola Internazionale Superiore di Studi Avanzati, Italy — [2]Christians-Albrechts-Universität zu Kiel, Germany

We discuss a new analytical tool to quantify the consonance of influence between nodes with respect to the whole network architecture: information par-

ity. Unlike traditional approaches to quantitative network analysis that consider only local or global scales, information parity instead quantifies pairwise statistical similarities over the entire network structure. Based on information theory and using the statistics of geodesic distances, information parity assesses how similarly a pair of nodes can influence and be influenced by the network. This allows us to quantify the access of information gathered by the nodes. To demonstrate the method's potential, we evaluate a social network and human brain networks. Our results indicate that emerging phenomena like an ideological orientation of nodes in social networks can be shaped by their information parities. We also show the potential of information parity to identify central network regions in structural brain networks placed near the mid-sagittal plane. We find that functional networks have, on average, greater information parity for inter-hemispheric homologous regions in comparison to the whole network. Finally, we explore functional brain networks under influence of a psychedelic substance.

Evolution of Socio- and Econophysics in the German Physical Society (DPG) — •Armin Pournaki[1,2], Sven Banisch[3], Philipp Hövel[4], and Eckehard Olbrich[1] — [1]Max Planck Institute for Mathematics in the Sciences, Germany — [2]Laboratoire Lattice, CNRS & ENS-PSL, France — [3]Karlsruhe Institute for Technology, Germany — [4]Christians-Albrechts-Universität zu Kiel, Germany

We present an interactive visualization (https://pournaki.com/soe/) that allows to explore the evolution of the semantic network of all abstracts that were submitted to the division *socio-economic systems (SOE)* of the DPG spring meetings from 2002 until 2022. The online interface allows to search for semantically related work in the *DPG-Verhandlungen* (book of abstracts) by also providing a textual interface that links the abstracts back to the actual website of the Verhandlungen. Employing a topic model on the data one can follow the evolution of central topics over time.

Moreover, we use the semantic network to study the role of the network paradigm as an integrative concept and its interaction within and across the different subfields of the SOE division.

SOE 8.2   Tue 14:15   ZEU 260

Network analysis of the Kyiv Bylyny cycle - East Slavic epic narratives — Petro Sarkanych[1,2], Nazar Fedorak[3,4], •Yurij Holovatch[1,2,5], Pádraig MacCarron[6], Joseph Yose[5,2], and Ralph Kenna[5,2] — [1]ICMP, NAS of Ukraine, Lviv, Ukraine — [2]L4 Collaboration Leipzig-Lorraine-Lviv-Coventry, Europe — [3]Ivan Franko National University of Lviv, Lviv, Ukraine — [4]Ukrainian Catholic University, Lviv, Ukraine — [5]Coventry University, Coventry, UK — [6]University of Limerick, Limerick, Ireland

In recent times, the advent of network science permitted new quantitative approaches to literary studies [see e.g. Maths Meets Myths: Complexity-science approaches to folktales, myths, sagas, and histories. R. Kenna, M. Mac Carron, P. Mac Carron (Editors), Springer, 2016]. Here, we bring the Kyiv bylyny cycle into the field - East Slavic epic narratives originating in modern-day Ukraine. By comparing them to other prominent European epics, we identify universal and distinguishing properties of the social networks in bylyny. We analyze community structures and rank most important characters. The method allows to bolster hypotheses from humanities literature - such as the position of Prince Volodymyr - and to generate new ones. We show how the Kyiv cycle of bylyny fits very well with narrative networks from other nations - especially heroic ones. We anticipate that, besides delivering new narratological insights, this study will aid future scholars and interested public to navigate their way through Ukraine's

epic story and identify its heroes [P. Sarkanych et al., Adv. Complex Syst. 25(4) (2022) 2240007].

SOE 8.3   Tue 14:30   ZEU 260

Dynamics of language features on complex networks: statistical physics analysis, and the introduction of linguistic temperature — •Christopher Kitching[1], Jordan Abbott[1], Tobias Galla[1,2], Henri Kauhanen[3], Deepti Gopal[4], and Ricardo Bermúdez-Otero[1] — [1]The University of Manchester, UK — [2]Instituto de Fisica Interdisciplinar y Sistemas Complejos (CSIC-UIB) — [3]University of Konstanz, Germany — [4]University of Cambridge, UK

Statistical physics has made important contributions to the study of language dynamics. Here, we focus on a stochastic individual-based model of the spatio-temporal evolution of language features. Features evolve through a combination of descent across generations, and the influence of geographically neighbouring languages.

The dynamics are a variation of the two-state voter model, with spontaneous changes of state and transmission errors in the imitation process. Previous work is restricted to lattices, here we focus on complex networks. We establish a parabolic relation between the feature frequency and the density of active interfaces, modulated by the network, and 'linguistic temperature' - a measure of a feature's stability.

Results are obtained by combining the voter model, pair approximation and a new approach to networks, based on random walks. While the theoretical work has applications in other areas (e.g. opinion dynamics), our main focus is in linguistics: the frequency and isogloss density of real-world language features can be obtained from WALS and from this we calculate their temperatures.

SOE 8.4   Tue 14:45   ZEU 260

The Characteristic Time Scale of Cultural Evolution — •Tobias Wand — Westfälische Wilhelms-Universität Münster, Institut für Theoretische Physik — Center for Nonlinear Sciences Münster

Cliodynamics is a field of research that models human societies as dynamical systems, treating the study of history as a scientific discipline. Previous research on the Seshat databank has revealed one dominant principle component as an indicator of social complexity across diverse geographies and time periods. Our research expands on these findings, showing that there is a typical growth phase in social complexity that can be modelled with a universal functional form for all geographic areas included in the databank. Our findings reveal a characteristic time scale of rapid growth and can serve as a baseline to detect outliers.

SOE 9: Focus Session: Critical Transitions in Society, Economy, and Nature (joint session SOE/DY)

Time: Wednesday 9:30–11:45   Location: ZEU 260

Topical Talk   SOE 9.1   Wed 9:30   ZEU 260

Many universality classes in an interface model restricted to non-negative heights — •Peter Grassberger[1], Deepak Dhar[2], and Pradeep Mohanty[3] — [1]JSC, Forschungszentrum Jülich, D-52425 Jülich, Germany — [2]Indian Institute of Science Education and Research, Pune, 411 008, India — [3]Indian Institute of Science Education and Research - Kolkata Mohanpur, 741 246, India

We present a simple 1-d stochastic model with two control parameters and a rich zoo of phase transitions. At each (discrete) site x and time t, there is an integer $n(x, t)$ that satisfies a linear interface equation with added random noise. Depending on the control parameters, this noise may or may not satisfy detailed balance, so that the model is – for suitable initial conditions – in the Edwards-Wilkinson (EW) or in the Kardar-Parisi-Zhang (KPZ) universality class. But in

contrast to these, there is also a constraint $n(x, t) \geq 0$. Points x where $n > 0$ on one side and $n = 0$ on the other are called "fronts". These fronts can be "pushed" or "pulled", depending on the control parameters. For pulled fronts, the lateral spreading is in the directed percolation (DP) universality class, while it is of a novel type for pushed fronts, with yet another novel behavior in between. In the DP case, the activity at each active site can in general be arbitrarily large, in contrast to previous realizations of DP. Finally, we find two different types of transitions when the interface detaches from the line $n = 0$ (with $\langle n(x, t) \rangle \to const$ on one side, and $\to \infty$ on the other), again with new universality classes. We also discuss a mapping of this model onto a directed Oslo rice pile model in specially prepared backgrounds.

Topical Talk   SOE 9.2   Wed 10:00   ZEU 260
Nonequilibrium phase transitions and critical behavior in networks — •Eckehard Schöll — Institut für Theoretische Physik, TU Berlin — Potsdam Institute for Climate Impact Research — Bernstein Center for Computational Neuroscience Berlin

Phase transitions in nonlinear dynamical systems far from thermodynamic equilibrium have been investigated since the 1970s and 1980s, and concepts from thermodynamics and statistical physics have been applied to describe self-organization, spatio-temporal pattern formation, phase coexistence, critical phenomena, and first and second order nonequilibrium phase transitions. Much more recently, phase transitions and critical phenomena have been studied in dynamical networks, where synchronization transitions may arise, giving birth to a plethora of partial synchronization patterns and complex collective behavior, with applications to many natural, socioeconomic, and technological systems. We review these developments, and draw some connections of tipping transitions, explosive synchronization, nucleation, critical slowing down, critical exponents, etc. with nonequilibrium thermodynamics. [1] Tumash, L., Olmi, S. and Schöll, E., Effect of disorder and noise in shaping the dynamics of power grids, Europhys. Lett. 123, 20001 (2018). Critical transition to monsoon: statistical physics principles of monsoon forecasting — •Elena Surovyatkina — Potsdam Institute for Climate Impact Research (PIK), Potsdam, Germany — Space Research Institute of the Russian Academy of Sciences (IKI), Moscow, Russia

Numerical weather models are limited to forecasting the weather for up to 5 days in the future. A fundamental problem lies in the chaotic nature of the spatial differential equations used to simulate the atmosphere. The limitations of current prediction models prevent further progress.

I present a recently developed approach fundamentally different from the numerical weather and climate models. It is based on statistical physics principles and recently discovered spatial-temporal regularities (or teleconnections between Tipping Elements) in a monsoon system.

First, I begin with evidence in observational data that the transition from pre-monsoon to monsoon is a critical transition. Second, I show how to detect the

Tipping elements in the spatial organization of monsoon using the phenomenon of critical growth of fluctuations. Third, I explain how the regularities between the Tipping Elements allow predicting the upcoming monsoon onset and withdrawal for 40 and 70 days in advance, respectively.

Furthermore, I present the results of retrospective tests from 1951 to 2015, which show 73 % success for monsoon onset and 84 % for a withdrawal date. Remarkably, that forecasts of future monsoons showed to be successful already seven years in a row, 2016-2022.

SOE 9.4   Wed 11:15   ZEU 260
Synchronization-desynchronization transitions in neural networks — •Anna Zakharova — BCCN Berlin, Germany

Synchronization of neurons is believed to play a crucial role in the brain under normal conditions, for instance, in the context of cognition and learning, and under pathological conditions such as Parkinson's disease or epileptic seizures. In the latter case, when synchronization represents an undesired state, understanding the mechanisms of desynchronization is of particular importance. In other words, the possible transitions from synchronized to desynchronized regimes and vice versa should be investigated. It is known that such dynamical transitions involve the formation of partial synchronization patterns, where only one part of the network is synchronized. The most prominent example is given by chimera states [1]. In the present talk, we discuss an alternative scenario. We show how the so-called solitary states in networks of coupled FitzHugh-Nagumo neurons can lead to the emergence of chimera states. By performing bifurcation analysis of a suitable reduced system in the thermodynamic limit we demonstrate how solitary states, after emerging from the synchronous state, become chaotic in a classical period-doubling cascade [2].

SOE 9.5   Wed 11:30   ZEU 260
The war in Ukraine, a statistical analysis — •Juergen Mimkes — Physics Department, Paderborn University

War is a serious disruption of normal social order and may be analyzed by statistics. In homogeneous systems the Lagrange function depends on two Lagrange factors: L (λ, p). In physics, they are mean energy or temperature (λ) and pressure (p). In politics, they are mean capital or standard of living (λ) and military pressure (p). The factors (λ),(p) determine the state or phases of a system. In materials we have solid, liquid, gas, in politics autocratic, democratic, global. Different phases can only coexist at equilibrium in the phase diagram. Outside of equilibrium water and ice cannot coexist in close contact, water is melting ice (climate crisis). Outside of equilibrium democracy and autocracy cannot coexist in close contact, democracy is *melting* autocracy since the Marshall plan in 1947. Accordingly, there has been an aggressive reaction by the autocracy: DDR 1953, Hungary 1956, CSR 1968, Ukraine 2014. There is no chance for peace, unless one party vanishes. The only solution to keep hot and cold together is a thermos, and to keep democracy and autocracy side by side is a new iron curtain like in Korea or Europe (1961 to 1989).

SOE 10: Traffic Dynamics, Urban and Regional Systems I

Time: Wednesday 15:00–16:30   Location: ZEU 260

SOE 10.1   Wed 15:00   ZEU 260
The random walks of ridepooling — •Benjamin Köhler[1], Philip Marszal[1], Marc Timme[1,2], and Malte Schröder[1] — [1]Chair for Network Dynamics, Institute of Theoretical Physics & Center for Advancing Electronics Dresden (cfaed), TU Dresden — [2]Lakeside Labs, Klagenfurt, Austria

Ridepooling services have become an increasingly attractive mobility option in urban areas. As users issue requests for transport, ridepooling vehicles drive through the road network, continually adjusting their routes to pick up and deliver users with similar trips in shared rides. The quality of such services strongly depends on the dynamics of evolving vehicle routes, which collectively emerge from the interactions of the vehicles and requests. So far, theories of ridepooling services have focused on macroscopic and mean-field dynamics, neglecting the underlying microscopic route evolution. Here we analyze the structure and dynamics of these random routes in the limit of high service efficiency. We find an emerging random walk of a route that is specified not only by the current location of the vehicle, but also by the route planned ahead to pick up or drop off passengers who are currently transported in the vehicle or have already requested a ride. We map this process to an ordinary Markov random walk on an abstract graph whose nodes represent the shortest paths of the original street network.

We thereby identify emerging routing patterns and evaluate their implications for the ridepooling service. Understanding these random route processes may help to further advance service quality, for instance by designing stop networks and routing algorithms to maximize flexibility.

SOE 10.2   Wed 15:15   ZEU 260
Scaling laws of ridepooling random routes — Philip Marszal, Marc Timme, and •Malte Schröder — Chair for Network Dynamics, Institute of Theoretical Physics & Center for Advancing Electronics Dresden (cfaed), TU Dresden

On-demand ridepooling services are emerging as a new form of urban mobility across the globe. Users request a trip, are assigned to one of the available ridepooling vehicles, and then transported in a shared ride. Despite the complex dynamics of these systems, their efficiency and service quality is characterized by universal macroscopic scaling laws. However, the scaling laws are typically derived from mean-field calculations neglecting the details of the microscopic dynamics of individual vehicles. Here, we analyze these microscopic dynamics in terms of the *ridepooling random routes* of the vehicles as a new type of random walk process. In contrast to standard random walks, random routes are characterized by a pre-planned route of scheduled stops evolving as new requests are

added to the route and users are picked up and delivered. We identify multiple timescales emerging in the routing dynamics and quantify the resulting structure of the random routes in terms of their persistence and diffusion properties. Importantly, microscopic scaling laws of the random route properties directly give rise to macroscopic scaling laws of the overall system efficiency. This perspective of microscopic random routes in ridepooling services may help to better understand their complex dynamics and scaling laws and optimize these services by identifying recurrent route patterns or adjusting allowed stop locations to guide the self-organized routing dynamics.

SOE 10.3   Wed 15:30   ZEU 260

Bi-modal transport: united against the private car — Puneet Sharma, •Knut Heidemann, Helge Heuer, Steffen Mühle, and Stephan Herminghaus — Max-Planck-Institut für Dynamik und Selbstorganisation, Göttingen, Germany
Motorized individual traffic leads to a prohibitive waste of energy and other resources. We show that combining a line service with a fleet of ride-pooling shuttles may provide on-demand door-to-door service with a service quality superior to customary public transportation, while at the same time consuming only about 20% of the energy a corresponding fleet of private cars would require, and with a road traffic volume reduced by orders of magnitude. We find favorable performance not only in urban, but also in rural settings. While the first part relies on a mean-field model and a simple model geometry, in part two, we test our results by simulations of real-word scenarios.

SOE 10.4   Wed 15:45   ZEU 260

Demand-driven design of bike path networks — •Christoph Steinacker[1], David-Maximilian Stroch[1], Marc Timme[1,2], and Malte Schröder[1] — [1]Chair for Network Dynamics, Institute of Theoretical Physics & Center for Advancing Electronics Dresden (cfaed), TU Dresden — [2]Lakeside Labs, Klagenfurt, Austria
Cycling is crucial for sustainable urban transportation. Promoting cycling critically relies on a sufficiently developed bicycle infrastructure. In general, designing efficient infrastructure networks constitutes a highly complex problem that requires balancing multiple, often opposing, constraints. In particular, bike path networks need to enable both safe and direct travel for all cyclists with an often strongly limited budget and strong competition for limited road space.

Here, we present a framework to create families of efficient bike path networks [1]. We reverse the network formation process and iteratively remove bike paths from an initially complete bike path network. In addition, we continually update cyclists' route choices, explicitly taking into account the cyclists' demand and their safety and convenience preferences. In this way, we create a sequence of networks that is always adapted to the current cycling demand.

We illustrate the applicability of this demand-driven planning scheme with empirical infrastructure and demand data. The framework may thus enable us to study properties of the structure of efficient bike path networks across cities and quantify the impact of different demand distributions.

[1] Steinacker *et al.*, Nat. Comput. Sci. **2**, 655-664 (2022).

SOE 10.5   Wed 16:00   ZEU 260

Does unorganized outperform organized public transport? — •Kush Mohan Mittal[1], Malte Schröder[1], and Marc Timme[1,2] — [1]Chair for Network Dynamics, Institute of Theoretical Physics & Center for Advancing Electronics Dresden (cfaed), TU Dresden — [2]Lakeside Labs, Klagenfurt, Austria
Organized public transport is commonly assumed to be more efficient compared to unorganized or self-organized mobility services that often prevail in the Global South. Here, we analyze OpenStreetMap route data from a total of 4500 routes of both organized and unorganized public transport services in more than 40 cities across the globe. Dividing bus routes into smaller segments and comparing their length to the shortest path distance between the segments endpoints, we find that segments more central in a route consistently exhibit substantially less detour than those towards the ends of the route. This non-homogeneous detour distribution occurs universally, irrespective of whether a city is dominated by organized or unorganized transport. These structural properties of the routes have significant implications for the attractiveness of public transport, as people living in the outskirts at the end of the routes typically both have overall longer trips and experience more (relative) detours than people living in the city center. Intriguingly, we provide quantitative evidence that decentrally self-organized transport routes typically exhibit less heterogeneity and at the same time achieve smaller overall detours. Moreover, they may also outperform organized transport in terms of social accessibility and route interconnectivity.

SOE 10.6   Wed 16:15   ZEU 260

Fix or flex? How ridepooling complements public transport — •Verena Krall[1], Marc Timme[1,2], and Malte Schröder[1] — [1]Chair for Network Dynamics, Institute of Theoretical Physics & Center for Advancing Electronics Dresden (cfaed), TU Dresden, Germany — [2]Lakeside Labs, Klagenfurt, Austria
Urban mobility is changing rapidly, not least due to the global rise of on-demand ridepooling services. In contrast to classic public transport with fixed lines and schedules, these new services offer a flexible shared transport with stops and routes determined by demand. This flexibility might attract new users to shared transport and offer higher accessibility to mobility in districts with poor public transport infrastructure. However, a complete shift from fixed line-based to flexible on-demand services would be detrimental, increasing congestion and wasting existing infrastructure. How can the two different service types complement each other to improve public transport? We find that the service quality is optimal if both line-based and on-demand transport are available. Additionally, we investigate adaptations of public transport networks and find that replacing inefficient lines step-by-step with on-demand vehicles may strongly reduce the overall costs. Applying our approach to empirical public transport networks, we identify lines that should be replaced with on-demand service. Our study shows how the combination of classic line-based with on-demand mobility may contribute to a public transport system that is both sustainable and user-friendly.

SOE 11: Traffic Dynamics, Urban and Regional Systems II

Time: Wednesday 16:45–18:15   Location: ZEU 260

SOE 11.1   Wed 16:45   ZEU 260

Response functions as a new concept to study local dynamics in traffic networks — •Shanshan Wang, Michael Schreckenberg, and Thomas Guhr — Faculty of Physics, University of Duisburg-Essen, Duisburg, Germany
Vehicle velocities in neighbouring road sections are correlated with memory effects. We explore the response of the velocities in the sequence of sections to a congestion in a given section and its dynamic characteristics. To this end, we transfer the concept of response functions from previous applications in finance to traffic systems. The dynamical characteristics are of particular interest. We identify two phases, a phase of transient response and a phase of long-term response. The transient response is pronounced when considering the backward propagation of heavy congestions but almost vanishes for forward propagation. For each response phase, we find a linear relation between the velocity response and the congestion correlator, implying that the correlation of congestion is most likely the cause for the velocity response. We also construct a susceptible-decelerated-withdrawing model mathematically inspired by the susceptible-infectious-recovered (SIR) model in epidemiology to describe the transient response. We find that the heavy congestion on a section propagates forward and backward at a similar rate, but the forward sections are more likely to recover from the effect of heavy congestion than the backward sections.

SOE 11.2   Wed 17:00   ZEU 260

A Fast and Modular Framework for Simulating Ridepooling Systems — •Felix Jung[1], Debsankha Manik[1], and Marc Timme[1,2] — [1]Chair for Network Dynamics, Institute of Theoretical Physics & Center for Advancing Electronics Dresden (cfaed), TU Dresden, 01062 Dresden, Germany — [2]Lakeside Labs, Klagenfurt, Austria
Climate change and congested cities urgently call for a transformation of passenger road transport that today still largely relies on flexible but inefficient private cars. Ridepooling services may reduce the environmental impact while maintaining a high level of flexibility. They move passengers between arbitrary locations, ideally on-demand and on short notice, while dynamically combining trips of several passengers into the same vehicle. However, under which conditions these services are simultaneously efficient, sustainable, and performant is not well understood to date.

Most research into such questions primarily relies on extensive computer simulations, because real-world experiments are extremely expensive and may negatively influence user adoption. Existing simulation tools have a much broader scope but are hard to evaluate with respect to fundamental physical observables, are not sufficiently performant, or hard to use. Here we present a new simulation framework that overcomes these challenges and is easy to use, modular and fast. The framework is released under an Open Source license in the hope that it will benefit the research community and further collaborative development.

SOE 11.3   Wed 17:15   ZEU 260

Service Quality Paradox – Guaranteeing early deliveries causes overall delays in ride pooling services — •Philip Marszal[1,2], Marc Timme[1,2,3], and Malte Schröder[1,2] — [1]Center for Advancing Electronics Dresden (cfaed), Technical University of Dresden, 01062, Dresden, Germany — [2]Institute for Theoretical Physics, Technical University of Dresden, 01062, Dresden, Germany — [3]Lakeside Labs, Lakeside B04b, Klagenfurt, 9020, Austria

On-demand ride pooling services become increasingly important for modern human mobility and rely on advanced forms of dispatching and coordination algorithms [1,2]. A central algorithm matches the vehicles of service providers to the trip requests of customers, aiming to efficiently combine passenger trips in order to reduce service time and distance traveled [3]. Here we reveal a service quality (SQ) paradox emerging emerging from how such services self-organize given a dispatching strategy: enforcing a maximum delay an individual passenger can experience may increase the average delay of all passengers. We quantitatively evaluate the SQ paradox in terms of the vehicle route flexibility, a measure of how many possible passengers may be served by a single vehicle. Our results theoretically revealed conditions underlying the novel paradox and may inform future designs of ridepooling algorithms to improve the service quality of the shared mobility ecosystem.

SOE 11.4   Wed 17:30   ZEU 260

Short walks enable fast and sustainable ride sharing — •Charlotte Lotze[1], Philip Marszal[1], Malte Schröder[1], and Marc Timme[1,2] — [1]Chair for Network Dynamics, Institute for Theoretical Physics & Center for Advancing Electronics Dresden (cfaed), Technical University of Dresden, 01069 Dresden — [2]Lakeside Labs, Klagenfurt, Austria

Ride sharing - the bundling of simultaneous trips of several people in the same on-demand vehicle - may help to reduce the carbon footprint of human mobility. Yet, predicting the efficiency and sustainability of ride-sharing systems is hard due to their complex collective dynamics. Compared to individual motorized vehicle transportation, standard door-to-door ride sharing services reduce the total distance driven per user. However, they also increase the average travel times due to several additional stops and thus detours to pick up or drop off users. Here we show that requiring some users to walk to nearby shared stops reduces detours for the buses and thus the time users wait for their bus and drive in the bus. These time savings might overcompensate the additional walk time for the users. In this way, dynamic stop pooling reduces the average travel time and may break the trade-off between distance driven and travel time prevailing in door-to-door ride sharing. For example, ride sharing providers may reduce the fleet size to save distance driven without longer travel times when users walk a short part of their trip. Dynamic stop pooling may thus enable more sustainable ride sharing services without compromising service quality.

SOE 11.5   Wed 17:45   ZEU 260

Long-range correlations in city systems — Yunfei Li[1], Jan W. Kantelhardt[2], Celine Rozenblat[3], and •Diego Rybski[1,4] — [1]Potsdam Institute for Climate Impact Research - PIK, Member of Leibniz Association, P.O. Box 601203, 14412 Potsdam, Germany — [2]Institute of Physics, Martin-Luther-University, Halle (Saale), Germany — [3]Institute of Geography and Sustainability, Faculty of Geoscience, University of Lausanne; — [4]Complexity Science Hub Vienna, Josefstädterstrasse 39, A-1090 Vienna, Austria

City systems are characterized by the functional organization of cities on a regional or country scale. While there is relatively good empirical and theoretical understanding of city size distributions, insights about their spatial organization remain on a conceptual level. Here we analyze empirically the correlations between the sizes of cities (in terms of area) across long distances. Therefore, we (i) define city clusters, (ii) obtain the neighborhood network from Voronoi cells, and (iii) apply a fluctuation analysis along all shortest paths. We find that most European countries exhibit long-range correlations but in several cases these are anti-correlations. In an analogous way we study a model inspired by Central Places Theory and find that depending on the level of disorder, both positive and negative long-range correlations can be simulated. We conclude that the interactions between cities of different sizes extend over distances reaching country scale.

SOE 11.6   Wed 18:00   ZEU 260

Mapping the social structure of cities with Diffusion Maps — •Thilo Gross — Helmholtz Institute for Functional Marine Biodiversity,, Oldenburg, Germany — Carl-von-Ossietzky University, Oldenburg, Germany — Alfred-Wegener Institute, Helmholtz Center for Marine and Polar Research, Bremerhaven, Germany

Human society is aggregating and accelerating, leading to a rapid growth of cities. It is well known that the social structure of cities is important for a long list of reasons, including livability, security, sustainability, and disaster resilience. Analysis of the social structure can profit from two complementary data sources: Census datasets provide a wealth of high quality, highly structured information, but are typically only available once per decade. By contrast novel sources of mobility data (e.g. from phone traces) offer an unstructured and indirect, but rich and near-real-time glimpse of human social behavior. In this talk I illustrate how diffusion maps, a network-driven analysis method, reveal important patterns in both of these types of data.

Networks in space and time – Exploring the physics in graph learning — •Ingo Scholtes — Julius-Maximilians-Universität Würzburg, Chair of Machine Learning for Complex Networks, Center for Artificial Intelligence and Data Science, D-97074 Würzburg, Germany

Network Analysis and Graph Neural Networks have become cornerstones for the application of data science and machine learning to complex systems. Addressing geometric machine learning in non-Euclidean data, I will introduce key concepts that help to apply deep learning to graphs. We cover message passing algorithms, convolutional filters, discrete Laplacians and neural representation learning and highlight relationships between graph learning and physics.

We finally explore how time-resolved data on dynamic networks helps us to better understand complex systems and how we can incorporate the time dimension into deep graph learning. We introduce De Bruijn Graph Neural Networks (DBGNNs), a novel time-aware graph neural network architecture. Our approach accounts for temporal-topological patterns that unfold via causal walks, i.e. temporally ordered sequences of links by which nodes can influence each other over time. We develop a graph neural network architecture that utilizes De Bruijn graphs of multiple higher orders to implement a message passing scheme that follows a non-Markovian dynamics, which enables us to learn patterns in the causal topology of complex networks.

SOE 15.1   Thu 10:00   ZEU 260

Understanding Braess' Paradox in power grids — •Benjamin Schäfer[1], Thiemo Pesch[2], Debsankha Manik[3], Julian Gollenstede[4], Guosong Lin[4], Hans-Peter Beck[4], Dirk Witthaut[2], and Marc Timme[5,3] — [1]Karlsruhe Institute of Technology — [2]Forschungszentrum Jülich — [3]Max Planck Institute for Dynamics and Self-Organization — [4]Clausthal University of Technology — [5]Technical University of Dresden

The ongoing energy transition requires power grid extensions to connect renewable generators to consumers and to transfer power among distant areas. The process of grid extension requires a large investment of resources and is supposed to make grid operation more robust. Yet, counter-intuitively, increasing the capacity of existing lines or adding new lines may also reduce the overall system performance and even promote blackouts due to Braess' paradox. Braess' paradox was theoretically modeled but not yet proven in realistically scaled power grids. Here, we present an experimental setup demonstrating Braess' paradox in an AC power grid and show how it constrains ongoing large-scale grid extension projects. We present a topological theory that reveals the key mechanism and predicts Braessian grid extensions from the network structure. These results offer a theoretical method to understand and practical guidelines in support of preventing unsuitable infrastructures and the systemic planning of grid extensions.

Evolutionary Optimization of networks towards complexity: role of link distribution and cross-consistency of network complexity measures — Archan Mukhopadhyay and •Jens Christian Claussen — University of Birmingham, UK

In a framework utilizing complexity measures for optimizing graphs and networks towards complexity, we use one complexity measure as fitness function of an evolutionary algorithm, and evaluate the resulting graphs through other complexity measures and network properties. We consider both evolution of graphs where the total number of links can evolve, as well as the case of constrained number of links. We find that in a certain range MAg optimizes towards degree-regular graphs, which is not observed for other complexity measures. We also investigate the consistency among the complexity measures on artificial and real-world datasets.

SOE 15.3   Thu 10:30   ZEU 260

On the role of deleterious mutant regime in steering long-term evolution — Nikhil Sharma[1], •Joachim Krug[2], and Arne Traulsen[1] — [1]Department of Evolutionary Theory, Max Planck Institute for Evolutionary Biology, 24306 Plön, Germany — [2]Institute for Biological Physics, University of Cologne, Köln, Germany

Evolutionary Graph Theory aims to understand the interplay of natural selection and genetic drift on spatial structures. A spatial structure is modeled as a graph with nodes representing asexually reproducing individuals, and edges dictate the interaction among these individuals. Based on the fixation probabilities of mutants on graphs, graphs are mainly categorised as amplifiers of selection and suppressors of selection. We study Moran Birth-death origin fixation dynamics on graphs, see https://doi.org/10.1073/pnas.2205424119. As expected, amplifiers of selection attain higher steady-state average fitness than the complete graph. However, we found that a suppressor of fixation, having a lower probability of fixing mutants regardless of their fitness values compared to the complete graph, beats the complete graph in the long term by attaining higher average fitness. It happens because of the suppressor's ability to reject deleterious mutants more efficiently. Similarly, an amplifier of fixation, a structure with a higher probability of fixing mutants regardless of their fitness values, attains lower steady-state average fitness. It happens because of the amplifier's poor ability to reject deleterious mutants. These two examples illustrate the importance of the deleterious mutant regime in steering long-term evolution, which, to our knowledge, has been overlooked in the literature.

SOE 16.1   Thu 11:00   ZEU 260

Individual bias and fluctuations in collective decision making: from algorithms to Hamiltonians — •Mariana Krasnytska[1,2,3], Petro Sarkanych[1,2], Luis Gómez-Nava[4,5], Abel Jonen[4], Pawel Romanczuk[4,5], and Yurij Holovatch[1,2,6] — [1]ICMP, NAS of Ukraine, Lviv, Ukraine — [2]L4 Collaboration Leipzig-Lorraine-Lviv-Coventry — [3]Université de Lorraine, Nancy, France — [4]Humboldt Universität zu Berlin, Germany — [5]Research Cluster of Excellence "Science of Intelligence", Berlin, Germany — [6]Coventry University, UK

We reconsider the spin model suggested recently to understand some features of collective decision making among higher organisms [A.T. Hartnett et al., Phys. Rev. Lett. 116 (2016) 038701]. Within the model, the state of an agent is described by the pair of variables corresponding to its opinion and a bias towards any of the opposing opinions. Collective decision making is interpreted within the non-linear voter model subject to social pressure. Here, we push such physical analogy further and give the statistical physics interpretation of the model via explicit calculation of its partition function. In such interpretation, the temperature serves as a measure of fluctuations that were not taken into account within the original formulation. We find exact solutions for the thermodynamics and dynamics of the model on the complete graph. We discuss the advantages and flaws of such an approach as well as its utility in understanding the impact of population heterogeneity, type of local interaction and fluctuations in collective decision making.

SOE 16.2   Thu 11:15   ZEU 260

Following the information footprint of firms — •Edward Lee[1], Alan Kwan[2], Rudolf Hanel[1], Anjali Bhatt[3], and Frank Neffke[1] — [1]Complexity Science Hub Vienna, Austria — [2]Hong Kong University, China — [3]Harvard Business School, Boston, USA

What a firm does is more revealing than how much it makes, but firms are often described with metrics for economic size. Instead, we characterize what firms know in terms of what they read, the information footprint, using a data set of hundreds of millions of records of news articles accessed by employees in millions of firms. We discover that the reading habits of firms are of limited diversity. This observation suggests that information constraints act on firms. To understand how, we relate a firm's information footprint with economic variables, showing that the former grows superlinearly with the latter. This exaggerates the classic Zipf's law inequality in the economic size of firms and reveals an economy of scale with respect to information. Second, we reconstruct the topic space firms inhabit, finding that the space resembles a tangled "hairball" with a few dense knots of topics and many specialized strands sticking out. Some of the topics are ubiquitous, indicating inescapable demand regardless of firm size. Finally, we connect these pieces in a model of how firms grow in the space of topics. We show that diversity in firm reading habits can be explained by a mixed strategy of local exploration and recurrent exploitation on the topic graph. This shows that the constraints that the space of ideas imposes on firm growth provide a useful and new perspective on firm development.

SOE 16.3   Thu 11:30   ZEU 260

Influence of confirmation biases on collective decision-making in fluctuating environments — •Clémence Bergerot[1,2], Wolfram Barfuss[3], and Pawel Romanczuk[2,4] — [1]Charité - Universitätsmedizin Berlin, Einstein Center for Neurosciences Berlin, Germany — [2]Humboldt Universität zu Berlin, Germany — [3]Tübingen AI Center, University of Tübingen, Germany — [4]Research Cluster of Excellence "Science of Intelligence", Berlin, Germany

In experimental studies of decision-making, it is now established that human agents tend to update confirmatory information with a higher weight than disconfirmatory information. This confirmation bias has been modeled within a reinforcement learning framework, using asymmetric updating of prediction errors. Interestingly, such a bias has been suggested to enhance individual performance in a wide range of multi-armed bandit tasks. However, little is known about the impact of the confirmation bias on collective performance. In order to characterize the circumstances that make this bias beneficial or detrimental to collective decision-making, we develop a multiagent model in which reinforcement learning agents can observe others' actions and rewards, and update this information asymmetrically. With agent-based simulations, we seek to understand how the confirmation bias affects collective performance in changing environments, and how network topology modulates this effect. We also study our multiagent system in the deterministic limit [W. Barfuss et al., Phys. Rev. E, 99(4) (2016) 043305], which allows us to gain an analytical understanding of the biased learning dynamics.

SOE 16.4   Thu 11:45   ZEU 260

Population waves in sessile organisms — •Niraj Kushwaha and Edward Lee — Complexity Science Hub Vienna, Josefstädter Straße 39, 1080 Vienna, Austria

The mathematical laws of life manifest scaling regularities such as the relationship between mass and metabolism for the smallest to the largest organisms on Earth. These laws lack essential components representing interaction between organisms while sharing limited resources. Once accounted for, these components can bring significant variation to the predicted demographic laws using just metabolic scaling theory and can give mathematical descriptions for observed ecological phenomena. The oscillations in population number, where spikes in the number of organisms of a specific size propagate from small to large organisms is an example of such a phenomena. Here, we incorporate spatial competition and resource variation in a differential equation model for the population dynamics of sessile organisms. We use analytic and numerical tools to solve the corresponding equations and to characterize the form of instabilities that generate the oscillations, which we use to identify hidden mechanisms that may drive instabilities in ecological systems such as forests. As a result, we may be able to identify the most significant factors that affect the stability of an ecosystem corresponding to resource fluctuations that may become more prominent with climate change.

SOE 16.5   Thu 12:00   ZEU 260

The role of escape angle in predator-prey interactions: the emergence of fountain effect — •Palina Bartashevich[1,2] and Pawel Romanczuk[1,2] — [1]Institute for Theoretical Biology, Humboldt-Universität zu Berlin, 10115 Berlin, Germany — [2]Excellence Cluster Science of Intelligence, Technische Universität Berlin, 10587 Berlin, Germany

Empirical studies of fish schooling widely described the variety of ways in which fish escape to reduce the chances of being caught by a predator while trying at the same time to stay in a group. The "fountain effect" is one such evasion maneuver that allows small fish to out-maneuver the fast-moving predator by swimming away at a constant angle determined by the rear limit of the visual cone [1]. Our spatially-explicit agent-based numerical simulations recover the same optimal prey-fleeing angle as confirmed by empirical studies. Moreover, our results show that the fleeing angle not only minimizes the distance to the predator but creates a sequence of information flows that best facilitates the information propagation throughout the collective. This finding highlights the direct role of social interaction in the emergence of the fountain effect which was not addressed before. We also address the questions of how the stimulus characteristics such as the initial predator angle of attack and distance to the first responders affect the response as a whole, allowing us to make biological predictions.

[1] Hall SJ, Wardle CS and MacLennan DN 1986. Predator evasion in a fish school: test of a model for the fountain effect. Mar. Biol. 91: 143-148.

SOE 17: Evolutionary Game Theory (joint session SOE/DY)

Time: Thursday 15:00–15:30   Location: ZEU 260

SOE 17.1   Thu 15:00   ZEU 260

Bet hedging in populations evolving in fluctuating environments — Rubén Calvo[1] and •Tobias Galla[2] — [1]Instituto Carlos I de Física Téorica y Computaciona, and Departamento de Electromagnetismo y Física de la Materia, Facultad de Ciencias, Universidad de Granada, 18071 Granada, Spain — [2]Instituto de Física Interdisciplinar y Sistemas Complejos IFISC (CSIC-UIB), Campus Universitat de les Illes Balears, E-07122 Palma de Mallorca, Spain

Bet-hedging strategies are strategies aimed at reducing risk in the face of uncertainty. For example, biological organisms face uncertain time-varying environmental conditions, such as dry years versus wet years. Similarly, future conditions in financial markets or other social systems are often unknown. Traditional bet-hedging theory shows that a reduction of the variance of an agent's payoff may increase their success even when their mean payoff is also reduced. Bet-hedging strategies are often built on maximum growth. Here instead, we ask how a mutant invading a resident wildtype population can maximise its chances of taking over the population (i.e., the fixation probability of the mutant). We consider a birth-death dynamics in fluctuating environments, and show that, depending on the distribution of payoffs across environmental states, a reduction in variance can either be beneficial or detrimental to the mutant. We establish conditions for either scenario to be realised, and show how this is related to the skewness of the payoff distribution.

SOE 17.2   Thu 15:15   ZEU 260

Hawk Dove Game on Networks with Continuous Populations — •Lennart Gevers[1,2], Tobias Wand[1,2], and Svetlana V. Gurevich[1,2] — [1]Institute for Theoretical Physics, University of Münster, Wilhelm-Klemm-Straße 9, D-48149 Münster, Germany — [2]Center for Nonlinear Science (CeNoS), University of Münster, Corrensstrasse 2, D-48149 Münster, Germany

Evolutionary game theory is a population-based approach to game theoretical scenarios by analyzing the evolution of populations resembling competing strategies.

We expand the classical model analysed by (1), which assumes that no spatial or social segregation of populations occurs, with a network-based approach to the hawk-dove game which models the ability of contestants to migrate between neighboring realizations of the game by adapting different migratory behaviors. Our model reveals that competitive and cooperative populations can show preferred strategies on how to spatially organize on such territories.

Furthermore, we find that the resulting outcomes of the participating species diverge from the original model with increasing mobility of species.

SOE 18: Social Systems, Opinion and Group Dynamics I

Time: Thursday 15:30–16:30   Location: ZEU 260

SOE 18.1   Thu 15:30   ZEU 260

Homophily-based social group formation in a spin-glass self-assembly framework — •Jan Korbel[1,2], Simon Lindner[1,2], Tuan Pham[1,2,3], Rudolf Hanel[1,2], and Stefan Thurner[1,2,4] — [1]Section for the Science of Complex Systems, CeMSIIS, Medical University of Vienna, Spitalgasse 23, A-1090, Vienna, Austria — [2]Complexity Science Hub Vienna, Josefstädterstrasse 39, A-1080, Vienna, Austria — [3]Niels Bohr Institute, Blegdamsvej 17, 2100 Copenhagen, Denmark — [4]4Santa Fe Institute, 1399 Hyde Park Road, Santa Fe, NM, 87501, USA

Homophily, the tendency of humans to attract each other when sharing similar features, traits, or opinions, has been identified as one of the main driving forces behind the formation of structured societies. Here we ask to what extent homophily can explain the formation of social groups, particularly their size distribution. We propose a spin glass-inspired framework of self-assembly, where opinions are represented as multidimensional spins that dynamically self-assemble into groups; individuals within a group tend to share similar opinions (intra-group homophily), and opinions between individuals belonging to different groups tend to be different (inter-group heterophily). We compute the associated non-trivial phase diagram by solving a self-consistency equation for magnetization (combined average opinion). Below a critical temperature are two stable phases: one ordered with non-zero magnetization and large clusters, the other disordered with zero magnetization and no clusters. The system exhibits a first-order transition to the disordered phase.

SOE 18.2   Thu 15:45   ZEU 260

Heider balance observed for multidimensional attributes — Joanna Linczuk[1], Piotr J Górski[1], Boleslaw K Szymanski[2,3], and •Janusz A Hołyst[1] — [1]Faculty of Physics, Warsaw University of Technology, Warsaw, Poland — [2]Social Cognitive Networks Academic Research Center, Rensselaer Polytechnic Institute, Troy, USA — [3]Społeczna Akademia Nauk, Łódź, Poland

The majority of measured and studied social interactions arise from dyadic relations. An exception is the Heider Balance Theory (HBT) that postulates the existence of a social triad dynamics. Most of the past literature on HBT focuses on opinions about a single topic in such triads. In contrast, we study opinions of university students on a multidimensional set of topics. We discover limits of HBT observability by considering a novel agent-based model that accounts for: (i) multiple topics on opinions of individual students, (ii) influence of such opinions on dyadic relations (social link polarization), and (iii) influence of triadic relations on individual's sets of opinions on all topics. Using longitudinal records of university student behavior, we create a coevolving social network on which we introduce models of student interactions. We validate the model by showing that the triadic influence is empirically measurable for static and dynamic observables in this network. However, when we consider opinions on each topic separately from the others, the influence of triadic interactions is indistinguishable from the noise.

Evolution of signed relations due to principles of structural balance and status theories — •Adam Sulik[1], Piotr J. Górski[1], Georges Andres[2], Giacomo Vaccario[2], and Janusz Hołyst[1] — [1]Faculty of Physics, Warsaw University of Technology — [2]Chair of System Design, ETH Zürich

One of the issues of social science is the analysis of why and how human relationships are formed. The causes of these phenomena are explained by structural balance theory and status theory, among others. Although the structural balance model by Antal et al. is a breakthrough in modeling the formation of social relationship structures, but by the diverse nature of positive and negative relationships in real-world social networks, it is unable to capture a complete picture of the relationships between users of different online communities. In addition to stability as understood by Heider's hypothesis, which is contained in structural balance theory, dynamics based on social status should also be taken into account.

We present two new models: an extended model of structural balance on directed networks and a model combining dynamics of structural balance and status theories. Presented numerical simulation results are consistent with analytical expectations. The theoretical observations have been verified on real networks, where the effect of status on the relationship between users of the studied websites has been noticed.

SOE 18.4　Thu 16:15　ZEU 260

Analysing the structure of opinion spaces — •Eckehard Olbrich[1] and Sven Bansich[2] — [1]Max Planck Institute for Mathematics in the Sciences — [2]Karlsruhe Institute for Technology

Data for understanding opinion dynamics arise in a variety of contexts: from voting patterns and multi-item surveys to hashtags use and users participation in different online groups. Despite their different origins they have a similar mathematical structure: a matrix with rows representing members of a population and columns representing e.g. items of a survey or political issues. Recently various novel methods have been proposed to make sense of correlational patterns in such data in order to identify them with cultural schemata [3] or dimensions of an underlying political space [1]. In this contribution we will compare different such methods including (1) issue bundles [1], (2) latent space models [2] and (3) correlational class analysis [3]. We will discuss their advantages and disadvantages using data sets from a survey on attitudes towards Corona measures and from Swiss public votes.

SOE 19.1　Thu 16:45　ZEU 260

Evidence-based policy-making in sports funding using a data-driven optimization approach — •Jan Hurt[1], Liuhuaying Yang[1], Johannes Sorger[1], Thomas J. Lampoltshammer[2], Nike Pulda[5], Ursula Rosenpichler[5], Stefan Thurner[3,1,4], and Peter Klimek[3,1] — [1]Complexity Science Hub, Vienna, Austria — [2]University for Continuing Education Krems, Krems, Austria — [3]Section for Science of Complex Systems, CeMSIIS, Medical University of Vienna, Vienna, Austria — [4]Santa Fe Institute, Santa Fe, NM, USA — [5]Austria

Many European countries face rising obesity rates among children. Access to sports facilities depends on multiple factors, such as geographic location, proximity to population centers, budgetary constraints, and other socio-economic covariates. Here we show how an optimal allocation of government funds towards sports facilitators (e.g. sports clubs) can be achieved in a data-driven simulation model that maximizes children's access to sports facilities. We find a characteristic sub-linear relationship between the number of active club members and the budget, which depends on the socio-economic conditions of the clubs' districts. In the model, we evaluate different funding strategies. We show that an optimization strategy outperforms a naive approach by up to 115% for 5 million Euros of additional funding to attract children to sports clubs. Our results suggest that the impact of public funding strategies can be substantially increased by tailoring them to regional socio-economic characteristics in an evidence-based and individualized way.

SOE 19.2　Thu 17:00　ZEU 260

Fitting Polling Data with a Minimal Voter Model — •Philipp G. Meyer and Ralf Metzler — Institute for Physics and Astronomy, University of Potsdam, Potsdam-Golm, Germany

The numerous versions of the voter model have various applications in opinion dynamics. We consider a two-state voter model for approval rates measured by political polls. We find that three features are essential for a realistic model.

Firstly, adding zealots (that never change their state) on both sides, prevents consensus. This behavior corresponds to the observations in the polling of parties. Such a voter model can be regarded as a stochastic process in a confining potential. Secondly, the measurement uncertainty of the polls has to be taken into account. It can be modeled by additive noise. Finally, we identify short-time autocorrelations between the steps, which lead to a higher variance than expected from the naive model.

We use techniques developed for voter models along with methods from stochastic processes for fitting data from political polls to the adapted voter model.

Reddit Revisited — João Pinheiro Neto and •Riccardo Carlucci — Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen

Social media research using Reddit as a data source has greatly increased in recent years. Researchers have used Reddit to study a wide variety of issues such as political polarization, depression, astroturfing, and market manipulation to name a few.

This is primarily made possible by the Pushshift project, which offers an almost-complete dataset of Reddit. Such a degree of completeness is unique among major social media platforms, and bypasses sampling issues that may otherwise make large-scale analysis challenging.

However, a considerable fraction of Reddit research uses data which is now already a few years old. At the same time Reddit has been steadily growing, both in terms of content and userbase. For example: half of all threads and comments ever created date back to the last 2 years, despite Reddit being more than 15 years old. In addition, the global COVID-19 pandemic is known to have affected users' social media consumption.

Here we present an updated overview of Reddit as seen through the Pushshift dataset, using data up to August 2022. First we discuss the evolution over time of various statistical observables from a large-scale perspective. Next, we study the life cycle of subreddits, users, and submissions. Finally, we study the response of individual subreddits to external events.

SOE 19.4　Thu 17:30　ZEU 260

Topological insulators and enhancers in complex systems under generic problem-solving dynamics — •Johannes Falk[1], Edwin Eichler[2,3], Katja Windt[3,1], and Marc-Thorsten Hütt[1] — [1]Constructor University, Bremen, Germany — [2]EICHLER Consulting AG, Weggis, Switzerland — [3]SMS Group GmbH, Düsseldorf, Germany

The collective coordination of distributed tasks in a complex system can be represented as decision dynamics on a graph. For the case of social differentiation tasks, experimental studies on human subject networks demonstrated that shortcuts in small-world networks can speed up the finding of global solutions. Using a computational model, we illustrate that this is not always true: Depending on the actors' reasoning and the length of the added links, shortcuts can serve as topological enhancers that speed up the finding of a solution, but also as topological insulators that make the network more difficult to solve. Our findings have implications for situations where in distributed decision systems regional solutions emerge which are globally incompatible such as e.g. known from the emergence of standards.

SOE 19.5　Thu 17:45　ZEU 260

The emergence of echo-chambers in spatial collective estimation with limited connectivity — •Mohsen Raoufi[1], Heiko Hamann[2], and Pawel Romanczuk[1] — [1]Department of Biology, Humboldt Universität zu Berlin, Berlin, Germany — [2]Department of Computer and Information Science, University of Konstanz, Konstanz, Germany

Using a method inspired by the wisdom-of-crowds effect [1] we study the speed-vs-accuracy tradeoffs (SAT) in a spatial collective estimation scenario. In this work, we highlight the link between the speed-vs-accuracy and exploration-vs-exploitation tradeoffs. Here we elaborate upon the role of network connectivity in the tradeoffs. On one hand, the network structure influences the dynamics of consensus-making in collectives. On the other, agents modify the network based on their opinion. We model this behaviour of agents based on homophily– the tendency of nodes to establish links with other like-minded nodes. This co-evolution of the network structure and opinion of agents shows rich dynamics,

even for spatial networks. In particular, we demonstrate that in systems with limited connectivity, homophily can lead to the emergence of echo-chambers, which prevents consensus. Our focus for future work is to provide solutions within the capability of agents to bring global connectivity and thus the consensus back to the collective. [1] Raoufi, M., et. al. Speed-vs-Accuracy Tradeoff in Collective Estimation: An Adaptive Exploration-Exploitation Case. In 2021 International Symposium on Multi-Robot and Multi-Agent Systems (MRS) (pp. 47-55). IEEE.

Invited Talk   SOE 21.1   Fri 9:30   ZEU 260
Marginal Stability and Excess volatility in firm networks — •Jean-Philippe Bouchaud — CFM — Academie des Sciences
Will a large economy be stable? Building on Robert May's original argument for large ecosystems, we conjecture that evolutionary and behavioural forces conspire to drive the economy towards marginal stability. We study networks of firms in which inputs for production are not easily substitutable, as in several real-world supply chains. We argue that such networks generically become dysfunctional when their size increases, when the heterogeneity between firms becomes too strong, or when substitutability of their production inputs is reduced. At marginal stability and for large heterogeneities, we find that the distribution of firm sizes develops a power-law tail, as observed empirically. Crises can be triggered by small idiosyncratic shocks, which lead to avalanches of defaults characterized by a power-law distribution of total output losses. This scenario would naturally explain the well-known small shocks, large business cycles puzzle, as anticipated long ago by Bak, Chen, Scheinkman, and Woodford.

SOE 22: Financial Markets and Risk Management II

SOE 22.1   Fri 10:00   ZEU 260
Microscopic origin of the persistent order flows: microscopic data analysis — Yuki Sato[1] and •Kiyoshi Kanazawa[2] — [1]University of Tsukuba, Tsukuba, Japan — [2]Kyoto University, Kyoto, Japan
In financial markets, it is a stylised fact that the order flow exhibits persistence (or called the long-range correlation, LRC): if you observe a buy (sell) order, you will likely observe a buy (sell) order even in future. This character can be quantified as the power-law decay of the order-sign autocorrelation function $C(\tau) \propto \tau^{-\gamma}$. In explaining the origin of the LRC, the order-splitting hypothesis was proposed as a promising theory. Further, Lillo, Mike, and Farmer proposed a minimal stochastic model of order-splitting traders in 2005, showing a quantitative prediction connecting the relationship between the microscopic and macroscopic behaviour. However, the LMF quantitative prediction has not yet been verified in the lack of appropriate microscopic datasets. In this talk, we solve this long-standing econophysics problem by analysing a huge microscopic dataset in the Tokyo Stock Exchange market. We apply a strategy clustering to identify the set of splitting traders and then measure the power-law exponent α in the metaorder-length distribution for splitting traders. We finally verify the quantitative prediction of the LMF model ($\gamma = \alpha - 1$) by providing the scatterplot between α and γ.

SOE 22.2   Fri 10:15   ZEU 260
Collective Effects Relative to the Collective Market Motion in Financial Markets — •Anton J. Heckens and Thomas Guhr — Universität Duisburg-Essen, Lotharstr. 1, 47048 Duisburg
Financial markets are usually non-stationary and their dynamics is dominated by strong collective effects. We introduce new measures for collectivity derived from covariance and correlation matrices [1]. The largest eigenvalue of covariance and correlation matrices corresponds to the collective motion of the whole system. By removing the collective motion of the system as a whole, we detect a remaining collectivity which corresponds to the industrial sectors. We use risk-phase diagrams to compare the remaining collectivity with the market collectivity. The time evolution of the remaining collectivity shows a remarkable property as a potential precursor for the Lehman crash in 2008. As of 2015/2016 the collectivity in the US stock markets changed fundamentally. It is connected to trend shifts from smaller mean covariances or correlations to larger ones, especially in recent years. Hence, this new kind of collectivity is connected to systemic instabilities which appear more often in recent years according to our new measures.
[1] A. J. Heckens and T. Guhr, New Collectivity Measures for Financial Covariances and Correlations, Physica A: Statistical Mechanics and its Applications 604, 127704 (2022), arXiv:2202.00297.

SOE 22.3   Fri 10:30   ZEU 260
Quantifying the exposure of banking system to the propagation of supply chain shocks in large scale firm-level production networks — •Zlata Tabachová[1], Christian Diem[1], András Borsos[1,2], and Stefan Thurner[1] — [1]Complexity Science Hub Vienna, Josefstädter Strasse 39, A-1080 Vienna, Austria — [2]Central Bank of Hungary, Szabadság tér 9, 1054 Budapest, Hungary
The credit risk assessment is core to sound banking business and financial stability. Traditional credit risk and macro-prudential stress testing models using solely node-level financial information can not take the risk of supply chain (SC) contagion into account, leading to potential underestimation of risks. Recent crises such as pandemic or natural disasters have drastically revealed that the propagation of shocks along SCs can potentially lead to large financial losses of firms. Based on a unique country wide dataset, we simulate how an initial failure of firms spread along the SC leading to additional firm defaults and losses to banks. We first define a financial systemic risk index (FSRI) of a firm that measures financial losses due to the SC disruptions caused by failure of that firm. We show that a small fraction of firms pose sizeable risks to the financial system, affecting up to 16% of overall bank equity. Second, we calculate expected losses, value at risk and expected shortfall of banks with and without supply network contagion. Our simulations show that these risk measures can be underestimated by a factor of 4. This indicates that it is crucial for regulators financial systemic risk assessment to monitor SC shock propagation.

SOE 23: Economic Models

Stochastics in action: how to generate profit by exploiting the inefficiencies of the soccer betting market — •Ralph Stömmer — Private researcher, Ottobrunn, Germany
In economy, markets are denoted as efficient when it is impossible to systematically generate profits which outperform the average. In the past years, the concept has been tested in other domains such as the growing sports betting market. Surprisingly, despite its large size and its level of maturity, sports betting shows traits of inefficiency. The anomalies indicate the existence of strategies which slightly shift betting from a game of chance towards a game of skill.

   This presentation shows an example for an inefficiency detected in the German soccer betting TOTO 13er Wette, which is operated by state-run lottery agen-

cies. Gamblers have to guess the outcome (win, draw, loss) of 13 soccer matches listed on a lottery tip. Applying stochastic methods, a recipe is presented to determine tendencies for single match outcomes, currently resulting in hit rates > 47,7%. More important, the recipe provides the number of lottery tips required to achieve a specific number of strikes (number of correct match forecasts per lottery tip) for a given level of safety (for instance 99,9%). As additional benefit, a useful approximation is derived with Stirling*s formula to cope with large numbers in hypergeometric distributions, valid under certain constraints.

Overall, the strategy does lead to price expectations exceeding the aggregated lottery fees, resulting in consistent profits.

Assessing the impact of extreme weather events on the global market for staple food — •Nkongho Ayuketang Arreyndip[1] and Ebobenow Joseph[2] — [1]Institute of Applied Geosciences, Technical University of Darmstadt, Darmstadt, Germany — [2]Physics Department, University of Buea, Cameroon.

The impacts of increasing extreme weather events under future warming may exacerbate global food insecurity. Assessing the economic impact of these disasters in the agricultural sector is critical for early mitigation planning. We model the impacts of extreme weather events by perturbing the agricultural sectors of some breadbasket regions (USA, EU, and China) with a uniform forcing for both single and concurrent extreme weather event scenarios. We consider forcing data from the 2018 Summer European heatwave. This heatwave simultaneously affected multiple Northern-hemisphere mid-latitude locations. We compute and compare the production and consumption value losses in the corn, rice, wheat, soybean, and other agricultural sectors using the FAO data and an agent-based economic model Acclimate. We show that simultaneous extreme weather events can exacerbate the loss of value of agricultural production relative to single extreme weather events. The highest global repercussion is felt in the rice sector compared to other sectors under study for concurrent extreme events scenarios involving China. Moreover, the global commodity market is hardest hit when regions that are major producers of that commodity are affected by extreme weather events such as corn for the USA, wheat for Europe, rice for Southeast Asia, and soybean for Brazil.

SOE 23.3　Fri 11:30　ZEU 260

Forecasting power grid frequency using transformers — •Hadeer El Ashhab and Benjamin Schäfer — Institute for Automation and Applied Informatics, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany

The power grid frequency is the central observable in power system control, as it measures the balance of electrical supply and demand. A reliable frequency forecast can facilitate rapid control actions and may thus greatly improve power system stability. Here, we develop a forecasting model based on transformers and investigate its performance on data recorded in different power grids.

SOE 23.4　Fri 11:45　ZEU 260

Measuring the Robustness of Production Networks — •Tobias Reisch[1], Georg Heiler[1,2], Christian Diem[1], Peter Klimek[1,3], and Stefan Thurner[1,3,4] — [1]Complexity Science Hub Vienna, Vienna, Austria — [2]Institute of Information Systems Engineering, TU Wien, Vienna, Austria — [3]Section for Science of Complex Systems, CEMSIIS, Medical University of Vienna, Vienna, Austria — [4]Santa Fe Institute, Santa Fe, NM, USA

In modern economies manufacturing happens typically along supply chains. These supply chains intersect and overlap, forming complex networks of production. The failure of single firms in production networks can cause large disruptions. To assess the robustness of economic networks, we develop a firm-level shock spreading model that takes node-specific production functions into account. We define the Economic Systemic Risk Index (ESRI) of a firm as the size of the production interruptions the firm's initial failure causes. First, we apply the new index to the empirical production network of Hungary based on VAT data. Second, we use mobile phone data to reconstruct the production network of a second country that cannot be disclosed. For both countries we find a core of less than 100 high-systemic risk firms that can affect more than 20% of the respective economy. The high-systemic risk core cannot be identified by firm-size. We discuss the network properties that give rise to the observed patterns of systemic risk. Our results contribute to the broader field of network resilience with the introduction of node specific shock spreading dynamics.

Overview of Invited Talks and Sessions
(Lecture halls HSZ 101, HSZ 103, HSZ 201, HSZ 204, and HSZ 304; Poster P2/2OG, P2/3OG, and P2/4OG)

Tutorial "Physics Meets Machine Learning (joint session DY/TT)"

TT 1.1	Sun	16:00–16:45	HSZ 01	**Machine Learning for Quantum Technologies** — •Florian Marquardt
TT 1.2	Sun	16:45–17:30	HSZ 01	**The Unreasonable Effectiveness of Gaussians in the Theory of Deep Neural Networks** — •Zohar Ringel
TT 1.3	Sun	17:30–18:15	HSZ 01	**Computing learning curves for large machine learning models using the replica approach** — •Manfred Opper

Plenary Talk

PLV X	Thu	14:00–14:45	HSZ 02	**Single-electron-spin-resonance detection by microwave photon counting** — •Patrice Bertet

Invited Talks of the joint Symposium SKM Dissertation Prize 2023 (SYSD)
See SYSD for the full program of the symposium.

SYSD 1.1	Mon	9:30–10:00	HSZ 04	**Diffusion of antibodies in solution: from individual proteins to phase separation domains** — •Anita Girelli
SYSD 1.2	Mon	10:00–10:30	HSZ 04	**Intermediate Filament Mechanics Across Scales** — •Anna V. Schepers
SYSD 1.3	Mon	10:30–11:00	HSZ 04	**Ultrafast Probing and Coherent Vibrational Control of a Surface Structural Phase Transition** — •Jan Gerrit Horstmann
SYSD 1.4	Mon	11:00–11:30	HSZ 04	**Electro-active metasurfaces employing metal-to-insulator phase transitions** — •Julian Karst
SYSD 1.5	Mon	11:30–12:00	HSZ 04	**The role of unconventional symmetries in the dynamics of many-body systems** — •Pablo Sala

Invited Talks of the joint Symposium Ultrafast Excitation Pathways of Quantum Materials (SYUE)
See SYUE for the full program of the symposium.

SYUE 1.1	Wed	9:30–10:00	HSZ 01	**Dynamics and control in quantum materials using multi-terahertz spectroscopy** — •Richard Averitt
SYUE 1.2	Wed	10:00–10:30	HSZ 01	**Accessing the nonthermal phonon populations in 2D materials with femtosecond electron diffuse scattering** — •Hélène Seiler
SYUE 1.3	Wed	10:30–11:00	HSZ 01	**Exciting potentials – Exploring the realms of ultrafast phase transitions** — •Laurenz Rettig
SYUE 1.4	Wed	11:15–11:45	HSZ 01	**Sub-cycle multidimensional spectroscopy of strongly correlated materials** — •Olga Smirnova
SYUE 1.5	Wed	11:45–12:15	HSZ 01	**Witnessing many-body entanglement in light-driven quantum materials** — •Matteo Mitrano
SYUE 1.6	Wed	12:15–12:45	HSZ 01	**Optical responses of photoexcited materials: from parametric amplification to photoinduced superconductivity** — •Eugene Demler

Invited Talks of the joint Symposium Topology in Quantum and Classical Physics – From Topological Insulators to Active Matter (SYQC)

See SYQC for the full program of the symposium.

SYQC 1.1	Wed	15:00–15:30	HSZ 01	**Topological magnetic whirls for computing** — •Karin Everschor-Sitte
SYQC 1.2	Wed	15:30–16:00	HSZ 01	**Topological waves from solids to geo/astrophysical flows** — •Pierre Delplace
SYQC 1.3	Wed	16:00–16:30	HSZ 01	**Topological Phase Transitions in Population Dynamics** — •Erwin Frey
SYQC 1.4	Wed	16:45–17:15	HSZ 01	**Topological invariants protect robust chiral currents in active matter** — •Evelyn Tang
SYQC 1.5	Wed	17:15–17:45	HSZ 01	**Topological defects in biological active matter** — •Amin Doostmohammadi

Invited Talks of the joint Symposium Real-Time Measurements of Quantum Dynamics (SYQD)

See SYQD for the full program of the symposium.

SYQD 1.1	Thu	9:30–10:00	HSZ 01	**Real-time measurement and control of spin dynamics in quantum dots** — •Seigo Tarucha
SYQD 1.2	Thu	10:00–10:30	HSZ 01	**Quantum Dot arrays for Quantum Information Transfer** — •Gloria Platero
SYQD 1.3	Thu	10:30–11:00	HSZ 01	**Optical Detection of Real-Time Quantum Dynamics in Quantum Dots** — •Martin Geller
SYQD 1.4	Thu	11:30–12:00	HSZ 01	**Cooper Pair Splitting in Real-Time** — •Christian Flindt
SYQD 1.5	Thu	12:00–12:30	HSZ 01	**Trajectory-based detection in stochastic and quantum thermodynamics** — •Jukka Pekola

Invited Talks of the joint Symposium Topological Superconductor-Magnet Heterostructures (SYTS)

See SYTS for the full program of the symposium.

SYTS 1.1	Thu	15:00–15:30	HSZ 01	**Blending of superconductivity and magnetism via topological solitons** — •Christos Panagopoulos
SYTS 1.2	Thu	15:30–16:00	HSZ 01	**Topological landscaping in magnet-superconductor heterostructures** — •Sebastián A. Díaz
SYTS 1.3	Thu	16:00–16:30	HSZ 01	**Experimental study of minigaps and end states in bottom-up designed multi-orbital Shiba chains** — •Jens Wiebe
SYTS 1.4	Thu	16:45–17:15	HSZ 01	**Quantum spins and hybridization in artificially-constructed chains of magnetic adatoms on superconducting 2H-NbSe$_2$** — •Katharina J. Franke
SYTS 1.5	Thu	17:15–17:45	HSZ 01	**Braiding of Majorana zero modes** — •Stephan Rachel

Invited Talks of the joint Symposium Physics of van der Waals 2D Heterostructures (SYHS)

See SYHS for the full program of the symposium.

SYHS 1.1	Fri	9:30–10:00	HSZ 01	**Novel moiré excitons and ultrafast optical dynamics in van der Waals 2D heterostructures** — •Steven G. Louie
SYHS 1.2	Fri	10:00–10:30	HSZ 01	**Interaction induced magnetism in 2D semiconductor moiré superlattices** — •Xiaodong Xu
SYHS 1.3	Fri	10:30–11:00	HSZ 01	**Ions in tight places: intercalation and transport of ions in van der Waals heterostructures** — •Irina Grigorieva
SYHS 1.4	Fri	11:15–11:45	HSZ 01	**Spin-orbit proximity in van der Waals heterostructures** — •Felix Casanova
SYHS 1.5	Fri	11:45–12:15	HSZ 01	**Plethora of many-body ground states in magic angle twisted bilayer graphene** — •Dmitri Efetov

Invited Talks of the Focus Session "Physics Meets ML I - Machine Learning for Complex Quantum Systems (joint session DY/TT)"

TT 2.1	Mon	9:30–10:00	HSZ 03	**Enhanced variational Monte Carlo for Rydberg atom arrays** — •Stefanie Czischek
TT 2.2	Mon	10:00–10:30	HSZ 03	**Data mining the output of quantum simulators – from critical behavior to algorithmic complexity** — •Marcello Dalmonte
TT 2.3	Mon	10:30–11:00	HSZ 03	**Reinforcement learning for quantum technologies** — •Florian Marquardt
TT 2.4	Mon	11:00–11:30	HSZ 03	**Machine learning of phase transition** — •Christof Weitenberg

Invited Talks of the Focus Session "Physics Meets ML II - Understanding Machine Learning as Complex Interacting Systems (joint session DY/TT)"

TT 13.1	Mon	15:00–15:30	ZEU 250	**The challenge of structured disorder in statistical physics** — •Marc Mezard
TT 13.2	Mon	15:30–16:00	ZEU 250	**The emergence of concepts in shallow neural-networks** — •Elena Agliari
TT 13.3	Mon	16:00–16:30	ZEU 250	**Adaptive Kernel Approaches to Feature Learning in Deep Neural Networks** — •Zohar Ringel
TT 13.5	Mon	17:00–17:30	ZEU 250	**Analysing the dynamics of message passing algorithms** — •Manfred Opper
TT 13.6	Mon	17:30–18:00	ZEU 250	**Deep Learning Theory Beyond the Kernel Limit** — •Cengiz Pehlevan

Invited Talks of the Focus Session "New Perspectives for Adiabatic Demagnetization Refrigeration in the Kelvin and sub-Kelvin Range (joint session TT/MA)"

TT 19.1	Tue	9:30–10:00	HSZ 03	**Self-cooling molecular spin quantum processors** — •Marco Evangelisti
TT 19.2	Tue	10:00–10:30	HSZ 03	**Triangular rare-earth borates for milli-Kelvin adiabatic demagnetization refrigeration** — •Philipp Gegenwart
TT 19.3	Tue	10:30–11:00	HSZ 03	**A millikelvin scanning tunnelling microscope in ultra-high vacuum with adiabatic demagnetisation refrigeration** — •Ruslan Temirov
TT 19.4	Tue	11:15–11:45	HSZ 03	**ADR cryostats in low temperature physics and their applications** — •Doreen Wernicke
TT 19.5	Tue	11:45–12:15	HSZ 03	**Frustrated dipolar materials for low-temperature magnetic refrigeration** — •Mike Zhitomirsky

Invited Talks of the Focus Session "Unconventional Transport Phenomena in Low-Dimensional Superconducting Heterostructures"

TT 27.1	Wed	9:30–10:00	HSZ 03	**Superconducting diode effect in Rashba superlattice** — •Teruo Ono
TT 27.2	Wed	10:00–10:30	HSZ 03	**Quasiparticle-based and Cooper-pair based superconducting diodes** — •Maria Spies
TT 27.3	Wed	10:30–11:00	HSZ 03	**Non-reciprocal superconductivity and the field free Josephson diode** — •Mazhar Ali

Invited Talks of the Focus Session "Correlations in Moiré Quantum Matter"

TT 35.1	Wed	15:00–15:30	HSZ 03	**Strongly correlated excitons in atomic double layers** — •Phuong Nguyen
TT 35.2	Wed	15:30–16:00	HSZ 03	**The Quantum Twisting Microscope** — •Shahal Ilani
TT 35.3	Wed	16:00–16:30	HSZ 03	**Light-driven phenomena in two-dimensional and correlated quantum materials** — •Angel Rubio
TT 35.4	Wed	16:45–17:15	HSZ 03	**Cascade of transitions in twisted and non-twisted graphene layers within the van Hove scenario** — •Laura Classen
TT 35.5	Wed	17:15–17:45	HSZ 03	**Topology and strong correlation: From twisted bilayer graphene to the boundary zeros of Mott insulators** — •Giorgio Sangiovanni

Invited Talks of the Focus Session "Superconducting Nickelates"

TT 44.1	Thu	9:30–10:00	HSZ 03	**Atomic-scale insights to lattice and electronic structure in superconducting nickelates** — •Berit Goodge
TT 44.2	Thu	10:00–10:30	HSZ 03	**Nickelate and cuprate superconductors: Similar yet different** — •Vamshi Mohan Katukuri
TT 44.3	Thu	10:30–11:00	HSZ 03	**Superconducting instabilities in strongly-correlated infinite-layer nickelates** — •Andreas Kreisel
TT 44.5	Thu	11:45–12:15	HSZ 03	**Superconducting layered square-planar nickelates: Synthesis, properties, and progress** — •Grace Pan
TT 44.4	Thu	11:15–11:45	HSZ 03	**Infinite-layer nickelate thin films: From synthesis to spectroscopy** — •Daniele Preziosi

Invited Talks not included in Focus Sessions

TT 8.1	Mon	15:00–15:30	HSZ 103	**Molecules on a superconductor: Inducing magnetism and resonance-enhanced vibrational spectroscopy** — •Richard Berndt
TT 17.3	Mon	17:15–17:45	HSZ 304	**Noise signatures of anyon statistics and Andreev scattering in the $v = 1/3$ fractional quantum Hall regime** — •Anne Anthore
TT 22.6	Tue	11:00–11:30	HSZ 204	**Higgs spectroscopy of superconductors in nonequilibrium** — •Dirk Manske
TT 28.6	Wed	10:45–11:15	HSZ 103	**Studying the Fulde-Ferrell-Larkin-Ovchinnikov order parameter in quasi-2D organic superconductors** — •Tommy Kotte
TT 39.1	Wed	15:00–15:30	HSZ 304	**Sensing and control of MHz photons with microwave photon-pressure** — •Daniel Bothner
TT 66.1	Fri	9:30–10:00	HSZ 304	**Towards ultrasensitive calorimetric detection in superconducting quantum circuits** — •Bayan Karimi

Sessions

TT 1.1–1.3	Sun	16:00–18:15	HSZ 01	**Tutorial: Physics Meets Machine Learning (joint session DY/TUT/TT)**
TT 2.1–2.9	Mon	9:30–13:00	HSZ 03	**Focus Session: Physics Meets ML I – Machine Learning for Complex Quantum Systems (joint session TT/DY)**
TT 3.1–3.13	Mon	9:30–13:00	HSZ 103	**Superconductivity: Properties and Electronic Structure**
TT 4.1–4.13	Mon	9:30–13:00	HSZ 201	**f-Electron Systems and Heavy Fermions I**
TT 5.1–5.14	Mon	9:30–13:15	HSZ 204	**Correlated Electrons: Method Development**
TT 6.1–6.13	Mon	9:30–13:00	HSZ 304	**Topological Semimetals**
TT 7.1–7.14	Mon	9:30–13:00	HSZ 403	**Spin Transport and Orbitronics, Spin-Hall Effects (joint session MA/TT)**

- Miscellaneous

Sessions
– Invited Talks, Topical Talks, Tutorials, Contributed Talks, and Posters –

TT 1: Tutorial: Physics Meets Machine Learning (joint session DY/TUT/TT)

Machine learning has revolutionized many application fields such as computer vision and natural language processing. In physics there is a growing interest in using machine learning to enhance the analysis of experimental data and to devise and optimize experiments or numerical simulations. On the other hand physicists use their intuition and methods from statistical physics and complex systems theory to better understand the working principles of modern machine learning methods. This tutorial session introduces some subfields within this area and the basic methods involved.

Organized by Sabine Andergassen (Tübingen), Martin Gärttner (Heidelberg), Moritz Helias (Jülich), and Markus Schmitt (Cologne)

Time: Sunday 16:00–18:15   Location: HSZ 01

Tutorial   TT 1.1   Sun 16:00   HSZ 01
Machine Learning for Quantum Technologies — •FLORIAN MARQUARDT — Max Planck Institute for the Science of Light and Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany
Machine learning is revolutionizing science and technology. In the past few years, it has become clear that it promises significant benefits as well for the development of quantum technologies. In this tutorial I will first give a brief introduction to neural networks. I will then discuss a number of areas and examples in which machine learning is being successfully applied in this context. These include measurement data analysis and quantum state representation, approximate quantum dynamics, parameter estimation, discovering strategies for hardware-level quantum control, the optimization of quantum circuits, and the discovery of quantum experiments, discrete quantum feedback strategies, and quantum error correction protocols.

Tutorial   TT 1.2   Sun 16:45   HSZ 01
The Unreasonable Effectiveness of Gaussians in the Theory of Deep Neural Networks — •ZOHAR RINGEL — Racah Institute of Physics, Hebrew University in Jerusalem
Physical Sciences are in many ways the success story of explaining fundamental phenomena using simple math [1]. The fact that physical phenomena could be arranged in that manner is remarkable. Yet this simplicity does not necessarily carry over to life sciences or data sciences. Indeed prominent authors have argued against our desire to rely on neat mathematical structures when analyzing big data [2].

In the past half-decade several results have emerged which balance mathematical simplicity with data-induced complexity. These could be seen as a middle ground between the above juxtaposing views. The common divider here is the use of Gaussian distributions as approximants of various different quantities in deep neural networks (DNNs). Specifically these Gaussians emerge when describing outputs of DNNs with random weights, outputs of trained DNNs at random times, outputs of fixed DNNs over random input data, and fluctuations of hidden DNN pre-activations. In this tutorial I will present these quantities, provide arguments supporting their Gaussianity, and outline several theoretical implications.

Tutorial   TT 1.3   Sun 17:30   HSZ 01
Computing learning curves for large machine learning models using the replica approach — •MANFRED OPPER — Inst. für Softwaretechnik und Theor. Informatik, TU Berlin — Centre for Systems Modelling and Quantitative Biomedicine, University of Birmingham, UK
Methods of statistical physics have been used for a long time to mathematically analyse the typical performance of machine learning models in the limit where both the number of data and the number of parameters (such as network weights) is large. By defining Boltzmann-Gibbs probability distributions over parameters where the cost function of the machine learning problem plays the role of a hamiltoninan, one can derive analytical expressions for training errors and generalisation errors using the corresponding partition functions and free energies in terms of a usually small number of order parameters.

Since the models depend on a set of random data to be learnt, additional appropriate statistical (so-called quenched) averages of free energies over this 'disorder' have to be performed. The replica approach is a prominent analytical tool from the statistical physics of disordered systems to solve this nontrivial technical challenge.

In this tutorial I will give an introduction to this approach. Starting with an explicit calculation for simple single layer perceptrons, I will then argue how the method can be applied to more complex problems such as kernel machines (support vector machines and Gaussian processes) and multilayer networks.

TT 2: Focus Session: Physics Meets ML I –
Machine Learning for Complex Quantum Systems (joint session TT/DY)

Modern machine learning methods open new perspectives on the high-dimensional data arising naturally in complex quantum systems. The applications range from the analysis of experimental observations over optimal control to the enhancement of numerical simulations in and out of equilibrium. This focus session brings together experts in the field to discuss recent progress and promising directions for future research.

Organizers: Markus Schmitt (University of Cologne), Martin Gärttner (University of Heidelberg)

Time: Monday 9:30–13:00   Location: HSZ 03

Invited Talk   TT 2.1   Mon 9:30   HSZ 03
Enhanced variational Monte Carlo for Rydberg atom arrays — •STEFANIE CZISCHEK — Department of Physics, University of Ottawa, Ottawa, Canada, K1N 6N6
Rydberg atom arrays are promising candidates for high-quality quantum computation and quantum simulation. However, long state preparation times limit the amount of measurement data that can be generated at reasonable timescales. This restriction directly affects the estimation of operator expectation values, as well as the reconstruction and characterization of quantum states.

Over the last years, neural networks have been explored as a powerful and systematically tuneable ansatz to represent quantum wave functions. Via tomographical state reconstruction, such numerical models can significantly reduce the amount of necessary measurements to accurately reconstruct operator expectation values. At the same time, neural networks can find ground state wave functions of given Hamiltonians via variational energy minimization.

While both approaches experience individual limitations, a combination of the two leads to a significant enhancement in the variational ground state search by naturally finding an improved network initialization from a limited amount

of measurement data. Additional specific modifications of the neural network model and its implementation can further optimize the performance of variational Monte Carlo simulations for Rydberg atom arrays and provide significant insights into their behaviour.

Invited Talk   **TT 2.2   Mon 10:00   HSZ 03**
Data mining the output of quantum simulators – from critical behavior to algorithmic complexity — •Marcello Dalmonte — Abdus Salam International Centre for Theoretical Physics, Trieste (I)
Recent experiments with quantum simulators and noisy intermediate-scale quantum devices have demonstrated unparalleled capabilities of probing many-body wave functions, via directly probing them at the single quantum level via projective measurements. However, very little is known about to interpret and analyse such huge datasets. In this talk, I will show how it is possible to provide such characterisation of many-body quantum hardware via a direct and assumption-free data mining. The core idea of this programme is the fact that the output of quantum simualtors and computers can be construed as a very high-dimensional manifold. Such manifold can be characterised via basic topological concepts, in particular, by their intrinsic dimension. Exploiting state of the art tools in non-parametric learning, I will discuss theoretical results for both classical and quantum many-body spin systems that illustrate how data structures undergo structural transitions whenever the underlying physical system does, and display universal (critical) behavior in both classical and quantum mechanical cases. I will conclude with remarks on the applicability of our theoretical framework to synthetic quantum systems (quantum simulators and quantum computers), and emphasize its potential to provide a direct, scalable measure of Kolmogorov complexity of output states.

Invited Talk   **TT 2.3   Mon 10:30   HSZ 03**
Reinforcement learning for quantum technologies — •Florian Marquardt — Max Planck Institute for the Science of Light and Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany
Complex quantum devices require sophisticated control. Discovering such control strategies from scratch with the help of machine learning will enable us to keep pace with the ever-increasing demands encountered when scaling up quantum computers. In this talk, I will describe how the field of reinforcement learning can deliver on this promise. I will present examples ranging from the optimization of quantum circuits to the model-based discovery of better quantum feedback strategies. Moreover, in a recent collaboration with our experimental colleagues, we could show how to train a novel latency-optimized neural network by reinforcement learning in an experiment, acting on a superconducting qubit in cycles of less than one microsecond.

Invited Talk   **TT 2.4   Mon 11:00   HSZ 03**
Machine learning of phase transition — •Christof Weitenberg — Universität Hamburg, Institut für Laserphysik, Hamburg, Germany
Machine learning is emerging as vital tool in many sciences. In quantum physics, notable examples are neural networks for the efficient representation of quantum many-body states and reinforcement learning of preparation and read-out routines. In this talk, I will present our results on machine learning of quantum phase transitions using classification techniques. This approach works very well even on noisy experimental data both with supervised and unsupervised machine learning, as we demonstrate for quantum simulators based on ultracold atoms. Next to the practical advantages, such techniques might in the future reveal phase transitions, for which conventional order parameters are not known.

15 min. break

                                    TT 2.5   Mon 11:45   HSZ 03
Machine learning optimization of Majorana hybrid nanowires — •Matthias Thamm and Bernd Rosenow — Institut für Theoretische Physik, Universität Leipzig
As the complexity of quantum systems such as quantum bit arrays increases, efforts to automate expensive tuning are increasingly worthwhile. We investigate machine learning based tuning of gate arrays using the CMA-ES algorithm for the case study of Majorana wires with strong disorder. We find that the algorithm is able to efficiently improve the topological signatures, learn intrinsic disorder profiles, and completely eliminate disorder effects. For example, with only 20 gates, it is possible to fully recover Majorana zero modes destroyed by disorder by optimizing gate voltages.

                                    TT 2.6   Mon 12:00   HSZ 03
Model-independent learning of quantum phases of matter with quantum convolutional neural networks — •Yu-Jie Liu[1], Adam Smith[2], Michael Knap[1], and Frank Pollmann[1] — [1]Technical University of Munich, 85748 Garching, Germany — [2]University of Nottingham, Nottingham, NG7 2RD, UK

Quantum convolutional neural networks (QCNNs) have been introduced as classifiers for gapped quantum phases of matter. Here, we propose a model-independent protocol for training QCNNs to discover order parameters that are unchanged under phase-preserving perturbations. We initiate the training sequence with the fixed-point wavefunctions of the quantum phase and then add translation-invariant noise that respects the symmetries of the system to mask the fixed-point structure on short length scales. Without the translational invariance or other additional symmetries, we prove that a phase-classifying QCNN cannot exist. We illustrate this approach by training the QCNN on phases protected by time-reversal symmetry in one dimension, and test it on several time-reversal symmetric models exhibiting trivial, symmetry-breaking, and symmetry-protected topological order. The QCNN discovers a set of order parameters that identifies all three phases and accurately predicts the location of the phase boundary. The proposed protocol paves the way towards hardware-efficient training of quantum phase classifiers on a programmable quantum processor.

                                    TT 2.7   Mon 12:15   HSZ 03
Simulating spectral functions of two-dimensional systems with neural quantum states — •Tiago Mendes Santos[1], Markus Schmitt[2], and Markus Heyl[1] — [1]University of Augsburg, Augsburg, Germany — [2]Forschungszentrum Jülich, Jülich, Germany
Spectral functions are key tools to characterize and probe condensed matter systems. Simulating such quantities in interacting two-dimensional quantum matter is, however, still an outstanding challenge. This work presents a numerical approach to simulate spectral functions using Neural Quantum States. As the key aspect, our scheme leverage the flexibility of artificial-neural-network wave functions to access spectral properties by simulating the dynamics of localized excitations with the time-dependent variational Monte Carlo. For demonstration, we study the dynamical structure factor (DSF) of models describing two-dimensional quantum phase transitions, namely, the quantum Ising and a square-lattice Rydberg Atom Arrays model in a regime of parameters relevant to quantum simulators. When combined with deep network architectures whose number of variational parameters increase at a mild polynomial expense with the number of spins, we showcase that our approach reliably describes the DSF for unprecedented system sizes and time scales.

                                    TT 2.8   Mon 12:30   HSZ 03
Efficient optimization of deep neural quantum states toward machine precision — •Ao Chen and Markus Heyl — Center for Electronic Correlations and Magnetism, University of Augsburg, 86135 Augsburg, Germany
Neural quantum states (NQSs) have emerged as a novel promising numerical method to solve the quantum many-body problem. However, it has remained a central challenge to train modern large-scale deep network architectures, which would be key to utilize the full power of NQSs and to make them competitive or superior to conventional numerical approaches. Here, we propose a minimum-step stochastic reconfiguration (MinSR) method that reduces the optimization complexity by orders of magnitude while keeping similar accuracy as compared to conventional stochastic reconfiguration. In this talk, I will show MinSR allows for an accurate training on unprecedentedly deep NQS with up to 64 layers and more than 10^5 parameters in the spin-1/2 Heisenberg J_1-J_2 models on the square lattice. With limited numerical resources, partly obtained on single workstations, we find that this approach yields better variational energies as compared to existing NQS results and we further observe that the accuracy of our ground state calculations approaches different levels of machine precision on modern GPU and TPU hardware.

                                    TT 2.9   Mon 12:45   HSZ 03
Time-dependent variational principle for quantum and classical dynamics — •Moritz Reh[1], Markus Schmitt[2], and Martin Gärttner[1,3,4] — [1]Kirchhoff-Institut für Physik, Universität Heidelberg, Im Neuenheimer Feld 227, 69120 Heidelberg, Germany — [2]Institut für Theoretische Physik, Universität zu Köln, 50937 Köln, Germany — [3]Physikalisches Institut, Universität Heidelberg, Im Neuenheimer Feld 226, 69120 Heidelberg, Germany — [4]Institut für Theoretische Physik, Universität Heidelberg, Philosophenweg 16, 69120 Heidelberg, Germany
The solution of many-body quantum dynamics is a challenging feat due to the curse of dimensionality, hindering the exploration of dynamics beyond a mediocre number of qubits. Neural Networks can variationally approximate the state of interest and therefore present a promising tool as they allow to efficiently represent the quantum state at the expense of truncating the Hilbert space.

We present such a scheme that is aimed at solving dissipative quantum dynamics using a probabilistic framework, i.e. the so-called POVM-formalism and demonstrate it for spin chains of up to 40 spins. We then show that the generality of the approach allows us to translate this formalism directly to the case of partial differential equations in high dimensions, defeating the exponential growth of grid cells when adding dimensions.

TT 3: Superconductivity: Properties and Electronic Structure

Time: Monday 9:30–13:00   Location: HSZ 103

TT 3.1   Mon 9:30   HSZ 103

Band-selective quasiparticle scatterers in a two-band superconductor — •Thomas Gozlinski[1], Qili Li[1], Nola Warwick[1], Janic Beck[1], and Wulf Wulfhekel[1,2] — [1]Physikalisches Institut (PHI), Karlsruher Institut für Technologie (KIT) — [2]Institute for Quantum Materials and Technologies (IQMT), Karlsruher Institut für Technologie (KIT)

We study stacking fault tetrahedra (SFTs) in a bulk Pb crystal by mK scanning tunnelling microscopy and spectroscopy and find that the Bogoliubons of the two superconducting bands produce different quasiparticle interference patterns owed to the respective Fermi surface anisotropy. We believe that such extended crystal defects provide a platform to experimentally study interband couplings and scattering rates in a multiband superconductor.

TT 3.2   Mon 9:45   HSZ 103

Symmetry breaking and emergent phases in a noncentrosymmetric superconductor — •Feifan Wang[1], Xianghan Xu[2], Sang-Wook Cheong[2], and Manfred Fiebig[1] — [1]Dept. of Materials, ETH Zurich, Switzerland — [2]Dept. of Physics and Astronomy, Rutgers University, USA

Symmetry breaking raises rich physics in condensed matters, such as Rashba splitting, Weyl fermions, unconventional superconducting, multiferroic ordering, etc. Nonlinear optical processes, being extremely sensitive to material symmetries, offer a direct access to the observation of subtly broken or even hidden symmetries. Here we discover emergant phases in a noncentrosymmetric superconductor, Mo_3Al_2C, and resolve the symmetry lowering using second harmonic generation measurements. Together with temperature-dependent electronic conductivity measurements, the phase transition from a normal metal at high temperatures to a charge-density-wave state is proposed. In the former, all mirror symmetries are broken bringing in the structural chirality. The correlation between superconductivity/charge-density-wave transition and noncentrosymmetry/chirality will then be discussed. Exotic properties in a low-symmetry system such as Mo_3Al_2C may add new ingredients to the strong-correlation physics.

TT 3.3   Mon 10:00   HSZ 103

Hunt for FFLO superconductivity in transition metal dichalcogenides — •Jiawei Zhang[1], Dennis Huang[1], Yosuke Matsumoto[1], Masahiko Isobe[1], Thomas Palstra[1,2], and Hidenori Takagi[1,3,4] — [1]Max Planck Institute for Solid State Research, Heisenbergstr. 1, 70569 Stuttgart, Germany — [2]University of Twente, Drienerlolaan 5, 7522 NB Enschede, The Netherlands — [3]Institute for Functional Matter and Quantum Technologies, University of Stuttgart, 70569 Stuttgart, Germany — [4]Department of Physics, University of Tokyo, 113-0033 Tokyo, Japan

The Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state was proposed almost half a century ago. In contrast to the Bardeen-Cooper-Schrieffer state, the FFLO state hosts Cooper pairs with finite center-of-mass momentum, giving rise to a modulation of the superconducting gap in real space. Two-dimensionality plays an essential role in the materialization of the FFLO state. With 1T buffer layers that reduce the interlayer coupling between successive 1H superconducting layers, $4H_b$-TaS_2 is a promising FFLO candidate. I will talk about the two-dimensional nature of superconductivity in this system as revealed by the Berezinskii-Kosterlitz-Thouless transition. Electrical transport measurements with in-plane magnetic field show that the superconductivity survives above the Pauli limit, providing a high-field regime in the phase diagram to host a possible FFLO state.

TT 3.4   Mon 10:15   HSZ 103

Tuning metal/superconductor to insulator/superconductor coupling via control of proximity enhancement between NbSe$_2$ monolayers — •O. Chiatti[1], K. Mihov[1], T. Griffin[1], C. Grosse[1], L. Grote[1], K. Hite[2], D. Hamann[2], M. B. Alemayehu[2], A. Mogilatenko[3], D. C. Johnson[2], and S. F. Fischer[1] — [1]Novel Materials Group, Humboldt-Universität zu Berlin, 10099 Berlin, Germany — [2]Solid State Chemistry, University of Oregon, Eugene OR 97403-1253, U.S.A. — [3]Ferdinand-Braun-Institut, Leibniz-Institut für Höchstfrequenztechnik, 12489 Berlin, Germany

The interplay between charge transfer and electronic disorder in transition-metal dichalcogenide multilayers [1] gives rise to superconductive coupling driven by proximity enhancement, tunneling and superconducting fluctuations. Artificial spacer layers introduced with atomic precision change the density of states by charge transfer. Here, we tune the superconductive coupling between NbSe$_2$ monolayers from proximity-enhanced to tunneling-dominated and correlate normal and superconducting properties in $[(SnSe)_{1+\delta}]_m[NbSe_2]_1$ tailored multilayers with varying SnSe layer thickness (m=1-15). We show cross-overs between three regimes: metallic with proximity-enhanced coupling, disordered-metallic with intermediate coupling and insulating with Josephson tunneling. [1] A. Devarakonda *et al.*, Science **370**, 231 (2020) [2] M. Trahms *et al.*, Supercond. Sci. Technol. **31**, 065006 (2018)

TT 3.5   Mon 10:30   HSZ 103

Higgs-CDW hybrid mode in coherently-driven 2H-NbSe$_2$ and La$_{2-x}$Sr$_x$CuO$_4$ — •Liwen Feng[1,2,3,4], Jiayuan Cao[2], Tim Priessnitz[1], Gennady Logvenov[1], Bernhard Keimer[1], Yuan Huang[7], Jan-Christoph Deinert[5], Sergey Kovalev[5], Tao Dong[6], Stefan Kaiser[1,3,4], and Hao Chu[1,2] — [1]Max Planck Institute for Solid State Research, Stuttgart, Germany — [2]Shanghai Jiaotong University, Shanghai, China — [3]University of Stuttgart, Stuttgart, Germany — [4]Technical University Dresden, Dresden, Germany — [5]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [6]Peking University, Beijing, China — [7]Beijing Institute of Technology, Beijing, China

Superconductivity and a charge-density-wave (CDW) are often found as close neighbors in the thermodynamic phase diagram of many materials at low temperatures. A prototypical system showing the co-existence of the two orders is 2H-NbSe$_2$. Here, we coherently drive collective oscillations by terahertz radiation and report on third harmonic generation (THG) from both CDW amplitude oscillations and Higgs oscillations. We find the interaction between two orders leads to a Fano interference of THG signals, which displays as an out-of-phase interference in the time-domain. This we characterize as Higgs-CDW hybrid that can be controlled by the THz driving field. Additionally, a similar phenomenon manifestes in the underdoped cuprate La$_{2-x}$Sr$_x$CuO$_4$ ($x \sim 0.12$) under non-perturbative drive. As such non-linear THz drives of order parameter oscillations opening up possibilities of investigating intertwined orders in the future.

TT 3.6   Mon 10:45   HSZ 103

Clean-limit superconductivity at 197 K in high-pressure sulfur hydride — •Sam Cross[1], Israel Osmond[1], Owen Moulding[1], Takaki Muramatsu[1], Annabelle Brooks[1], Oliver Lord[2], Timofey Fedotenko[3], Jonathan Buhot[1], and Sven Friedemann[1] — [1]HH Wills Physics Laboratory, University of Bristol, UK — [2]School of Earth Sciences, University of Bristol, UK — [3]Photon Science, DESY, Germany

The search for room temperature superconductivity in hydrogen rich compounds has accelerated since the discovery of superconductivity in sulfur hydride, H_3S, in 2015 [1]. Controlled synthesis of hydrides remains a challenge, and further work on the formation pathways will prove vital in the search for room temperature superconductivity in such compounds. Here we confirm the synthesis of cubic Im3m H_3S by laser heating elemental sulfur and hydrogen donor ammonia borane, NH_3BH_3. Superconductivity is characterised using electrical transport measurements in a diamond anvil cell, confirming a transition temperature T_c = 197 K at 153 GPa, in agreement with previous studies. The coherence length extracted from measurements of the critical field H_{c2} together with estimations of the carrier mean free path from the normal state resistance suggest that H_3S follows clean-limit behaviour. The work further highlights the potential for in-situ synthesis of clean hydrides using ammonia borane, a more accessible synthesis alternative to pure hydrogen.

TT 3.7   Mon 11:00   HSZ 103

Unraveling charge transfer to understand superconductivity in MgB$_2$ — •Simon Marotzke[1,2], Jan Oliver Schunck[1,3], Amina Alic[4], Octave Duros[4], Moritz Hoesch[1], Alessandro Nicolaou[5], Gheorghe Sorin Chiuzbaian[4], and Martin Beye[1] — [1]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]Christian-Albrechts-Universität zu Kiel, Kiel, Germany — [3]Universität Hamburg, Hamburg, Germany — [4]Sorbonne Université, Paris, France — [5]Synchrotron SOLEIL, Saint-Aubin, France

Magnesium diboride (MgB$_2$) holds the world-record for the highest transition temperature (T_C = 39 K) in a conventional Bardeen-Cooper-Schrieffer (BCS)-type, i.e., phonon-mediated, superconductor. The undoped electron configuration of MgB$_2$ is still disputed as contradicting results on the appearance of charge transfer upon crossing T_C have been reported. To settle this question, we conducted high-resolution resonant X-ray emission spectroscopy (XES) as well as X-ray absorption spectroscopy (XAS) measurements around the boron K-edge at the SEXTANTS beamline at the synchrotron SOLEIL. In order to investigate the charge transfer between in-plane and out-of-plane states, we varied the polarization of the incoming photons as well as the incidence and emission angle. We report on differences in the spectral intensity for both the absorption and emission spectra upon crossing T_C to be first indications of changes in the density of the boron $2p$ states. Complementary density of states calculations showing good agreement with the experimental data were performed.

15 min. break

TT 3.8   Mon 11:30   HSZ 103

Emergence of incipient superconductivity in CrB_2 under anisotropic strain — Alexander Regnat[1], •André Deyerling[1], Christoph Resch[1], Jan Spallek[1], Alfonso Chacon[1], Philipp G. Niklowitz[1,2], Andreas Bauer[1], Marc A. Wilde[1], and Christian Pfleiderer[1] — [1]Physik-Department, Technical University of Munich, D-85748 Garching, Germany — [2]Department of Physics, Royal Holloway, University of London, Egham TW20 0EX, UK

Resistivity studies of the hexagonal C32 diborides MoB_2[1], WB_2[2], and CrB_2[3,4] under ultra-high pressures of the order $100\,GPa$ have recently revealed superconducting transitions, where the precise pressure conditions are unknown. We report a study of the electrical resistivity of the itinerant-electron antiferromagnet CrB_2 [5,6] under uniaxial, hydrostatic, and quasi-hydrostatic pressures up to $0.5\,GPa$, $2.2\,GPa$ and $8\,GPa$, respectively. Tracking the magnetic transition temperature and the onset of incipient superconductivity we derive a phase diagram as a function of the ratio of lattice constants c/a. Supported by detailed electronic structure calculations, we suggest that the reduction of lattice constant c controls the suppression of magnetic order and concomitant emergence of superconductivity in CrB_2.

TT 3.9   Mon 11:45   HSZ 103

Annealeing microstructured crystals of cuprate superconductor $Tl_2Ba_2CuO_{6-x}$ — •Ayanesh Maiti[1,2,3], Seunghyun Khim[1], Carsten Putzke[2], and Andrew P Mackenzie[1,3] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden — [2]Max Planck Institute for Structure and Dynamics of Matter, Hamburg — [3]University of St Andrews, Scotland

Cuprates exhibit a variety of interesting physics that is not well understood, ranging from unconventional superconductivity to strange metal behaviour. Past experiments have mostly focused on underdoped cuprates that have complex phases due to competing orders. Studies with overdoped samples were limited by the rarity of candidate materials and the difficulty to probe crystals with surface reconstructions. $Tl_2Ba_2CuO_{6-x}$ is a naturally overdoped cuprate that can be grown with high enough purity to show quantum oscillations, and we can suppress the effects of surface reconstructions by using focused ion beam (FIB) microstructuring techniques. However, FIB procedures remove oxygen from the crystal surface and introduces inhomogeneities in samples, making it hard to study their intrinsic behavior. We are developing annealing techniques to re-homogenize our microstructures, using measurements of the doping-dependent high-temperature resistivity to monitor their oxygen content. This will allow us to study the overdoped part of the cuprate phase diagram and hence improve our understanding of unconventional superconductivity. Our techniques will also enable studies with the full range of doping on a single specimen, eliminating sample-to-sample variations from future experiments.

TT 3.10   Mon 12:00   HSZ 103

Vortex matching at 6 T in $YBa_2Cu_3O_{7-\delta}$ by imprinting an ultradense hexagonal pinning array with focused helium ion irradiation — •Bernd Aichner[1], Lucas Backmeister[1], Max Karrer[2], Katja Wurster[2], Christoph Schmid[2], Reinhold Kleiner[2], Edward Goldobin[2], Dieter Koelle[2], and Wolfgang Lang[1] — [1]Fakultät für Physik, Universität Wien, Wien, Österreich — [2]Physikalisches Institut, Center for Quantum Science (CQ) and LISA+, Universität Tübingen, Tübingen, Deutschland

The focused beam of a helium ion microscope (HIM) is used to locally suppress superconductivity in thin films of the prototypical copper-oxide superconductor $YBa_2Cu_3O_{7-\delta}$ (YBCO). In these pillar-shaped regions, the critical temperature T_c is reduced or entirely suppressed due to pair-breaking by point defects.

The narrow spacing of these nanopillars leads to vortex commensurability effects at high magnetic fields, which appear as pronounced maxima of the critical current and corresponding resistance minima. In accordance with the calculation, these effects appear at an unprecedented high magnetic field of $6\,T$ in a hexagonal nanopillar lattice with $20\,nm$ spacing. In contrast to previous observations, matching phenomena persist in the whole accessible temperature range, from the onset of superconductivity down to a temperature of $2\,K$. At the matching field, we observe a novel behavior in voltage-current isotherms, which we

attribute to an ordered Bose glass phase. These results establish the HIM as a versatile platform for creating ultradense vortex pinning landscapes with complex designs in copper-oxide superconductors.

TT 3.11   Mon 12:15   HSZ 103

Quantum interference in a finite-width mesoscopic ring with superconducting vortices — Gian Paolo Papari[1,2,3] and •Vladimir M. Fomin[4,5] — [1]Dipartimento di Fisica, Università di Napoli "Federico II", I-80126 Napoli, Italy — [2]CNR-SPIN, UOS Napoli, I-80126 Napoli, Italy — [3]Istituto Nazionale di Fisica Nucleare (INFN), Naples Unit, I-80126 Napoli, Italy — [4]Institute for Integrative Nanosciences (IIN), Leibniz IFW Dresden, D-01069 Dresden, Germany — [5]Moldova State University, MD-2009, Chişinău, Republic of Moldova

We analyze the origin of the parabolic background of magnetoresistance oscillations measured in finite-width superconducting mesoscopic rings with input and output stubs and in patterned films. The transmission model [1] explaining the sinusoidal oscillation of magnetoresistance is extended to address the background as a function of the magnetic field. Apart from the interference mechanism activated by the ring, pinned superconducting vortices as topological defects introduce a further interference-based distribution of supercurrents that affects, in turn, the voltmeter-sensed quasiparticles. The onset of vortices changes the topology of the superconducting state in a mesoscopic ring in a such a way that the full magnetoresistance dynamics can be interpreted owing to the interference of the constituents of the order parameter induced by both the ring itself and the vortex lattice in it.

TT 3.12   Mon 12:30   HSZ 103

Frequency-locking effect in Nb open nanotubes — Igor Bogush[1,2], Oleksandr V. Dobrovolskiy[3], and •Vladimir M. Fomin[1,2] — [1]Institute for Integrative Nanosciences (IIN), Leibniz IFW Dresden, D-01069 Dresden, Germany — [2]Department of Theoretical Physics, Moldova State University, MD-2009 Chişinău, Republic of Moldova — [3]University of Vienna, Faculty of Physics, Nanomagnetism and Magnonics, Superconductivity and Spintronics Laboratory, 1090 Vienna, Austria

We study alternating voltage generation in Nb open nanotubes under weakly modulated transport current and magnetic field by numerically solving the time-dependent Ginzburg-Landau equation [1]. Under stationary currents and fields, as a rule, an alternating voltage with a fixed frequency is generated in the nanotube. The frequency is associated with the period of the vortex nucleation at the nanotube edges. If the transport current is modulated by a weak ac component with a frequency close to the nucleation frequency, we reveal the effect of frequency-locking of the vortex nucleation, i.e., the nucleation frequency becomes equal to the external frequency of the modulated transport current. The frequency-locking width is discussed as a function of the modulation depth. Its sensitivity to the magnetic field variation opens up opportunities for the experimental examination of the effect.

Superconductivity in curved 3D nanoarchitectures — •Vladimir M. Fomin[1,2] and Oleksandr V. Dobrovolskiy[3] — [1]Institute for Integrative Nanosciences (IIN), Leibniz IFW Dresden, D-01069 Dresden, Germany — [2]Laboratory of Physics and Engineering of Nanomaterials, Department of Theoretical Physics, Moldova State University, MD-2009 Chişinău, Republic of Moldova — [3]University of Vienna, Faculty of Physics, Nanomagnetism and Magnonics, Superconductivity and Spintronics Laboratory, 1090 Vienna, Austria

In recent years, superconductivity and vortex matter in curved 3D nanoarchitectures have turned into a vibrant research avenue because of the rich physics of the emerging geometry- and topology-induced phenomena and their prospects for applications in (electro)magnetic field sensing and information technology. We outline the experimental techniques capable of the fabrication of curved 3D nanostructures and present a selection of own results on the intertwined dynamics of screening superconducting currents, Abrikosov vortices and slips of the phase of the superconducting order parameter therein. We share our vision regarding the prospect directions and current challenges in this research domain, arguing that curved 3D nanoarchitectures open a new dimension in superconductors research and possess great potential for magnetic field sensing, bolometry, and fluxonic devices [1].

The potential of resonant x-ray scattering for the study of Kondo lattices —
•MAREIN RAHN — Institute for Solid State and Materials Physics, Technical University of Dresden, 01062 Dresden, Germany

Kondo lattices represent a pivotal point of quantum matter - where local-itinerant correlations start being shaped by a material's lattice character and their consequences can no longer be reduced to local/mean-field models. Many traditional experimental probes cannot provide insights "beyond the mean field" because they themselves average this phenomenon over time and space. In this talk, I will showcase recent advances in momentum-resolved spectroscopies that can reveal the fine structure and dynamics of Kondo quasiparticles in unprecedented detail. Synchrotron-based techniques like resonant inelastic x-ray scattering provide a particularly interesting new perspective. Their experimental possibilities in f-electron systems have been hardly exploited, which should also be a strong motivation for progress in computational approaches.

TT 4.2   Mon 9:45   HSZ 201

Kondo screening and coherence on the Kagome lattice: Energy scales of the Kondo effect in the presence of at bands — •CHRISTOS KOURRIS and MATTHIAS VOJTA — Institut für Theoretische Physik, TU Dresden, Dresden, Germany

The formation of a heavy Fermi liquid in metals with local moments is characterized by multiple energy and temperature scales, most prominently the Kondo temperature and the coherence temperature, characterizing the onset of Kondo screening and the emergence of Fermi-liquid coherence, respectively. In the standard setting of a wide conduction band, both scales depend exponentially on the Kondo coupling. Here we discuss how the presence of flat, i.e., dispersionless, conduction bands modifies this situation. The Kagome Kondo-lattice model, due to its rich band structure, leads to a plethora of non-conventional Kondo behaviour emerging at different fillings. We utilize a parton mean-field approach to determine both the Kondo temperature and the coherence temperature as function of the conduction-band filling n_c, both numerically and analytically. For n_c values corresponding to the flat conduction band, we show that the exponential is replaced by linear and quadratic dependences for the Kondo and coherence temperature respectively, while a cubic power law emerges in the coherence temperature at n_c corresponding to the band edge between the flat and dispersive bands. We discuss implications of our results for pertinent experimental data.

TT 4.3   Mon 10:00   HSZ 201

Uniaxial strain tuning the signature of Kondo effect in the electrical resistance of heavy-fermion metals — •SOUMENDRA PANJA, ANTON JESCHE, BIN SHEN, and PHILIPP GEGENWART — Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg, 86159 Augsburg, Germany

Physical properties of Kondo lattices are determined by the interplay of the Kondo effect and the RKKY interaction, which both depend sensitively on the antiferromagnetic exchange J between f- and conduction electrons. This competition is extremely sensitive to pressure, as evidenced by very large Gruneisen parameters found in these materials. We intend to tune the Kondo-maximum signature in the electrical resistance of such materials with tensile and compressive strain by utilizing a commercial piezo-strain device. In this talk, first results will be discussed under experimentally accessible strains.

TT 4.4   Mon 10:15   HSZ 201

Kondo breakdown transitions and phase-separation tendencies in valence-fluctuating heavy-fermion materials — •PEDRO MONTEIRO CÔNSOLI and MATTHIAS VOJTA — Institut für Theoretische Physik, TU Dresden

The breakdown of the lattice Kondo effect in local-moment metals can lead to nontrivial forms of quantum criticality and a variety of non-Fermi-liquid phases. Given indications that Kondo-breakdown transitions involve criticality not only in the spin but also in the charge sector, we investigate the interplay of Kondo breakdown and strong valence fluctuations in generalized Anderson lattice models. We employ a parton mean-field theory to describe the transitions between deconfined fractionalized Fermi liquids and various confined phases. As a result, we find that rapid valence changes near Kondo breakdown can render the quantum transition first order. This leads to phase-separation tendencies which, upon inclusion of longer-range Coulomb interactions, will produce intrinsically inhomogeneous states near Kondo-breakdown transitions. We connect our findings to unsolved aspects of experimental data.

TT 4.5   Mon 10:30   HSZ 201

Quantum spin liquid in an RKKY-coupled two-impurity Kondo system —
•KRZYSZTOF P. WÓJCIK[1,2,3] and JOHANN KROHA[3] — [1]M. Curie-Skłodowska University, 20-031 Lublin, Poland — [2]Institute of Molecular Physics, PAS, 60-179 Poznań, Poland — [3]Physikalisches Institut, Universität Bonn, 53115 Bonn, Germany

We consider a 2-impurity Anderson model with spin-exchange coupling within the conduction-band sector of the Hamiltonian. Our numerical renormalization group calculations show that for strong intraband spin correlations their competition with the Kondo spin screening stabilizes a metallic spin-liquid phase of the localized spins, even without geometric frustration. It is characterized by nonuniversal impurity spectral density, fractionalization of the phase shift between the local and conduction-band parts, and large but not complete spin-spin correlations. For weak Kondo coupling the spin liquid and the Kondo singlet phase are separated by two quantum phase transitions and an intermediate RKKY spin-dimer phase, while beyond a critical coupling they are connected by a crossover. The results suggest how a quantum spin liquid may be realized in heavy-fermion systems near a spin-density wave instability.

TT 4.6   Mon 10:45   HSZ 201

Epitaxial EuPd$_2$ and EuPd$_3$ thin films — •SEBASTIAN KÖLSCH and MICHAEL HUTH — Goethe Universität, Frankfurt (Main)

Europium-based binary compounds reveal a variety of interesting phenomena, which are attributed to strong electronic correlations and a competition between two different valence states of the europium ion, which lie close in energy [1]. As a result Eu forms intermetallic compounds usually either in a divalent (e.g. EuPd$_2$) or trivalent (e.g. EuPd$_3$) state, depending on the surrounding environment, whereas most other rare earth elements are always trivalent. Some ternary compounds even exhibit a change between both valence states, which may be tuned by temperature, pressure or high magnetic fields. As one of these rare candidates, EuPd$_2$Si$_2$ gained much interest due to a temperature driven valence transition from nearly Eu^{2+} above 200 K to Eu^{3+} below 50 K [2]. Recently we achieved for the first time the growth of epitaxial EuPd$_2$Si$_2$ thin films, where the valence transition was completly suppressed due to biaxial strain [3]. Epitaxial thin films thus offer the possibility to manipulate the strongly correlated Eu-based systems. Here we present the successful growth of EuPd$_2$ and EuPd$_3$ as epitaxial thin films and report on first results regardings their properties.

Single crystal growth of EuPd$_2$Si$_2$ under enhanced gas pressure — •ALEXEJ KRAIKER, MARIUS PETERS, KRISTIN KLIEMT, and CORNELIUS KRELLNER — Physikalisches Institut, Goethe Universität Frankfurt, 60438 Frankfurt am Main, Germany

The study of collective phenomena raising from enhanced coupling between electrons and phonons is focussed on materials exhibiting phase transitions involving both, electronic and lattice-degrees of freedom. One system providing such a strongly coupled phase transition is EuPd$_2$Si$_2$ crystallizing in the ThCr$_2$Si$_2$ structure type. Because of the the high vapor pressure of Eu, high-quality single crystals of EuT$_2$X$_2$-compounds are very challenging to grow in larger size. One way to prevent Eu from evaporating out of the melt, is growing the crystals in argon overpressure. In this contribution, we present the crystal growth of EuPd$_2$Si$_2$ single crystals with a 20 bar and a 150 bar Czochralski-furnace. We show that the argon overpressure slows down the evaporation process of the Eu and leads to crystals with higher quality compared to Bridgman grown samples [1].

TT 4.8   Mon 11:30   HSZ 201

Tuning the ground state of EuPd$_2$(Si$_{1-x}$Ge$_x$)$_2$ using He-gas pressure —
•BERND WOLF, THERESA LUNDBECK, MARIUS PETERS, KRISTIN KLIEMT, CORNELIUS KRELLNER, and MICHAEL LANG — Physikalisches Institut, Goethe University, 60438 Frankfurt/Main, Germany

The strongly correlated intermetallic compound EuPd$_2$Si$_2$ shows a strong valence-change crossover in a small temperature range. This valence change is accompanied by pronounced lattice effects together with significant changes in the magnetic properties. The material is located on the high-pressure side (crossover range) of the second-order critical endpoint (CEP) where novel collective phenomena which originate from a particularly strong coupling between electronic-, magnetic- and lattice degrees of freedom can be expected. We present magnetic susceptibility measurements data taken on high-quality sin-

gle crystals of $EuPd_2(Si_{1-x}Ge_x)_2$ for nominal Ge-concentrations $0 \leq x_{nom} \leq 0.2$ in the temperature range $2\,K \leq T \leq 300\,K$ and He-gas pressure up to 0.5 GPa. For $x = 0$ at ambient pressure we observe a pronounced valence crossover centered around $T_V \sim 160\,K$. As expected, T_V shifts to lower temperatures with increasing Ge-concentration, reaching $T_V \sim 90\,K$ for $x_{nom} = 0.1$, while still showing a non-magnetic ground state. For $x_{nom} = 0.2$ we observe long-range antiferromagnetic order setting in below $T_N = 47.3\,K$. The important finding is that the application of a weak pressure as low as 0.2 GPa the long-range magnetic order can be suppressed giving way to a non-magnetic ground state with pronounced valence fluctuations.

TT 4.9　Mon 11:45　HSZ 201
Search for a critical endpoint in $Eu(Pd_{1-x}Au_x)_2Si_2$ single crystals — •Robert Möller, Marius Peters, Kristin Kliemt, and Cornelius Krellner — Physikalisches Institut, Goethe-Universität Frankfurt, Germany
In a general phase diagram for Eu compounds [1], the intermediate valent $EuPd_2Si_2$, $T_V \sim 150\,K$, is located very close, but slightly at the high-pressure side of a second order critical endpoint [2]. The analysis of polycrystalline samples of $Eu(Pd_{1-x}Au_x)_2Si_2$ revealed that in this series a critical endpoint can be found which separates the region of continuous from first order transitions. It was shown that the valence state of the material can be tuned via Au substitution and that for x between 0.04 and 0.2 the transition becomes a first order phase transition [3]. Using single crystals grown with the Czochralski method, several characterisations were done to understand the main factors affecting the valence transition of $Eu(Pd_{1-x}Au_x)_2Si_2$.

Orbital selective coupling in $CeRh_3B_2$: co-existence of high Curie and high Kondo temperature — Andrea Amorese[1,2], Philipp Hansmann[3], Andrea Marino[2], Peter Körner[1], Thomas Willers[1], Andrew Walters[4], Kejin Zhou[4], Kurt Kummer[5], Nicholas B. Brooks[5], Hong-Ji Lin[6], Chien-Te Chen[6], Pascal Lejay[7], Maurits W. Haverkort[8], Liu Hao Tjeng[2], and •Andrea Severing[1] — [1]Institute of Physics II, University of Cologne, Germany — [2]MPI-CPfS, Dresden, Germany — [3]Department of Physics, University of Erlangen-Nürnberg, Germany — [4]Diamond Light Source, Didcot, UK — [5]ESRF, Grenoble, France — [6]NSRRC, Hsinchu, Taiwan — [7]Institut Neel, CNRS, Grenoble, France — [8]Institute for Theoretical Physics, Heidelberg University, Germany
$CeRh_3B_2$ combines seemingly exclusive properties of strong intermediate valence and high temperature ferromagnetism below 116K with strongly reduced magnetic moments. Utilizing recent advances in synchrotron techniques (XAS & RIXS) in combination with ab-initio density functional calculations, we find that the Rh states are irrelevant for the high temperature ferromagnetism and the Kondo effect, and that the crystal-field strength is not sufficiently strong to account for the Ce moment reduction. Instead our investigation reveals that different Ce $4f$ orbitals contribute differently to the magnetic coupling and the Kondo-type hybridization in $CeRh_3B_2$. The manifestation of such selective orbital coupling is a new aspect in the world of the strongly correlated 4f intermetallics.

Superconductivity beyond the Pauli limit in high-pressure $CeSb_2$ — •Oliver Squire, Stephen Hodgson, Jiasheng Chen, Vitaly Fedoseev, Christian de Podesta, Theodore Weinberger, Patricia Alireza, and Malte Grosche — Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, UK

The Kondo lattice system $CeSb_2$ has been recently found to undergo a structural transition under applied pressure. Here, we focus on the low-temperature properties in the new high-pressure structure which hosts an ultra-heavy fermion electronic state and antiferromagnetic order.

We have accessed the high-pressure structure of $CeSb_2$ using both piston-cylinder and anvil pressure cells at mK temperatures, and suppressed the magnetic order to a quantum critical point. In the vicinity of the quantum critical point, we have discovered a superconducting dome with $T_c = 250$ mK. The upper critical field exceeds the conventional Pauli limit by almost an order of magnitude and displays an unusual S-shaped temperature dependence. We will discuss the relationship between the upper critical field, the locally non-centrosymmetric crystal structure and the strong electronic mass enhancement in $CeSb_2$.

TT 4.12　Mon 12:30　HSZ 201
Structural and electronic instabilities in high pressure $CeSb_2$ — •Christian K. de Podesta[1], Theodore I. Weinberger[1], Oliver P. Squire[1], Stephen A. Hodgson[1], Jiasheng Chen[1], Rustem Khasanov[2], Christine Beavers[3], Patricia L. Alireza[1], and F. Malte Grosche[1] — [1]Uniersity of Cambridge, UK — [2]Paul Scherrer Institut, Switzerland — [3]Diamond Light Soure, UK
The Kondo-lattice material $CeSb_2$ undergoes a cascade of at least three magnetic transitions below 16 K and - unusually for a Ce system - settles on a ferromagnetic ground state. Whereas these transitions are initially hardly affected by applied pressure, they disappear abruptly above 18 kbar. We find that this disappearance is caused by a pressure induced structural change. The high pressure structure of $CeSb_2$ is profoundly different. It hosts a highly renormalised heavy fermion state which itself undergoes further magnetic transitions at very low temperature. Magnetic order within the high pressure structure extrapolates to zero at a pressure tuned quantum critical point, inducing a new superconducting phase with an anomalous field dependence[1].

We present the first detailed account of the high pressure crystal structure of $CeSb_2$ from X-ray diffraction, alongside a comprehensive study of the associated magnetic order, using μSR, AC-heat capacity and resistivity measurements. This provides the foundation on which to understand the anomalous superconducting properties which are thought to emerge from the quantum critical point.

TT 4.13　Mon 12:45　HSZ 201
Observation of anomalous magneto-transport properties in $CeAl_2$ — •Christian Oberleitner, Christian Franz, Alexander Regnat, Jan Spallek, Michael Petrov, Georg Benka, Andreas Bauer, Marc Wilde, and Christian Pfleiderer — Physik-Department, Technische Universität München, D-85748 Garching, Germany
Rare-earth compounds historically have attracted great interest due to their diverse low-temperature properties comprising complex magnetic order, superconductivity, and heavy fermion behaviour. We report a study of the electrical transport properties of non-centrosymmetric $CeAl_2$ at low temperatures and large magnetic fields. For our study single crystals were grown by means of optical float-zoning, where Laue and powder x-ray diffraction as well as low residual resistivities confirm excellent sample quality. Measurements of the magnetization, specific heat, and torque magnetization were used to map out the magnetic phase diagram for different crystallographic orientations. In the regime of the antiferromagnetic order, which supports multi-k antiferromagnetic structures, the magnetoresistance and Hall effect are highly anomalous suggestive of an intricate interplay of anomalous and topological contributions.

Generalized Bogoliubov-Hartree-Fock theory for the Hubbard model — •Chris Koschenz[1] and Carsten Timm[1,2] — [1]Institute of Theoretical Physics, TU Dresden, 01062 Dresden, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, 01062 Dresden, Germany
We present the phase diagram of the Hubbard model on the square lattice up to a four-site unit cell derived via a generalized Bogoliubov-Hartree-Fock theory. Our approach allows to study magnetic ordering, charge ordering, and superconductivity on the same footing and gives additional information about the so-called mixed phases [1]. These phases emerge in parameter ranges where the system is potentially strongly affected by fluctuations and cannot be described by any set of usual Hartree-Fock states (Slater determinants) [1,2]. Furthermore, we show how to obtain the self-consistent set of order parameters by straightforward

unrestricted global minimization of the appropriate Landau functional [3]. This method allows us to study the coexistence and competition of various magnetic orders and can be used to study the possibility of additional phase transitions in the coexistence regime. [1] E. Langmann and M. Wallin, J. Stat. Phys. **127**, 825 (2007) [2] V. Bach et al., J. Stat. Phys. **76**, 3 (1994) [3] R. Agra et al., Eur. J. Phys. **27**, 407 (2006)

Competing instabilities with fRG in highly symmetric triangular lattice Hubbard models — •Hannes Braun — Max Planck Institute for Solid State Research
Motivated by, e.g., simulations via cold atomic gases and twisted multi-layer transition metal dichalcogenides, we consider Hubbard models with SU(N)*SU(M) symmetry. Such highly symmetric systems with additional degrees of freedom

offer possibilities for novel types of symmetry-broken phases and their competition. To analyse the competing correlated phases of the resulting Hubbard models, we generalise the functional Renormalization Group (fRG) approach for correlated fermionic systems to efficiently incorporate the high symmetries. The truncated unity fRG provides us with unbiased fluctuation diagnostics and allows us to analyse the interplay between charge, spin, and pairing instabilities on equal footing. We present the new set of SU(N)*SU(M)-symmetric fRG equations and first results for the two-dimensional Hubbard model on the triangular lattice.

TT 5.3   Mon 10:00   HSZ 204

Functional renormalization group without functional integrals — Peter Kopietz, Rüdiger Krämer, and •Andreas Rückriegel — Institut für Theoretische Physik, Universität Frankfurt, Max-von-Laue Str. 1, 60438 Frankfurt

We show that exact functional renormalization group (FRG) flow equations for quantum systems can be derived directly within a Hamiltonian operator formalism without using functional integrals. This can be useful for teaching FRG methods to students unfamiliar with functional integrals and also opens new possibilities for applying FRG methods to quantum systems with projected Hilbert spaces such as quantum spin models or strongly interacting fermionic lattice models. In particular, by representing the Hubbard model and the $t - J$-model in terms of so-called Hubbard X-operators we construct a new strong-coupling FRG approach to these models.

TT 5.4   Mon 10:15   HSZ 204

Reduced basis modeling of quantum spin systems based on DMRG — •Paul Brehmer[1], Michael Herbst[2], Matteo Rizzi[3,4], Benjamin Stamm[5], and Stefan Wessel[1] — [1]Institute for Theoretical Solid State Physics, RWTH Aachen University, 52074 Aachen, Germany — [2]Applied and Computational Mathematics, RWTH Aachen University, 52062 Aachen, Germany — [3]FZ Jülich GmbH, Institute of Quantum Control, Peter Grünberg Institut (PGI-8), 52425 Jülich, Germany — [4]Institute for Theoretical Physics, University of Cologne, 50937 Köln, Germany — [5]Institute of Applied Analysis and Numerical Simulation, University of Stuttgart, 70569 Stuttgart, Germany

Within the reduced basis modeling approach, an effective low-dimensional subspace of a quantum many-body Hilbert space is constructed in order to investigate, e.g., the ground-state phase diagram. The basis of this subspace is built from solutions of snapshots, i.e., ground states corresponding to particular and well-chosen parameter values. Here, we show how a greedy strategy to assemble the reduced basis and thus to select the parameter points can be implemented based on density-matrix-renormalization-group (DMRG) calculations. Once the reduced basis is computed, observables required for the computation of phase diagrams can be computed with a computational complexity independent of the underlying Hilbert space for any parameter value. We illustrate the efficiency and accuracy of this approach for different one-dimensional quantum spin-S models with both $S = 1/2$ and $S = 1$, including anisotropic as well as biquadratic exchange interactions, leading to rich quantum phase diagrams.

TT 5.5   Mon 10:30   HSZ 204

Novel degrees of freedom in cluster Mott insulators — •Vaishnavi Jayakumar and Ciarán Hickey — Institute for Theoretical Physics, University of Cologne, Germany

The Hubbard model provides a playground for investigating the physics of a wide range of strongly correlated systems. An important feature of these systems is the Mott insulating phase, where at half-filling, an electron gets localised on a single lattice site. In this work, we study cluster Mott insulators – where electrons are now localised on clusters of sites. To that end, we study an extended Hubbard-Kanamori model on a plethora of clusters with multiple orbitals per site, at different electron fillings. We then explore different regimes of interplay between strong correlations and hopping within these clusters, and the effective degrees of freedom that emerge. It is seen, for example, that high ground-state degeneracies are possible that are due to a combination of both spatial and orbital symmetries. We further include crystal field splitting and spin-orbit coupling to bring our model closer to real materials. Once a blueprint for these building blocks has been established, the clusters can be connected through inter-cluster terms, giving rise to potentially novel Hamiltonians.

TT 5.6   Mon 10:45   HSZ 204

Numerical linked cluster expansions for the ordered low-field phase of the transverse-field Ising model — •Matthias Mühlhauser, Max Hörmann, and Kai Phillip Schmidt — Institute for Theoretical Physics I, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany

We present a hypergraph approach to numerical linked cluster expansions (NLCEs) in the low-field limit of the transverse-field Ising model (TFIM) where the Z2-Symmetry of the TFIM is spontaneously broken and the ground state is magnetically ordered.

Conventional NLCEs in this limit are performed as site expansions where the magnetic order of the ground state is taken into account by longitudinal boundary fields on the graphs.

Here, using an isospectral dual description of the TFIM where the ordered phase is mapped to an effective (symmetry unbroken) polarized phase in the dual desciption, we demonstrate that a straightforward hypergraph expansion can be executed so that no boundary fields are necessary. This allows us to obtain competitive results for the ground-state energy of the ordered low-field phase of the TFIM.

TT 5.7   Mon 11:00   HSZ 204

Projective cluster-additve block-diagonalisation method — •Max Hörmann and Kai Phillip Schmidt — Institut für Theoretische Physik I, Universität Erlangen-Nürnberg, Staudtstraße 7, 91058 Erlangen

We present an efficient block-diagonalisation method that only relies on the lowest eigenvectors and eigenvalues and allows for a linked-cluster expansion. The method is applied to a low-field expansion of the transverse-field Ising model on the square lattice. Both the single spin-flip and bound-state dispersion is calculated perturbatively and non-perturbatively. The origin of the breakdown of the non-perturbative linked-cluster expansion for the bound-state dispersion at a critical field value is discussed and potential solutions to overcome this problem are examined.

TT 5.8   Mon 11:30   HSZ 204

Series expansions with multiple quasi-particle types for the dual Dicke-Ising model — •Andreas Schellenberger, Lea Lenke, and Kai Phillip Schmidt — FAU Erlangen-Nürnberg, Erlangen, Deutschland

The established approach of perturbative continuous unitary transformations (pCUT) constructs effective quantum many-body Hamiltonians in a perturbative series that conserve the number of one quasi-particle type. We extend the pCUT method to similarity transformations – dubbed pcst^{++} – allowing for multiple quasi-particle-types with complex-valued energies. This enlarges the field of application to closed and open quantum many-body systems with unperturbed operators corresponding to arbitrary superimposed ladder spectra. To illustrate the new possibility of the pcst^{++} method to specifically tackle interacting light-matter systems, we discuss the dual Dicke-Ising model. We determine low-energy spectral properties and investigate potential conversion processes between different quasi-particle types.

TT 5.9   Mon 11:45   HSZ 204

Series expansions in open and non-Hermitian quantum many-body systems with multiple quasi-particle types — •Lea Lenke, Andreas Schellenberger, and Kai Phillip Schmidt — FAU Erlangen-Nürnberg

The established approach of perturbative continuous unitary transformations (pCUT) constructs effective quantum many-body Hamiltonians in a perturbative series that conserve the number of one quasi-particle type. We extend the pCUT method to similarity transformations – dubbed pcut^{++} – allowing for multiple quasi-particle-types with complex-valued energies. This enlarges the field of application to closed and open quantum many-body systems with unperturbed operators corresponding to arbitrary superimposed ladder spectra. To this end a generalized counting operator is combined with the quasi-particle generator for open quantum systems recently introduced by Schmiedinghoff and Uhrig [1]. The pcut^{++} then yields model-independent quasi-particle conserving effective Hamiltonians and Lindbladians allowing a linked-cluster expansion similar to the conventional pCUT method. We illustrate the application of the pcut^{++} method by discussing representative open and non-Hermitian quantum systems. [1] G. Schmiedinghoff and G. S. Uhrig, arXiv:2203.15532 [cond-mat.quant-ph].

TT 5.10   Mon 12:00   HSZ 204

Multi-scale space-time ansatz for correlation functions of quantum systems — •Hiroshi Shinaoka[1], Markus Wallerberger[2], Yuta Murakami[3], Kosuke Nogaki[4], Rihito Sakurai[1], Philipp Werner[5], and Anna Kauch[2] — [1]Department of Physics, Saitama University, Saitama 338-8570, Japan — [2]Institute of Solid State Physics, TU Wien, 1040 Vienna, Austria — [3]Center for Emergent Matter Science, RIKEN, Wako, Saitama 351-0198, Japan — [4]Department of Physics, Kyoto University, Kyoto 606-8502, Japan — [5]Department of Physics, University of Fribourg, 1700 Fribourg, Switzerland

Correlation functions of quantum systems are central objects in quantum field theories, which may be defined in high-dimensional space-time domains. The numerical treatment of these objects suffers from the curse of dimensionality, which hinders the application of sophisticated many-body theories to interesting problems.

In this talk, we propose a quantum-algorithms-inspired Multi-Scale Space-Time Ansatz (MSSTA) for correlation functions of quantum systems [1]. The space-time dependence is mapped to auxiliary qubit ($S = 1/2$ spin) degrees of freedom describing exponentially different length scales, and the ansatz assumes a separation of length scales. We numerically verify the ansatz for various equilibrium and nonequilibrium systems and show essential building blocks of diagrammatic equations, such as convolutions or Fourier transforms are formulated in the compressed form using tensor networks.

Dynamical mean-field study of a photon-mediated ferroelectric phase transition — •Katharina Lenk[1], Jiajun Li[2,3], Philipp Werner[2], and Martin Eckstein[1] — [1]I. Institut für Theoretische Physik, Universität Hamburg, 22607 Hamburg — [2]Department of Physics, University of Fribourg, 1700 Fribourg Switzerland — [3]Paul Scherrer Institute, Condensed Matter Theory, PSI Villigen, Switzerland

The interplay of light and matter gives rise to intriguing cooperative effects in quantum many-body systems. This is even true in thermal equilibrium, where the electromagnetic field can hybridize with collective modes of matter, and virtual photons can induce interactions in the solid. Here, we treat these light-mediated interactions using dynamical mean-field theory. We consider a minimal model of a two-dimensional material that couples to a surface plasmon polariton mode of a metal-dielectric interface. Within the mean-field approximation, the system exhibits a ferroelectric phase transition that is unaffected by the light-matter coupling. Bosonic dynamical mean-field theory provides a more accurate description and reveals that the photon-mediated interactions enhance the ferroelectric order and stabilize the ferroelectric phase.

TT 5.13   Mon 12:45   HSZ 204

Energy correlations of excited states in localization landscape theory — •Torsten Weber, Johannes Dieplinger, Christoph Forster, Lucas Resch, Ferdinand Evers, and Klaus Richter — Universität Regensburg, Regensburg, Deutschland

The localization landscape method, first described in [1], is a method that enables the prediction of the localization regions of eigenfunctions of a localized system. Additionally, the method gives a prediction of the energy of low-lying localized eigenfunctions by defining an effective potential from the landscape function [2]. This energy prediction, although providing good results for low energy eigenfunctions, ceases to work for higher energy states. Studying the method for a one-dimensional disordered system we observe a characteristic form of the ratio of the predicted eigenvalue by the landscape method and the actual eigenvalue for this region of the spectrum. We provide a possible explanation for this behaviour by extending the method leading to the energy prediction by including excited states of the effective potential. By harnessing the universal technique of quantifying excited states by counting nodes we observe a correspondence of the n-th excited states with the n-th repetition of a substructure of the characteristic behaviour described above. We go further to also find an analytic estimate for the structures.

Extended quasiparticle Padé approximation for non-Fermi liquids — •Klaus Morawetz — Münster University of Applied Sciences,Stegerwaldstrasse 39, 48565 Steinfurt, Germany — International Institute of Physics- UFRN,Campus Universitário Lagoa nova,59078-970 Natal, Brazil

The extended quasiparticle picture is adapted to non-Fermi systems by suggesting a Padé approximation which interpolates between the known small scattering-rate expansion and the deviation from the Fermi energy. The first two energy-weighted sum rules are shown to be fulfilled independent of the interpolating function. For various models of one-dimensional Fermions scattering with impurities the quality of the Padé approximation for the spectral function is demonstrated and the reduced density matrix or momentum distribution is shown to be reproduced not possessing a jump at the Fermi energy. Though the two-fold expansion is necessary to reproduce the spectral function and reduced density it is shown that for the description of transport properties the extended quasiparticle approximation is sufficient. The T-matrix approximation leads to the delay time as the time two particles spend in a correlated state. This contributes to the reduced density matrix and to an additional part in the conductivity which is presented at zero and finite temperatures. Besides a localization at certain impurity concentrations, the conductivity shows a maximum at small temperatures interpreted as onset of superconducting behaviour triggered by impurities. The Tan contact reveals the same universal behaviour as known from electron-electron scattering.

TT 6.1   Mon 9:30   HSZ 304

Anomalous Hall and Nernst effects in Kane fermions — •Karun Gadge[1,3], Sumanta Tewari[2], and Girish Sharma[3] — [1]Institute for Theoretical Physics University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen — [2]Department of Physics and Astronomy, Clemson University, Clemson, South Carolina, 29634, USA — [3]School of Basic Sciences, Indian Institute of Technology, Mandi, Mandi 175005, India

Kane fermions are characterized by a linear Dirac cone intersecting with a flat band, resembling a pseudo-spin-1 Dirac semimetal. Similar to relativistic Dirac fermions, Kane fermions satisfy a linear energy-momentum relation and can be classified as being pseudorelativistic. Unlike Dirac fermions, they are not protected by symmetry or by topology, but respect time-reversal symmetry, and can emerge by suitable band engineering, for example, in mercury-telluride compounds. Here we discuss the reminiscences of Berry-phase physics in Kane fermions that emerge in the presence of broken time-reversal symmetry. We discuss anomalous transport in Kane fermions and show its similarity to transport in a Dirac semimetal. Furthermore, we study anisotropy in their response that can be probed in current experiments.

Automatic generation and topological classification of low-energy Hamiltonians at multi-fold degeneracies — •Kirill Alpin — Max Planck Institute for Solid State Research, Stuttgart, Germany

In this talk, we show a method of generating general high-symmetry Hamiltonian with the goal of topologically classifying all possible multi-fold crossings in bandstructures of condensed matter systems. To do so, we found all higher-dimensional irreducible representations at all high-symmetry points in all space groups. The topological phase diagrams of the automatically generated low-energy Hamiltonian at these k-points were mapped out. During this process, we identified a prevalent topological phase with an unusually high Chern number of 5 in multi-fold point crossings. A material was found featuring this topological phase. Further ab-initio calculations of this materials surface DOS showed a high number of Fermi arcs.

TT 6.3   Mon 10:00   HSZ 304

Finite-size effects in a two-dimensional non-symmorphic wallpaper group lattice — •Miguel Ángel Jiménez Herrera[1] and Dario Bercioux[1,2] — [1]Donostia International Physics Center, 20018 San Sebastian, Spain — [2]IKERBASQUE, Basque Foundation for Science, Euskadi Plaza, 5, 48009 Bilbao, Spain

We investigate the spectral properties of a two-dimensional electronic lattice belonging to the non-symmorphic wallpaper group: the herringbone lattice. Specifically, we focus on the cases of ribbons and flakes geometry. Within a tight-binding description, we study how the different states localize inside the system both for ribbons and flakes. We apply different perturbations and symmetry breaking distortions to the lattice and investigate the robustness of the spectral features. Similarly to the bulk case, where we can gap the band structure or merge the Dirac cones into semi-Dirac cones [1], we recover the same properties along the two main directions that ribbons can be constructed. Finally, we study the finite size effects on this lattice, both on ribbon and flake geometries, and report a spectral flow of states across the bulk-like bands.

TT 6.4   Mon 10:15   HSZ 304

Landau quantization in the topological semimetal WTe$_2$ — •R. Sanchez-Barquilla[1], F. Martin-Vega[1], J. J. Baldovi[2], M. Ochi[3], R. Arita[4], N. H. Jo[5], S. L. Bud'ko[5], P. C. Canfield[5], H. Suderow[1], and I. Guillamon[1] — [1]Laboratorio de Bajas Temperaturas y Altos Campos Magnéticos, UAM, E-28049, Spain — [2]ICMol, UV, 46980 Paterna, Spain. — [3]Department of Physics, Osaka University, Osaka 560-0043, Japan — [4]RIKEN Center, Saitama 351-0198, Japan — [5]Department of Physics and Astronomy, Ames, IA 50011

WTe$_2$ is a layered semimetal which has sparked much interest due to the non-saturating linear MR and possible non-trivial band structure properties, such as

Weyl type-II fermions. Quantum oscillations under magnetic fields signal the passage of Landau levels (LL) through the Fermi level and are easily observed in macroscopic measurements, providing a rather complete view of the FS. However, the Landau quantization of the band structure above and below the Fermi energy has not yet been resolved in detail. We present mK STM measurements up to 14T. We have obtained the band structure close to the Fermi level and identified the main electron and hole pockets thanks to QPI experiments at 0T. When applying magnetic field, the spatially averaged tunneling conductance is devoid of LL and shows no field dependence. Atomically resolved measurements present however Landau quantization. We show that the contribution from the electron and hole pockets to the tunneling density of states (DOS) compensates LL peaks in the spatially averaged DOS. We describe Landau quantization at atomic scale and show a non-trivial energy shift of the LL structure.

TT 6.5   Mon 10:30   HSZ 304

Landau levels in NbAs as seen in magneto-optics: experiment versus modeling — S. Polatkan[1], M. Orlita[2], C. Shekhar[3], C. Felser[3], M. Dressel[1], and •A. V. Pronin[1] — [1]1. Physikalisches Institut, Universität Stuttgart, 70569 Stuttgart, Germany — [2]LNCMI, CNRS-UGA-UPS-INSA-EMFL, 38042 Grenoble, France — [3]Max-Planck-Institut für Chemische Physik fester Stoffe, 01187 Dresden, Germany

We measured the inter-Landau-level transitions the Weyl semimetal NbAs in magneto-optical experiments and found that the fits with pure Weyl bands do not lead to a satisfactory agreement between theory and experiment. We thus propose a coupled hyperbolic band model, supplemented by detailed 2D band structure cuts, attributing a secondary role to the presence of Weyl points. We argue that this minimalist model is sufficient to describe the measured magneto-optical spectra.

TT 6.6   Mon 10:45   HSZ 304

Static and dynamic magnetic properties of RAlSi Weyl semimetals — •Tillmann Weinhold[1], Hank Wu[2,3], Rajib Sarkar[1], George Gill[2], Vadim Grinenko[4], Fazel Tafti[5], Stephen Blundell[2], and Hans-Henning Klauss[1] — [1]TU Dresden, Germany — [2]University of Oxford — [3]MPI for Solid State Research, Stuttgart, Germany — [4]Shanghai JiaoTong University, China — [5]Boston College, MA, USA

Weyl semimetals show interesting electronic transport behavior like anomalous Hall effect and negative magnetoresistance. In the magnetic semimetal NdAlSi spin-density wave order was found below 7.2 K. It is proposed that the magnetic order is driven by RKKY interaction of Weyl fermions on narrow Fermi pockets.

We used NMR and μSR experiments to gain information about local static and dynamic magnetic properties of NdAlSi and discuss the results in comparison with diamagnetic LaAlSi and canted ferromagnetic CeAlSi.

TT 6.7   Mon 11:00   HSZ 304

Optically enhanced terahertz harmonic generation in the Dirac semimetal Cd_3As_2 — •Patrick Pilch[1], Changqing Zhu[1], Renato M. A. Dantas[2], Anneke Reinold[1], Yunkun Yang[3], Faxian Xiu[3], and Zhe Wang[1] — [1]TU Dortmund University, Germany — [2]University of Basel, Switzerland — [3]Fudan University, Shanghai, China

High harmonic generation provides an efficient tool to investigate nonequilibrium dynamics of a driven system, and is also very interesting for applications. Cd_3As_2 is a well-established three-dimensional Dirac semimetal with a topologically protected crossing of linear bands at the Fermi level. Terahertz harmonic generation is observed in Cd_3As_2 due to field-driven intraband kinetics [1]. By optically pumping the electron-doped Cd_3As_2, we observe a strong enhancement of the terahertz third harmonic generation. By investigating the dependence of the terahertz third harmonic generation on the pump fluence and time delay, we can ascribe this enhancement to the kinetics of a long-lived nonequilibrium state which corresponds to a population inversion of electrons and holes in the Dirac cone with a characteristic relaxation time $\tau \leq 10$ ps.

Signatures of a magnetic-field-induced Lifshitz transition in the ultra-quantum limit of the topological semimetal $ZrTe_5$ — •Stanislaw Galeski[1,2] and Henry Legg[3] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, germany — [2]Physics Institute, Universität Bonn, Bonn, Germany — [3]Department of Physics, University of Basel, Basel, Switzerland

The quantum limit (QL) of an electron liquid, realised at strong magnetic fields, has long been proposed to host a wealth of strongly correlated states of matter. Electronic states in the QL are, for example, quasi-one dimensional (1D), which implies perfectly nested Fermi surfaces prone to instabilities. Whereas the QL typically requires unreachably strong magnetic fields, the topological semimetal $ZrTe_5$ has been shown to reach the QL at fields of only a few Tesla. Here, we characterize the QL of $ZrTe_5$ at fields up to 64 T by a combination of electrical-transport and ultrasound measurements. We find that the Zeeman effect in

$ZrTe_5$ enables an efficient tuning of the 1D Landau band structure with magnetic field. This results in a Lifshitz transition to a 1D Weyl regime in which perfect charge neutrality can be achieved. Since no instability-driven phase transitions destabilise the 1D electron liquid for the investigated field strengths and temperatures, our analysis establishes $ZrTe_5$ as a thoroughly understood platform for potentially inducing more exotic interaction-driven phases at lower temperatures.

TT 6.9   Mon 11:45   HSZ 304

The anomalous photo-Nernst effect in a Dirac semimetal — •Maanwinder Partap Singh[1,2], Jonas Kiemle[1,2], Waldemar Schmunk[1,2], Alexander Holleitner[1,2], and Christoph Kastl[1,2] — [1]Walter Schottky Institut, Technical University of Munich, Am Coulombwall 4a, 85748 Garching, Germany. — [2]Munich Center of Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 Munich, Germany

The 3D Dirac semimetal $HfTe_5$ is a model system to study unconventional Hall transport phenomena, such as quasi quantized and anomalous Hall efects, in the limit of very low charge carrier densities. Here, we report on anomalous photocurrents in $HfTe_5$, which are intimately linked to the anomalous Hall and the related Nernst conductivities. As the dominant mechanism of photocurrent generation, we establish a, hitherto hidden, anomalous photo-Nernst effect of 3D Dirac electrons. The anomalous photo-Nernst effect manifests itself as a long-range, photoresponse along the crystal edge arising from a Shockley-Ramo type response and the local symmetry breaking at the edge. The observed temperature and density dependences of the anomalous photo-Nernst currents are consistent with a dominating intrinsic Berry curvature mechanism.

TT 6.10   Mon 12:00   HSZ 304

Field-tunable inverted band gap in GdPtBi: A magneto-optical study — •S. Polatkan[1], E. Uykur[1], A. V. Pronin[1], M. Orlita[2], I. Mohelsky[2], J. Wyzula[2], C. Shekhar[3], C. Felser[3], and M. Dressel[1] — [1]1. Physikalisches Institut, Universität Stuttgart, 70569 Stuttgart, Germany — [2]LNCMI, CNRS-UGA-UPS-INSA-EMFL, 38042 Grenoble, France — [3]Max-Planck-Institut für Chemische Physik fester Stoffe, 01187 Dresden, Germany

GdPtBi is a half-Heusler compound that was suggested to host triple-point fermions. Such fermions may be transformed into Weyl fermions in magnetic fields. We present magneto-optical data alongside a $\mathbf{k} \cdot \mathbf{p}$ model, evidencing the exchange-interaction mediated pseudo-Zeeman splitting of the parabolic band touching at the Γ point predicted by DFT, and thus prove the existence of highly tunable Weyl cones.

TT 6.11   Mon 12:15   HSZ 304

Anisotropic optics and gravitational lensing of tilted Weyl fermions — •Viktor Könye[1], Lotte Mertens[1,2], Corentin Morice[3], Dmitry Chernyavsky[1], Ali G. Moghaddam[4,5], Jasper van Wezel[2], and Jeroen van den Brink[1,6] — [1]Institute for Theoretical Solid State Physics, IFW Dresden and Wurzburg-Dresden Cluster of Excellence ct.qmat, Helmholtzstr. 20, 01069 Dresden, Germany — [2]Institute for Theoretical Physics, University of Amsterdam, Science Park 904, 1098 XH Amsterdam, The Netherlands — [3]Laboratoire de Physique des Solides, CNRS UMR 8502, Universite Paris-Saclay, F-91405 Orsay Cedex, France — [4]Department of Physics, Institute for Advanced Studies in Basic Sciences (IASBS), Zanjan 45137-66731, Iran — [5]Computational Physics Laboratory, Physics Unit, Faculty of Engineering and Natural Sciences, Tampere University, FI-33014 Tampere, Finland — [6]Institute for Theoretical Physics, TU Dresden, 01069 Dresden, Germany

We show that tilted Weyl semimetals with a spatially varying tilt provide a platform for studying analogues to problems in anisotropic optics as well as curved spacetime. Considering particular tilting profiles, we numerically evaluate the time evolution of wave packets. We demonstrate that electron trajectories in such systems can be obtained from Fermat's principle in the presence of an inhomogeneous, anisotropic effective refractive index. On the other hand, we show how the electrons dynamics reveal gravitational features and use them to simulate gravitational lensing around a synthetic black hole.

TT 6.12   Mon 12:30   HSZ 304

Black hole mirages: Electron lensing and Berry curvature effects in inhomogeneously tilted Weyl semimetals — •Andreas Haller[1], Suraj Hedge[2], Chen Xu[2], Christophe De Beule[1,3], Thomas L. Schmidt[1], and Tobias Meng[2] — [1]Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg, Luxembourg — [2]Institute of Theoretical Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01069 Dresden, Germany — [3]Department of Physics and Astronomy, University of Pennsylvania, Philadelphia PA 19104, USA

In this talk, I present our recent study about electronic transport in Weyl semimetals with spatially varying nodal tilt profiles. We discuss two complementary approaches that characterise the electron flow: solutions of the semiclassical equations of motion, in analogy to those encountered in black hole spacetimes, and large-scale microscopic simulations of a scattering region surrounded by semi-infinite leads. We show that the two approaches lead to equivalent results

when the wave packet is sufficiently far from the center of the tilt. The two methods are arguably a powerful toolset in the pursuit of tiltronic devices such as e.g. electronic lenses.

TT 6.13   Mon 12:45   HSZ 304
Weyl-type parallel spin-momentum locking in a chiral topological semimetal — •Niels B. M. Schröter — Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle (Saale), Germany

Orthogonal Rashba-type spin-momentum locking is well-known from semiconductors and topological insulator surface states and has inspired many theoretical proposals for technological applications. In contrast, Weyl-type purely parallel spin-momentum locking – which can be considered the natural counterpart of the Rashba-type – has remained elusive in experiments because all experimentally confirmed Weyl-fermion are described by Pauli matrices that act on an

orbital pseudospin rather than the proper electron spin. Recently, chiral topological semimetals (CTS) that host single- and multifold band crossings [1,2] have been predicted to realize parallel spin-momentum locking. Here, we use spin-resolved photoemission to probe the spin-texture Fermi-arc surface states in the CTS PtGa. We find that the electron spin points orthogonal to the Fermi surface contour for momenta close to the projection of a bulk multifold fermion, which is consistent with parallel spin-momentum locking of the latter [3]. We anticipate that our discovery of parallel spin-momentum locking of multifold fermions will lead to the integration of chiral topological semimetals in novel spintronic devices that can be used for field-free switching of magnets with perpendicular magnetic anisotropy, and other novel phenomena.

Topological information device operating at the Landauer limit — •Ahmet Mert Bozkurt[1,2,3], Alexander Brinkman[4], and Inanc Adagideli[3,4] — [1]QuTech, Delft University of Technology, 2600 GA Delft, The Netherlands — [2]Kavli Institute of Nanoscience, Delft University of Technology, 2600 GA Delft, The Netherlands — [3]Faculty of Engineering and Natural Sciences, Sabanci University, Orhanli-Tuzla, Istanbul, Turkey — [4]MESA+ Institute for Nanotechnology, University of Twente, The Netherlands

We propose and theoretically investigate a novel Maxwell's demon implementation based on the spin-momentum locking property of topological matter. We use nuclear spins as a memory resource which provides the advantage of scalability. We show that this topological information device can ideally operate at the Landauer limit; the heat dissipation required to erase one bit of information stored in the demon's memory approaches $k_B T \ln 2$. Furthermore, we demonstrate that all available energy, $k_B T \ln 2$ per one bit of information, can be extracted in the form of electrical work. Finally, we find that the current-voltage characteristics of the topological information device satisfy the conditions of an ideal memristor.

TT 7.2   Mon 9:45   HSZ 403
Controlling 3D spin textures by manipulating sign and amplitude of interlayer DMI with electrical current — •Fabian Kammerbauer[1], Won-Young Choi[1], Freimuth Frank[1,2], Robert Frömter[1], Yuriy Mokrousov[1,2], and Mathias Kläui[1] — [1]Institute of Physics, Joahnnes Gutenberg University, Staudingerweg 7, 55128 Mainz, Germany — [2]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany

The recently discovered interlayer Dzyaloshinskii-Moriya interaction (IL-DMI) in multilayers with perpendicular magnetic anisotropy favors a canting of spins in the in-plane direction [1]. It could thus stabilize exciting spin textures such as Hopfions. A key requirement for nucleation is to control the IL-DMI and so, we investigate the influence of an electric current on the strength of the IL-DMI, as previously found for FMI. The IL-DMI is quantified using out-of-plane hysteresis loops while applying a static in-plane magnetic field at varied azimuthal angles. We observe a shift in the azimuthal dependence with increasing current, which is concluded to originate from the additional in-plane symmetry breaking introduced by the current flow. Fitting the angular dependence we demonstrate the presence of an additive current-induced term [3]. With this, an easily accessible possibility to manipulate 3D spin textures by current is realized.

Nonequilibrium dynamics in a spin valve with noncollinear magnetization — •Rudolf Smorka[1], Pavel Baláž[2], Michael Thoss[1], and Martin Žonda[3,1] — [1]University of Freiburg, Germany — [2]Institute of Physics of the Czech Academy of Sciences Prague, Czech Republic — [3]Charles University Prague, Czech Republic

Manipulation of magnetization by electric currents enables novel functions for spin-transfer torque devices. We study the nonequilibrium spin dynamics and spin-transfer torques in noncollinear spin-valve heterojunctions using a mixed quantum-classical Ehrenfest approach.

In an isolated valve for short spacer layers and weak spin-electron couplings, magnetization dynamics of the ferromagnetic layers is in agreement with the macrospin approximation. For large spacer layers, our quantum-classical approach predicts electron-induced spin relaxation. For intermediate electron-spin couplings, a change in the localization character of the electronic eigenstates

from metallic-like to insulator-like leads to a reduced indirect exchange interaction between spins mediated by the conduction electrons. In a spin valve coupled to leads, spin relaxation times differ by several orders of magnitude depending on whether the DC bias is introduced by shifting the electrochemical potentials of both leads symmetrically about the equilibrium Fermi level of the spin valve (reminiscent of a gate-tunable junction) or by shifting the chemical potential of only one lead (as realized in a scanning tunneling microscope geometry).

Nonrelativistic spin currents in altermagnets — •Rodrigo Jaeschke-Ubiergo, Jairo Sinova, and Libor Šmejkal — Institut für Physik, Johannes Gutenberg Universität Mainz, D-55099 Mainz, Germany

Altermagnetism has emerged recently as a third basic collinear magnetic phase [1], in addition to ferromagnets and antiferromagnets. Conventional antiferromagnets exhibit two sublattices with opposite magnetic moment related by translation or inversion. In altermagnets the magnetic sublattices are connected by a rotation or a mirror operation. The particular symmetry causes that altermagnets display time-reversal (T) symmetry breaking and spin split band structure even in absence of spin-orbit coupling [2]. In this work, we study the spin conductivity tensor in altermagnets by using spin group theory formalism [1]. We also use Kubo's linear response to calculate the spin conductivity tensor in all the altermagnetic spin point groups models. Additionally, we identify and sort 200 altermagnetic candidates into spin conductivity tensor classes. We will discuss some spin point groups that allow for a transverse spin current in detail. This is the case of spin splitter current in RuO2 [3,4], which is a nonrelativistic effect that conserves spin unlike in general magnetic spin Hall effect in noncollinear magnets. Moreover, the spin conductivity tensor is symmetric and T-odd, which makes it different from the conventional spin Hall effect. [1] Šmejkal et al., PRX, 12, 031042 (2022). [2] Šmejkal, et al. Sci.Adv 2020. [3] Gonzalez- Hernandez, et al. PRL 2021. [4] Šmejkal, et al. PRX 12, 011028 (2022).

Quantification and modulation of intrinsic spin transport in 5d transition metals — •Akash Bajaj, Reena Gupta, Andrea Droghetti, and Stefano Sanvito — School of Physics and CRANN, Trinity College Dublin, Dublin 2, Ireland

Spin-Hall effect (SHE) enables charge-to-spin conversion in heavy transition metals, such as Ta and Pt, with strong spin-orbit coupling (SOC) strengths. It has been extensively studied as a viable mechanism for the development of next-generation spintronics-based non-volatile memory devices. Numerous experimental and first-principles approaches have been devised to quantify the charge-to-spin conversion efficiency i.e., the spin-Hall angle (SHA), for the SHE. However, such approaches unavoidably involve interface contributions and, in general, extrinsic effects such as disorder and impurities, which are known to be less dominant than the bandstructure-only intrinsic contribution in such heavy metals. In this work, we use density functional theory combined with a bond-current-based non-equilibrium Green's functions approach to quantify the intrinsic SHAs of bulk elemental and thin-film models of 5d transition metals. We then computationally demonstrate a strategy for modulating the SHA within the same device, using Pt and Au as contrasting examples. Our computational work not only provides a quantitative estimation of the intrinsic SHAs for these materials, but also enables its theoretical understanding aimed towards the development of higher performance and power-efficient spintronics-based non-volatile memory devices.

TT 7.6 Mon 10:45 HSZ 403

Influence of Disorder at Insulator-Metal Interface on Spin Transport — Mahsa Alsadat Seyed Heydari, Wolfgang Belzig, and •Niklas Rohling — Department of Physics, University of Konstanz

Motivated by experimental work showing enhancement of spin transport between yttrium iron garnet and platinum by the thin antiferromagnetic insulator NiO [1] between them, we consider spin transport trough the interface of a nonmagnetic metal and a ferro- or antiferromagnetically ordered insulator. The spin transport is carried by spin-polarized electrons in the metal and by magnons in the insulator. Spin current can be generated by a spin accumulation in the metal due to the inverse spin Hall effect, a microwave field exciting magnons in the insulator, or by a thermal gradient (spin Seebeck effect). The spin current can be computed using Fermi's Golden Rule [2]. For a perfectly clean interface, the in-plane momentum is conserved for the electron-magnon scattering events which govern the spin transport through the interface. We calculate how disorder-induced broadening of the scatting matrix elements with respect to the in-plane momentum influences the spin current. As a general result, we observe that for many experimental setups, one should expect a rather small effect of interface disorder on the measured spin current.

TT 7.7 Mon 11:00 HSZ 403

Long-range orbital-Hall torques in Nb(or Ru)/Ni Heterostructures — Arnab Bose[1], Fabian Kammerbauer[1], •Rahul Gupta[1], Dongwook Go[2], Yuriy Mokrousov[1,2], Gerhard Jakob[1], and Mathias Kläui[1,3] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, 55128 Mainz, Germany — [2]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — [3]Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, NO-7491 Trondheim, Norway

We report a large orbital Hall torque (OHT) generated by Nb and Ru via strong dependence of torques on the ferromagnets, Ni, in Nb(Ru)/Ni heterostructures. We found the sign reversal of the damping-like torque in Nb/Ni. Moreover, the long-range orbital transport in the ferromagnet was revealed by the thickness dependences of Ni in Ni/Nb(or Ru) heterostructure, which are markedly different from the regular spin absorption in the ferromagnet that takes place within a few angstroms and thus it uniquely distinguishes OHT from the spin Hall torque. The experimentally measured effective orbital-Hall conductivities are found to be $6.1 \times 10^4 \frac{\hbar}{2e}$ $(\Omega m)^{-1}$ and $5.86 \times 10^4 \frac{\hbar}{2e}$ $(\Omega m)^{-1}$ for Nb and Ru, respectively, which is an order of magnitude higher than their measured spin Hall conductivities, as also confirmed by the density functional theory. This study opens a plethora of possibilities to further engineering the torques, utilizing the orbital degree of freedom.

TT 7.8 Mon 11:15 HSZ 403

Layer-resolved spin-orbit torque assisted magnetization dynamics in Pt/Co heterostructure — •Harshita Devda[1], András Deák[2], Leandro Salemi[3], Levente Rózsa[1], László Szunyogh[2], Peter M. Oppeneer[3], and Ulrich Nowak[1] — [1]Universität Konstanz, Konstanz, Germany — [2]Budapest University of Technology and Economics, Budapest, Hungary — [3]Uppsala University, Uppsala, Sweden

It is well known that the spin-orbit torque (SOT) mechanism is more reliable for current induced magnetization dynamics than the spin-transfer torque. The key phenomenon behind the SOT in heavy metal/ferromagnet (HM/FM) bilayers is attributed to the spin Hall effect (SHE) and the spin Rashba-Edelstein effect (SREE). However, the exact mechanism is still under debate. So far various works have studied the SOT-driven magnetic behavior in different magnetic systems, but the layer-resolved understanding of the SOT effect in the HM/FM bilayer due to spin-orbit coupling (SOC) in heavy metal is still lacking. We focus on current-induced magnetization dynamics in a Pt/Co bilayer assisted by the SOC in Pt. We use a multiscale model which links ab initio calculations with atomistic spin dynamics simulations. We implement a linear-response formalism to compute the electrically induced magnetic moments, caused by SHE in bulk and SREE at the interface, and utilize these in atomistic spin dynamics simulations. We analyse the layer-resolved behavior of both field-like and damping-like torques in FM and determine how they affect magnetization dynamics in ferromagnets.

TT 7.9 Mon 11:30 HSZ 403

Spin and orbital Edelstein effect in a bi- and trilayer system with Rashba interaction — •Sergio Leiva[1], Jürgen Henk[1], Ingrid Mertig[1], and Annika Johansson[2] — [1]Martin Luther University Halle-Wittenberg, Halle, Germany — [2]Max Planck Institute of Microstructure Physics, Halle, Germany

The spin Edelstein effect has proved to be a promising phenomenon to generate spin polarization from a charge current in systems without inversion symmetry. In recent years, current-induced orbital magnetization, also called the orbital Edelstein effect, has also been predicted for several systems with broken inversion symmetry [1-6].

In the present work, we calculate the current-induced spin and orbital magnetization for a bilayer and a trilayer system with Rashba interaction for the interface and the free-standing slab configurations. We use the modern theory of orbital magnetization [7] and the Boltzmann transport theory. We found a significantly larger orbital than spin effect, with a strong dependence on the model parameters, such as effective mass and spin-orbit coupling per layer. This dependence allows us to enhance and even revert the sign of the orbital effect.

Optical detection of the orbital Hall effect in a light metal Ti — •Young-Gwan Choi[1,2], Daegeun Jo[3], Kyung-Hun Ko[1], Dongwook Go[4,5], Kyung-Han Kim[3], Hee Gyum Park[6], Changyoung Kim[7,8], Byoung-Chul Min[6], Uri Vool[2], Gyung-Min Choi[1,9], and Hyun-Woo Lee[3,10] — [1]DOES, SKKU, Suwon, Korea — [2]MPI-CPfS, Dresden, Germany — [3]Physics, POSTECH, Pohang, Korea — [4]PGI and IAS, FZJ and JARA, Julich, Germany — [5]GSE Mainz, Mainz, Germany — [6]Center for Spintronics, KIST, Seoul, Korea — [7]Physics, SNU, Seoul, Korea — [8]CCES, IBS, Seoul, Korea — [9]CINAP, IBS, Suwon, Korea — [10]APCTP, Pohang, Korea

Electrical generation of the angular momentum current enables the development of novel memory devices, similar to spin current generation. Recently, it has been theoretically proposed that the orbital angular momentum (OAM) current can be driven by a charge current, called as the orbital Hall effect (OHE). Here we report evidence of the OHE, measured by magneto-optical Kerr effect microscopy. We detect large Kerr signals in one of the 3d transition metals, Ti, in which the high orbital Hall conductivity is predicted. We also find that the large OAM is accumulated by the OHE with a relaxation length ~70 nm. Moreover, we present the torque results in Ti/Ni. The high torque efficiency shows that the OAM injection allows for the electrical control of the magnetization. We also propose magnetic imaging using a nitrogen-vacancy scanning probe to measure OAM accumulation directly. Our results can pave the way for a deep understanding and provide techniques for generating and detecting orbital transport.

TT 7.11 Mon 12:00 HSZ 403

Spin and orbital Edelstein effects at oxide interfaces — •Annika Johansson[1], Börge Göbel[2], Sara Varotto[3], Srijani Mallik[3], Ingrid Mertig[2], and Manuel Bibes[3] — [1]Max Planck Institute of Microstructure Physics, Halle, Germany — [2]Martin Luther University Halle-Wittenberg, Halle, Germany — [3]Unité Mixte de Physique, CNRS, Université Paris-Saclay, Palaiseau, France

The spin Edelstein effect (SEE) provides charge-spin interconversion in nonmagnetic systems with broken inversion symmetry [1,2]: An external electric field generates a charge current as well as a homogeneous spin density. Further, a finite current-induced magnetization originating from the electrons' orbital moments can be generated, which is called orbital Edelstein effect (OEE) [3-5]. In this talk, the SEE and OEE at $SrTiO_3$- and $KTaO_3$-based two-dimensional electron gases are discussed within a semiclassical Boltzmann approach [6-8]. The OEE is predicted to exceed its spin counterpart by one order of magnitude, which can be understood by a band-resolved analysis of the SEE and OEE. Further, we suggest design rules for Rashba-like systems to enhance spin-charge interconversion efficiencies.

TT 7.12 Mon 12:15 HSZ 403

Anisotropic anomalous Hall effect in altermagnetic Mn_5Si_3 — •Miina Leiviskä[1], Rafael Lopes Seeger[1], Helena Reichlová[2,3], Ismaïla Kounta[4], Libor Šmejkal[5,3], Javier Rial[1], Sebastian Beckert[2], Antonín Badura[6,7], Isabelle Joumard[1], Dominik Kriegner[2,3], Eva Schmoranzerová[6], Jairo Sinova[5], Tomáš Jungwirth[3], Sebastian Goennenwein[7], Lisa Michez[4], and Vincent Baltz[1] — [1]Univ. Grenoble Alpes, CNRS, CEA, Grenoble INP, IRIG-SPINTEC, F-38000 Grenoble — [2]Institute of Solid State and Materials Physics, TU Dresden, Dresden, Germany — [3]Institute of Physics, Czech Academy of Sciences, Prague, Czechia — [4]Aix-Marseille University, CNRS, CINaM, Marseille, France — [5]Institute for Physics, Johannes Gutenberg University Mainz, Mainz, Germany — [6]Department of Chemical Physics and Optics, Faculty of Mathematics and Physics, Charles University, Prague, Czechia — [7]Department of Physics, University of Konstanz, Konstanz, Germany

The altermagnetic epitaxial films of Mn_5Si_3 exhibit anomalous Hall effect (AHE) despite the vanishing net magnetization [1]. This can be explained by non-

relativistic time-reversal symmetry breaking, which allows for momentum-locked alternating spin-splitting of the bands [2]. Here, we investigate the anisotropy of the AHE by varying both the external field and the current channel orientations. In both cases, we observe unconventional, anisotropic behaviour that deviates from the typical behaviour of ferromagnets.

TT 7.13   Mon 12:30   HSZ 403

Observation of nonreciprocal magnon Hanle effect — •Janine Gückelhorn[1,2], Sebastián de-la-Peña[3], Matthias Grammer[1,2], Monika Scheufele[1,2], Matthias Opel[1], Stephan Geprägs[1], Juan Carlos Cuevas[3], Rudolf Gross[1,2,4], Hans Huebl[1,2,4], Akashdeep Kamra[3], and Matthias Althammer[1,2] — [1]Walther-Meißner-Institut, BAdW, Garching, Germany — [2]Physik-Department, School of Natural Sciences, TUM, Garching, Germany — [3]IFIMAC and Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, Madrid, Spain — [4]Munich Center for Quantum Science and Technology, München, Germany

The realization of the magnon Hanle effect, which is based on the precession of magnon pseudospin about the equilibrium pseudofield, via electrically injected and detected spin transport in an antiferromagnetic insulator demonstrates its high potential for devices and as a convenient probe for the underlying spin interactions in antiferromagnets. Here, we observe a nonreciprocity in the magnon Hanle signal measured in hematite (α-Fe_2O_3) using two spatially separated platinum electrodes as spin injector/detector [1]. Interchanging their roles was found to alter the detected magnon spin signal. The recorded difference depends on the applied magnetic field and reverses sign when the signal passes its nominal maximum at the so-called compensation field. We explain these observations in terms of a spin transport direction-dependent pseudofield. The latter leads to a nonreciprocity, which is found to be controllable via the applied magnetic field.

[1] J. Gückelhorn et al., arXiv:2209.09040 (2022).

TT 7.14   Mon 12:45   HSZ 403

Spontaneous anomalous Hall effect arising from an unconventional compensated magnetic phase in a semiconductor — •Dominik Kriegner[1,2], Ruben Dario Gonzalez Betancourt[1,2,3,4], Jan Zubáč[1,3], Rafael Julian Gonzalez Hernandez[5], Kevin Geishendorf[4], Gunther Springholz[6], Kamil Olejník[1], Jakub Železný[1], Libor Šmejkal[7], Andy Thomas[2,4], Helena Reichlová[1,2], Sebastian Tobias Benedikt Goennenwein[8], and Tomas Jungwirth[1,9] — [1]Institute of Physics, AV ČR, Prague, Czech Republic — [2]IFMP, TU Dresden — [3]Charles University, Prague — [4]IFW Dresden — [5]Universidad del Norte, Barranquilla, Colombia — [6]JKU Linz, Austria — [7]JGU, Mainz — [8]University of Konstanz — [9]University of Nottingham, United Kingdom

The anomalous Hall effect, commonly observed in metallic magnets, has been established to originate from the time-reversal symmetry breaking by an internal macroscopic magnetization in ferromagnets or by a non-collinear magnetic order. Here we observe a spontaneous anomalous Hall signal in the absence of an external magnetic field in an epitaxial film of MnTe, which is a semiconductor with a collinear antiparallel magnetic ordering of Mn moments and a vanishing net magnetization. The anomalous Hall effect arises from an unconventional phase with strong time-reversal symmetry breaking and alternating spin polarization in real-space crystal structure and momentum-space electronic structure.

TT 8: Yu-Shiba-Rusinov Systems

Time: Monday 15:00–17:15   Location: HSZ 103

Invited Talk   TT 8.1   Mon 15:00   HSZ 103

Molecules on a superconductor: Inducing magnetism and resonance-enhanced vibrational spectroscopy — •Richard Berndt[1], Jan Homberg[1], Alexander Weismann[1], Manuel Gruber[2], and Troels Markussen[3] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, Germany — [2]Fakultät für Physik, Universität Duisburg-Essen, Germany — [3]Synopsys Denmark, Copenhagen, Denmark

Magnetic impurities can induce so-called Yu-Shiba-Rusinov (YSR) resonances in the energy gap of a superconductor. We use these resonances for spin detection in a scanning tunneling microscope and demonstrate that diamagnetic phthalocyanine molecules acquire a spin when they are arranged into supramolecular arrays on superconducting Pb(100). Spectroscopy and modeling reveal that the electrostatic fields of its neighbors render a molecule paramagnetic.

Inelastic tunneling spectroscopy of vibrational excitations usually suffers from low sensitivity and limited spectral resolution. We harness YSR resonances to enhance the inelastic signal by more than an order of magnitude and to improve the energy resolution beyond the thermal broadening limit. As a result, 46 vibrational peaks are resolved from Pb-phthalocyanine enabling a comparison with calculated modes. The method may help to further probe the interaction of molecules with their environment and to better understand selection rules for vibrational excitations.

TT 8.2   Mon 15:30   HSZ 103

Yu-Shiba-Rusinov impurity bound states in superconductors from first principles — •David Antognini Silva[1], Philipp Rüssmann[1,2], and Stefan Blügel[1] — [1]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, Jülich, Germany — [2]Würzburg Universität, Germany

Materials that combine magnetism, spin-orbit interaction and conventional s-wave superconductivity are a suitable platform to study Majorana zero modes (MZM) [1], that can be used as building blocks of fault-tolerant topological qubits. In general, magnetic impurities in superconductors leads to localized Yu-Shiba-Rusinov (YSR) states at the impurity [2]. Understanding their interplay with MZMs is crucial to achieve topological quantum computers in the future.

In our work, we implemented the Bogoliubov-de Gennes (BdG) formalism in the juKKR Korringa-Kohn-Rostoker Green function impurity code (https://iffgit.fz-juelich.de/kkr/jukkr) to allow the material-specific description of defects perfectly embedded in superconductors from first principles. We apply it to an Fe impurity embedded in bulk Pb in the normal and superconducting state, then analyse the YSR states of different magnetic transition-metal adatoms placed on a superconducting Nb(110) surface where the influence of the impurity-substrate distance on the energy of the YSR states is discussed.

TT 8.3   Mon 15:45   HSZ 103

Yu-Shiba-Rusinov states of quantum impurities in spin-split superconductors — •Anastasiia Skurativska[1], Jon Ortuzar[2], Sebastian Bergeret[1,3], Dario Bercioux[1,4], and Miguel Angel Cazalilla[1,4] — [1]DIPC, 20018 San Sebastian, Spain — [2]CIC nanoGUNE-BRTA, 20018 San Sebastian, Spain — [3]CFM-MPC Centro Mixto CSIC-UPV/EHU, 20018 San Sebastian, Spain — [4]IKERBASQUE, Basque Foundation for Science, 48009 Bilbao, Spain

Yu-Shiba-Rusinov (YSR) states arise as a sub-gap excitations in a system of magnetic impurity coupled to a superconducting host. Despite the quantum nature of their spin degree of freedom, magnetic impurities in such systems are often described by a classical spin. Taking into account quantum nature of the impurity-spin has proven to give useful insights into the ground-state and excitation properties of the magnetic impurity-superconductor system.

Here, we report on the spectral properties of the YSR states of a magnetic impurity on a spin-split superconductor. Using the zero-bandwidth approximation we obtain the spectral function of the YSR states. Unlike the classical model which predicts full spin polarization for the YSR peaks, we find the quantum model predicts partial polarization. The parity-changing phase transition switches the spin polarization of the YSR peaks after crossing at the center of the superconducting gap. We discuss the possibility of using this effect as a tunable spin-filter in a quantum dot or a molecule in proximity to a spin-split superconductor.

TT 8.4   Mon 16:00   HSZ 103

Building crystalline topological superconductors from Shiba lattices — •Martina Ondina Soldini[1], Felix Küster[2], Glenn Wagner[1], Souvik Das[2], Amal Aldarawsheh[3,5], Ronny Thomale[4,6], Samir Lounis[3,5], Stuart S. P. Parkin[2], Paolo Sessi[2], and Titus Neupert[1] — [1]University of Zurich, Winterthurerstrasse 190, 8057 Zurich, Switzerland — [2]Max Planck Institute of Microstructure Physics, Halle, Germany — [3]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich & JARA, Jülich, Germany — [4]Institut fur Theoretische Physik und Astrophysik, Universitat Wurzburg, Wurzburg, Germany — [5]Faculty of Physics, University of Duisburg-Essen and CENIDE, Duisburg, Germany — [6]Department of Physics and Quantum Centers in Diamond and Emerging Materials (QuCenDiEM) Group, Indian Institute of Technology Madras, Chennai, India

Majorana boundary modes are the key feature of topological superconductors. Lattices of Shiba bound states, arising from magnetic adatoms placed on the surface of a conventional superconductor, may host these topological excitations. With scanning tunneling microscopy we create and probe adatom lattices to create topological crystalline superconductors. We combine theoretical modeling

and experimental analysis to reveal signatures consistent with mirror-symmetry protected topological superconductors, hosting edge and higher-order corner states. Our results show the immense versatility of Shiba lattices to design the topology of 2D superconductors.

TT 8.5   Mon 16:15   HSZ 103

Mn clusters on superconducting Ta(110) surface — •András Lászlóffy[1], Bendegúz Nyári[2,3], László Szunyogh[2], and Balázs Újfalussy[1] — [1]Wigner Research Centre for Physics, Budapest, Hungary — [2]Budapest University of Technology and Economics, Budapest, Hungary — [3]ELKH-BME Condensed Matter Physics Research Group, Hungary

Over the past decade, the formation of Yu-Shiba-Rusinov (YSR) states around magnetic impurities proximity coupled to superconducting materials raised considerable interest. The hybridization between these states leads to bands in magnetic chains being potential candidates for hosting Majorana edge states. In this work we solve the Bogoliubov-de Gennes equation as implemented in the first-principles Korringa-Kohn-Rostoker Green's function method. First, we provide an in-depth analysis of the YSR states of a single Mn adatom on Ta(110), and the hybridization between them in Mn dimers. We then study the formation of a minigap and zero energy states in chains with various directions and nearest-neighbor distances, making a strong implication that Majorana zero modes can emerge in these systems.

TT 8.6   Mon 16:30   HSZ 103

Effect of Fe impurities on the superconducting state of Ir/Nb overlayer — •Bendegúz Nyári[1,2], András Lászlóffy[3], Krisztián Palotás[3], László Szunyogh[1,2], Levente Rózsa[4], and Balázs Újfalussy[3] — [1]Department of Theoretical Physics, Budapest University of Technology and Economics, Hungary — [2]ELKH-BME Condensed Matter Physics Research Group, Hungary — [3]Wigner Research Centre for Physics, Institute for Solid State Physics and Optics, Hungary — [4]Department of Physics, University of Konstanz, Germany

Artificial magnetic chains on top of superconducting surfaces, where in the presence of large spin-orbit coupling or non-collinear magnetic states a topological gap can appear, are potential candidates to host Majorana edge states. Iridium as an overlayer on various metallic substrates appeared to be a good platform for the formation of spin-spiral states in magnetic overlayers and chains.

By solving the relativistic Bogoliubov–de Gennes equations, first we investigate the superconducting properties of 10 monolayers of Ir on top of Nb(110) surface. In the Ir layer we observe a strong reduction of the superconducting or-

der parameter, but the gap just slightly decreases as compared to bulk Nb. Then the effect of Fe impurities on the superconducting state is studied in different setups. For a single Fe impurity we find a huge spatial extension of the Yu–Shiba–Rusinov states. Disordered Fe impurities modelled within the coherent-potential approximation in the dilute concentration limit seem to rapidly destroy the superconducting state of the Ir overlayer.

TT 8.7   Mon 16:45   HSZ 103

Yu-Shiba-Rusinov states in small Fe clusters on Pb(111) — •Nora Kucska, Krisztián Palotás, Andras Laszloffy, and Balazs Ujfalussy — Wigner Research Centre for Physics, Budapest, Hungary

By solving the fully relativistic Bogoliubov-de Gennes equations by band-theoretical methods, we investigate the Yu-Shiba-Rusinov (YSR) states of single, double and triple magnetic Fe adatoms on the top of Pb(111) surface. First, we show that the local density of states in the normal state plays a key role in the formation of the YSR states that appear in the interior of the superconducting gap. We discuss the effects of different atomic arrangements, the role of lattice relaxations and various spin configurations on the YSR states, and we compare our results to recent experiments.

TT 8.8   Mon 17:00   HSZ 103

Yu-Shiba-Rusinov band dispersion of an infinite chain on a semi-infinite surface — •Rik Broekhoven, Artem Pulkin, Antonio Manesco, Sander Otte, Anton Ahkmerov, and Michael Wimmer — Delft University of Technology, Delft, the Netherlands

Chains of magnetic atoms on s-wave superconductors have been proposed to become topological superconductors, when their in-gap Yu-Shiba-Rusinov (YSR) band is p-wave gapped by for example spin-orbit coupling. As recently shown through STM experiment, however, realistic systems have many YSR bands and relatively small spin-orbit coupling limiting the topological phase. Ab initio models can help to increase our understanding and find regions of material and parameter space where the system is still predicted to be topological. These finite-size simulations must however overestimate the superconducting gap to ensure the system is smaller than the superconductor coherence length.

We combine ab initio calculation with multi-dimensional Green's functions formalism to extend the model beyond this limit. This allows us to do calculations with realistic gap size. We compute the dispersion of an infinite chain on top of a semi-infinite surface. We focus on Mn atoms on Nb(110) and show how our model compares with the dispersion measured by Schneider et al. in 2021.

TT 9: f-Electron Systems and Heavy Fermions II

Time: Monday 15:00–17:00   Location: HSZ 201

TT 9.1   Mon 15:00   HSZ 201

Quantum oscillations in heavy-fermion ferromagnet YbNi$_4$P$_2$ over many Zeeman induced Lifshitz transitions — •William Broad[1], Sven Friedemann[1], Owen Moulding[1], Takaki Muramatsu[1], Kristin Kliemt[2], and Cornelius Krellner[2] — [1]University of Bristol, Bristol, United Kingdom — [2]Goethe-Universität, Frankfurt am Main, Germany

YbNi$_4$P$_2$ is a heavy-fermion metal situated near a very rare ferromagnetic quantum critical point (FM QCP). Understanding the nature of this ferromagnetism requires knowledge of the Fermi surface; it has been speculated that this FM QCP is enabled by a quasi-1D Fermi surface. At the same time, the strongly renormalised band structure is readily modified by relatively small magnetic fields, with nine Lifshitz transitions below 20 T due to Zeeman splitting. Here, we present Shubnikov–de Haas oscillations up to 35T, including detailed rotation and mass studies. We present analysis over several of these Lifshitz transitions, observing frequency changes and appearances/disappearances. We model the band structure with DFT calculations of the local 4f reference compound LuNi$_4$P$_2$ and use rigid-band shifts to approximate the effect of the Kondo hybridisation. At highest fields, the Fermi surface is well modelled with a small shift to increase the Fermi volume. As the field is reduced, we find better agreement with a larger shift corresponding to stronger hybridisation of 4f electrons. Finally, we present models for the topology of the Lifshitz transitions.

TT 9.2   Mon 15:15   HSZ 201

Exploring the effect of different substitutions on the valence transition in YbInCu$_4$ single crystals — •Michelle Ocker, Bereket Ghebretinsae, Bernd Wolf, Kristin Kliemt, Michael Lang, and Cornelius Krellner — Physikalisches Institut, Goethe-Universität Frankfurt, 60438 Frankfurt/Main, Germany

At ambient pressure the compound YbInCu$_4$ undergoes a 1st order valence transition at T$_v$ = 42 K by changing the temperature [1]. Thus, ytterbium in the compound is present in the Yb$^{2.9+}$ state at high temperatures and as Yb$^{2.7+}$ at low temperatures [2]. In analogy to Eu compounds, the line of first order valence transitions might end in a second order critical endpoint [3]. In order to

study the nature of the phase transition in more detail, single crystal samples can be prepared in In-Cu flux which are substituted with silver and gold [4]. With increasing substitution level, negative chemical pressure within the crystal is increased and the characteristics of the valence transition changes significantly. Here, we report on the single crystal growth with different substitution levels and the results of our structural, chemical and physical characterization.

TT 9.3   Mon 15:30   HSZ 201

Impact of Fe substitution on the electronic structure of URu$_2$Si$_2$ — •Andrea Marino[1], Denise S. Christovam[1], Chun-Fu Chang[1], Johannes Falke[1], Chang-Yang Kuo[2], Chi-Nan Wu[2], Martin Sundermann[1,3], Andrea Amorese[1,3], Hlynur Gretarsson[4,5], Camilla Moir[6], M. Brian Maple[6], Peter Thalmeier[1], Liu Hao Tjeng[1], and Andrea Severing[3] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]National Synchrotron Radiation Research Center, Hsinchu, Taiwan — [3]University of Cologne, Cologne, Germany — [4]Max Planck Institute for Solid State Research, Stuttgart, Germany — [5]PETRA III, DESY, Hamburg, Germany — [6]University of California, San Diego, USA

The application of pressure as well as the substitution of Ru with Fe in the hidden order (HO) compound URu$_2$Si$_2$ lead to the formation of the large moment antiferromagnetic phase (LMAFM), with the respective phase diagrams bearing similarities for low Fe content (<0.3). For higher Fe content (>1) URu$_{(2-x)}$Fe$_{(x)}$Si$_2$ adopts the Pauli paramagnetic ground state of UFe$_2$Si$_2$. However, the question remains open what causes the suppression of HO in favour of the LMAFM phase. We investigate the URu$_{(2-x)}$Fe$_{(x)}$Si$_2$ series with 4f core-level photoelectron spectroscopy. The 4f satellite features are enhanced at low Fe content (x<0.4) and suppressed as x increases, following the trend shown by the ordered moment. We discuss this in terms of the variation of the filling of the 5f shell. Implications for the exchange interaction in a Doniach phase diagram picture are then also considered.

TT 9.4 Mon 15:45 HSZ 201

High-resolution tender x-ray RIXS at the example of UGa$_2$ — •MARTIN SUNDERMANN[1,2], ANDREA MARINO[1], DENISE CHRISTOVAM[1], ANDREA AMORESE[1,3], LADISLAV HAVELA[4], BERNHARD KEIMER[5], HLYNUR GRETARSSON[1,2,5], PETER THALMEIER[1], LIU HAO TJENG[1], and ANDREA SEVERING[1,3] — [1]MPI-CPfS, Dresden, Germany — [2]DESY/PETRA-III, Hamburg, Germany — [3]Institute of Physics II, University of Cologne, Germany — [4]Condensed Matter Physics, Karls-Universität, Prag, Czech — [5]MPI-FKF, Stuttgart, Germany

The nature of the $5f$ electrons in U intermetallic compounds, usually thought to be on the verge between localization and itinerant states, still challenges the reach of well-established condensed matter physics' techniques. Yet, it is not uncommon that U-based compounds show no inelastic neutron scattering excitations, and the question remains, if these compounds are fully delocalized or if multiplet states are present but not observable. Cutting-edge instrumental developments enables us to perform tender x-ray high-resolution (150 meV) resonant inelastic X-ray scattering (RIXS) experiments at the strong U $M_{4,5}$ absorption edges. We demonstrate the potential of this technique at the example of the intermetallic high T_C ferromagnet UGa$_2$. We observe mutliplet excitations that are well reproduced with a full multiplet calculation that includes the crystal-electron field splitting and is based on an U $5f^2$ configuration. Further we show that, although crystal-field splittings are too small to be resolved, the directional dependence of the scattering cross-section gives access to the ground-state symmetry.

TT 9.5 Mon 16:00 HSZ 201

Electronic structure of UO$_2$ studied by high-resolution tender-x-ray RIXS — •DENISE S. CHRISTOVAM[1], MARTIN SUNDERMANN[1,2], ANDREA MARINO[1], DAISUKE TAKEGAMI[1], ANDREA AMORESE[1,3], HLYNUR GRETARSSON[2,4], BERNHARD KEIMER[4], PHILIPP RAISON[5], ROBERTRO CACIUFFO[5], ANDREA SEVERING[1,3], and LIU HAO TJENG[1] — [1]MPI-CPfS, Dresden, Germany — [2]DESY/PETRA-III, Hamburg, Germany — [3]Institute of Physics II, University of Cologne, Germany — [4]MPI-FKF, Stuttgart, Germany — [5]Joint Research Centre, Euorpean Commission, Karlsruhe, Germany

The investigation of the $5f$ electronic states in uranium-based compounds is a great challenge for x-ray instrumentation. Recent instrumental developments in the tender x-ray regime enable us to carry out resonant inelastic x-ray scattering (RIXS) experiments at the strong U $M_{4,5}$ absorption edge with an experimental resolution of 150 meV. In this work, we studied the electronic structure of UO$_2$. We observe the excitations the U^{4+} $5f^2$ ionic multiplet states as well as the excitations involving the O $2p$ to U $5f$ charge transfer satellites. Detailed insight in the many-body nature of the ground state and excited states of UO$_2$ is obtained by analysing the data with full-multiplet cluster calculations which also take into account crystal field and hybridization effects.

TT 9.6 Mon 16:15 HSZ 201

Strain-tuning of charge frustration in the heavy 3d fermion oxide LiV$_2$O$_4$ — •RYOSUKE OKA[1,2], DENNIS HUANG[1], MINU KIM[1], PETER WOCHNER[1], and HIDENORI TAKAGI[1,2,3] — [1]Max Planck Institute for Solid State Research, Stuttgart, Germany — [2]Department of Physics, University of Tokyo, Tokyo, Japan — [3]Institute for Functional Matter and Quantum Technologies, University of Stuttgart, Stuttgart, Germany

The mixed-valent spinel LiV$_2$O$_4$ is the first discovered 3d electron system showing heavy fermion behavior without localized f moments, but its origin has remained a decades-old mystery. Amongst numerous scenarios proposed so far, including an analogy with a dense Kondo system, one of the leading scenarios is charge frustration inherent in the pyrochlore sublattice of the spinel. In this scenario, the ground state is composed of a macroscopic number of degenerate charge orderings (COs), and the frustration prevents the system from undergoing a metal-to-insulator transition, thereby enhancing the effective mass. By applying external perturbations that lift the degeneracy in different ways, various insulating COs can be selected out of the frustrated metallic ground state. For example, hydrostatic pressure and biaxial tensile strain in the (001) plane stabilize distinct [111]- and [001]-oriented COs, respectively. We have grown LiV$_2$O$_4$ thin films on various substrates, in order to apply uniaxial strain in different directions. We used synchrotron x-ray diffraction to characterize the applied strain and transport measurements to probe how the heavy fermion phase in LiV$_2$O$_4$ moves toward possible distinct charge-ordered states.

TT 9.7 Mon 16:30 HSZ 201

Evolution of the 4f states in TmSe$_{1-x}$Te$_x$ from semimetals to semiconductors — •CHUL HEE MIN[1], SIMON MÜLLER[2], MICHAEL HEBER[3], LENART DUDY[4], HENDRIK BENTMANN[3], MATTHIAS KALLÄNE[1], MARKUS SCHOLZ[3], WOOJAE CHOI[5], YONG SEUNG KWON[5], FRIEDRICH REINERT[2], and KAI ROSSNAGEL[1,3] — [1]IEAP, CAU Kiel, Germany — [2]EP7 and ct.qmat, University of Würzburg, Germany — [3]DESY, Hamburg, Germany — [4]Synchrotron SOLEIL, Saint-Aubin, France — [5]Dep. of EMS, DGIST, South Korea

Localized 4f states are often considered to become coherent states at low temperatures by hybridizing with itinerant conduction 5d states. In the standard Anderson model, only one type of interaction between the two states is taken into account, which is sufficient to describe Kondo physics. However, additional interaction has been suggested for the mixed valence regime to satisfy the Friedel sum rule when two charge states exist on a short time scale [1]. Here we present photoemission results of mixed-valent Thulium monochalcogenide TmSe$_{1-x}$Te$_x$. This system allows us to study the evolution of the localized 4f states between semimetallic and semiconducting phases without applying external pressure and disturbing the periodicity of Tm ions. Our results show two different interactions between 4f and 5d states across the phase transition.

TT 9.8 Mon 16:45 HSZ 201

Orbital-selective Mott transition and heavy-fermion physics in the van der Waals ferromagnet Fe$_{3-x}$GeTe$_2$ — •FRANK LECHERMANN[1], XIAOJIAN BAI[2], YAOHUA LIU[2], YONGQIANG CHENG[2], ALEXANDER I. KOLESNIKOV[2], FENG YE[2], TRAVIS J. WILLIAMS[2], SONGXUE CHI[2], TAO HONG[2], GARRETT E. GRANROTH[2], ANDREW F. MAY[3], and STUART CALDER[2] — [1]Institut für Theoretische Physik III, Ruhr-Universität Bochum, D-44780 Bochum, Germany — [2]Neutron Scattering Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA — [3]Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA

The van der Waals ferromagnet Fe$_{3-x}$GeTe$_2$ is a fascinating material that attracts combined strong interest from magnetoelectronics as well as from strong correlation physics. While near room temperature, the possibilities to exfoliate conducting ferromagnetic layers is investigated, at temperatures below $T \sim 100$ K the system displays surprising signatures of heavy-fermion physics. By means of first-principles many-body calculations, we here show that the latter temperature regime is governed by a rare orbital-selective Mott phase. This leads to emergent Kondo(-lattice) behavior in an unique transition-metal 3d compound, accompanied by antiferromagnetic fluctuations within the ferromagnetic phase. These fluctuations are experimentally revealed by neutron scattering.

Towards a complete quantum oscillatory assessment of the Fermi surface of CoSi — •NICO HUBER[1], SIMON RÖDER[1], GEORG BENKA[1], ANDREAS BAUER[1], SANU MISHRA[2,3], ILYA SHEIKIN[2], CHRISTIAN PFLEIDERER[1], and MARC A. WILDE[1] — [1]Physik-Department, TU Munich, D-85748 Garching, Germany — [2]LNCMI-CNRS, Grenoble, France — [3]Los Alamos National Laboratory, Los Alamos, USA

The B20 compound CoSi has recently attracted great interest due to its electronic structure hosting multifold fermions at the Γ- and R-point [1] and topologically non-trivial nodal planes on the Brillouin zone boundary [2,3]. While quantum oscillations (QOs) arising from the Fermi surface (FS) around the R-point have been studied in great detail and are well understood [3,4], only limited information has been presented on QOs related to the FS around the Γ-point [5]. Here, we report the experimental identification of previously unobserved QOs arising from heavy FS sheets around Γ in the Shubnikov-de Haas and de Haas-van Alphen spectra of CoSi. The oscillation frequencies, their angular dispersion, and the associated effective masses are in good agreement with first principle calculations. Our observations confirm the calculated bandstructure of CoSi, thus completing the experimental verification of the Fermi surface based on quantum oscillations.

TT 10.2 Mon 15:15 HSZ 204

Miniaturized setup for quantum oscillatory studies under temperature modulation — •MICHELLE HOLLRICHER, CHRISTIAN PFLEIDERER, and MARC A. WILDE — Physik-Department, Technical University of Munich, D-85748 Garching, Germany

Measurements of the magnetization and its derivatives provide fundamental insights into the magnetic properties of metals. In particular this is true for magnetic quantum oscillations. We report the development of a miniaturized setup for direct measurements of the temperature derivative of the magnetization as a function of magnetic field and temperature, using a modular setup comprising AC heating with inductive signal pick-up. The dimensions of our setup have been optimized to permit use in combination with standard mechanical rotators, this way enabling measurements of the magnetization as a function of magnetic field orientation down to ultra-low temperatures. Following thorough characterization of the frequency response of our miniaturized setup, we revisited the de Haas-van Alphen effect in bismuth, focusing on the electronic structure of the electron pockets.

TT 10.3 Mon 15:30 HSZ 204

Torque magnetometry of FeSi at low temperatures — •CAROLINA BURGER, VIVEK KUMAR, ANDREAS BAUER, and CHRISTIAN PFLEIDERER — Physik-Departement, Technical University of Munich, D-85748 Garching, Germany

We report a study of the torque magnetization of the correlated small-band-gap semiconductor FeSi in the regime of the saturation of the resistivity at temperatures below a few Kelvin. The magnetic field dependence of the electrical transport properties provides strong circumstantial evidence of a high-mobility surface conduction channel, that is insensitive to the additional presence of an impurity band in the bulk [1, 2]. The surface conduction channel shares great similarities with properties reported for topological insulators, but displays a striking lack of sensitivity to the presence of ferromagnetic impurities as studied by means of a series of single crystals with slightly different starting compositions. We discuss the torque magnetization observed in FeSi with respect to key characteristics observed in the field-polarized state of isostructural magnetic B20 compounds such as MnSi or $Fe_{1-x}Co_x Si$.

TT 10.4 Mon 15:45 HSZ 204

Metal-insulator transition and onset of magnetic order in $Fe_{1-x}Co_x Si$ — •JULIUS GREFE[1], PHILIPP HERRE[1], YANNIS HILGERS[1], FELIX LABBUS[1], NINA LÜER[1], MAURICIO DE MELO[1,2], JOCHEN LITTERST[1], STEFAN SÜLLOW[1], and DIRK MENZEL[1] — [1]Inst. für Physik der Kondensierten Materie, Technische Universität Braunschweig, Germany — [2]Departamento de Fisica, Universidade Estadual de Maringá, Brazil

The B20 transition metal silicides (Fe,Co,Mn)Si have been under investigation for many decades. Although the general observations regarding the electronic and magnetic properties are similar, various details of the phase diagram of $Fe_{1-x}Co_x Si$ are not yet well-established. We have prepared a series of $Fe_{1-x}Co_x Si$ single crystals and investigated the metal-insulator transition as well as the onset of magnetic order in the low Co percentage range by means of transport and susceptibility measurements. In addition, we present for the first time single-crystal Mössbauer spectroscopy experiments in order to complement our study using a microscopic probe. Our investigation sheds light on the physics of quantum criticality and metal-insulator transition and their interplay in the regime of small Co concentrations.

TT 10.5 Mon 16:00 HSZ 204

Temperatur dependence of the lattice constants of $Mn_{1-x}Fe_x Si$ and $Mn_{1-x}Co_x Si$ — •TOBIAS KONRAD, ALEXANDER ENGELHARDT, CHRISTOPH RESCH, ANDREAS BAUER, and CHRISTIAN PFLEIDERER — Physik Department, Technical University Munich, D-85748 Garching, Germany

When magnetic order in the chiral magnet MnSi is suppressed under hydrostatic pressure, topological non-Fermi-liquid behavior emerges, where neutron Larmor diffraction of the lattice constants establishes the absence of quantum criticality [1-3]. Magnetic order in MnSi may also be suppressed by substitutional replacement of iron or cobalt on the manganese sites [4,5]. Using powder x-ray diffraction, we have studied the temperature dependence of the lattice constants of $Mn_{1-x}Fe_x Si$ ($0 \leq x \leq 0.22$) and $Mn_{1-x}Co_x Si$ ($0 \leq x \leq 0.04$) between room temperature and $\sim 12\,K$. The evolution of the lattice constants as a function of iron and cobalt concentration is discussed in comparison to changes of the lattice constants of MnSi under hydrostatic pressure.

Effect of anion substitution on the Mott insulating instability in the organic conductors κ-(BEDT-TTF)$_2$X studied by magnetic quantum oscillations — •SHAMIL ERKENOV[1,2], FLORIAN KOLLMANNSBERGER[1,2], WERNER BIBERACHER[1], ILYA SHEIKIN[3], TONI HELM[4], NATALIA KUSHCH[1], RUDOLF GROSS[1,2], and MARK KARTSOVNIK[1] — [1]Walther-Meißner-Institut, Garching, Germany — [2]Technische Universität München, Garching, Germany — [3]Laboratoire National

des Champs Magnétiques Intenses, Grenoble, France — [4]Hochfeld-Magnetlabor Dresden, HZDR, Dresden, Germany

The layered organic charge-transfer salts κ-(BEDT-TTF)$_2$X have been extensively employed as model systems for studying the Mott metal-insulator transition. The insulating instability in these materials is very sensitive to external pressure and to minor chemical changes, e.g., variation of the insulating anion. The anion substitution is broadly believed to act similarly to pressure, leading to a modification of the correlation strength ratio U/t. However, recent first-principles band-structure calculations [1] suggest that anion substitution in κ salts influences the ground state chiefly through the spin-frustration effect by changing the transfer-integral anisotropy ratio t'/t rather than through U/t. Here we report on comparative studies of magnetic quantum oscillations in the salts with X = NCS, Cl, and Br, aiming at disentangling the roles of the electronic correlations and spin frustration in the insulating instability within this family.

Mott criticality in the deuterated variant of κ-(BEDT-TTF)$_2$ Cu[N(CN)$_2$]Br studied by thermal expansion under He-gas pressure — •YASSINE AGARMANI, HARALD SCHUBERT, BERND WOLF, and MICHAEL LANG — PI, GU Frankfurt, CRC/TRR288, DE

The understanding of the nature of the critical behavior at the Mott transition has recently been given a new twist by thermodynamic measurements on the Mott insulator κ-(ET)$_2$Cu[N(CN)$_2$]Cl (κ-Cl). While so far mainly electronic scenarios have been considered to describe the Mott transition, the observations of strong non-linearities in the strain-stress relation around the Mott critical endpoint in κ-Cl showed that the lattice degrees of freedomn play a crucial role [1]. This behavior has been found to be consistent with the proposed scenario of critical elasticity [2], which considers a non-perturbatively strong coupling of the elastic- to the electronic degrees of freedom, causing a softening of the lattice. These observations raise the question of the implication of critical elasticity for our understanding of the general phase diagram of the κ-(ET)$_2$X family. To address this question, we have chosen a system related to κ-Cl, namely the fully deuterated κ-(ET)$_2$Cu[N(CN)$_2$]Br, which is known to be near the Mott critical endpoint at ambient pressure. By using an extension [3] of the setup used in [1], which enables us to fine-tune the He-gas pressure while performing high-resolution measurements of length changes, we aim to compare our results with those on κ-Cl in terms of the extension of the range of critical elasticity.

Effect of uniaxial strain on the phononic and electronic excitations of Ta_2NiS_5 — •MAI YE, AMIR-ABBAS HAGHIGHIRAD, and LE TACON MATTHIEU — Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76021 Karlsruhe, Germany

Semiconductor Ta_2NiS_5 exhibits a structural transition from orthorhombic phase to monoclinic phase at 120 K, driven by acoustic instability [1]. Two Raman-active phonon modes, which have the same symmetry as the order parameter (B_{2g} symmetry), show continuous frequency softening on cooling from 300 K to 20 K. Moreover, a sharp exciton mode in the B_{2g} symmetry channel has been observed at 0.3 eV. We study the phonon modes and interband excitations of Ta_2NiS_5 under uniaxial strain at low temperature. With increasing tensive strain along crystallographic a axis, the frequency of the two B_{2g}-symmetry phonon modes and the band gap of this semiconductor both increase, with a 6.5% frequency increase of the lowest-energy B_{2g} phonon mode corresponding to a 4.1% increase of the gap size. On the contrary, the frequency change of the non-softening phonons is less than 1%. By analyzing the phonon intensity, we further find that the magnitude of the order parameter, and in turn the phase transition temperature, increases with the tensive strain. These experimental results demonstrate Ta_2NiS_5 as a suitable platform to explore the manipulation of lattice dynamics and electronic structure by applying uniaxial strain.

TT 10.9 Mon 17:15 HSZ 204

Magnetic anisotropy and low-energy spin dynamics in magnetic van der Waals compounds $Mn_2P_2S_6$ and $MnNiP_2S_6$ — •JOYAL JOHN ABRAHAM[1,2], YURII SENYK[1], YULIIA SHEMERLIUK[1], SEBASTIAN SELTER[1], SAICHARAN ASWARTHAM[1], BERND BÜCHNER[1,3], VLADISLAV KATAEV[1], and ALEXEY ALFONSOV[1] — [1]Leibniz IFW Dresden, D-01069 — [2]Institute for Solid State and Materials Physics, TU Dresden, D-01069 — [3]Institute for Solid State and Materials Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, D-01062

We report a comprehesive high-field electron spin resonance (ESR) study performed on single crystals of $Mn_2P_2S_6$ and $MnNiP_2S_6$ in the broad ranges of temperatures, frequencies and magnetic fields. Analysing the antiferromagnetic

modes well below the ordering temperature T_N, we have found that the ground state, the order type and magnetic anisotropy (MA) change with increasing x in $(Mn_{1-x}Ni_x)_2P_2S_6$. In the case of $Mn_2P_2S_6$, an application of the linear spin wave theory enabled us to determine the anisotropy and exchange constants, important for a quantitative description of the ground state. A systematic increase of the g-factor and its anisotropy, measured at $T \gg T_N$, is observed with increasing Ni content, which, in turn, sheds light on the nature of MA in the ordered state. The investigation of the T-dependence of line shifts from the paramagnetic resonance position reveals already well above T_N the presence of the short range spin-spin correlations static on ESR time scale, which are more pronounced in $MnNiP_2S_6$.

TT 10.10   Mon 17:30   HSZ 204

Switching of magnetic anisotropy from out-of-plane to in-plane in quasi-2D van der Waals $(Mn_{1-x}Ni_x)_2P_2S_6$ single crystals — •Yuliia Shemerliuk, Anja U. B. Wolter, Bernd Büchner, and Saicharan Aswartham — Institut für Festkörperforschung, Leibniz IFW Dresden, Helmholtzstraße 20, 01069 Dresden, Germany

In the recent years magnetic two-dimensional van der Waals materials are at the forefront of the research. Magnetism has been extensively investigated in the family of $TM_2P_2S_6$ (TM= Ni, Co, Fe, Mn & V). Transition metal TM substitution has been used as a technique to control magnetism in this family of compounds [1-3]. In this talk, we will present crystal growth by chemical vapor transport together with a thorough structural and magnetic characterization of the quasi-2D magnets $(Mn_{1-x}Ni_x)_2P_2S_6$ with x = 0, 0.3, 0.5, 0.7 & 1. As-grown crystals exhibit a layered morphology with weak van der Waals interlayer interactions parallel to the crystallographic ab plane of the monoclinic symmetry in the space group C2/m (No. 12). In this series, the two neighboring members $Mn_2P_2S_6$ and $Ni_2P_2S_6$ differ in magnetic atoms, magnetic easy axes, spin anisotropy, and nearest neighbor magnetic interactions. The magnetization measurements show an antiferromagnetic ground state for all grown crystals. The magnetic ordering temperature TN shows nonmonotonic behavior. The magnetic anisotropy switches from out-of-plane to in-plane as a function of composition.

TT 10.11   Mon 17:45   HSZ 204

Single crystal growth, structural and transport properties of the Mott insulator $BaCoS_2$ — •Haneen Abushammala, Teslin Thomas, Andreas Kreyssig, and Anna Böhmer — Institute for Experimentalphysik IV, Ruhr-Universität Bochum, Universitätsstrasse 150, 44801 Bochum, Germany.

The quasi-2D $BaCoS_2$ is a Mott insulator with a stripe-like antiferromagnetic ordering at T_N=290 K. Both chemical doping or hydrostatic pressure drive the system into a paramagnetic metallic phase. Interestingly, there is no structural transition at the metal-insulator transition of this phase, which offers ideal conditions to investigate the Mott transition in a model multiband system [1].

Nevertheless, $BaCoS_2$ remains little studied, and the interplay of electronic and structural features is still unclear. High-quality single crystals are needed to elucidate this issue. The synthesis of single-crystalline $BaCoS_2$ is challenging owing to its metastability, with a decomposition into Ba_2CoS_3, CoS and S below 850°C. The $BaCoS_2$ phase can only be obtained via quenching from high temperature. Moreover, $BaCoS_2$ melts incongruently, which calls for a flux growth method necessitating separation of the crystals from the flux by the end of the growth. We have successfully grown single crystals of pure and the hole-doped $BaCoS_2$ using a self-flux method with high-temperature flux separation and quench. The structural and anisotropic electrical transport properties are determined and discussed.

TT 10.12   Mon 18:00   HSZ 204

Spin-orbit entangled crystal-field excitations in $5d^4$ $j = 0$ osmates — •Philipp Warzanowski[1], Marco Magnaterra[1], Philipp Stein[1], Quentin Faure[2], Christoph Sahle[2], Holger Schwab[1], Thomas Lorenz[1], Petra Becker[3], Ladislav Bohatý[3], Paul H. M. van Loosdrecht[1], and Markus Grüninger[1] — [1]Institute of Physics II, University of Cologne — [2]European Synchrotron Radiation Facility, Grenoble Cedex, France — [3]Sect. Crystallography, Institute of Geology and Mineralogy, University of Cologne

For strong spin-orbit coupling, the d^4 electron configuration may show a non-magnetic $j = 0$ ground state. In $5d^4$ iridates, magnetic behavior has been discussed controversially and finally it has been attributed to defects, while excitonic magnetism has been proposed for $4d^4$ ruthenates. We show that the $j = 0$ state is very well realized in the cubic antifluorite-type $5d^4$ osmates K_2OsCl_6 and K_2OsBr_6. The magnetic susceptibility exhibits van-Vleck type magnetism without a sizeable Curie-Weiss contribution. Employing resonant inelastic x-ray scattering (RIXS) and infrared spectroscopy as complementary techniques, we investigate the electronic excitations and determine the electronic parameters by comparison with local multiplet calculations. The cubic crystal-field splitting 10 Dq and the charge transfer energy are 15% smaller for the chlorine compound than for its bromide sister, whereas the intra-t_{2g} excitation energies are reduced by 4%. This allows us to quantify the influence of the e_g orbitals on the effective spin-orbit coupling for the t_{2g} orbitals.

Van der Waals/non-van der Waals hybrids for superconducting spintronics — Roman Hartmann, Alfredo Spuri, Danilo Nikolic, Wolfgang Belzig, Elke Scheer, and •Angelo Di Bernardo — Universität Konstanz, Konstanz, Germany

The realization of Cooper pairs of electrons with parallel-aligned spins (i.e., spin-triplet pairs) has been demonstrated for a variety of three-dimensional (3D) superconductor/ferromagnet (S/F) heterostructures. Several studies have shown that using S/F system with a magnetically inhomogeneous F [1-2] it is possible to convertthe spin-singlet pairs of a conventional S into fully-polarized spin triplets - this has paved the way for superconducting spintronics. Van-der-Waals (vdW) heterostructures host a variety of unconventional phases, both superconducting and magnetic, which can be explored to realize two-dimensional (2D) superspintronic devices with novel functionalities and types of control compared to devices based on 3D S/F hybrids. The conversion of spin singlets into spin triplets across a 2D S/F vdW interface represents, however, the first step towards superconducting spintronics based on vdW hybrids. In this talk, I will show recent magnetotransport experiments obtained on F nanoflakes that are cleaved from 3D ionic F single crystals through a new approach. The unique properties of these nanoflakes are used for the fabrication of novel superspintronics devices, where the nanoflakes are coupled to conventional 2D vdW S materials.

Thermal transport in weakly coupled spin-$\frac{1}{2}$ Heisenberg ladders — •Anja Wenger, Christian Northe, and Ewelina Hankiewicz — Institut für Theoretische Physik und Astrophysik, Universität Würzburg, 97074 Würzburg, Germany

We investigate the weakly coupled spin-$\frac{1}{2}$ Heisenberg ladder in the low energy limit. As magnetic excitations significantly contribute to the thermal transport, we expose the ladder to a magnetic field and analyze the thermal conductivity and the specific heat capacity depending on the magnetization. Starting point is the spin-$\frac{1}{2}$ Heisenberg chain and its fermionic and bosonic description by conformal field theory. From coupling two spin chains and applying the (rescaled) bosonisation technique, a free theory for spin-ladders and its spectrum is obtained. Special interest lies on the conformal anomaly and the Tomonaga-Luttinger Liquid parameters. Introducing temperature to the theory gives access to the thermal transport properties.

TT 11.3   Mon 15:30   HSZ 304

Critical current control in ferromagnetic proximity junctions by magnetization and spin injection — •Lukas Kammermeier and Elke Scheer — Universität Konstanz, Konstanz, Germany

We exploit the inverse proximity effect of a ferromagnet on a superconductor to locally suppress the superconductivity in a thin wire and thereby create a Josephson junction.

We show that we can control the critical current I_c over a wider range by manipulating the magnetization state of the ferromagnet, possibly sensitive to single magnetic domains in proximity to the constriction. Additionally, the efficiency of spin injection by running a current from the spin-polarized ferromagnet into the junctions constriction will be presented.

TT 11.4   Mon 15:45   HSZ 304

On the connection between the chiral-induced spin selectivity effect and the chiro-optical activity: The case of an electron in a helix — •Solmar Varela[1], Gianaurelio Cuniberti[1], Rafael Gutierrez[1], Ernesto Medina[2], Vladimiro Mujica[3], and Jesus Ugalde[4] — [1]Chair of Materials Science and Nanotechnology, TU Dresden, Dresden — [2]Departamento de \'isica, Colegio de Ciencias e Ingenier\'ia, Universidad San Francisco de Quito, Ecuador — [3]School of Molecular Sciences, Arizona State University, USA — [4]Kimika Fakultatea, Euskal Herriko Unibertsitatea (UPV/EHU), Spain

We have obtained a connection between the chiro-optical activity and the spin-orbit interaction for a model system of an electron constrained to a helix, taking explicitly spin into account, in the presence of an electromagnetic field as a perturbation. Because of the chiral nature of the system, spatial inversion symmetry is broken, which in turn induces a connection between the electric and the magnetic responses of the system to the external electromagnetic field, that is absent in achiral systems. Despite the apparent simplicity of the model, it contains most of the relevant physics involved in this problem, and we have established a relationship between the optical activity response, via the Rosenfeld tensor and the spin polarization, defined as the average value of the Pauli spin-1/2 matrices. This relationship between the optical response and the CISS responses, can guide new efforts in the fields of reticular chemistry and material design for spintronics, and spin-selective chemistry.

TT 11.5　Mon 16:00　HSZ 304

Electron and spin-phonon interaction in DNA: A minimum analytical model — •Mayra Peralta[1], Solmar Varela[1], Vladimiro Mujica[2], Rafael Gutiérrez[1], Ernesto Medina[3], and Gianaurelio Cuniberti[1] — [1]Institute of Materials Science and Nanotechnology, Technische Universität Dresden, Dresden 01062, Germany — [2]School of Molecular Sciences, Arizona State University, TEMPE, AZ 85287 — [3]Departamento de Física, Colegio de Ciencias e Ingeniería, Universidad San Francisco de Quito, Diego de Robles y Vía Interoceánica, Quito, 170901, Ecuador

We analyze the influence of electron-phonon and spin-phonon interaction in a model for electron transfer(ET) in DNA in terms of the envelope function approach. We are specifically concerned with the effect of these interactions on the coherence of the ET process and how to model the interaction of DNA with phonon reservoirs of biological relevance. We assume that the electron bearing orbitals are half filled and derive the physics of the electron- and spin-phonon

coupling in the vicinity in reciprocal space. In a first model for spinless electrons we find that at half filling, the acoustical modes are decoupled to ET at first order, while optical modes are predominant. The latter are associated with inter-strand vibrational modes in consistency with previous studies involving polaron models of ET. Coupling to acoustic modes depends on electron doping of DNA, while optical modes are always coupled within our model. When the spin is included, through the Spin-orbit coupling whose intensity is geometry dependent, we find that acoustical phonons become coupled independently of the doping.

Gate-tunable insulator-metal transition and weak antilocalization in two-dimensional tellurium — •Dorsa Fartab[1], José Guimarães[1,2], Marcus Schmidt[1], and Haijing Zhang[1] — [1]Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany — [2]School of Physics and Astronomy, University of St Andrews, St Andrews KY16 9SS, UK

Charge carrier density control is a key factor to modify the electronic functionality of materials. The ability to induce high charge carrier concentration into various two-dimensional materials has led to exotic phenomena such as insulator-metal transition and superconductivity. So far, different techniques have been used to achieve this. Meanwhile, electric double layer transistor (EDLT) is a highly promising platform as it can provide high charge carrier density of up to $10^{15}\,cm^{-2}$ in its channel material. This is two orders of magnitude larger than that in the conventional transistors as a result of using ionic liquids instead of common solid dielectrics. First, I will give a short overview on the EDLTs, then I will present our experimental results of ionic liquid gated two-dimensional tellurium (Te). Our results show the possibility of gate tuning insulator-metal phase transition and the gate and temperature-dependent weak antilocalization in p-type Te films. More interestingly, we have shown the ability of controlling the spin-orbit interaction in the material by changing the applied gate voltage.

Benchmark study of symmetry-adapted ML-DFT models for magnetically doped topological insulators — •Johannes Wasmer[1], Rubel Mozumder[1], Philipp Rüssmann[1,2], Ira Assent[1,3], and Stefan Blügel[1] — [1]Forschungszentrum Jülich, Germany — [2]University of Würzburg, Germany — [3]Aarhus University, Denmark

We present a benchmark study of surrogate models for impurities embedded into crystalline solids. Using the Korringa-Kohn-Rostoker Green Function method [1], we have built databases of several thousand calculations of single impurities (monomers) embedded into different elemental crystals, as well as magnetic transition metal impurity dimers embedded in the topological insulator Bi_2Te_3. We predict the converged monomer impurity electron potential and the isotropic exchange interaction of the impurity dimer in the classical Heisenberg model. From these surrogates, we intend to build transferable models for larger systems in the future, which will accelerate the convergence of our DFT codes. The study compares various recent E(3)-equivariant models such as ACE and MACE [2] in terms of performance and reproducible end-to-end workflows.

High thorughput magnetic topological materials search II — •Iñigo Robredo[1,2], Yuanfeng Xu[3,4], Andrei Bernevig[2,3], Claudia Felser[1], Nicolas Regnault[3,6], Luis Elcoro[5], and Maia G. Vergniory[1,2] — [1]MPI CPFS Dresden — [2]DIPC — [3]Princeton University — [4]Zhejiang University — [5]Basque Country University — [6]Sorbonne Université

The development of topological quantum chemistry has proven to be a game changing tool for predicting topological phases in realistic materials, both non-magnetic and magnetic. Building on the work of previous studies, in this work we expand the family of magnetic insulators and semimetals with non-trivial topological properties. We analyzed 408 magnetic structures from the Bilbao Crystallographic Server magnetic database, whose crystal and magnetic structures have been experimentally reported. To take into account the localized nature of magnetic elements, we perform electronic structure calculations and topological diagnosis as a function of the Hubabrd U parameter. This results in a topological phase iagram for each material as a function of the Hubbard interaction potential. We provide full details of the materials, which can be readily grown to explore their new topological phenomena.

TT 12.3　Mon 15:30　HSZ 403

Manipulating topological feature of massive Dirac particle with scalar potential — •Sumit Ghosh[1,2], Yuriy Mokrousov[1,2], and Stefan Blügel[1] — [1]PGI-1, Forschungszentrum Jülich, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, Germany

Topology is one of the central aspect of modern spintronics. Different physical observables as well as transport properties that originates from the nontrivial topology of the system shows significant robustness against different external perturbation. Manipulating the topology of a system on the other hand is a highly non-trivial task since it requires tuning the internal degrees of freedom. In this presentation we are going to present an intrinsic mechanism to manipulate the topological feature and associated transport properties by using scalar potential. We systematically demonstrate how a scalar potential can invert the mass term of a massive Dirac particle which subsequently leads to the change of the topological index. We further demonstrate how this mechanism can be exploited to control the formation of edge states which can control the transport properties. This study thus provides a better understanding of the origin of the topological properties as well as a simple way to manipulate them. [https://arxiv.org/abs/2204.06412]

Mapping out the topological phase diagram of FeSn — Soumya Sankar[1], Ruizi Liu[2], Xuejian Gao[1], Qifang Li[3,4], JiaChang Zheng[1], Caiyun Chen[1], Chengping Zhang[1], Kun Qiang[2], Zi Yang Meng[3,4], Kam Tuen Law[1], Qiming Shao[1,2], and •Berthold Jäck[1] — [1]HKUST, Clear Water Bay, Kowloon, Hong Kong SAR — [2]HKUST, Department of Computer Science and Electrical Enginerring, Clear Water Bay, Kowloon, Hong Kong SAR — [3]Hong Kong University, Department of Physics, Pokfulam Road, Hong Kong SAR — [4]University of Tokyo, Department of Physics, Hongo, Bunkyo City, Tokyo

Metallic kagome magnets exhibit a flat band and a Dirac point in their electronic structure and long-range magnetic order. The combination of these properties creates favourable conditions to search for strongly correlated and topological electronic states. The near-ideal kagome band structure of the inter metallic kagome series X1Y1 offers opportunities to study the interplay between strong electronic correlations, topology, and magnetism.

We have used molecular beam epitaxy and electronic transport measurements to study the interplay of magnetism and band topology in thin films of antiferromagnetic FeSn. We will present results from a magnetic field and temperature dependent study of the anomalous Hall effect. Combining these measurements with magnetic Monte-Carlo simulations and theoretical model calculations, we map out the topological phase diagram of FeSn over a large temperature range.

We acknowledge support by the GRC, and the Croucher Foundation.

Investigation of the magnetic topological insulator family (MnPn2Te4) (Pn2Te3) n, (Pn=Bi, Sb) by μSR and NMR — •Manaswini Sahoo[1,2], Anna Isaeva[1], Bernd Büchner[1], and Roberto De Renzi[2] — [1]Leibniz IFW Dresden, Dresden, Germany — [2]University of Parma,Parma, Italy

Time-reversal symmetry breaking in a topological insulator (TI) opens a surface gap and distinguishes chiral quantum states that could eventually be exploited in electrically controlled spintronic devices. The recent discovery of layered van der Waals materials opens a new approach to achieve this.(MnBi2Te4) (Bi2Te3) n is one of the first such examples, where the increasing number n of TI layers controls the magnetic dimensionality of the material. These compounds do display the quantum anomalous Hall effect, where spontaneous magnetization and spin-orbit coupling lead to a topologically non-trivial electronic structure. In the case of (MnBi2Te4) (Bi2Te3) n, Zero Field μSR shows more than one internal field at the muon site with the majority one decreasing in value when n is increased. The muon spin precessions display very fast relaxations of static inhomogeneous nature. Whereas in the sister compound MnSb2Te4, Zero Field μSR shows a broader distribution of magnetic field at the muon due to larger intermixing between Mn/Sb in the sample. Importantly, the weak Transverse Field shows a sharp magnetic transition at the same Tc, with a clear relaxation peak due to critical fluctuations, taking place in the whole volume of the material. This local information from μSR together with NMR is crucial to correctly interpret macroscopic magnetization data.

TT 12.6   Mon 16:30   HSZ 403

Magnetic dilution effect and topological phase transitions in antiferromagnet $Mn_{1-x}Pb_xBi_2Te_4$ — •Yueh-Ting Yao[1], Tiema Qian[2], Tay-Rong Chang[1,3,4], and Ni Ni[2] — [1]Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan — [2]Department of Physics and Astronomy and California NanoSystems Institute, University of California, Los Angeles, California 90095, USA — [3]Center for Quantum Frontiers of Research and Technology (QFort), Tainan 701, Taiwan — [4]Physics Division, National Center for Theoretical Sciences, Taipei 10617, Taiwan

The interplay between magnetism and topology have taken the central stage of modern condensed matter physics in the past three years. The fine control of magnetism and topology in a magnetic topological insulator is crucial for realizing various novel magnetic topological phases, such as axion insulator, magnetic Weyl semimetals, etc. In this work, we investigate the evolution of magnetism and band topology in $Mn_{1-x}Pb_xBi_2Te_4$ via angle resolved photoemission spectroscopy (ARPES), first-principles calculations, and electronic transports. We present the comprehensive phase diagram by controlling Pb content and magnetism in this alloy system. Moreover, we provide the first topological crystalline insulator with non-trivial glide mirror Chern number in MnBi2Te4-family materials, which is protected by non-symmorphic symmetry arise from antiferromagnetic (AFM) configuration. Our work provides a fruitful platform with continuously tunable magnetism and topology for investigating emergent phenomena and pave a way towards potential new applications of nanoelectronics.

TT 12.7   Mon 16:45   HSZ 403

Thermal Hall Effect of Magnon-Phonon Hybrid Quasiparticles in a Fluctuating Heisenberg-Kitaev Antiferromagnet — •Robin R. Neumann[1], Alexander Mook[2], Jürgen Henk[1], and Ingrid Mertig[1] — [1]Martin Luther University Halle-Wittenberg, Halle (Saale), Germany — [2]Johannes Gutenberg University, Mainz, Germany

Magnons, the quantized excitations of localized spins, and phonons, the quantized excitations of the lattice, are two types of quasiparticles that are responsible for heat transport in magnetic insulators. However, phonons by themselves do not contribute to the *transverse* heat current induced by a temperature gradient, i.e., the thermal Hall effect (THE). Magnons, on the other hand, may exhibit a Berry curvature, a magnetic field in reciprocal space, that leads to an intrinsic THE.

In this talk, I address the THE in a Heisenberg-Kitaev antiferromagnet subjected to a magnetic field. The applied field drives the system from a zigzag antiferromagnetic to a spin-flop state. The magnon-driven THE indicates the magnetic phase transition by a sign change at the critical field. Furthermore, when the magnetoelastic interaction is considered, the phonon and magnon bands hybridize and additional Berry curvature at the avoided crossings emerge. Depending on the strength of the spin-phonon coupling, this may lead to an overall reversal of the THE while the field-induced sign change at the critical field remains mostly robust. These results showcase that magnon-phonon hybridization can be pivotal for the interpretation of transport experiments.

TT 12.8   Mon 17:00   HSZ 403

Limitations of the Bulk-Boundary Correspondence in Topological Magnon Insulators due to Magnon-Magnon Interactions — •Jonas Habel[1], Johannes Knolle[1], Alexander Mook[2], and Josef Willsher[1] — [1]Technical University of Munich, Germany (Theory of Quantum Matter and Nanophysics) — [2]Johannes Gutenberg University Mainz, Germany

Magnon excitations in ordered quantum magnets can exhibit topological band structures characterized by non-zero Chern numbers. Such magnonic Chern insulators are widely believed to host protected chiral edge modes due to the bulk-boundary correspondence, in analogy to electronic Chern insulators. However, in contrast to electrons, magnons are bosons and can thus be subject to exotic number-non-conserving many-body interactions, enabling potentially strong spontaneous decays at zero temperature.

To assess their effect on the chiral edge magnons, we study a topological honeycomb-lattice ferromagnet with Dzyaloshinskii-Moriya interactions using many-body perturbation theory. We discover that non-harmonic terms of the spin-wave expansion may lead to severe lifetime reduction of edge modes and their delocalisation into the bulk. For sufficiently strong interactions, the spectral weight of the chiral edge magnons vanishes entirely. These findings indicate that topological magnon bands within the harmonic framework do not necessarily give rise to protected edge modes in the full spin theory, suggesting limitations of the bulk-boundary correspondence in this case.

TT 13: Focus Session: Physics Meets ML II – Understanding Machine Learning as Complex Interacting Systems (joint session DY/TT)

Machine-learning has recently entered and is now transforming many fields of science, enabling discoveries in a data-driven manner. As a scientific method, however, ML often lacks one defining feature: Explainability. We here seek discussions with pioneers in understanding, explaining, and improving machine learning methods from the point of view as a physical system of interacting elements. In fact, the history of approaching neuronal networks and problems of inference and learning as a problem of statistical physics has a long history, with a number of important discoveries early on. The close relation between spin glasses and neuronal networks are being currently exploited to address pressing questions, such as the remarkable generalization properties of neuronal networks despite their massive overparameterization and their behavior reminiscent of renormalization group transformations.

The challenge of structured disorder in statistical physics — •Marc Mezard — Bocconi University, Milano

Statistical physics offers many interesting tools to study machine learning. In most cases it needs to use a statistical ensemble of data. Most of the theoretical work has relied on unstructured data. Yet, the highly structured character of data used in training deep networks is a crucial ingredient of their performance. Modelling structured data, analyzing the learning and the generalization of deep networks trained on this data, are major challenges. This talk will describe several recent developments in this direction.

Adaptive Kernel Approaches to Feature Learning in Deep Neural Networks — •ZOHAR RINGEL — Racah Institute of Physics, Hebrew University in Jerusalem
Following the ever-increasing role of deep neural networks (DNNs) in our world, a better theoretical understanding of these complex artificial objects is desirable. Some progress in this direction has been seen lately in the realm of infinitely overparameterized DNNs. The outputs of such trained DNNs behave essentially as multivariate Gaussians governed by a certain covariance matrix called the kernel. While such infinite DNNs share many similarities with the finite ones used in practice, various important discrepancies exist. Most notably the fixed kernels of such DNNs stand in contrast to feature learning effects observed in finite DNNs. Such effects are crucial as they are the key to understanding how DNNs process data. To accommodate such effects within the Gaussian/kernel viewpoint, various ideas have been put forward. Here I will provide a short overview of those efforts and then discuss in some detail a general set of equations we developed for feature learning in fully trained/equilibrated DNNs. Interestingly, our approach shows that DNNs accommodate strong feature learning via mean-field effects while having decoupled layers and decoupled neurons within a layer. Furthermore, learning is achieved not by compression of information but rather by increasing neuron variance along label-relevant directions in function space.

                                            TT 13.4   Mon 16:30   ZEU 250
Interpreting black-box ML with the help of physics — •MIRIAM KLOPOTEK — University of Stuttgart, SimTech Cluster of Excellence EXC 2075, Stuttgart, Germany
Complexity is an unavoidable part of systems with emergent or even so-called intelligent capabilities. Ultimately, it stems from the many microscopic constituents with multiple possible states, which introduces a vast space of degrees of freedom. This is true both for many-body systems as well as modern machine learning (ML) systems. Today, the latter suffer notoriously from the 'black-box problem', i.e. they are inherently opaque. We argue that an engagement with physics can offer deep insights ultimately for a theory of operation and thus an interpretation, as well as powerful ways to assess their reliability and shortcomings. We show some results for a case study with beta-variational autoencoders (β-VAEs) [1], which we trained on data from a well-characterized model system of hard rods confined to 2D lattices [2].

Analysing the dynamics of message passing algorithms — •MANFRED OPPER[1,2] and BURAK CAKMAK[1] — [1]Institut für Softwaretechnik und Theoretische Informatik, Technische Universität Berlin, 10587, Germany — [2]Centre for Systems Modelling and Quantitative Biomedicine, University of Birmingham, B15 2TT, United Kingdom
Message passing algorithms are deterministic methods which are designed for efficiently computing marginal statistics for probabilistic, Bayesian data models used in machine learning and statistics. Such algorithms have been developed in parallel within the machine learning and the statistical physics communities. They often provide highly accurate approximations at a much higher speed compared to exact Monte Carlo sampling. The fixed points of such algorithms can be analysed for high dimensional models (under the assumption of specific data distributions) using the replica method of statistical physics. In this talk we will focus on the dynamical properties of the algorithms. Applying dynamical func-

tional techniques to the nonlinear dynamics, the degrees of freedom which interact via a random matrix can be decoupled in the limit of large systems resulting in exact stochastic single node dynamics. For general dynamical models, it is hard to further analyse this effective dynamics due to the occurence of memory terms. Surprisingly, for message passing algorithms memory terms are absent and exact results for convergence rates and stability can be derived for specific data distributions.

Invited Talk   TT 13.6   Mon 17:30   ZEU 250
Deep Learning Theory Beyond the Kernel Limit — •CENGIZ PEHLEVAN — Harvard University, USA
Deep learning has emerged as a successful paradigm for solving challenging machine learning and computational problems across a variety of domains. However, theoretical understanding of the training and generalization of modern deep learning methods lags behind current practice. I will give an overview of our recent results in this domain, including a new theory that we derived by applying dynamical field theory to deep learning dynamics. This theory gives insight into internal representations learned by the network under different learning rules.

                                            TT 13.7   Mon 18:00   ZEU 250
Solving the Bethe–Salpeter equation with exponential convergence — •MARKUS WALLERBERGER[1], HIROSHI SHINAOKA[2], and ANNA KAUCH[1] — [1]TU Wien, Vienna, Austria — [2]Saitama University, Japan
The Bethe–Salpeter equation plays a crucial role in understanding the physics of correlated fermions, relating to optical excitations in solids as well as resonances in high-energy physics. Yet, it is notoriously difficult to control numerically, typically requiring an effort that scales polynomially with energy scales and accuracy. This puts many interesting systems out of computational reach.

Using the intermediate representation and sparse modeling for two-particle objects on the Matsubara axis, we develop an algorithm that solves the Bethe–Salpeter equation in $O(L^8)$ time with $O(L^4)$ memory, where L grows only logarithmically with inverse temperature, bandwidth, and desired accuracy. This opens the door for computations in hitherto inaccessible regimes. We benchmark the method on the Hubbard atom and on the multiorbital weak-coupling limit, where we observe the expected exponential convergence to the analytical results. We then showcase the method for a realistic impurity problem.

                                            TT 13.8   Mon 18:15   ZEU 250
Making machines untangle the parquet equations — •SAMUEL BADR[1], ANNA KAUCH[1], HIROSHI SHINAOKA[2], KARSTEN HELD[1], and MARKUS WALLERBERGER[1] — [1]TU Wien, Vienna, Austria — [2]Saitama University, Saitama, Japan
Diagrammatic theories at the two-particle level are increasingly important in understanding the subtle interplay of phenomena occurring in strongly correlated electron systems. The parquet equations are a centerpiece of many such theories, since they are the simplest unbiased topological classification of two-particle diagrams. However, due to their eponymous interlocking structure, the parquet equations are vexingly difficult to solve, requiring prohibitive amounts of memory.

We tackle this problem using the recently developed, machine learning inspired, techniques: firstly, the overcomplete intermediate representation, a highly compressed model for two-particle objects which is guaranteed to converge exponentially; secondly, a sparse set of Matsubara frequencies tailored to the structure of the parquet equations. This allows us to perform convolutions and frequency shifts at no loss of accuracy.

We benchmark our solver for the Hubbard atom, where we reproduce analytic results, and then showcase the solver for more extended systems.

TT 14: Focus Session: Graphene Quantum Dots (joint session HL/TT)

Quantum dots have emerged as one of the contenders for a future quantum information processor. Bilayer graphene is now established as a material that allows high quality bi-polar Coulomb blockade measurement, time-dependent transport measurements and first relaxation time measurements. In contrast to the more conventional GaAs and Si-based systems, several exiting and unexpected observations in graphene have been explained by the peculiar graphene bandstructure, which is gate- tunable, the additional valley degree of freedom, and spin-valley coupling.

Spin and valley lifetime in graphene quantum dots — •GUIDO BURKARD — University of Konstanz, Germany
Graphene with its low nuclear spin density and weak spin-orbit coupling allows for long electron spin relaxation and coherence times. The spin and valley de-

grees of freedom of localized electrons can therefore be seen as potential embodiments of classical or quantum bits for computation. However, the formation of localized states in quantum dots requires some form of badgap engineering, and the mechanisms for spin and valley relaxation have not been completely understood so far. Bilayer graphene has an electrically controllable bandgap that

allows for the formation of quantum dots. We present general theoretical considerations regarding the formation of quantum dots in graphene and report on recent progress in understanding the relevant physical mechanisms of spin and valley relaxation in electrostatically gated bilayer graphene quantum dots.

Invited Talk　　　　　　　TT 14.2　Mon 15:30　POT 361
Microscopic modelling of electrostatically induced bilayer graphene quantum dots — •Angelika Knothe — Institut für Theoretische Physik, Universität Regensburg, D-93040 Regensburg, Germany
Quantum nanostructures, e.g., quantum wires and quantum dots, are needed for applications in quantum information processing devices, such as transistors or qubits. In gapped bilayer graphene, one can confine charge carriers purely electrostatically, inducing smooth confinement potentials and thereby limiting edge-induced perturbances while allowing gate-defined control of the confined structure. In this talk, I will give an overview of our recent contributions toward the theoretical modelling of gate-defined bilayer graphene quantum dots, taking into account microscopic details of the material properties and the confinement. As an outlook, I will point towards current and future challenges in describing coupled bilayer graphene nanostructures, e.g., setups with multiple bilayer graphene quantum dots.

TT 14.3　Mon 16:00　POT 361
Valley relaxation in a single-electron bilayer graphene quantum dot — •Lin Wang and Guido Burkard — Department of Physics, University of Konstanz, D-78457, Germany
Bernal-stacked bilayer graphene (BLG) has a tunable gap controlled by an out-of-plane electric field. This makes BLG a possible candidate to form quantum dots (QDs) via quantum confinement. Spin-based qubits in BLG QDs have received great attention due to outstanding spin-coherence properties. Very recently, long spin relaxation times of a single-electron state in BLG QDs was reported [1,2]. In addition to spin, valley pseudospin is another degree of freedom in BLG. The two valleys experience opposite Berry curvatures and associated magnetic moments via an out-of-plane electric field. This provides a promising way to control valleys and further establish valley qubits. To assess the potential of valley qubits, the valley relaxation time is a crucial parameter since it directly limits the lifetime of encoded information. Here, we investigate the valley relaxation in a single-electron BLG QD due to intervalley coupling assisted by (i) 1/f charge noise and (ii) electron-phonon couplings arising from the deformation potential and bond-length change. Our calculation shows that valley relaxation time decreases with a power law dependence as a function of magnetic field, which is in a good agreement with very recent experiment.

Single-shot spin and valley Pauli blockade read-out in bilayer graphene quantum dots — •Chuyao Tong[1], Rebekka Garreis[1], Wister Wei Huang[1], Annika Kurzmann[1,2], Jocelyn Terle[1], Samuel Jele[1], Kenji Watanabe[3], Takashi Taniguchi[3], Thomas Ihn[1], and Klaus Ensslin[1] — [1]ETH Zurich, CH-8093 Zurich, Switzerland — [2]RWTH Aachen University, Aachen, 52074, Germany — [3]National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan
In bilayer graphene quantum dots, apart from spins up and down, the additional valley degree of freedom K- and K+ gives rise to an unconventional single-dot two-carrier ground state: spin-triplet valley-singlet, altering the canonical even-odd double dot Pauli spin blockade picture. This ground state can be switched to a spin-singlet valley-triplet by a perpendicular magnetic field, allowing us to switch between valley-blockade at low, and spin-blockade at higher magnetic field for the two-carrier Pauli blockade (1,1) to (0,2). We employ charge sensing technology and perform single-shot Pauli blockade read-out at the two field regimes, probing characteristic relaxation times T1 between spin or valley -triplet and -singlet. The spin-T1 is measured to be up to 60ms, drastically decreasing with increasing inter-dot tunnel coupling and corroborating with recent experiments performed with single-dot Elzerman read-out. Moreover, we observe exceedingly long valley T1 longer than 500ms, robust with inter-dot tunnel coupling. These promisingly long spin- and valley T1 herald for long-living spin and valley bilayer graphene quantum dot qubits.

Invited Talk　　　　　　　TT 14.5　Mon 17:15　POT 361
Particle-hole symmetry protects spin-valley blockade in graphene quantum dots — •Christian Volk[1,2], Luca Banszerus[1,2], Samuel Möller[1,2], Katrin Hecker[1,2], Eike Icking[1,2], Kenji Watanabe[3], Takashi Taniguchi[4], Fabian Hassler[5], and Christoph Stampfer[1,2] — [1]JARA-FIT and 2nd Institute of Physics, RWTH Aachen University — [2]Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich — [3]Research Center for Functional Materials, NIMS, Tsukuba, Japan — [4]International Center for Materials Nanoarchitectonics, NIMS, Tsukuba, Japan — [5]JARA-Institute for Quantum Information, RWTH Aachen University
Particle-hole symmetry plays an important role for the characterization of topological phases in solid-state systems. Graphene is a prime example of a gapless particle-hole symmetric system. The intrinsic Kane-Mele spin-orbit coupling in graphene leads to a lifting of the spin-valley degeneracy and renders graphene a topological insulator in a quantum spin-Hall phase while preserving particle-hole symmetry.

Here, we show that the Kane-Mele spin-orbit gap leads to a lifting of the spin-valley degeneracy in bilayer graphene quantum dots, resulting in Kramer's doublets with different ordering for electron and hole states preserving particle-hole symmetry. We observe the creation of single electron-hole pairs with opposite quantum numbers and use the electron-hole symmetry to achieve a protected spin-valley blockade in electron-hole double quantum dots. The latter will allow spin-to-charge and valley-to-charge conversion, which is essential for the operation of spin and valley qubits.

Local Chern patches and networks of chiral modes in quantum Hall phases with spatial magnetic field profiles. — •Suraj Hegde and Tobias Meng — Institute of Theoretical Physics and Wurzburg-Dresden Cluster of Excellence ct.qmat, Technische Universitat Dresden, 01069 Dresden, Germany.
Transport experiments on curved Hall bars show a variety of non-trivial transport signatures. Motivated by these experiments, we develop a model that accounts for various features in multi-terminal Hall bar measurements and perform numerical simulations using KWANT. We model the effect of curvature of the sample through spatial variation of the magnetic field profile and find that it results in patches of quantum Hall phases characterised by different local Chern markers. We find that most of the transverse and longitudinal transport can be understood in terms of local Chern patches and an intricate interplay of chiral modes at the interface of different patches. We also show that the spatial magnetic field textures could provide a novel platform to engineer lattices formed by networks of chiral modes.

Multilayer structures consisting of alternating magnetic and undoped topologi-

cal insulator layers have been proved so far to be a convenient platform for creating a quantum Anomalous Hall state with a high Chern number [1]. However, in previous proposals, the Chern number can only be tuned by varying the doping concentration or the width of the magnetic topological insulator TI layers. This restricts the applications of the dissipationless chiral edge currents in electronics, since the number of conducting channels remains fixed. In this work, we propose a way of varying the Chern number at will by means of an external electric field applied along the stacking direction. The electric field generates the hybridization of the inverted bands, generating new topological channels. In this way, the number of Chern states can be tuned externally in the sample, without the need of modifying the number and width of the layers or the doping level. We showed that this effect can be uncovered by the variation of the transverse conductance as a function of the electric field at constant injection energy at the Fermi level. [2]

Novel thermo-electric transport channel in the conformal limit of tilted Weyl semimetals — Thorvald Ballestad[1], Alberto Cortijo[2], Maria Vozmediano[3], and •Alireza Qaiumzadeh[1] — [1]Center for Quantum Spintronics, Norwegian University of Science and Technology, Trondheim, Norway — [2]Universidad Autonoma de Madrid, Madrid, Spain — [3]Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain

Recently, a new contribution to the Nernst current was proposed in 3D Dirac and Weyl semimetals, originated from quantum conformal anomaly [1,2]. In the present study, we analyze the effect of the tilt on the transverse thermo-electric coefficient of Weyl semimetals in the conformal limit, i.e., zero temperature and zero chemical potential. Using the Kubo formalism, we find a non-monotonic behavior of the thermoelectric conductivity as a function of the tilt perpendicular to the magnetic field, and a linear behavior when the tilt is aligned to the magnetic field. An "axial Nernst" current is generated in inversion symmetric materials when the tilt vector has a projection in the direction of the magnetic field. This analysis will help in the design and interpretation of thermo-electric transport experiments in recently discovered topological quantum materials [3].

Selective scattering between counter-propagating edge states in a topological insulator — •Meng Hao[1,2], Li-Xian Wang[1,2], Fabian Schmitt[1,2], Hartmut Buhmann[1,2], and Laurens W. Molenkamp[1,2] — [1]Institute for Topological Insulators, Würzburg, Germany — [2]Physikalisches Institut (EP III) Würzburg University, Würzburg, Germany

The quantum Hall state, known by its dissipationless nature, comprises chiral edge states in a two-dimensional electron gas (2DEG). In the ordinary quantum Hall effect, all edge states propagate in the same direction, populated equally. Thus, they are immune to inter-edge-state scattering. In contrast, counter-propagating edge states, populated unequally, are naturally sensitive to the scattering process. However, a realization of this scenario so far was only possible by stacked layers of high-mobility 2DEGs, e.g., quantum wells or graphene. Here we realize the counter-propagating edge states in a three-dimensional topological insulator controlled by top and bottom gates. Surprisingly, the counter-propagating edge states prove to scatter into each other selectively. Our first attempt shows that this inter-edge-state scattering occurs exclusively between Landau levels with the same Landau index. We further propose a cross bar equipped with split-gates to determine the selection rule of scattering and scattering parameters unambiguously. Following this proposal, we will show some preliminary results and report our experimental advances.

Edge modes, Hall conductivity and topological features of a dice lattice: Fate of flat bands under strain — •Sayan Mondal and Saurabh Basu — Indian Institute of Technology Guwahati

We study the topological properties of a dice lattice, which has three atoms per unit cell (A, B, and C). In addition, the bands are systematically deformed via the introduction of anisotropy among the nearest neighbour (NN) hoppings in two distinct ways. In the first case, we apply the uniaxial strain, which alters the NN hoppings (between the sublattices A-B and B-C) along the direction of applied strain. While in the second case, we selectively tune the NN hopping between A and B sublattices which may be achieved by a controlled chemical pressure. The first case yields the Chern insulating lobes in the phase diagram with $C = \pm 2$ till a certain critical anisotropy, where the spectral gap vanishes. The quantized plateau in the anomalous Hall conductivity and the pair of chiral

edge modes at each edge of a ribbon support the obtained values of the Chern numbers. Whereas, the second case (selective strain) shows distorted flat band in the dispersion spectrum, which alters the gap-closing condition as compared to the case of uniaxial strain. Also, the Chern insulating lobes in the phase diagram and the Hall conductivity have distinct features compared to the case above. However, in both cases, topological phase transitions take place which is demonstrated via the Chern number changing discontinuously from ±2 to zero across the gap-closing transitions.

TT 15.6   Mon 16:45   POT 251

Structure-imposed electronic topology in graphene nanoribbons — •Florian Arnold[1], Tsai-Jung Liu[1], Agnieszka Kuc[2], and Thomas Heine[1,2,3] — [1]Technische Universität Dresden, Dresden, Germany — [2]HZDR, Leipzig, Germany — [3]Yonsei University, Seoul, Republic of Korea

Zigzag graphene nanoribbons (ZGNR) can be transformed into new structure types by removing terminal carbon atoms in a regular pattern. When a single atom is removed on each zigzag edge so-called cove-edged ZGNR (ZGNR-C) are created, while removing multiple atoms results in gulf-edged ZGNR (ZGNR-G). In our seminal work, we demonstrated the direct structure-electronic structure relation based on the structural parameters that unambiguously characterize ZGNR-C. This allowed to create a scheme that classifies their electronic state, i.e., if they are metallic, topological insulators or trivial semiconductors, and to find an empirical formula for the band gap of the semiconducting ribbons. Since then, we were able to expand this description to ZGNR-G systems where the chemical space of possible structures increases further due to the variable size of the gulf edges. With this, we give guidance to realize new graphene nanoribbon heterojunctions hosting topological states and investigate the transport properties of exemplary systems.

TT 15.7   Mon 17:00   POT 251

Massive and topological surface states in strained HgTe and evidence for parity anomaly — •Wouter Beugeling[1,2], Lixian Wang[1,2], David M. Mahler[1,2], Valentin L. Müller[1,2], Ewelina M. Hankiewicz[3], Hartmut Buhmann[1,2], and Laurens W. Molenkamp[1,2] — [1]Institute for Topological Insulators, Würzburg, Germany — [2]Physikalisches Institut (EP III), Würzburg University, Würzburg, Germany — [3]Institute for Theoretical Physics and Astrophysics (TP IV), Würzburg University, Würzburg, Germany

The idea that band inversion in a narrow-gap material can lead to Dirac-type surface states was noted by Volkov and Pankratov in the 1980's. Only about two decades later, it was realized that the surface states of topological insulators are the gapless Dirac states predicted by them. The massive Volkov-Pankratov states received much less attention. They are pulled from the bulk in a sufficiently large electric field and are topologically trivial. Until recently, direct evidence in the form of transport measurements was elusive.

From our magneto-transport experiments on a three-dimensional topological insulator heterostructure (strained HgTe), we demonstrate the coexistence of massless and massive Volkov-Pankratov states. The well-developed Hall quantization in the n- and p-type regime is due to the topological surface state and the massive Volkov-Pankratov states, respectively, as confirmed by k·p theory. In a second series of experiments, we find a remarkable re-entrant quantum Hall effect in the p-type regime, which we can trace to spectral asymmetry, a salient manifestation of parity anomaly in a solid-state system.

Asymmetric and spatially resolved power dissipation in quantum transport — •Nico Leumer — Université de Strasbourg, CNRS, IPCMS, UMR 7504, F-67000 Strasbourg, France

Dissipation is a natural byproduct of quantum transport caused by various inelastic scattering events of electrons and their lost energy stimulates in turn the temperature profile of the underlying bulk material. Importantly though, electronic current may run only through a narrow part of the sample as, for instance, happens in the quantum Hall regime of graphene due to chiral edge channels (1); thus, dissipation has to be seen as a local quantity. The still rather recent invention of the Squid-on-tip technique in 2016 (2), paved the way to experimental access this challenge, where the temperature increases by merely a few hundred micro Kelvin on length scales of the order of nanometers.

Quantum point contacts (QPC's) are of particular interest in nanoscale transport, as electrons experience now a -perhaps energy dependent- transmission probability. On a hand waving level, QPC's increase the resistance electrons face from the sample locally, which is accompanied by areas of higher dissipation. In our recent project, we predict where and how much power is dissipated.

TT 16.2   Mon 15:00   P2/OG4

Resistive switching and peculiarities of conductivity of TiTe$_2$ point contacts — •Oksana Kvitnitskaya[1], Luminita Harnagea[2], Dmitri Efremov[3], Bernd Büchner[3,4], and Yurii Naidyuk[1] — [1]B.Verkin Institute for Low Temperature Physics and Engineering, NASU, Kharkiv, Ukraine — [2]Dep. of Physics, Indian Institute of Science Education and Research, Pune, Maharashtra, India — [3]Institute for Solid State Research, IFW Dresden, Dresden, Germany — [4]Institut für Festkörper- und Materialphysik and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, Dresden, Germany

Ti-based dichalcogenides TiX$_2$ (X - S, Se, Te), display a variety of physical properties, depending on their lattice distortions, native defects, self-doping effects, intercalation, external pressure. They can exhibit semiconducting, semimetallic, CDW, and superconducting behavior, which together with their layered structure and unique properties upon exfoliation to monolayer limit, make them particularly interesting. Recently, we observed the resistive switching effect in TiTe$_2$ point-contacts (PCs). We attributed the effect to Se vacancy drift due to a high electric field in the PC core. Here we report the resistive switching in PCs with isoelectronic TiTe$_2$, where the ratio of the high resistance state to the low resistance state was so far up to several times, contrary to up to two orders of magnitude for TiSe$_2$. Additionally, we observed "camel-like" $dV/dI(V)$ spec-

tra of TiTe$_2$ at helium temperature with two symmetric *vs* V=0 humps around +/-(200-300) mV, which vanished near 200 K.

TT 16.3   Mon 15:00   P2/OG4

Nonmonotonous Temperature Dependence of the Thermopower of Gold Atomic Contacts — Thomas Möller[1], •Marcel Strohmeier[1], Ruben Zerfass[1], Kim Nikolai Kirchberger[1], Danial Majidi[2], Juan Carlos Cuevas[3], Johannes Boneberg[1], Paul Leiderer[1], Wolfgang Belzig[1], and Elke Scheer[1] — [1]University of Konstanz, 78457 Konstanz, Germany — [2]Université Grenoble Alpes, CNRS, Grenoble INP, Institut Néel, 38042 Grenoble, France — [3]Universidad Autónoma de Madrid, E-28049 Madrid, Spain

We present measurements of the thermopower of atomic-size gold contacts realized by the mechanically controllable break junction (MCBJ) technique over a temperature range from 10 K to 295 K. While the conductance histograms confirm the quantum nature of the transport, we observe a non-monotonous temperature dependence of the ensemble-averaged thermopower (taking into account contacts between 1 and 20 $G_0 = 2e^2/h$) with a minimum of -2 μV/K at about 150 K. Our observations at low and high temperature are compatible with values reported in the literature [1-5], but the non-monotonous behavior in between disagrees with the expected linear increase of the thermopower for quantum coherent conductors described by the Landauer formula. We discuss several possible mechanisms, that may be at the origin of the deviation, such as phonon contributions or an energy-dependent transmission function. Both aspects can be addressed experimentally by analyzing current-voltage characteristics. We present here results obtained for Au and for Cu atomic contacts.

TT 16.4   Mon 15:00   P2/OG4

Analyzing vibrational instabilities arising from non-conservative current-induced forces in nanosystems with a semi-classical approach — •Robin L. Grether, Samuel Rudge, and Michael Thoss — Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Deutschland

Understanding the electric properties of nanosystems such as molecular junctions is a crucial task for modern physics. For molecular junctions, these properties are often governed by an electronic-vibrational coupling, which can lead to an instability of the junction in some cases.

We provide an in-depth analysis of the vibrational instabilities caused by non-conservative current-induced forces in a molecular junction using a semi-classical approach that exploits the time-scale separation between the fast electronic dynamics and the much slower vibrational dynamics. In particular, we use a Born-Markov master equation for the electronic degrees of freedom in combination with a semi-classical Langevin equation for the vibrational dynamics [1]. Within this framework, we study the dynamics of a junction composed of two electronic levels and two harmonic vibrational modes [2] for various parameters.

Full counting statistics of electron transport through periodically driven quantum dots analysed with factorial cumulants — •Johann Zöllner, Eric Kleinherbers, and Jürgen König — Theoretische Physik, Universität Duisburg-Essen, Lotharstr. 1, 47048 Duisburg

The electron transport through quantum dots is a stochastic process. Factorial cumulants of full counting statistics can be used to analyse current and current fluctuations of electrons [1]. We present methods to calculate factorial cumulants for periodically driven systems. This makes it possible to investigate effects in which a periodic drive and noise both take part. An example for such an effect is stochastic resonance, which has already been observed in quantum dots [2]. We will explain the meaning of factorial cumulants for stochastic resonance.

Rational design of halide perovskite-based quantum dots using ab-inotio many body techniques — •Manaswita Kar, Benjamin Lenz, and Michele Casula — IMPMC, Sorbonne Université-CNRS, Jussieu, 75005 Paris, France
Quantum dots (QDs) have attracted increasing attention as next generation functional materials, because of their unique size dependent colour tunability, due to quantum-confinement effect. However, the cost of production of these QDs is very high, thereby limiting their large scale industrial applications. Halide perovskite-based QDs provide single photon emission at room temperature and can be manufactured comparatively easily. These perovskites have a complex structural form and bears a large compositional space. As a result of this, only a limited number of these perovskite QDs have been tested so far. Here, we aim to identify the most promising perovskite based QDs for coherent photon emission applications by characterising their optical properties from theoretical simulations. Towards this aim, we employ the many body Green's function (GW) and Bethe-Salpeter equation (BSE) techniques to study the excited state properties of the QDs, which are known to be not well captured by standard ground state methods, such as Density Functional Theory (DFT). From this study, we finally envision find the best halide perovskite based quantum dot, that is both structurally and thermodynamically stable and can be manufactured for large scale commercial applications.

TT 16.7   Mon 15:00   P2/OG4

Device and contact engineering of MoS$_2$ nanotubes and nanoribbons — •Konstantin D. Schneider[1], Robin T. K. Schock[1], Jonathan Neuwald[1], Matthias Kronseder[1], Luka Pirker[2], Maja Remškar[2], and Andreas K. Hüttel[1] — [1]Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Solid State Physics Department, Institute Jožef Stefan, 1000 Ljubljana, Slovenia

Even though low-temperature transport measurements of a MoS$_2$ nanotube have already demonstrated Coulomb blockade at 300 mK,[1] Fermi level pinning near the conduction band at the metal-MoS$_2$ interface requires reactive low-work function metals, which then damage the MoS$_2$. Recently, bismuth[2] was shown to drastically reduce contact resistances in planar MoS$_2$.

Here, we present millikelvin transport measurements on MoS$_2$ nanotubes and nanoribbons with bismuth contacts.[3] Our nanotubes are grown via a chemical transport reaction, yielding diameters down to 7 nm and lengths up to several millimeters. Nanotubes were either suspended or placed on hexagonal boron nitride (hBN) in order to reduce disorder from the SiO$_2$ substrate. The resulting devices show Coulomb blockade, with a rich set of features. Contacts are transparent, and the temperature dependence hints at single level transport.

Weak localization in semiconductor heterostructures with strong spin orbit interaction — •Simon Feyrer, Jaydean Schmidt, Michael Prager, Dominique Bougeard, and Christoph Strunk — Institute of Experimental and Applied Physics, University of Regensburg, Germany

We present measurements of weak localization (WL) and weak anti-localization (WAL) performed on quasi-1D wires patterned into an InAs based quantum well. Due to the confinement of the electrons along the wires, the D'yakonov-Perel spin relaxation is expected to be suppressed resulting in WL instead of WAL. As consequence of the spin orbit interaction anisotropy, the amplitude of the WL is sensitive to the direction of an applied in-plane magnetic field and provides an estimate of the ratio between the Rashba and Dresselhaus spin orbit coefficient [1,2].

By fitting the measured WAL and WL-curves, the highest spin relaxation rate was extracted for the wires orientated along the [01$\bar{1}$] crystal axis. A clear suppression of spin relaxation was observed along the [001] wire direction.

Revealing the role of Klein tunneling in Aharanov-Bohm graphene rings — •Ching-Hung Chiu and Ming-Hao Liu — Department of Physics, National Cheng Kung University, Tainan City, Taiwan

Graphene, the ideal testbed of relativistic quantum mechanics, have been widely used to explore not only the exotic transport properties of Dirac fermions but also to confirm classic quantum-mechanical phenomena such as the Aharanov-Bohm effect. Motivated by a recent experiment [1], here we perform quantum transport simulations in the ballistic limit at zero temperature, considering an Aharanov-Bohm ring made of graphene with the same sample and gate geometry as the experiment. Preliminary properties from our simulations such as the gate and magnetic field dependence of the two-terminal conductance are rather consistent with the experiment, confirming their claim of the observed Aharanov-Bohm effect. To probe the effect of Klein tunneling, however, we propose a modified design using a local gate that makes pn interfaces perpendicular to the arm of the ring, different from the experiment. Based on our new design, we show that Klein tunneling may sharpen the Aharanov-Bohm oscillation frequency due to the screening of the transverse modes.

Transport properties of pn junctions in 2D materials: Graphene vs MoS$_2$ — •Yu-Ting Xiao and Ming-Hao Liu — Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan

Graphene and monolayer MoS$_2$ both belong to the family of 2D materials. The former is known as a Dirac semimetal where electrons behave like relativistic Dirac fermions due to the gapless energy band linear in momentum, while the latter shows typical semiconducting behaviors due to the gapped energy band quadratic in momentum, with which electrons behave as standard Schrödinger fermions. In terms of transport, Dirac and Schrödinger electrons exhibit distinct behaviors, among which the so-called Klein tunneling [1] is perhaps one of the best known. To further identify their difference in transport properties, here we perform quantum transport simulations for pn junctions in various 2D systems, including graphene, MoS$_2$, and other toy models for 2D semiconductors. Our

results identify transport properties that are unique to Dirac fermions as well as those that do not significantly differ from the two.

Quantum transport simulation for graphene devices with sawtooth-shaped n-p-n junctions — •Zhe-Bin Hsu and Ming-Hao Liu — Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan

Graphene, a gapless two-dimensional semimetal made of carbon atoms arranged in a honeycomb lattice, is an ideal platform for studying electron optics both experimentally and theoretically. Because of its lack of energy gap, n- and p-type carriers in graphene can be easily tuned simply by electrical gating. Typical graphene n-p-n junctions are created by local gates of rectangular shapes that exhibit Fabry-Pérot interference of electron waves in the clean limit. A recent experiment [1] realized a Dirac fermion reflector of graphene using sawtooth-shaped npn junctions, reporting not only the suppressed Fabry-Pérot interference but also resistance enhancement. Motivated by this experiment, we perform quantum transport simulations for graphene considering similar gate and sample geometries. Good consistency between our simulation and the experiment [1] will be shown. Further tests on other shaped top gates are performed in order to find the optimal gate geometry for best enhanced resistance. Our work shows that sawtooth-shaped graphene n-p-n junctions cannot work as a field-effect transistor (FET), even though the transmission can be reduced by a certain amount.

Electron correlation and confinement effects in quasi-one-dimensional quantum wires at high-density — Ankush Girdhar[1], Vinod Ashokan[1], Neil Drummond[2], •Klaus Morawetz[3,4], and Kare Narain Pathak[5] — [1]Department of Physics, Dr. B.R. Ambedkar National Institute of Technology, Jalandhar (Punjab), 144 011, India — [2]Department of Physics, Lancaster University, Lancaster LA1 4YB, United Kingdom — [3]Münster University of Applied Sciences, Stegerwaldstrasse 39, 48565 Steinfurt, Germany — [4]International Institute of Physics- UFRN,Campus Universitário Lagoa nova,59078-970 Natal, Brazil — [5]Centre for Advanced Study in Physics, Panjab University, 160014 Chandigarh, India

The correlation energy, pair-correlation function, static structure factor, and momentum density of ferromagnetic quasi-one-dimensional quantum wires are calculated using the quantum Monte Carlo (QMC) method for various wire widths b and density parameters r_s. The peak in the static structure factor at $k = 2k_F$ grows as the wire width decreases. The Tomonaga-Luttinger liquid parameter K_ρ is found to increase by about 10% between wire widths $b = 0.01$ and $b = 0.5$. The ground-state properties of finite thickness wires is compared to the first-order random phase approximation (RPA), which is exact in the high-density limit. Analytical expressions for the static structure factor and correlation energy are derived.

Ground state properties of electron-electron biwire systems — Rajesh O. Sharma[1], Neil Drummond[2], Vinod Ashokan[1], Kare Narain Pathak[3], and •Klaus Morawetz[4,5] — [1]Department of Physics, Dr. B.R. Ambedkar National Institute of Technology, Jalandhar (Punjab), 144 011, India — [2]Department of Physics, Lancaster University, Lancaster LA1 4YB, United Kingdom — [3]Centre for Advanced Study in Physics, Panjab University, 160014 Chandigarh, India — [4]Münster University of Applied Sciences, Stegerwaldstrasse 39, 48565 Steinfurt, Germany — [5]International Institute of Physics- UFRN,Campus Universitário Lagoa nova,59078-970 Natal, Brazil

Variational Monte Carlo (VMC) method is used to study the ground-state properties of a parallel infinitely-thin electron-electron quantum biwire system. The ground-state energy, the correlation energy, the interaction energy, the pair-correlation function (PCF), the static structure factor (SSF), and the momentum distribution (MD) function is calculated. As two parallel wires approach each other, inter-wire correlations increase while intra-wire correlations decrease. The SSF shows a peak at $2k_F$ at higher densities. A second peak starts to appear at $4k_F$ when $r_s = 2$ and $d = 0.2$ a.u. For lower densities, the first peak completely disappears and the height of the second peak keeps increasing with r_s and d. The behaviour of the PCF and SSF show that the electron-electron biwire system under goes into a quasi-Wigner crystalline state at densities higher compared to the case of a single wire.

Integrating coplanar resonators and carbon nanotubes for microwave optomechanics — Akong Loh, Fabian Stadler, •Furkan Özyigit, Nicole Kellner, Niklas Hüttner, and Andreas K. Hüttel — Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany

The optomechanical coupling of a carbon nanotube and a superconducting coplanar microwave resonator has been achieved [1,2] in our previous work. The carbon nanotube acts as a quantum dot, responding to gate voltages in a highly nonlinear way. This can be used to enhance the optomechanical coupling strength by several orders of magnitude. Recent work has focused on improving the electronic properties of the microwave resonators, to maximize quality factors in presence of the nanotube coupling electrodes. Currently, we redevelop insertion of carbon nanotubes as the mechanical counterpart. Here, we give an overview of recent improvements and ongoing measurements on this fascinating optomechanical system: at proper optimization, it can have figures of merit close to several interesting parameter regimes, as, e.g., strong optomechanical coupling (with hybridization of vibrons and photons) and the quantum coherent limit (where manipulation is faster than thermal decoherence).

Description of defective graphene by means of the Dirac equation coupled to curvature and torsion — •Enkeleta Berisha and Nikodem Szpak — Fakultät für Physik, Universität Duisburg-Essen, Duisburg, Germany

The continuum theory of lattice defects (dislocations and disclinations) offers a practical description of the electron transport at the mesoscale at which the microscopic (ab initio) models become too complex. It can be linked to the geometrical concepts of curvature and torsion whithin the Riemann-Cartan geometry. In General Relativity there is an ongoing discussion about the equivalence of these two objects. In solid state physics both objects have concrete interpretations in terms of disclinations and dislocations. The application to a two-dimensional system can shed new light on this problem. We focus on graphene whose electron dynamics is described by the Dirac equation which exhibits such defects. This leads to the coupling of the effective Dirac equation to curvature and torsion, thus opening the possibility of mapping these objects onto each other. We study particular lattice configurations and interpret them in terms of curvature or torsion. Moreover, we compare the quantum current flows with the semiclassical trajectories in the effective Riemann-Cartan geometry.

Strain-induced pseudo-Landau levels in semimetals from dimensional reduction — •Fabian Köhler and Matthias Vojta — Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, Germany

Non-uniform strain applied to graphene's honeycomb lattice can induce pseudo-Landau levels in the single-particle spectrum. We generalize this procedure to d-dimensional hyperdiamond-lattices and solve the corresponding continuum theory. The unstrained tight-binding Hamiltonian has semimetallic bandstructure with a (d-2)-dimensional nodal manifold, which transforms into a series of relativistic Landau levels under suitable strain. We show that a mechanism of dimensional reduction is at play here that goes beyond the conventional minimal coupling framework. This mechanism generates two-dimensional Landau-level problems with identical level spacing at each point of the nodal manifold.

Semi-classical vibrational dynamics in molecular junctions: Anharmonic potentials and non-linear couplings — •Martin Mäck, Samuel Rudge, and Michael Thoss — Physikalisches Institut, Universität Freiburg

Non-conservative current-induced forces can lead to vibrational instabilities in molecular junctions, even at low bias voltages [1]. A common approach is to treat the vibrational dynamics semi-classically as influenced by quantum mechanical electronic degrees of freedom. Within these treatments, the vibrational modes are often assumed to be harmonic and linearly coupled to the electronic degrees of freedom. However, at the onset of vibrational instabilities, such harmonic potentials might no longer realistically describe the dynamics.

In this contribution, we use a recently developed hierachical equations of motion (HEOM) approach [2] to semi-classical Langevin dynamics [3] to study systems for which the introduction of anharmonic potentials and non-linear electron-vibrational coupling might play an important role for the vibrational dynamics of the system.

Solving non-interacting open bosonic systems — •Steven Kim and Fabian Hassler — JARA Institute for Quantum Information, RWTH Aachen University

Open quantum systems that interact with their Markovian environment are described by a Lindblad master equation. We study non-interacting bosonic systems that are subject to single photon loss. The corresponding Liouvillian superoperator is at most of quadratic order in ladder operators. An analysis of the eigenvalues can give insight into possible instabilites as well as phase transitions. Especially the latter has gained growing interest for PT-symmetric systems. The

difficulty in solving such systems for its eigenmodes lies in preserving the canonical commutation relation, which is why the standard way of diagonalization is not possible. In this work, we propose a new method to obtain the diagonalized form of any non-interacting bosonic system using symplectic transformations. We are able to diagonalize a general complex matrix, while maintaining the symplectic form that encodes the commutation relations of the bosonic ladder operators. We show that non-Hermitian Hamiltonians naturally appear while solving the Lindblad master equation and that the eigenmodes can be obtained by solving a reduced system. Including counting fields into the Lindbladian makes the efficient calculation of the cumulant generating functions of arbitrary observables possible.

TT 17: Topology: Quantum Hall Systems

Time: Monday 16:45–18:45 Location: HSZ 304

TT 17.1 Mon 16:45 HSZ 304

Quantum Hall effect in the 2d topological insulator HgTe in pulsed magnetic fields of up to 65 T — •Christopher Fuchs[1,2], Tobias Kiessling[1,2], Saquib Shamim[1,2], Lena Fürst[1,2], Hartmut Buhmann[1,2], and Laurens W. Molenkamp[1,2] — [1]Physikalisches Institut, Universität Würzburg, Germany — [2]Institute for Topological Insulators, Würzburg, Germany

HgTe quantum wells are a two-dimensional topological insulator with highest electron mobilities as large as $1 \cdot 10^6$ cm^2/Vs. As a result of this outstanding sample quality, the material shows a well-resolved electron-type as well as hole-type quantum Hall effect, which has been studied extensively at lowest temperatures and in fields of up to 16 T. Here, we present an extension of this parameter space all the way to 65 T using pulsed magnetic fields. The high field behavior of the electron-type quantum Hall effect is studied, revealing that it forms a smooth continuation of the low field (< 20 T) behavior. For example, a characteristic breakdown of the quantum Hall effect, which occurs at the filling factor $\nu = 1/2$, is observed at > 50 T for corresponding carrier densities. In addition, a general circuit, wiring and analysis scheme for measurements of the quantum Hall effect within a few milliseconds (a magnetic field pulse lasts only around 100 ms) is presented, along with design rules for gated samples. The presented method is universal and can be applied to any other gated semiconductor/2d sample for transport studies in pulsed magnetic fields.

TT 17.2 Mon 17:00 HSZ 304

Robustness of the topological quantization of the Hall conductivity for correlated lattice electrons at finite temperatures — Anton Markov[1], •Georg Rohringer[2], and Alexey Rubtsov[1] — [1]Moscow, Russia — [2]Institute of Theoretical Physics, University of Hamburg, 20355 Hamburg, Germany

Electrons on a two-dimensional lattice which is exposed to a strong uniform magnetic field show intriguing physical phenomena. The spectrum of such systems exhibits a complex (multi)band structure known as Hofstadter's butterfly. For fillings at which the system is a band insulator, one observes a quantized integer-valued Hall conductivity σ_{xy} corresponding to a topological invariant, the first Chern number C_1 . This is robust against many-body interactions as long as no changes in the gap structure occur. Strictly speaking, this stability holds only at zero temperatures T , while for $T > 0$ correlation effects have to be taken into account. In our paper, we address this question by presenting a dynamical mean-field theory (DMFT) study of the Hubbard model in a uniform magnetic field. The inclusion of local correlations at finite temperature leads to (i) a shrinking of the integer plateaus of σ_{xy} as a function of the chemical potential and (ii) eventually to a deviation from these integer values. We demonstrate that these effects can be related to a correlation-driven narrowing and filling of the band gap, respectively.

Invited Talk TT 17.3 Mon 17:15 HSZ 304

Noise signatures of anyon statistics and Andreev scattering in the $\nu = 1/3$ fractional quantum Hall regime — •Anne Anthore, Pierre Glidic, Olivier Maillet, Colin Piquard, Abdel Aassime, and Frédéric Pierre — U Paris Cité, U Paris-Saclay, CNRS, C2N, Palaiseau (France)

Anyons are exotic quasiparticles which can carry a fractional charge of an electron and with an exchange statistics inbetween that of fermions and bosons. These properties were revealed using quantum point contacts (QPC) in the fractional quantum Hall regime[1,2].

In this talk, I will report further noise investigation of anyon physics. Sourcing e/3 anyons at a first QPC, noise measured on a downstream "analyzer" QPC reveals different mechanisms. Setting the analyser to allow e/3 tunneling charges, we reproduce the negative cross-correlations previously observed[2], indicative of a non-trivial anyon exchange phase[3]. When 1 e charges tunnel across the analyser, the braid phase is predicted to be trivial. Our observation of negative cross-correlations points on a scattering mechanism akin to Andreev reflection at Normal/Superconductor interfaces, as suggested in[4].

Remarkably, in both cases, electrical conduction across the analyzer conserves neither the nature nor the number of quasiparticles, rending the beam-splitter analogy of a QPC lapsed.

TT 17.4 Mon 17:45 HSZ 304

Topological properties of a two-dimensional non-symmorphic wallpaper group lattice — •Miguel Ángel Jiménez Herrera[1] and Dario Bercioux[1,2] — [1]Donostia International Physics Center, 20018 San Sebastian, Spain — [2]IKERBASQUE, Basque Foundation for Science, Euskadi Plaza, 5, 48009 Bilbao, Spain

We investigate the topological spectral properties of a two-dimensional electronic lattice belonging to a non-symmorphic wallpaper group: the herringbone lattice. We induce the topological phase either by applying an external magnetic field perpendicular to the plane of the lattice, and by enabling spin-orbit coupling of Kane-Mele type. On the one hand, when applying a magnetic field, the bands of the lattice rearrange into Landau levels. The phase diagram of the system shows a fractal disposition of the band gaps, known as the Hofstadter butterfly. Each gap is characterized by a non-zero Chern number whose distribution follows the Diophantine equation. On the other hand, we study the effects of enabling spin-orbit coupling in the lattice. We study both bulk and ribbon geometry, to reveal the helical states appearing at the edges of the ribbon, arising from the topological properties of the bulk.

TT 17.5 Mon 18:00 HSZ 304

Hofstadter butterflies in hyperbolic space — •Alexander Stegmaier[1], Lavi Upreti[4], Ronny Thomale[1], and Igor Boettcher[2,3] — [1]Institut für Theoretische Physik und Astrophysik, Universität Würzburg, 97074 Würzburg, Germany — [2]Department of Physics, University of Alberta, Edmonton, Alberta T6G 2E1, Canada — [3]Theoretical Physics Institute, University of Alberta, Edmonton, Alberta T6G 2E1, Canada — [4]Department of Physics, University of Konstanz, 78464 Konstanz, Germany

Hofstadter's Butterfly is the spectrum of a charged particle moving in a tight binding lattice under a constant magnetic field. Beyond its well-known fractal-shaped spectrum, this model is also relevant as a prototypical topological Chern insulator.

In light of recent interest in the physics of lattices in hyperbolic space, we reconsider the problem of Hofstadter's butterfly in {p,q} lattices. They tile the hyperbolic plane, a 2D space with constant negative curvature, with regular p-gons, q of which meet at each vertex. We develop methods to calculate the bulk spectra of a hyperbolic tight-binding system and apply them to uncover the features of Hofstadter's Butterflies in hyperbolic space. We find that the move to negatively curved space destroys the spectra's fractality, but preserves features of the spectral gaps, depending on the type of tiling {p,q}.

TT 17.6 Mon 18:15 HSZ 304

Observation and applications of non-Hermitian topology in a multi-terminal quantum Hall device — •Kyrylo Ochkan[1], Viktor Könye[1], Anastasiia Chyzhykova[1,2], Jan Budich[3], Jeroen van den Brink[1], Cosma Fulga[1], and Joseph Kyrylo[1] — [1]IFW Dresden, Deutschland — [2]Taras Shevchenko National University of Kyiv, Ukraine — [3]TU Dresden, Deutschland

One of the simplest examples of non-Hermitian topology is encountered in the Hatano-Nelson (HN) model, a one-dimensional chain where the hopping in one direction is larger than in the opposite direction. We present here the first experimental observation of non-Hermitian topology in a quantum condensed-matter system. The measurements are done in a multi-terminal quantum Hall device etched in a high mobility GaAs/AlGaAs two-dimensional electron gas ring. The conductance matrix that connects the currents flowing from the active contacts

to the ground with the voltage of the active contacts is topologically equivalent to the HN Hamiltonian.

In our device, we directly measure and evidence the non-Hermitian skin effect. We also compute for our experimental device two topological invariants that are found to be more robust than the Chern number. We finally use the unique properties of our system and continuously tune the system configuration between open and periodic boundary conditions.

In this talk, we present the latest developments with regard to the application of the devices with these topological properties.

TT 17.7　Mon 18:30　HSZ 304
Dirac Landau levels on a pseudosphere — •MAXIMILIAN FÜRST[1], DENIS KOCHAN[1,2], COSIMO GORINI[3], and KLAUS RICHTER[1] — [1]Universität Regensburg, 93053 Regensburg, Deutschland — [2]Slovak Academy of Sciences, 84511 Bratislava, Slovakia — [3]Université Paris-Saclay, 91191 Gif-sur-Yvette, France
Topological insulator nanowires host Dirac-like surface states with strongly suppressed backscattering [1]. As suggested in Ref. [2], surfaces with conical singularity could host Quantum Hall states which lead to an intrinsic angular momentum quantization of an electronic fluid which is put on the tip of the singularity. Topological insulators might be a good platform to examine this experimentally. However, they host surface states with Dirac-like dispersion instead of Schrödinger-like which is assumed in Ref. [2]. This raises the question if such effect may also be observed in those systems. A first step towards the answer is to choose an appropriate surface and calculate the Dirac Landau levels on it. We choose the pseudosphere which has a conical singularity and allows for analytical solution of the emerging eigenvalue equations. The spectrum and the eigenstates are computed for a constant magnetic field which is aligned perpendicularly to the surface. We further use the tight-binding package *Kwant* [3] to verify our analytically gained results numerically (see Ref. [4]).

Microwave optomechanics of the transversal carbon nanotube vibration — •AKONG LOH, FABIAN STADLER, FURKAN ÖZYIGIT, NICOLE KELLNER, NIKLAS HÜTTNER, and ANDREAS K. HÜTTEL — Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany
Recently, optomechanical coupling of a carbon nanotube and a coplanar microwave resonator has been achieved[1,2]. In this case, the nanotube acts as a mechanical resonator as well as a quantum dot. The coupling is enhanced by several order of magnitude by via the nonlinearity of Coulomb blockade. This novel optomechanical system presents several interesting features. For optimized paramters, e.g., strong optomechanical coupling (with hybridization of vibrons and photons) and the quantum coherent limit (where manipulation is faster than thermal decoherence) could be reached. Significant improvements of our microwave resonators have recently been achieved. Ongoing work aims to optimize the mechanical resonator, via improving the nanotube growth and the transfer of the nanotubes onto the resonator chip, as well as the cryogenic millikelvin setup for the measurements.

TT 18.2　Mon 17:30　HSZ 201
Squeezed mechanical states in nano-electromechanical systems — •KORBINIAN RUBENBAUER[1,2,3], THOMAS LUSCHMANN[1,2,3], RUDOLF GROSS[1,2,3], and HANS HUEBL[1,2,3] — [1]Walther-Meißner-Institut, Bayrische Akademie der Wissenschaften, Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technologies, Munich, Germany
The generation of nonclassical quantum states in a mechanical system such as squeezed states is not only an essential milestone for quantum-enhanced sensing of ultra-small forces and accelerations, but will also enhance our understanding of the foundations of quantum theory. Optomechanical systems coupling a mechanical displacement to a microwave resonator represent one way to implement protocols resulting in squeezed mechanical states and their readout. Here, we experimentally explore a scheme for the generation and detection of squeezed mechanical states using microwave control and spectroscopy of a nano-electromechanical system. In detail, we investigate a system based on a nanomechanical string resonator inductively coupled via a SQUID to a superconducting microwave resonator. Within this presentation, we discuss the challenges regarding the experimental implementation and the required parameter regime, and present preliminary experimental data.

TT 18.3　Mon 17:45　HSZ 201
Nanowire deflection detection based on a coupled mechanical oscillator — MANEESHA SHARMA, ANIRUDDHA SATYADHARMA PRASAD, NORBERT H. FREITAG, BERND BÜCHNER, and •THOMAS MÜHL — Leibniz Institute for Solid State and Materials Research IFW Dresden, 01069 Dresden, Germany
The field of nanowire (NW) technology represents an exciting and steadily growing research area with applications in ultra-sensitive mass and force sensing. Existing detection methods for NW deflection and oscillation include optical and field emission approaches. However, they are challenging for detecting small diameter NWs because of heating produced by the laser beam and the impact of the high electric field. Alternatively, the deflection of a NW can be detected indirectly by co-resonantly coupling the NW to a cantilever and measuring it using a scanning probe microscope. Here, we prove experimentally that co-resonantly coupled devices are sensitive to small force derivatives in a similar way as standalone NWs do. We detect force derivatives as small as 10^{-9} N/m with a bandwidth of 1 Hz at room temperature. The detection technique presented in this work verifies a major step in boosting NW-based force and mass sensing.

TT 18.4　Mon 18:00　HSZ 201
Symmetry breaking in a parametrically modulated quantum oscillator — •DANIEL BONESS[1], MARK DYKMAN[2], and WOLFGANG BELZIG[1] — [1]Department of Physics, University of Konstanz, 78457 Konstanz, Germany — [2]Department of Physics and Astronomy, Michigan State University, East Lansing, Michigan 48824, USA
A weakly damped nonlinear oscillator modulated close to twice its eigenfrequency has two stable states, which have the same vibration amplitudes but opposite phases. The states are equally populated due to classical or quantum fluctuations.

An extra force at half the modulation frequency lifts the symmetry of the states, generally. We study how the symmetry breaking occurs in the quantum regime.

As we show, a significant change of the state populations can take place already for a weak extra force. The mechanism is the force-induced change of the rates of interstate switching. The change is exponential in the ratio of the force amplitude to the appropriately scaled quantum length. It is large even where the effect of the force on the mean-field oscillator dynamics is small.

TT 18.5　Mon 18:15　HSZ 201
Quantum friction between metals in the hydrodynamic — •KUNMIN WU, THOMAS SCHMIDT, and MARIA BELÉN FARIAS — Faculty of Science, Technology and Medicine, 162 A, avenue de la Faïencerie, L-1511 Luxembourg
In this work, we study the phenomenon of quantum friction in a system consisting on a moving atom at a constant speed parallel to a metallic slab. We use a hydrodynamic model to describe the degrees of freedom of a clean metal without internal dissipation. The moving and polarizable atom is modeled as a two-level system with a unique ($l = 0$) ground state and a three-fold degenerate ($l = 1$) excited state. We show that a quantum frictional force is present even in the absence of intrinsic damping in the metal, but that there is a velocity threshold giving rise to such a force. In particular, to have non-vanishing friction demands that the atom must move at a velocity larger than the effective speed of sound in the material. We provide analytical arguments to show that this result holds at all orders in perturbation theory. Besides, we also explore how the spatial dispersion, which is determined by the sound speed in the hydrodynamic regime, affects the friction. Our numerical results show that the spatial dispersion has less effect on the friction when the speed of atom is much higher than the sound speed.

TT 19: Focus Session: New Perspectives for Adiabatic Demagnetization Refrigeration in the Kelvin and sub-Kelvin Range (joint session TT/MA)

Efficient cooling into the Kelvin and sub-Kelvin range is a long-standing challenge relevant to both fundamental research and future quantum technologies. The standard cooling cycle based on vapor compression exploits expensive and rare helium. Low-temperature physicists world-wide are presently looking for cheaper and accessible alternatives, not to mention the need of compact cooling technology for desktop quantum technology, or special requirements for applications such as space missions and scanning tunneling microscopes. One of the key candidates is adiabatic demagnetization refrigeration (ADR). ADR is based on magnetic solids with a huge magnetocaloric effect and requires no helium. Even if paramagnetic salts are known and used for ADR applications for almost a century, there is an ongoing quest for materials with better magnetocaloric and mechanical properties, thermal conductivity, and vacuum compatibility. In this symposium, new fundamental ideas and the recent successful design and characterization of quantum materials for improved ADR will be highlighted. These materials exploit collective phenomena in correlated electron systems, such as the concept of geometrically frustrated magnetism to push the entropy to low temperatures, as well as heavy-fermion, and quantum-critical states.

Invited Talk   TT 19.1   Tue 9:30   HSZ 03
Self-cooling molecular spin quantum processors — •Marco Evangelisti[1], Fernando Luis[1], Elias Palacios[1], David Aguilà[2], and Guillem Aromí[2] — [1]INMA, CSIC & Universidad de Zaragoza, Spain — [2]Dept. Química Inorgànica, Universidad de Barcelona, Spain

Cryogenic refrigeration is crucial for a wide range of emerging applications in the field of quantum technologies. Indeed, thermal energy must be minimized to avoid the excitation of vibrational motions that could disturb quantum operations. Synthetic chemistry provides a sophisticated methodology for the design and synthesis of materials displaying a wide variety of properties. Molecular materials are capable of excellent and unique characteristics that can be exploited either for caloric cooling[1] or spin-based quantum computing[2]. However, these features are not yet being implemented as such to act together within the same material, that is, at the molecular scale. Here, we show that a spin qubit (or qudit) can be brought into proximity with a spin centre that acts as a cooler. To this end, we make use of rare-earth-based asymmetric molecular dimers. A chemically engineered structural asymmetry introduces different coordination environments for each metal ion, operating similarly as for molecular quantum gates reported by some of us[3]. This strategy allows selecting individually both constituent ions, leading to e.g. the direct observation of the cooling of a single Er(III) ion qubit, or a Tm(III) electronuclear spin qudit, driven chiefly by the demagnetization of a single Gd(III) ion located within the same molecule.

Triangular rare-earth borates for milli-Kelvin adiabatic demagnetization refrigeration — •Philipp Gegenwart — Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg

Adiabatic demagnetization refrigeration (ADR) is a classical cooling technique with renewed recent attention as alternative to costly and elaborate ^{3}He/^{4}He dilution refrigeration. Established water containing ADR salts suffer from chemical instability which requires delicate treatment to avoid degradation and ensure good thermal contact. Water-free KBaYb(BO$_3$)$_2$ is an excellent alternative with high entropy density that allows ADR to below 20 mK [1]. Sintered pellets with silver powder admixture to ensure good thermal coupling are easy to manufacture, inexpensive and long-term stable even upon heating up to 700°C, enabling also ultra-high vacuum applications. KBaYb(BO$_3$)$_2$ belongs to a family of rare-earth-based borates with triangular arrangement of magnetic moments. We discuss the impact of geometrical frustration and structural randomness on its low-temperature properties and demonstrate the enormous tunability of cooling power and operating temperature by chemical substitution.

A millikelvin scanning tunnelling microscope in ultra-high vacuum with adiabatic demagnetisation refrigeration — •Ruslan Temirov — Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany — University of Cologne, Institute of Physics II, Cologne, Germany

Scanning tunnelling microscopes (STMs) operating in ultra-high vacuum (UHV) and low-temperature conditions are used widely for imaging and precise manipulation of surface nanostructures. A growing interest in studies of quantum-coherent phenomena in such nanostructures stimulates the develop-

ment of STMs that operate at very low millikelvin temperatures. This contribution presents the design of a first-ever UHV STM cooled by adiabatic demagnetisation refrigeration (ADR) to below 30 mK. The use of ADR makes the STM design modular and helps it to reach a remarkable degree of mechanical stability. Tunnelling spectra collected on an atomically clean superconducting Al(100) surface reveal that the electronic temperature of the tunnelling junction is less than 80 mK. The inelastic electron tunnelling spectroscopy of an individual electron spin performed in magnetic fields of up to 8 Tesla validates the STM capabilities for quantum nanoscience research.

ADR cryostats in low temperature physics and their applications — •Doreen Wernicke — Entropy GmbH, Gmunder Str. 37a, 81379 München

Entropy GmbH is a company founded in 2010 in Munich, Germany, specializing in the development and manufacture of low temperature cryostats. All Entropy cryostats are based on closed-cycle pre-cooling to temperatures below 3K. Further cooling stages such as ADR units, Joule-Thomson stages, and dilution refrigerators including electronics and software are proprietary developments. The modular design of all cryostats offers the possibility of adaptation to many different experiments and applications. One of Entropy's most common products are the ADR cryostats. The presentation will explain the principle of ADR cooling and features such as base temperature and holding time at operating temperature. Applications for low temperature device operation such as various types of superconducting detectors (TES, MKIDs, SQUIDs, SNSPDs) and Qubit characterization will be presented to demonstrate the performance and limitations of adiabatic demagnetization refrigeration.

Invited Talk   TT 19.5   Tue 11:45   HSZ 03
Frustrated dipolar materials for low-temperature magnetic refrigeration — •Mike Zhitomirsky — Institute of Interdisciplinary Research, CEA-Grenoble, France

Low-temperature refrigeration is crucial for emergent quantum-information technologies and other scientific applications that outstretch from space telescopes to medicine. This growing demand fuels an interest in alternative low-temperature techniques including the adiabatic demagnetization refrigeration. The existing ADR technologies for the sub-Kelvin range utilize dilute paramagnetic salts of Cr and Fe magnetic ions, which have limited efficiency at higher temperatures. I shall discuss general directions of the ongoing search of prospective refrigerant materials by exploring collective effects in systems of interacting magnetic moments as opposed to noninteracting moments in paramagnetic salts. Specifically, I focus on geometrically frustrated magnets with a residual ground-state degeneracy as well as on dipolar magnets. I present new experimental and theoretical results obtained recently in Grenoble for two dipolar materials: Yb$_3$Ga$_5$O$_{12}$, which is a spin-1/2 dipolar ferromagnet on a hyper-Kagome lattice, and GdLiF$_4$, which exhibits a hidden magnetic frustration. The striking properties of the latter material including a fractional magnetization plateau demonstrate importance of new magnetocaloric materials not only for applied but also for basic research in magnetism.

TT 19.7   Tue 12:30   HSZ 03

ADR below the ordering temperature in triangular KBaGd(BO$_3$)$_2$ — •Noah Winterhalter-Stocker[1], Alexander Bellon[1], Fabian Hirschberger[1], Sebastian Bachus[1], Sebastian Erdmann[1], Alexander Tsirlin[1,2], Yoshifumi Tokiwa[1,3], Anton Jesche[1], and Philipp Gegenwart[1] — [1]Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg, D-86159 Augsburg, Germany — [2]Felix Bloch Institute for Solid-State Physics, Leipzig University, D-04103 Leipzig, Germany — [3]Advanced Science Research Center, Japan Atomic Energy Agency, Tokai, Ibaraki 319-1195, Japan

Compared to the triangular ADR magnet KBaYb(BO$_3$)$_2$ [1] the isostructural sister compound KBaGd(BO$_3$)$_2$ with spin 7/2 moments has a three times enhanced magnetic entropy density of 192 mJK^{-1}cm^{-3}. We report a low-temperature magnetic and thermodynamic investigation of polycrystalline KBaGd(BO$_3$)$_2$ down to 50 mK. Specific heat indicates an antiferromagnetic phase transition at 263 mK, strongly broadened due to randomness and frustration, that becomes suppressed beyond 0.5 T. Further increase of magnetic field shifts the available entropy of R log 8 towards high temperatures. Interestingly, ADR of a pellet utilizing the same setup as used in [1] reveals a minimal temperature if T_{min}=122 mK that is more than twice below T_N along with a hold time of more than 8 hours. The combination of minimal temperature and entropy density in KBaGd(BO$_3$)$_2$ is outstanding among known ADR materials.

TT 19.8   Tue 12:45   HSZ 03

Magnetocaloric properties of (RE)$_3$Ga$_5$O$_{12}$ (RE=Tb, Gd, Nd, Dy) — Markus Kleinhans[1], Klaus Eibensteiner[1,2], Jon Leiner[1], •Christoph Resch[1], Lukas Worch[1], Marc Wilde[1], Jan Spallek[1,2], Alexander Regnat[1,2], and Christian Pfleiderer[1] — [1]Physik Department, Technical University Munich, D-85748 Garching, Germany — [2]kiutra GmbH, Rupert-Mayer-Str. 44, D-81379 Munich, Germany

We report the characteristic magnetic properties of several members of the rare earth garnet family, Gd$_3$Ga$_5$O$_{12}$ (GGG), Dy$_3$Ga$_5$O$_{12}$ (DGG), Tb$_3$Ga$_5$O$_{12}$ (TGG), and Nd$_3$Ga5O$_{12}$ (NGG), and compare their relative potential utility for magnetocaloric cooling, including their minimal adiabatic demagnetization refrigeration (ADR) temperatures and relative cooling parameters. A main objective of this work was to find potential improvements over the magnetocaloric properties of GGG for use in low temperature ADR cryostats. Using Tb^{+3} and Dy^{+3} in the RE-site oers, in principle, a higher saturation magnetization and Nd^{+3} gives a lower de Gennes factor and therefore potentially low transition temperature. Our results show that Dy$_3$Ga$_5$O$_{12}$ yields an optimal relative cooling parameter (RCP) at low applied fields and a low transition temperature, which would allow for the design of more efficient ADR cryostats.

Study of the large rotational magnetocaloric effect in Ni(*en*)(H$_2$O)$_4$SO$_4$·2H$_2$O — •Róbert Tarasenko, Petro Danylchenko, Erik Čižmár, Vladimír Tkáč, Alexander Feher, Alžbeta Orendáčová, and Martin Orendáč — Institute of Physics, Faculty of Science, Pavol Jozef Šafárik University, Park Angelinum 9, 041 54 Košice, Slovakia

The title compound Ni(*en*)(H$_2$O)$_4$SO$_4$·2H$_2$O (*en* = ethylenediamine) has been identified as a spin-1 paramagnet with the nonmagnetic ground state introduced by the easy-plane anisotropy D/k_B = 11.6 K with E/D = 0.1 and negligible exchange interactions $J \approx 0$. We present an experimental study of the rotational magnetocaloric effect (MCE) in single crystals at temperatures above 2 K, associated with adiabatic crystal rotation between the easy plane and hard axis in magnetic fields up to 7 T. The experimental observations are completed with *ab* initio calculations of the anisotropy parameters. Theoretical simulations of the rotational MCE in the $S = 1$ paramagnet were performed and the simulations were compared with experimental data. A large rotational magnetic entropy change ≈16.9 Jkg^{-1}K^{-1} has been achieved in 7 T. The adiabatic rotation of the crystal in 7 T starting at the initial temperature of 4.2 K leads to the cooling of the sample down to 0.34 K, which suggests the application of this material in low-temperatures cooling. Our simulations show that $S = 1$ Ni(II)-based systems with easy-plane anisotropy can have better rotational magnetocaloric properties than costly materials containing rare-earth elements.

Supported by project No. APVV-18-0197.

TT 20: Superconductivity: Tunnelling and Josephson Junctions

Time: Tuesday 9:30–13:00   Location: HSZ 103

TT 20.1   Tue 9:30   HSZ 103

Calorimetry of a phase slip in a Josephson junction — Efe Gümüs[1], Danial Majidi[1], Danilo Nikolic[2], Patrick Raif[2], Bayan Karimi[3], Joonas Peltonen[3], Elke Scheer[2], Jukka Pekola[3], Hervé Courtois[1], Wolfgang Belzig[2], and •Clemens Winkelmann[1] — [1]Univ. Grenoble Alpes, CNRS, Grenoble INP, Institut Néel, Grenoble, France — [2]Fachbereich Physik, Universität Konstanz, Konstanz, Germany — [3]Centre of Excellence, Department of Applied Physics, Aalto University School of Science, Aalto, Finland

Josephson junctions are a central element in superconducting quantum technology; in these devices, irreversibility arises from abrupt slips of the quantum phase difference across the junction. This phase slip is often visualized as the tunnelling of a flux quantum in the transverse direction to the superconducting weak link, which produces dissipation. Here we detect the instantaneous heat release caused by a phase slip in a Josephson junction, signalled by an abrupt increase in the local electronic temperature in the weak link and subsequent relaxation back to equilibrium. Beyond the advance in experimental quantum thermodynamics of observing heat in an elementary quantum process, our approach could allow experimentally investigating the ubiquity of dissipation in quantum devices, particularly in superconducting quantum sensors and qubits.

TT 20.2   Tue 9:45   HSZ 103

Measurement of two coupled Bloch oscillators based on Al/AlO$_x$/Al-Josephson junctions — •Fabian Kaap and Sergey Lotkhov — Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Deutschland Braunschweig

We investigate a system of two coupled Bloch oscillators based on ~ 50×50 nm^2 Josephson junctions, where one oscillator is a flux tunable SQUID and one is a single junction, respectively. To suppress the quantum oscillations of charge and enable the occurrence of coherent Bloch oscillations, the leads include high ohmic microstrips made from oxidized titanium. Between the resistors and junctions, we design the connection via a capacitively coupled pair of high-kinetic-inductance meanders of granular aluminum. When only the single junction is actively driven by an external bias current I_{B1} the Coulomb blockade of this junction can be tuned by the flux through the passive, non-driven SQUID. If additionally a current I_{B2} is applied through the SQUID we observe synchronisation effects in the IV-curves of both Bloch oscillators when the currents coincide, $I_{B1} \approx I_{B2}$. We address experimental issues, such as electron overheating in the leads, the presence of higher harmonics at low bias currents and the onset of Zener tunneling.

TT 20.3   Tue 10:00   HSZ 103

Phase-dependent transport in thermally driven superconducting single-electron transistors — Alexander G. Bauer and •Björn Sothmann — Theoretische Physik, Universität Duisburg-Essen and CENIDE, D-47048 Duisburg, Germany

We investigate thermally driven transport of heat and charge in a superconducting single-electron transistor by means of a real-time diagrammatic transport theory. Our theoretical approach allows us to account for strong Coulomb interactions and arbitrary nonequilibrium conditions while performing a systematic expansion in the tunnel coupling. We find that a temperature bias across the system gives rise to finite heat and charge currents close to the particle-hole symmetric point which depend both on the gate voltage as well as on the phase difference between the superconducting reservoirs. The finite thermoelectric effect arises due to level renormalization from virtual tunneling processes. Fur-

thermore, we find that the phase bias can give rise to finite charge currents even in the presence of an inversion-symmetric temperature bias.

TT 20.4   Tue 10:15   HSZ 103

Josephson nanojunctions fabricated by He focused ion beam irradiation — •Edward Goldobin[1], Max Karrer[1], Christoph Schmid[1], Katja Wurster[1], Ramón Manzorro[2,3], Javier Pablo-Navarro[2,3], Cesar Magen[2,3], Reinhold Kleiner[1], and Dieter Koelle[1] — [1]Physikalisches Institut, Center for Quantum Science (CQ) and LISA[+], Universität Tübingen, Germany — [2]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Spain — [3]Laboratorio de Microscopías Avanzadas (LMA), Universidad de Zaragoza, Spain

We use a focused He ion beam (He-FIB) for the nanofabrication of Josephson junctions (JJs) and more complex devices based on $YBa_2Cu_3O_{7-\delta}$ (YBCO) thin films [1]. Using an optimum He-FIB irradiation dose, we "write" Josephson barriers across YBCO microbridges. Such JJs have RCSJ-like I–V characteristics, and the dependence of the critical current vs. magnetic field resembles a Fraunhofer pattern. Using higher irradiation doses, we induce insulating regions that can be used for nanopatterning of various circuits, i.e., patterning of SQUID loops, constriction JJs (cJJs), etc.

Investigations of the irradiated regions by scanning transmission electron microscopy (STEM) provide information on the modification of the crystalline structure of YBCO on the atomic scale. STEM analysis reveals the amorphization thresholds for irradiation of 1D and 2D patterns (depending on the beam size), and provides insights into the current resolution limits for the fabricaton of YBCO cJJs.

TT 20.5   Tue 10:30   HSZ 103

Theory of scanned Josephson tunneling spectroscopy in cuprates — •Peayush Choubey[1] and Peter Hirschfeld[2] — [1]Department of Physics, Indian Institute of Technology Roorkee, Roorkee 247667, India — [2]Department of Physics, University of Florida, Gainesville, Florida 32611, USA

The scanned Josephson tunneling spectroscopy (SJTS) is a direct local probe of superconducting gap order parameter. To the best of our knowledge, SJTS studies have been limited to the cases where superconducting sample and superconducting tip, both, have the same gap symmetry- either s-wave or d-wave. One might assume that in an s-to-d SJTS study of cuprates the critical current would vanish everywhere, as naively expected for planar junctions. We show here that this is not the case. Employing first-principles Wannier functions for $Bi_2Sr_2CaCu_2O_8$, we develop a scheme to compute Josephson critical current and quasiparticle tunneling current measured by SJTS with sub-angstrom resolution. We demonstrate that the critical current due to tunneling between an s-wave tip and a superconducting cuprate sample has largest magnitude above O sites and it vanishes above Cu sites as a direct consequence of the d-wave gap symmetry in cuprates. Moreover, we predict various signatures of pair density waves in underdoped cuprates that can be tested in future SJTS studies.

TT 20.6   Tue 10:45   HSZ 103

Critical temperature of superconductor-ferromagnetic bilayers with helimagnetic metals — •Danilo Nikolic, Subrata Chakraborty, Alfredo Spuri, Elke Scheer, Angelo Di Bernardo, and Wolfgang Belzig — Fachbereich Physik, Universität Konstanz, D-78457 Konstanz, Germany

Motivated by recent experiments on the proximity effect in superconductor-ferromagnet structures with the helimagnetic ordering of magnetization in the latter, we present a systematic theoretical study of the critical temperature of such systems. By employing the quasiclassical Usadel approach [1], we account for two different configurations of magnetization in the ferromagnet and investigate their impact on the critical temperature (T_c) of the superconductor. Besides recovering the known results for the case of uniform magnetization [2], we find a nontrivial behavior of T_c in the case of spiral magnetization. Our theory suggests that this can be attributed to the emergence of long-range spin-triplet correlations generated in the ferromagnet [3]. Finally, our model predicts that the presence of spiral magnetization can reduce the critical temperature in the experimentally relevant range of parameters. This effect is the subject of ongoing experiments.

TT 20.7   Tue 11:00   HSZ 103

Equal-spin Cooper pair injection in superconducting spintronics devices — •Matthias Eschrig[1] and Xavier Montiel[2] — [1]Institute of Physics, University of Greifswald, Germany — [2]Department of Materials Science & Metallurgy, University of Cambridge, UK

In a number of recent experiments unusual behavior was observed in ferromagnet/ferromagnet/superconductor devices when a precession of the magnetization was induced by ferromagnetic resonance. By using a non-equilibrium Us-

adel Green function formalism, we solve for spin-resolved distribution functions and demonstrate that the spin injection process in superconductors is governed by the inverse proximity effect in the superconducting layer. We find that equal-spin Cooper pairs, which are produced by the two misaligned ferromagnetic layers, transport spin inside the S layer. This then results in an increase of the injected spin current below the superconducting critical temperature. Our calculations provide the first evidence of the essential role of equal-spin Cooper pairs on spin-transport properties of S/F devices and pave new avenues for the design of superconducting spintronics devices.

TT 20.8   Tue 11:30   HSZ 103

Vortex phase transitions in frustrated two-dimensional semiconductor-superconductor Josephson junction arrays — •Simon Reinhardt[1], Christian Baumgartner[1], Sergei Gronin[2], Geoffrey C. Gardner[2], Tyler Lindemann[2], Michael J. Manfra[2], Tatyana I. Baturina[1], Nicola Paradiso[1], and Christoph Strunk[1] — [1]Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Purdue University, West Lafayette, Indiana 47907, USA

We study two-dimensional Josephson junction arrays in hybrid aluminum/InGaAs/InAs semiconductor-superconductor heterostructures. Using a cold resonator technique, we measure both the inductive response as well as the DC transport properties of the array. A perpendicular magnetic field induces highly ordered vortex configurations for integer and fractional values of the frustration parameter. In the vicinity of the matching fields we observe pronounced dip-to-peak transitions of the differential resistance as a function of current bias, which have previously been interpreted as signatures of a non-equilibrium vortex Mott transition [1]. The scaling behaviour of the differential conductance in our array of ballistic SNS junctions is compared with previous results on diffusive Josephson junction arrays.

TT 20.9   Tue 11:45   HSZ 103

Engineering the speedup of quantum tunneling in Josephson systems via dissipation — •Dominik Maile[1], Joachim Ankerhold[1], Sabine Andergassen[2], Wolfgang Belzig[3], and Gianluca Rastelli[4] — [1]Institut für Komplexe Quantensysteme, Universität Ulm — [2]Institut für Theoretische Physik and Center for Quantum Science, Universität Tübingen — [3]Fachbereich Physik, Universität Konstanz — [4]INO-CNR BEC Center and Dipartimento di Fisica, Università di Trento

We theoretically investigate the escape rate occurring via quantum tunneling in a system affected by tailored dissipation [1]. Specifically, we study the environmental assisted quantum tunneling of the superconducting phase in a current-biased Josephson junction. We consider Ohmic resistors inducing dissipation both in the phase and in the charge of the quantum circuit. We find that the charge dissipation leads to an enhancement of the quantum escape rate. This effect appears already in the low Ohmic regime and also occurs in the presence of phase dissipation that favors localization. Inserting realistic circuit parameters, we address the question of its experimental observability and discuss suitable parameter spaces for the observation of the enhanced rate.

TT 20.10   Tue 12:00   HSZ 103

Complete magnetic control over the superconducting thermoelectric effect — •Jabir Ali Ouassou[1], César González-Ruano[2], Diego Caso[2], Farkhad G. Aliev[2], and Jacob Linder[1] — [1]Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, NO-7491 Trondheim, Norway — [2]Departamento Física de la Materia Condensada C-III, INC and IFIMAC, Universidad Autónoma de Madrid, Madrid 28049, Spain

Giant thermoelectric effects are known to arise at the interface between a superconductor and strongly polarized ferromagnet, and this enables the construction of efficient thermoelectric generators. We predict that the thermopower of such generators can be completely controlled by a magnetic input signal: not only can the thermopower be toggled on and off by rotating a magnet, but even the sign of the thermopower can be reversed. This *in situ* control diverges from conventional thermoelectrics, where the thermopower is usually fixed by the device design.

TT 20.11   Tue 12:15   HSZ 103

Quantum phases in a frustrated sawtooth chain of Josephson junctions — •Benedikt J.P. Pernack, Mikhail V. Fistul, and Ilya M. Eremin — Ruhr-Universität Bochum, Bochum Germany

We present a theoretical study of quantum phases occurring in a frustrated sawtooth chain of small Josephson junctions. In the model the frustration f arises due to the Josephson couplings having alternating signs (0 and π Josephson junctions) in a single lattice cell. At the critical value of $f = 3/4$ such a system displays a phase transition from the ordered state into the frustrated one with a highly degenerate ground state characterized by penetration of topological (anti)vortices

[1]. Introducing additional capacitances to the ground, we derive an effective Ising quantum spins model with a long-range interaction between well separated vortices/antivortices, and obtain various collective quantum phases and quantum phase transitions between them.

TT 20.12   Tue 12:30   HSZ 103

Low-energy model for superconducting quantum dot systems — •Vladislav Pokorný[1] and Martin Žonda[2] — [1]FZU - Institute of Physics, Czech Academy of Sciences, Na Slovance 2, 182 21 Prague, Czech Republic — [2]Faculty of Mathematics and Physics, Charles University, Ke Karlovu 5, 121 16 Prague, Czech Republic

We present a method to extract the Andreev bound state energies of a single-level quantum dot connected to superconducting leads from the imaginary-time results of quantum Monte-Carlo method without the use of analytic continuation techniques like maximum entropy method. We describe the system using the superconducting impurity Anderson model and show that for low energies it maps on an atomic-like model. The parameters of this model can be extracted from the self-energy calculated in imaginary-frequency domain using the hybridization-expansion quantum Monte Carlo method. We compare the results to zero-temperature numerical renormalization group data to show the limits of usability of the low-energy model.

TT 20.13   Tue 12:45   HSZ 103

Tracking current path in multi-terminal graphene Josephson junctions — •Devang Parmar — Institute for Quantum Materials and Technologies (IQMT), Karlsruhe institute of Technology, 76021 Karlsruhe, Germany.

Multiterminal Josephson junctions have been predicted to be platforms to observe various exotic phenomena such as new topological phases of matter [1], correlated states [2-5] or the so-called Andreev molecules [6,7]. In order to control the electronic properties of these complex devices, it is important to comprehend and track the supercurrent flow with respect to their geometries and superconducting lead peculiarities.

Here, we investigated the supercurrent in multi-terminal superconductor-graphene-superconductor (SGS) junctions. Together with magnetic interferometry experiments in these multiterminal graphene devices, we clearly observe that the contact transparencies can be very different from one lead to the other which mainly drives the entire transport properties in SGS. Our work provides insights of the supercurrent flow in multiterminal Josephson junctions and paves the way for further investigations in more complex multiterminal devices.

TT 21: Correlated Electrons: Electronic Structure Calculations

Time: Tuesday 9:30–11:45   Location: HSZ 201

TT 21.1   Tue 9:30   HSZ 201

Revealing electronic correlations in YNi_2B_2C using photoemission spectroscopy — •Aki Pulkkinen[1], Geoffroy Kremer[2], Vladimir Strocov[3], Frank Weber[4], Ján Minár[1], and Claude Monney[5] — [1]New Technologies-Research Center, University of West Bohemia, Pilsen, Czech Republic — [2]Département Physique de la Matière et des Matériaux, Institut Jean Lamour, Université de Lorraine/CNRS, France — [3]Paul Scherrer Institut, Swiss Light Source, Villigen, Switzerland — [4]Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, Karlsruhe, Germany — [5]Département de Physique and Fribourg Center for Nanomaterials, Université de Fribourg, Fribourg, Switzerland

YNi_2B_2C is an intermetallic borocarbide superconductor with a complex electronic band structure that has a very strong Ni character near the Fermi energy. We present density functional theory (DFT) and one-step model of photoemission results for YNi_2B_2C and compare them to experimental soft x-ray angle resolved photoemission spectroscopy (SX-ARPES) measurements. We show that moderate electron correlations have to be included, using dynamical mean field theory (DFT+DMFT) applied to the Ni d-states, to reach the best agreement between the experimental and theoretical SX-ARPES spectra. The one-step model calculations allow us to identify the effect of DFT+DMFT on the energy bands observed in the SX-ARPES measurements.

TT 21.2   Tue 9:45   HSZ 201

Distortion and pressure induced phase transitions in double perovskite La_2CoTiO_6 — •Sromona Nandi[1], Ashis K. Nandy[2], and Rudra Sekhar Manna[1] — [1]Department of Physics, Indian Institute of Technology Tirupati, Tirupati 517619, AP, India — [2]School of Physical Sciences, National Institute of Science Education and Research, An OCC of Homi Bhabha National Institute, Jatni-752050, India

We study the density-functional theory spin-polarized electronic structure calculations for a double perovskite La_2CoTiO_6 where the magnetic moment comes from the Co^{2+} as Ti is in 4^+ state. Due to the rotation and volume mismatch between the TiO_6 and CoO_6 octahedra ($\angle$Co-O-Ti is 151–153°), the system is distorted at ambient pressure. The Co-moments align antiferromagnetically at low temperature and show an insulating transport property with a band gap of 1 eV, consistent with the experiment [1]. With the removal of distortion, i.e., ideal undistorted structure ($\angle$Co-O-Ti = 180°) shows a metallic behavior. Such metallic state can also be achieved with the application of hydrostatic pressure on the distorted structure accompanied by the quenching of Co-moment in the metallic phase which can be understood by the shifting of the exchange splitting of the Co 3d orbitals at the Fermi level. In addition, atomic projected density of states analysis of the Co sublattices shows an interesting half-metallic like intermediate state which could be interesting for spintronics applications.

TT 21.3   Tue 10:00   HSZ 201

Oxygen vacancies at the origin of pinned moments in oxide interfaces: the example of tetragonal $CuO/SrTiO_3$ — •Benjamin Bacq-Labreuil[1], Benjamin Lenz[2], and Silke Biermann[3] — [1]Institut Quantique, Université de Sherbrooke, Sherbrooke, Canada — [2]Institut de Minéralogie, de Physique des Matériaux et de Cosmochimie, Sorbonne Université, Paris, France — [3]Centre de Physique Théorique, Ecole Polytechnique, Palaiseau, France

Obtaining an accurate theoretical description of the emergent phenomena in oxide heterostructures is a major challenge. Recently, intriguing paramagnetic spin and pinned orbital moments have been discovered by x-ray magnetic circular dichroïsm measurements at the Cu $L_{2,3}$-edge of a tetragonal $CuO/SrTiO_3$ heterostructure. Using first principles calculations, we propose a scenario that explains both types of moments [1], based on the formation of oxygen vacancies in the TiO_2 interface layer. We show the emergence of a paramagnetic 2D electron gas hosted in the interface CuO layer. It is invisible at the Ti $L_{2,3}$-edge since the valence of the Ti atoms remains unchanged. Strong structural distortions breaking both the local and global fourfold rotation C_4 symmetries at the interface lead to the in-plane pinning of the Cu orbital moment close to the vacancy. Our results, and in particular the pinning of the orbital moment, may have implications for other systems, especially monoxide/dioxide interfaces with similar metal-oxygen bond length and weak spin-orbit coupling.

TT 21.4   Tue 10:15   HSZ 201

New superexchange paths due to synergetic breathing and hopping in corner-sharing cuprates — •Nikolay A. Bogdanov[1], Giovanni Li Manni[1], Sandeep Sharma[1,2], Olle Gunnarsson[1], and Ali Alavi[1,3] — [1]Max Planck Institute for Solid State Research, Stuttgart, Germany — [2]Department of Chemistry, University of Colorado Boulder, Boulder, CO, USA — [3]University Chemical Laboratory, Cambridge, UK

We present *ab initio* quantum chemistry calculations of the nearest-neighbour superexchange antiferromagnetic spin coupling J for two cuprates, Sr_2CuO_3 and La_2CuO_4. Good agreement with experimental estimates is obtained for both systems. We also find that J increases substantially as the distance between Cu and apical O is increased.

Analysis of the correlated wavefunctions together with extended superexchange models shows that there is an important synergetic effect of the Coulomb interaction and the O–Cu hopping. When an extra electron hops into Cu 3d orbital, Coulomb interaction leads to the orbital breathing (expansion), which on its turn reinforces electron hopping. This correlated breathing-enhanced hopping mechanism is a new ingredient in superexchange models. Our analysis shows that suppression of the described mechanism leads to a drastic reduction in the antiferromagnetic coupling, indicating that it is of primary importance in generating the strong interactions.

TT 21.5   Tue 10:30   HSZ 201

DFT with corrections for an efficient and accurate description of strong electron correlations in NiO — •Julian Gebhardt[1,2] and Christian Elsässer[1,2,3] — [1]Fraunhofer IWM, 79108 Freiburg — [2]Cluster of Excellence livMatS, University of Freiburg — [3]Freiburg Materials Research Center, University of Freiburg

An efficient and accurate description of the electronic structure of a strongly correlated oxide like NiO has been notoriously difficult. Here, we study the capabilities and limitations of two frequently employed correction schemes, a DFT+U on-site correction and a DFT+1/2 self-energy correction. While both methods individually are unable to provide satisfactory results, in combination they provide a very good description of all relevant physical quantities. Since both methods cope with different shortcomings of common DFT methods (using local-density or generalized-gradient approximations), their combination is not mutually dependent and remains broadly applicable. The combined approach retains the computational efficiency of DFT calculations while providing significantly improved predictive power.

TT 21.6   Tue 10:45   HSZ 201

LaVO$_3$: A true Kugel-Khomskii system — •Xuejing Zhang[1], Erik Koch[1,2], and Eva Pavarini[1,2] — [1]Institute for Advanced Simulation, Forschungszentrum Jülich, 52425 Jülich, Germany — [2]JARA High-Performance Computing, 52062 Aachen, Germany

Almost 50 years ago, Kugel' and Khomskii (KK) showed in a classic paper that, in strongly correlated materials, orbital ordering can arise from pure superexchange interactions [1]. It can, however, also result from the crystal-field splitting via a lattice distortion, i.e., from electron-lattice coupling. Despite the intensive search, it has been hard to find an undisputed realization of a KK system. We identify that the t_{2g}^2 perovskite LaVO$_3$, in its orthorhombic phase, is a rare case of a system hosting an orbital-ordering KK phase transition rather than being controlled by the Coulomb-enhanced crystal-field splitting [2]. We find that, as a consequence of this, the magnetic transition is close to (and even above) the superexchange driven orbital-ordering transition, whereas typically magnetism arises at much lower temperatures than orbital ordering. To explore the effects of crystal-field splitting and filling, we compare to YVO$_3$ and t_{2g}^1 titanates. In all these materials the crystal field is sufficiently large to suppress the KK phase transition [3].

Orbital-selective metal-insulator transitions in the presence of strong magnetic fluctuations — •Evgeny Stepanov — CPHT, CNRS, École polytechnique, Institut Polytechnique de Paris, 91120 Palaiseau, France

Orbital-selective phenomena that can be realised in materials attract enormous interest. A prominent example is an orbital-selective Mott phase, where itinerant and localised electrons live in different orbitals of the same material. Since its theoretical prediction, the orbital-selective Mott transition has been intensively studied by the state-of-the-art theoretical methods that are based on local approximations to electronic correlations, namely the dynamical mean-field

theory and the slave-spin approach. Nevertheless, the existence of the orbital-selective Mott phase in realistic materials is still heavily debated and has not yet been realised experimentally.

In this talk, I will show that consistently taking into account non-local magnetic fluctuations completely changes the physical picture in the Hubbard-Kanamori model, where the orbital-selective Mott transition was predicted in the framework of the local theories. I will show that upon lowering temperature the considered system undergoes the Néel transition to an ordered antiferromagnetic phase before it experiences the orbital-selective Mott transition. Importantly, the former occurs simultaneously for all orbitals, which eliminates the orbital selectivity from the metal-insulator transition. The possibility to realise an orbital selective Néel transition will also be discussed.

TT 21.8   Tue 11:15   HSZ 201

Quantum chemical study on cobalt(II) in honeycomb lattices based on multi-configurational approaches — •Thorben Petersen and Liviu Hozoi — Leibniz IFW Dresden, 01069 Dresden, Germany

Quantum Spin Liquids (QSLs) are fascinating materials that display quantum entanglement and host unconventional fractionated excitations. While QSL behavior was found in Cu(II) $3d^9$ cuprates, $4d^5$ RuCl$_3$, $5d^5$ iridates and triangular-lattice $4f^{13}$ oxides, we here explore $3d^7$ Co(II) compounds such as Na$_2$Co$_2$TeO$_6$, which form spin-orbit-entangled J_{eff} = 1/2 pseudo-spin moments at Co(II) sites that potentially realize Kitaev-magnetism. In this study, we apply multi-configurational quantum-chemistry methods like CASSCF and beyond to model the $t_{2g}^5 e_g^2$ magnetic sites in these honeycomb oxides by carefully designing an embedded cluster model to represent the extended bulk lattice. With this, we quantify the extent of the $3d$-site multiplet structure and spin-orbit coupling associated with the $^4T_{2g}$ ground state term. Moreover, our model will be validated against experimental magnetization data and first impressions on the $3d^7$-$3d^7$ intersite couplings will be given.

TT 21.9   Tue 11:30   HSZ 201

Calculation of atomic forces for correlated materials, preliminary results — •Dorota Gotfryd[1], Robinson Outerovitch[1], Marc Torrent[1], Ambroise van Roekeghem[2], and Bernard Amadon[1] — [1]CEA, DAM, DIF 91297 Arpajon CEDEX, France — [2]CEA, LITEN 38054 Grenoble, France

Atomic forces are crucial ingredientis for phonon spectra or molecular dynamics calculations. Within Abinit package, one can currently perform such calculations for weakly or strongly correlated systems, obtaining forces via density functional theory (DFT) or DFT + U methods, correspondingly.

We are working on extending the existing implementation of atomic forces in Abinit to DFT+DMFT (dynamical mean-field theory). Such application would allow for the calculation of forces close to metal/Mott insulator transition where the details of electronic correlations matter and DFT + U approximation is often insufficient for capturing the physics.

We derive the atomic forces for DFT + DMFT as functional derivatives of the free energy functional over the atomic positions and transform them to the projector-augmented wave (PAW) approximation of DFT using Wannier functions as correlated orbitals. We show that the DFT and DFT + DMFT versions of the forces differ by just two terms in the PAW language and we discuss the details of the implementation.

Ultrafast dynamics of quantum many-body systems including dynamical screening and strong coupling — •Michael Bonitz[1], Jan-Philip Joost[1], Hannes Ohldag[1], Erik Schroedter[1], and Iva Brezinova[2] — [1]CAU Kiel, Institute for Theoretical Physics and Astrophysics — [2]TU Wien, Institute of Applied Physics, Vienna, Austria

Dynamical screening is a key property of charged many-particle systems. Its theoretical description is based on the GW approximation that is extensively applied for ground-state and equilibrium situations. The main limitation of the GW approximation is the neglect of strong electronic correlation effects. Here we derive the nonequilibrium dynamically screened ladder (DSL) approximation that self-consistently includes, in addition to the GW diagrams, also particle-particle and particle-hole T-matrix diagrams. Our DSL approach is formulated within the G1-G2 scheme [1,2] that is linear in time, in contrast to the cubic scaling of standard Nonequilibrium Green functions simulations. The price to pay for this speedup is the need to store the two-particle Green function. This can be avoided with a recently developed quantum fluctuations approach [3].

Spectral response of a charge density wave insulator to periodic driving — •Alexander Osterkorn, Constantin Meyer, and Salvatore Manmana — Institut für Theoretische Physik, Georg-August-Universität Göttingen, Germany

Periodically driven quantum many-body systems host unconventional behavior not realized at equilibrium. Here we address in detail the emergence of a cosine-like band in the gap region of the non-equilibrium single-particle spectral function of strongly interacting spinless fermions on a chain in the charge density wave phase [1]. We compare the dynamics of the periodically driven system to the quench dynamics with an effective Floquet Hamiltonian and discuss the role of doublon excitations in both cases. This is investigated using both matrix product state based time evolution techniques as well as time-dependent Hartree-Fock. [1] arXiv:2205.09557

TT 22.3   Tue 10:00   HSZ 204

Floquet engineering in tilted lattices — •Melissa Will[1], Pablo Sala[2,3], and Frank Pollmann[1] — [1]Department of Physics, T42, Technische Universität München, James-Franck-Straße 1, D-85748 Garching, Germany — [2]Department of Physics and Institute for Quantum Information and Matter, California Institute of Technology, Pasadena, California 91125, USA —

[3]Walter Burke Institute for Theoretical Physics, California Institute of Technology, Pasadena, California 91125, USA

Quantum many-body systems out of equilibrium can exhibit very rich and exciting phenomena. A particularly important question is whether and how a quantum system thermalizes under unitary evolution. In this context three classes of systems have been identified: ergodic, localized and an intermediate regime exhibiting so called quantum many-body scars. In this talk we discuss whether a time-periodic, local drive can induce thermalization of a localized system. We consider interacting hard-core bosons in an one dimensional, tilted system with periodic driving. We find that the system becomes ergodic for resonant driving frequencies. In contrast, if the tilt is not close to a multiple of driving frequency, the system stays localized. This observation can theoretically be understood by deriving an effective Hamiltonian using a Magnus expansion. Using large scale numerical methods, we explore entanglement entropy and imbalance over time. Our theoretical predictions are in good agreement with numerics.

TT 22.4   Tue 10:15   HSZ 204

Photoinduced spinful excitons in Hubbard systems with magnetic superstructures — Constantin Meyer and •Salvatore R. Manmana — Institute for Theoretical Physics, Göttingen University, Friedrich-Hund-Platz 1, 37077 Göttingen

The possibility to form excitons in photo-illuminated correlated materials is central from fundamental and application oriented perspectives. We show how the interplay of electron-electron interactions and a magnetic superstructure leads to the formation of a peculiar spinful exciton, which can be detected in the nonequilibrium spectral function and the time-dependent optical conductivity. We study these quantities by using matrix product states (MPS) following an electron-hole excitation in a class of one-dimensional Hubbard models with on-site interactions and alternating local magnetic fields, which realize correlated band insulators. An excitation in only one specific spin direction leads to an additional band in the gap region of the spectral function only in the opposite spin direction, and to an additional peak in the optical conductivity. We discuss implications for experimental studies in correlated insulator systems.

TT 22.5   Tue 10:30   HSZ 204

Photoinduced pairing states of excitonic insulators — •Satoshi Ejima — DLR Quantencomputing-Initiative, Hamburg, Germany

Applying the time-dependent density-matrix renormalization group technique, we explore photoinduced pairing states in the half-filled extended Falicov-Kimball model (EFKM) in one dimension, both with and without internal SU(2) symmetry. In the time-dependent photoemission spectra simulated with the optimal pump pulse parameters, an extra band appears above the Fermi energy after pulse irradiation, implying a photoinduced metallization. Even in the absence of the SU(2) structure, the electron-electron pair correlations can also be enhanced during the pump, while they decrease over time after pulse irradiation. This suggests a possible photoexcited metallization of Ta_2NiSe_5, a strong candidate for an excitonic insulator material, for which the EFKM is considered to be the minimal theoretical model. Computing the time-dependent photoemission spectra with the parameter set for this material, i.e., in the EFKM without SU(2) symmetry, we demonstrate the photoinduced insulator-to-metal transition, in accord with recent findings in time- and angle-resolved photoemission spectroscopy experiments on Ta_2NiSe_5.

Higgs spectroscopy of superconductors in nonequilibrium — •Dirk Manske — Max-Planck-Institut für Festkörperforschung

Higgs spectroscopy is a new and emergent field [1-3] that allows to classify and determine the superconducting order parameter by means of ultra-fast optical spectroscopy. There are two important ways to activate the Higgs mode in superconductors, namely a single-cycle *quench* or an adiabatic, multicycle *drive* pulse, which I will discuss in detail. Furthermore, I will review and report on the latest progress on Higgs spectroscopy, in particular on the role of the third-harmonic-generation (THG) [4-6] and the possible IR-activation of the Higgs mode by impurities or external dc current [7,8]. I also provide new predictions for time-resolved ARPES experiments in which, after a quench, a continuum of Higgs mode is observable and a phase information of the superconducting gap function would be possible to extract [9]. Finally, I show that the Higgs mode may shed some light on the 25-years-old A1g-puzzle in equilibrium Raman scattering on high-T_c cuprates [10].

Periodically driven spin-1/2 XXZ antiferromagnetic chains — •Aslam Parvej, Imke Schneider, and Sebastian Eggert — Technische Universität Kaiserslautern, Kaiserslautern, Germany

Time-periodically driven quantum systems are of great interest due to the possibility of unconventional states of matter and Floquet engineering. The interplay of many-body interactions and time-periodic manipulations facilitate new phenomena in the steady state. We analyze the Floquet steady states of finite spin-1/2 XXZ antiferromagnetic chains with periodically driven anisotropy parameter at frequencies below the band width, so that resonances are in principle possible. We use a numerical real-time approach with an adiabatic time evolution protocol by ramping up the driving amplitude of the external periodic drive to prepare a non-equilibrium Floquet steady state. Parametric resonances are expected when the driving frequencies are equal to twice the energy gaps in a finite system. However, the observed resonance absorption of energy and heating is surprisingly weak in our system even for large driving amplitude. This changes if a square wave is used for driving.

Controllable effects of the mass term in time-periodic driven sine-Gordon models. — •Dimo Claude[1], Simon Jäger[1], Christoph Dauer[1], Piotr Chudzinski[2], Imke Schneider[1], and Sebastian Eggert[1] — [1]Physics Department and Research Center OPTIMAS, Technische Universität Kaiserslautern, 67663 Kaiserslautern, Germany. — [2]Institute of Fundamental Technological Research, Polish Academy of Science, 02-106 Warszawa, Poland.

Recently, the full Floquet solution of a Luttinger Liquid with periodically modulated interactions has been derived and resonant wave-vectors have been identified. There, the quantum state can only be stabilized when damping mechanisms of the one-dimensional systems are included. In our work, we investigate the time-periodic Luttinger Liquid under a non-linear perturbation which originates from the Sine-Gordon potential. This term provides interactions among the different modes of the Luttinger Liquid and can potentially confine the parametrically amplified modes. We investigate this model up to fourth order of the phase field using a mean-field approach. The resulting effective model is quadratic in the field operators while the non-linearity remains, due to the explicit dependence of the frequencies on the time-dependent quantum state. Using a self-consistency relation between the number of density wave excitations and the systems' energy, we discuss the formation of a non-equilibrium steady state and study its stability.

Influence of phononic dissipation on impact ionization processes in a photo-driven Mott insulator — •Paolo Gazzaneo, Tommaso Maria Mazzocchi, Jan Lotze, and Enrico Arrigoni — Institute of Theoretical and Computational Physics, Graz University of Technology, 8010 Graz, Austria

It has been suggested that in strongly correlated materials, highly photoexcited charge carriers could use their extra energy to excite additional carriers across the Mott gap via impact ionization [1,2]. However, the influence of electron-phonon scattering on photocurrent and impact ionization in Mott photovoltaic setups is still an open question.

We address this issue in a nonequilibrium steady state study on the occurrence of impact ionization in a simplified model of a Mott photovoltaic device in presence of acoustic phonons [3], consisting of a Mott-insulating layer coupled to two wide-band fermion leads.

For a small hybridization to the leads, we obtain a peak in the photocurrent as a function of the driving frequency which can be associated with impact ionization processes, while for larger hybridizations we find a suppression of impact ionization with respect to direct photovoltaic excitations. The effect of acoustic phonons produces a slight enhancement of the photocurrent for small driving frequencies and a suppression at frequencies around the main peak at all considered hybridization strengths.

Correlated Mott insulators in strong electric fields: Role of phonons in heat dissipation — •Tommaso Maria Mazzocchi, Paolo Gazzaneo, Jan Lotze, and Enrico Arrigoni — Institute of Theoretical and Computational Physics, Graz University of Technology, 8010 Graz, Austria

Mott-insulating models can undergo an insulator-to-metal transition when subject to a constant bias voltage [1], which makes them suitable to describe the resistive switch observed in correlated insulators [2]. Nonequilibrium state-of-the-art techniques rely on the coupling to fermion baths to dissipate the field-induced excess energy [1,3]. However, a realistic description of heat-exchange requires the inclusion of phonons. In [4] we study a single-band Hubbard model in a

static electric field coupled to electron and acoustic phonon baths. The nonequilibrium steady-state is addressed via the dynamical mean-field theory using the auxiliary master equation approach as impurity solver. Phonons are included via the Migdal approximation. Using both the electron and phonon baths the steady-state current is slightly enhanced by phonons for field strengths close to half of the gap and suppressed at the gap resonance. With phonons alone, dissipation can occur only at the resonances and the current at the metallic phase is suppressed by almost one order of magnitude.

Correlated Mott insulators and photovoltaics out of equilibrium: phonons and heat dissipation — •Enrico Arrigoni, Tommaso Mazzocchi, Paolo Gazzaneo, Daniel Werner, and Jan Lotze — Institute of Theoretical and Computational Physics, Graz University of Technology, 8010 Graz Austria

I will present recent results for correlated Mott systems in a nonequilibrium driven steady state. Results are obtained via nonequilibrium Dynamical Mean Field Theory with an impurity solver based upon a combination of Keldysh Green's functions and Lindblad formalism for open quantum systems [1]. Recent improvements based upon a Configuration Interaction treatment of the many body Lindblad equation allow for an efficient solution of the impurity problem deep in the Kondo regime [2].

In particular, I will discuss the interplay of strong correlation and Joule dissipation by phonons near the Mott dielectric breakdown [3] and in photoexcitation induced transport across a Mott insulating gap [4].

Photoinduced prethermal order parameter dynamics in the two-dimensional large-N Hubbard-Heisenberg model — •Alexander Osterkorn and Stefan Kehrein — Institut für Theoretische Physik, Georg-August-Universität Göttingen, Germany

We study the microscopic dynamics of competing ordered phases in a two-dimensional correlated electron model [1], which is driven with a pulsed electric field of finite duration. In order to go beyond a mean-field treatment of the electronic interactions we adopt a large-N generalization of the Hubbard model and combine it with the semiclassical fermionic truncated Wigner approximation as a time evolution method. This allows us to calculate dephasing corrections to the mean-field dynamics and to obtain stationary states, which we interpret as prethermal order. We use this framework to simulate the light-induced transition between two competing phases (bond density wave and staggered flux) and find that the post-pulse stationary state order parameter values are not determined alone by the amount of absorbed energy but depend explicitly on the driving frequency and field direction. While the transition between the two prethermal phases takes place at similar total energies in the low- and high-frequency regimes, we identify an intermediate frequency regime for which it occurs with minimal heating [2].

Observation of magnon bound states in the long-range, anisotropic Heisenberg model — Florian Kranzl[1], •Stefan Birnkammer[2], Manoj Joshi[1], Alvise Bastianello[2], Rainer Blatt[1], Michael Knap[2], and Christian Roos[1] — [1]Universität Innsbruck, Innsbruck, Austria — [2]Technische Universität München, Garching, Germany

Over the recent years coherent, time-periodic modulation has been established as a versatile tool for realizing novel Hamiltonians. Using this approach, known as Floquet engineering, we experimentally realize a long-ranged, anisotropic Heisenberg model with tunable interactions in a trapped ion quantum simulator. We demonstrate that the spectrum of the model contains not only single magnon excitations but also composite magnon bound states. For the experimentally realized long-range interactions, the group velocity of magnons is unbounded. Nonetheless, for sufficiently strong interactions we observe bound states of these unconventional magnons which possess a non-diverging group velocity. By measuring the configurational mutual information between two disjoint intervals, we demonstrate the implications of the bound state formation on the entanglement dynamics of the system. Our observations provide key insights into the peculiar role of composite excitations in the non-equilibrium dynamics of quantum many-body systems.

Broadband optical investigations of the CDW state in Kagome metals AV_3Sb_5 (A = K, Rb, Cs) — •E. Uykur[1,2], M. Wenzel[1], B.R. Ortiz[3,4], S.D. Wilson[4], S. Winnerl[2], M. Dressel[1], and A. A. Tsirlin[5] — [1]1. Physikalisches Institut, Universität Stuttgart, 70569, Stuttgart, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Inst. Ion Beam Phys. & Mat. Res., 01328 Dresden, Germany — [3]Materials Department and California Nanosystems Institute,University of California Santa Barbara, Santa Barbara, CA, 93106, United States — [4]Materials Department, University of California Santa Barbara, Santa Barbara, CA, 93106, United States — [5]Felix Bloch Institute for Solid-State Physics, Leipzig University, 04103 Leipzig, Germany

We present a broadband optical study of non-magnetic Kagome metals AV_3Sb_5 (A = K, Rb, Cs) down to 10 K. Different contributions to the optical spectra have been discussed and compared with the DFT calculations in normal and charge density wave (CDW) states. Spectra reflect the response of the 2D Dirac fermions and are frequency-independent in a broad energy range. Low energies are governed by the itinerant and localized charge carriers that show a spectral weight redistribution below the CDW transition. Our results show that the CDW gaps evolve systematically between the siblings (K<Cs<Rb) in line with their transition temperatures. We further use the experimental spectral weight to gauge the effect of electronic correlations and find it increasing with reducing the size of A.

TT 23.2   Tue 9:45   HSZ 304
Complex charge order in the AV_3Sb_5 kagome metals — •Morten Christensen[1], Turan Birol[2], Brian Andersen[1], and Rafael Fernandes[3] — [1]Niels Bohr Institute, University of Copenhagen — [2]Department of Chemical Engineering and Materials Science, University of Minnesota — [3]School of Physics and Astronomy, University of Minnesota

The kagome lattice, consisting of an array of corner-sharing triangles, offers a rich platform to study the behavior of correlated electrons. In kagome metals, the electronic band structure exhibits Dirac points, flat bands, and van Hove singularities - features which promote the role of electronic correlations. A family of recently discovered kagome metals, AV_3Sb_5 (A=K, Rb, Cs), provides a realization of these features. These materials exhibit an enigmatic superconducting order, which emerges from a three-dimensional charge-density wave (CDW) phase. While the precise nature of the CDW phase is still unknown, there are indications of both time-reversal symmetry breaking and nematicity inside the charge-ordered phase. Starting from from the low-energy electronic states near the van Hove singularities, we construct a phenomenological model to describe the CDW phase. The order parameters of this model are either real, corresponding to bond distortions, or imaginary, corresponding to loop-currents. These CDW orders can coexist or compete which results in a rich landscape of subsidiary orders, including various types of multipolar magnetic orders. These have unique experimental signatures which can aid in pinpointing the precise nature of the CDW phase observed in experiments.

TT 23.3   Tue 10:00   HSZ 304
Investigation of the charge density wave in single crystal CsV_3Sb_5 under hydrostatic pressure — •Fabian Stier[1], Tobias Ritschel[1], Marein Rahn[1], Chandra Shekhar[2], Claudia Felser[2], and Jochen Geck[1] — [1]IFMP, TU Dresden, Germany — [2]MPI CPfS, Dresden, Germany

The topological Z_2 kagome materials AV_3Sb_5 (A = K, Rb, Cs) show a nontrivial electronic topology, exhibit superconductivity (SC) and a charge-density-wave (CDW) order. CsV_3Sb_5 shows a CDW below 90K with a 2x2x4 superstructure, which changes around 60K to a 2x2x2 superstructure. To investigate the interplay of CDW-order and SC we performed single crystal x-ray diffraction under hydrostatic pressure, with Argon as a pressure medium, up to 2 GPa and 20K. In this pressure range the SC shows two distinct domes, where Tc is enhanced and shows two maxima. The 2x2x2 CDW at low temperatues persists under pressure up to the first extremum of T_c ~ 0.7 GPa, where for a short pressure range both, the CDW and a new emerging incommensurate CDW coexists. While the

first CDW quickly vanishes, the incommensurate CDW persists up to pressures where the SC shows another extremum in T_c. Above this pressure, ~ 1.5GPa, no CDW could be detected. An accurate knowledge of these structural modifications will be essential to explain the relationship of topology and superconductivity in this class of materials.

TT 23.4   Tue 10:15   HSZ 304

Indication of a strong coupling charge density wave in CsV$_3$Sb$_5$ — •Leander Peis[1,2,3], Ge He[1,4], and Rudolf Hackl[1,2,3] — [1]Walther Meissner Institut, Bayerische Akademie der Wissenschaften, Garching 85748, Germany — [2]Technische Universität München, Garching 85748, Germany — [3]IFW Dresden, Dresden 01062, Germany — [4]University College Cork, Cork, Ireland

A prominent example for studying the interplay of electronic correlations and non-trivial topology is the material class of AV$_3$Sb$_5$ (A=K,Rb,Cs), displaying unconventional charge order in the range of 100 K and superconductivity at temperatures below 2.5 K. Here, we present a polarization-dependent Raman scattering study of the Kagome metal CsV$_3$Sb$_5$, focusing on the charge density wave (CDW). We resolve several signatures of strong-coupling between the lattice and the electronic system. First, the energy of the A$_{1g}$ Γ-point phonon exhibits a discontinuity at the phase transition temperature T_{CDW} = 95 K. Second, the magnitude and symmetry dependence of the observed CDW energy gap 2Δ suggest strong coupling and a substantial anisotropy. Third, the observed A$_{1g}$ amplitude mode depends weaker on temperature than expected and displays an asymmetric Fano-type line shape, particularly around 70 K. We interpret this deviation in terms of strong coupling between the phonon-like amplitude mode and the electronic continuum. To the best of our knowledge such an asymmetry of an amplitude mode has not been observed before.

TT 23.5   Tue 10:30   HSZ 304

X-ray diffraction on the charge-density wave in the Kagome superconductor RbV$_3$Sb$_5$ — •Sabreen Hammouda[1], Yu-Hui Liang[2], Po-Chun Chang[2], Carsten Paulmann[3], Yishui Zhou[1], Adrian Merrit[1], Pikesh Pal[1], Rahaf Yaseen[1], Hongxiong Liu[4], Youguo Shi[4], Chao-Hung Du[2], and Yixi Su[1] — [1]JCNS-MLZ, Forschungszentrum Jülich, 85748 Garching, Germany — [2]Dept. of Phys., Tamkang University, Tamsui 251, Taiwan — [3]DESY, 22607 Hamburg, Germany — [4]IOP, CAS, Beijing 100190, China

The newly discovered Kagome superconductors AV$_3$Sb$_5$ (A=K, Rb or Cs), in which non-trivial band topology, charge-density wave (CDW), and superconductivity are intertwined, have attracted tremendous interests. Despite extensive recent investigations via X-ray diffraction (XRD) and other complementary local probe techniques, it remains a major challenge to gain a consistent picture of the CDW modulation across different AV$_3$Sb$_5$ samples. In this talk, we will present our recent single-crystal XRD investigations (in-house and synchrotron) of the CDW modulations over a wide temperature range in the less-studied RbV$_3$Sb$_5$. A unique CDW modulation of the 2x2x2 type can be confirmed for RbV$_3$Sb$_5$ below T_{CDW} = 102 K, and no evidence for CDW fluctuations above T_{CDW} could be found. Our detailed temperature dependence measurements of the CDW superstructure reflections indicate a second-order phase transition with a 2D Ising character. A comparison to other AV$_3$Sb$_5$ compounds and possible implications on the understanding of the nature of the CDW in these Kagome superconductors will be given.

TT 23.6   Tue 10:45   HSZ 304

$\mathbb{Z}_2$ topological insulator and Hubbard interactions on the Kagome lattice — Irakli Titvinidze[1], •Julian Legendre[2,3], Maarten Grothus[1], Bernhard Irsigler[1], Karyn Le Hur[2], and Walter Hofstetter[1] — [1]Institut für Theoretische Physik, Goethe-Universität, 60438 Frankfurt am Main, Germany — [2]CPHT, CNRS, Institut Polytechnique de Paris, Route de Saclay, 91128 Palaiseau, France — [3]Department of Physics and Materials Science, University of Luxembourg, 1511 Luxembourg, Luxembourg

The study of topological phase transitions has been a very active field of research since the 80's; in recent decades topological insulators have been one of the major foci in this field. Understanding the role of the interactions in such systems is also currently is major challenge for the scientific community. In this talk, I will present a study of a time-reversal invariant topological model, with Hubbard interactions, on the Kagome lattice. The topological model contains intrinsic and Rashba spin-orbit coupling terms and position-dependent onsite energies. Relying on several analytical methods, I will show how the $\mathbb{Z}_2$ topological phase, resulting from the flux term, is tuned by varying the amplitude(s) of on-site energy terms and/or of the Rashba spin-orbit coupling term, at filling n = 2/3. Then, we will study the effect of Hubbard interactions on the topological properties for a specific on-site energy configuration and at vanishing Rashba spin-orbit coupling. We will use perturbation theory in the large Hubbard amplitude U limit and a mean-field method for smaller U. I will compare these analytical results with numerical results obtained by our collaborators.

TT 23.7   Tue 11:00   HSZ 304

Temperature-dependent pump-probe spectroscopy of the magetic Kagome metal Fe$_3$Sn$_2$ — •M. G. Faria[1], Q. Wang[2], H. C. Lei[2], A. Pashkin[1], S. Winnerl[1], M. Helm[1,3], and E. Uykur[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — [2]Department of Physics and Beijing Key Laboratory of Opto-electronic Functional Materials & Micro-nano Devices, Renmin University of China, 100872 Beijing, China — [3]Institute for Applied Physics, Technische Universität Dresden, 01069 Dresden, Germany

In this study, we present optical pump-probe measurements on a magnetic Kagome metal, Fe$_3$Sn$_2$, under different temperatures down to 10 K. The obtained spectra can be fitted with a double exponential decay, indicating that the system has two distinct relaxation processes. Additionally, some unexpected and pronounced oscillations are dominating the spectra, giving evidence of a strong electron-phonon coupling in Fe$_3$Sn$_2$, at least in this ultra-fast regime. The frequency of this coupled phonon is determined to be around 2.5 THz. Finally, we will discuss the temperature and pump fluence dependence of the observed phonon coupling and the distinct relaxation dynamics in this material.

15 min. break

TT 23.8   Tue 11:30   HSZ 304

Complex magnetic orders and the emergent topological Hall effect in the kagome metal ErMn$_6$Sn$_6$ — •Yishui Zhou[1], Changjiang Yi[2], Dmitry Khalyavin[3], Fabio Orlandi[3], Pascal Manuel[3], Sabreen Hammouda[1], Adrian Merritt[1], Claudia Felser[2], Thomas Brückel[4], and Yixi Su[1] — [1]JCNS-MLZ, Forschungszentrum Jülich GmbH, Garching, Germany — [2]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [3]ISIS Neutron & Muon Facility, STFC, Rutherford Appleton Laboratory, Didcot, UK — [4]JCNS-2 & PGI-4, Forschungszentrum Jülich GmbH, Jülich, Germany

Following the discovery of a quantum-limit magnetic Chern phase in TbMn$_6$Sn$_6$, the magnetic topological metal series RMn$_6$Sn$_6$ (R=Gd-Yb, and Y, Lu, etc.), that possesses an ideal Kagome lattice of Mn, has emerged as a new platform to explore exotic states and novel functionalities. We have recently carried out the growth of high-quality single crystals of the magnetic Kagome metal ErMn$_6$Sn$_6$, and the physical properties characterizations via the magnetic susceptibility, heat capacity, and Hall conductivity measurements. We have also undertaken comprehensive neutron diffraction experiments on both single-crystal and powder samples at the WISH diffractometer at ISIS. Our study has clearly hinted a fascinating interplay between topologically non-trivial electronic band structures, magnetism and electronic correlations in ErMn$_6$Sn$_6$.

TT 23.9   Tue 11:45   HSZ 304

Thermodynamics of the spin-half square Kagome lattice antiferromagnet — •Jürgen Schnack[1], Oleg Derzhko[2], and Johannes Richter[3] — [1]Fakultät für Physik, Universität Bielefeld, Germany — [2]Institute for Condensed Matter Physics, National Academy of Sciences of Ukraine, 79011 Lviv, Ukraine — [3]Institut für Physik, Universität Magdeburg & Max-Planck-Institut für Physik Komplexer Systeme, Dresden, Germany

Over the last decade, the interest in the spin-1/2 Heisenberg antiferromagnet (HAF) on the square Kagome lattice has been growing as a model system of quantum magnetism with a quantum paramagnetic ground state, flat-band physics near the saturation field, and quantum scars. Here, we present large-scale numerical investigations of the specific heat, the entropy, as well as the susceptibility by means of the finite-temperature Lanczos method for system sizes of N = 18, ..., 54. We find that the specific heat exhibits a low-temperature shoulder below the major maximum which can be attributed to low-lying singlet excitations filling the singlet-triplet gap, which is significantly larger than the singlet-singlet gap. For the susceptibility the singlet-triplet gap leads to an exponentially activated low-temperature behavior. The maximum of the susceptibility is found at a pretty low temperature T/J = 0.146 (for N = 42). We find a striking similarity of our data with the corresponding ones for the Kagome HAF down to very low temperatures.

TT 23.10   Tue 12:00   HSZ 304

Asymmetric melting of the 1/3-plateau for the Kagome lattice antiferromagnet — •Henrik Schlüter[1], Jürgen Schnack[1], and Johannes Richter[2] — [1]Bielefeld University, Bielefeld, Germany — [2]University of Magdeburg and MPIPKS Dresden, Germany

The Kagome lattice Heisenberg antiferromagnet (KHAF) is a rich source of unconventional physics not only regarding its spin-liquid ground state but also with respect to its behavior at non-zero field and temperature.

Here we investigate the phenomenon of the asymmetric melting of the magnetization plateau at 1/3 of the saturation magnetization, see Refs.[1, 2]. We explain the effect by discussing the energy diagram and the density of states constructed from finite-temperature Lanczos data for KHAF with up to 48 sites [3].

Classical and quantum frustrated models of planar *X-Y* **spins on the Kagome lattice: anisotropic magnetic patterns** — •Oliver Neyenhuys, Mikhail Fistul, and Ilya Eremin — Ruhr Universität Bochum

We present a theoretical study of various highly anisotropic magnetic patterns occurring in the geometrically frustrated model of planar *X-Y* spins on the Kagome two-dimensional lattice. Frustration is introduced by a specific spatial arrangement of both ferromagnetic and anti-ferromagnetic bonds between adjacent magnetic moments on the lattice vertices. At the critical value of frustration f = 3/4 such a system displays the phase transition from an ordered ferromagnetic state to frustrated regime featuring a highly degenerate ground state in which topological (anti)vortices penetrate each cell. Taking into account a generous amount of topological constraints, the thermal fluctuations and the quantum tunneling induced transitions between these vortices/anti-vortices, we derive an effective Ising spin Hamiltonian on the corresponding hexagonal lattice, in which a strong long-range interaction between a well separated (anti)vortices occurs. By making use of the mean field analysis and direct numerical diagonalization of the Hamiltonian we characterize various classical and quantum phases and phase transitions between them for large and small Kagome lattices. Experimental observation of such magnetic patterns with coherent networks of superconducting qubits will be discussed.

TT 23.12   Tue 12:30   HSZ 304

Magnon-phonon coupling in the Kagome-lattice antiferromagnet Mn_3Ge — •Aleksandr Sukhanov, Nikita Andriushin, Anton Kulbakov, and Dmytro Inosov — Institut für Festkörper- und Materialphysik, Technische Universität Dresden, D-01069 Dresden

Magnons and phonons, which are quanta of spin excitations and crystal-lattice vibrations in ordered materials, respectively, can be strongly coupled together when their dispersion relations intersect in reciprocal space. This results in hybridised collective spin-lattice excitations, also known as magnetoelastic (ME) modes.

The metallic hexagonal compound Mn_3Ge is characterized by a noncollinear spin order due to the geometric frustration of the Kagome lattice formed by Mn ions. Our earlier studies showed that Mn_3Ge belongs to a rare class of materials that possess very strong ME coupling. The ME effect is manifested in the large negative thermal expansion of the material and high-pressure tuning of its remarkable anomalous Hall effect. Most intriguing is a previous observation that the noncollinear spin structure of Mn_3Ge can be driven into a collinear ferromagnetic state under a hydrostatic pressure of ~5 GPa. This, in turn, provides hints on how the magnetic structure is linked to the unconventional electron transport phenomena in this material.

In this talk, we will discuss the results of our recent single-crystal inelastic neutron and x-ray scattering spectroscopy measurements of Mn_3Ge. We were able to clearly resolve momenta and energy of the ME hybridization. The experimental results are supported with the first-principle lattice dynamics calculations.

TT 23.13   Tue 12:45   HSZ 304

Raman scattering study of magnetism in the Kagome materials Fe_3Sn_2 and $Co_3Sn_2S_2$ — •Rudi Hackl[1,2,3], Ge He[4], and Leander Peis[1,2,3] — [1]Walther-Meissner-Institut, 85748 Garching, Germany — [2]Technische Universität München, 85748 Garching, Germany — [3]IFW Dresden, Dresden 01062, Germany — [4]University College Cork, Cork, Ireland

Fe_3Sn_2 and $Co_3Sn_2S_2$ have triangularly coordinated layers of $3d$ transition metal ions sitting on a Kagome network. Both compounds have Dirac and Weyl nodes in the band structure. Fe_3Sn_2 is ferromagnetic below 670 K, and the spins start to reorient from perpendicular to parallel to the Kagome layer below 150 K. This reorientation was first observed by Mössbauer spectroscopy but has in general little influence on other observables such as thermal expansion or magnetization. In our Raman study we find an anomaly of the line width and the energy of the lowest A_{1g} phonon where the Sn atoms vibrate perpendicular to the Fe plane. We interpret the anomaly in terms of an enhanced spin-phonon coupling below approximately 150 K. $Co_3Sn_2S_2$ starts ordering antiferromagnetically below 175 K and turns into a ferromagnet in the low-temperature limit. Here, the spins are first in plane and the order is nearly frustrated. Below 100 K the spins point along the c-axis and are parallel. The A_{1g} phonon couples strongly to a continuum as highlighted by the asymmetric Fano-type line shape. The asymmetry is maximal close to the magnetic transition. We argue that small changes of the lattice have an effect on the magnetism.

TT 24: Quantum Dots: Transport (joint session HL/TT)

Time: Tuesday 9:30–12:15   Location: POT 151

TT 24.1   Tue 9:30   POT 151

Contact formation analysis of nickel to SiGeOI to form Nickel-Germanosilicide using Flash lamp annealing — •Muhammad Moazzam Khan[1], Slawomir Prucnal[1], and Yordan M. Georgiev[1,2] — [1]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, D-01328 Dresden, Germany — [2]Institute of Electronics at the Bulgarian Academy of Sciences, 72, Tzarigradsko chaussee blvd, 1784-Sofia, Bulgaria

In CMOS technology, parasitic source/drain (S/D) resistance becomes more crucial in determining the overall device performance as the device dimensions get smaller. The contact resistance dominates this parasitic S/D resistance to a great extent, which limits the drive current. In order to have minimal impact on electrical performance, the contact should have linear Current-Voltage characteristics and negligible resistance in comparison to the device resistance. When replacing silicon with silicon-germanium as a channel material in future devices, it is necessary to investigate the contact formation mechanism in order to develop suitable contacts for energy-efficient devices. In this work, we are investigating metal semiconductor contact formation on SiGeOI using flash lamp annealing and studying their properties using structural and electrical characterization.

TT 24.2   Tue 9:45   POT 151

Predicting charge density maps in 2D nanostructures with machine learning techniques — •Amanda Teodora Preda[1,2,3], Calin Andrei Pantis-Simut[1,2,3], Nicolae Filipoiu[2,3], Lucian Ion[2], Andrei Manolescu[4], and George Alexandru Nemnes[1,2,3] — [1]Research Institute of the University of Bucharest (ICUB), Sos. Panduri 90, Bucharest, Romania — [2]University of Bucharest, Faculty of Physics, 077125 Magurele-Ilfov, Romania — [3]Horia Hulubei National Institute for Physics and Nuclear Engineering, 077126 Magurele-Ilfov, Romania — [4]Department of Engineering, Reykjavik University, Menntavegur 1, IS-102 Reykjavik, Iceland

Machine learning (ML) models have the potential to significantly improve and assist the design process of nanodevices that require precise control of the quantum states.

For 2D nanoelectronic structures, charge and spin densities are relevant observables and are also suited for ML techniques which employ image processing. The model systems that we considered are two dimensional quantum dots with multiple electrons and random confinement potentials. With convolutional neural networks, we built a ML model to predict whether a configuration displays singlet-triplet transitions in the ground state. For image translation problems, we used models based on conditional generative adversarial networks in order to predict the charge density distribution for arbitrary interacting systems taking as input either the non-interacting cases or just the shape of the confining potential.

TT 24.3   Tue 10:00   POT 151

Mesoscopic transport properties of individually prepared GaN-nanowire field-effect transistors — •Hannes Hergert[1,2], Matthias T. Elm[1,2,3], and Peter J. Klar[1] — [1]Institute of Experimental Physics I, Giessen, Germany — [2]Center for Materials Research, Giessen, Germany — [3]Institute of Physical Chemistry, Giessen, Germany

In order to keep the optimization of transistors within Moore's law new material systems as well as new transistor concepts such as GaN-nanowire field effect transistors (NW-FET) are needed. In this work we characterize the electrical transport properties of single NW-FET. Furthermore, we are able to obtain a deeper understanding of the mesoscopic transport processes. Unintentionally doped GaN-nanowires were fabricated using molecular-beam-epitaxy and device fabrication was performed by a combination of different lithographic methods and atomic layer deposition. After an annealing process the nanowire's resistance shows an ohmic behaviour. Electrical transport measurements were performed between 2 and 280 K. The investigated NW-FET exhibits a transfer characteristic identical to those of classical field-effect transistors. We show that the electrical transport is dominated by two transport processes: a transport within a metal-like impurity band at low temperatures and a hopping process at higher temperatures. Furthermore we were able to identify universal conductance fluctuations at temperatures below 140 K, which arise from the shift of the Fermi level when applying a topgate voltage.

TT 24.4   Tue 10:15   POT 151

Multi-Channel Kondo Effect in Few-Electron Quantum Dots — •Olfa Dani[1], Johannes C. Bayer[1], Timo Wagner[1], Gertrud Zwicknagl[2], and Rolf J. Haug[1] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, Germany — [2]Institut für Mathematische Physik, Technische Universität Braunschweig, Germany

The Kondo effect is a many particle entangled system, that involves the interaction between a localized spin in the quantum dot and free electrons in the

electron reservoirs. This entanglement can be calculated using simplifying assumptions concerning the electronic structure of the quantum dot.

In this work we investigate a quantum dot device formed electrostatically in a two-dimensional electron gas using top-gates. A quantum point contact is used as a sensitive charge detector to detect single-electrons tunneling through the system. This enables us to know the exact number of electrons in the quantum dot (Ne). By changing the applied gate voltage, we are able to control Ne.

A Zero-bias anomaly is observed for a strong coupling to the leads and possible symmetrical tunnel barriers. This Kondo resonance appears for successive Ne showing a deviation from the conjectured odd-even behavior. The Kondo resonance is strongest for Ne=9 and displays a particle-hole symmetry for Ne =7,..,11. It is absent for Ne =6 and Ne = 12. These observations indicate the influence of the shell structure [1] of the electronic states in the quantum dot where orbital degeneracy is present.

TT 24.5 Tue 10:30 POT 151

Highly Conductive Silicon Nanowires by Modulation-Doping via Aluminum-Induced Acceptor States in an SiO2-shell — •Daniel Hiller[1], Ingmar Ratschinski[1], Soundarya Nagarajan[2], Jens Trommer[2], Thomas Mikolajick[2,3], and Dirk König[4] — [1]Institute of Applied Physics, TU Bergakademie Freiberg, Germany — [2]Nanoelectronic Materials Laboratory gGmbH, Dresden, Germany — [3]Institute of Semiconductors and Microsystems, TU Dresden, Germany — [4]Integrated Materials Design Lab, ANU, Canberra, Australia

Silicon nanowires (Si NWs) enable maximum gate control over the source-drain current when configured in a gate-all-around FET-architecture. However, Si NWs with few nm in diameter suffer from severe difficulties with efficient impurity doping due to a multitude of physical and technological problems (diffusion, dielectric and quantum confinement, statistics of small numbers, etc.). Here, we present a novel doping concept for Si NWs comparable to the modulation doping approach of III-V semiconductors. Based on results from density functional theory (DFT) calculations, we use Al-doped SiO2 shells around the Si NWs, which contain unoccupied Al-induced acceptor states that are energetically located below the Si valence band edge. These states can capture electrons from the Si, creating free holes as majority charge carriers [1-5]. In this presentation, recent results from the experimental realization of this concept on Si NWs are shown. We demonstrate that modulation doping using SiO2:Al-shells allows for several orders of magnitude lower resistances when compared to undoped SiO2-shells.

TT 24.6 Tue 11:15 POT 151

Carrier dynamics in quantum-dot tunnel- injection structures: microscopic theory and experiment — •Michael Lorke[1], Igor Khanonkin[2], Stephan Michael[1], Johann Peter Reithmaier[3], Gadi Eisenstein[2], and Frank Jahnke[1] — [1]Institute for Theoretical Physics, University of Bremen, Otto-Hahn-Allee 1, Bremen, 28359, Germany — [2]Electrical Engineering Department and Rus- sel Berrie Nanotechnology Institute, Technion, Haifa, 32000, Israel — [3]Technische Physik, Institute of Nanostructure Technologies and Ana- lytics, Center of Interdisciplinary Nanostructure Science and Technol- ogy (CINSaT), University of Kassel, Kassel, 34132, Germany

Among the challenges for the next generation of semiconductor lasers is the enhancement of their modulation speed to satisfy the need for higher data transfer rates. For this purpose, tunnel injection lasers are an appealing concept, as they promise improved modulation rates and better temperature stability. Moreover, they eliminate a major detri- mental effect of quantum dot lasers, which is the gain nonlinearity caused by hot carriers. It is shown in this work how the aforemen- tioned improvements depend on the design of tunnel-injection devices. We perform a theory-experiment comparison on scattering times in tunnel injection devices to highlight the importance of alignment be- tween the injector well and the quantum dot ensemble. It is shown how differences in the coupling to the injector quantum well caused by the alignment lead to scattering times into the quantum dot ensemble that vary by an order of magnitude.

TT 24.7 Tue 11:30 POT 151

Electron transport through a quantum dot in controlled heat bath environment — •Hatef Ghannadi maragheh, Johannes C. Bayer, and Rolf J. Haug — Institute for Solid State Physics, Leibniz Universität Hannover, Appelstraße 2, 30167 Hannover, Germany

For optimizing any device, amongst them semiconductor-based qubit, one has to understand the effects of the environment on them. In this sort of devices, not just quantum states of the channel but also the state of the particles is affected [1-3]. The device consists of split-gate quantum dot in a GaAs/AlGaAs heterostructure. The temperature of the measurement ranged from 49.9 mK to 800 mK.

There have been several works on explaining how electron transport through the quantum dot system would behave for different temperatures [4-5]. As the temperature changes, the Fermi distribution of the lead*s changes. This influenced the conductivity of the dot since in the presence of the bias voltage the transport window gets altered. Besides, depending on the presence of energy levels in the transfer window, the conductivity is manipulated by changing the temperature. For low temperatures, due to the local density of states and coupling of the barrier gates to the leads, fluctuations start to emerge.

Manipulation of temporal correlations in single-electron tunneling — •Johannes C. Bayer, Adrian Schmidt, Timo Wagner, and Rolf J. Haug — Institut für Festkörperphysik, Leibniz Universität Hannover

Precisely timed single-particle operations are of critical importance for quantum technologies operating at fixed clock cycles. A detailed understanding of the interplay between an external drive and the response of the single-particle source is essential for achieving and improving the accuracy in the time domain. We here demonstrate a high level of control over the time domain of a driven single electron transistor (SET). Using a gate defined quantum dot connected to a highly sensitive charge detector [1] allows detecting electrons tunneling into and out of the SET in real-time [2, 3]. The tunneling rates of such devices are controllable by gate voltages. We drive the SET by modulating gate voltages periodically in time and use time-dependent tunneling rates [2] and waiting time distributions [4] to analyze the impact of the driving parameters on temporal correlations in the tunneling times.

Scalable integrated readout electronics for semiconductor quantum dots — •Jonas Bühler[1], Arun Ashok[1], Lammert Duipmans[1], Patrick Vliex[1], Christian Grewing[1], André Zambanini[1], and Stefan Van Waasen[1,2] — [1]Central Institute of Engineering, Electronics and Analytics, Electronics Systems (ZEA-2) Forschungszentrum Jülich GmbH, 52428 Jülich, Germany — [2]Faculty of Engineering, Communication Systems, University Duisburg-Essen, 47057 Duisburg, Germany

Quantum computing is one of the promising candidates to overcome the limitations of *classical* computing, e.g. von Neumann architecture. Nowadays much progress has been made on the implementation of scalable qubits. This work focuses on semiconductor qubits, which need operating temperatures near 0 K. Room temperature electronics for control and readout, which are limiting the bandwidth and the scalability due to parasitic elements and heat conduction, are still widely used. Some progress has been made to integrate the qubit control and readout in the direct vicinity of the qubit at cryogenic temperatures. Especially readout electronics still have a limited scalability because of circuit size and power consumption. This work tries to overcome those limitations by comparing different readout architectures and implement a multiplexed and integrated readout circuit with lower area and power consumption. This integrated circuit in a 22nm FD-SOI technology will be placed on top of scalable quantum computing architectures and therefore might be a crucial step on the way to a multi-million qubit quantum computer.

TT 25: Molecular Electronics and Photonics (joint session TT/CPP)

Time: Tuesday 12:00–13:00   Location: HSZ 201

TT 25.1   Tue 12:00   HSZ 201

Single photon emitters in hBN via ultra-low energy helium ion implantation — •Renu Rani[1], Mihn Bui[1,2], Chenfeng Lu[1,2], Bilal Malik[1,2], Felix Junge[3], Thorsten Brazda[1], Detlev Grützmacher[1,2], Hans Höfsäss[3], and Beata Kardynał[1,2] — [1]Peter Grünberg Institut-9, Forschungszentrum Jülich, Jülich — [2]Department of Physics, RWTH Aachen, Aachen — [3]II. Institute of Physics, University of Göttingen, 37077 Göttingen

A discovery of quantum emitters in hexagonal boron nitride (hBN) has recently incited immense interest for quantum technologies. It offers a platform for fundamental science but is also of interest for applications in quantum photonics owing to its robust single photon emission at room temperature. Recent studies have suggested that these SPEs are associated with intrinsic defects, which led to efforts to engineer the SPE in hBN by various methods such as plasma treatment, annealing, laser, e-beam and ion irradiation methods. Despite these efforts, the origin of single photon emission and the correlation of emission with particular defects still need to be scrutinized. Here we use ultra-low energy ion implantation to introduce defects in hBN. We show that helium ions with energies as low as 50 eV are extremely efficient in introducing single photon emitters in hBN. We also show that low temperature annealing increases the density of the emitters. We consider the possible defects that helium ions at the implantation energy can generate in hBN and use statistical data on single photon emitters to discuss the possible origin of the emission. Finally, we discuss the viability of creating emitters in pre-selected locations.

Mechanosensitive single-molecule junctions — •Fabian Pauly — University of Augsburg, Augsburg, Germany

Quantum interference of electron waves passing through a single-molecule junction provides a powerful way to influence its electrical properties. By distorting a molecule, showing a destructive quantum interference, small changes of electrode distance can lead to huge changes of electrical conductance. This mechanosensitivity is a desirable feature for highly sensitive stress sensors. Here, I will discuss recent combined experimental and theoretical studies of mechanosensitive molecular wires based on paracyclophanes and porphyrins [1-4]. Experimental findings are interpreted in terms of quantum interference effects between molecular frontier orbitals by theoretical calculations based on density functional theory and the Landauer scattering formalism.

Designing mechanosensitive molecules: A genetic algorithm-based approach — •Matthias Blaschke and Fabian Pauly — Institute of Physics, University of Augsburg, D-86159 Augsburg, Germany

Single molecules can be used as miniaturized functional electronic components, when connected to metallic electrodes. Mechanosensitivity describes a change of conductance for a certain change of electrode separation and is a desirable feature for applications such as ultrasensitive stress sensors [1-4]. We combine methods of artificial intelligence with high-level simulations based on electronic structure theory to design optimized mechanosensitive molecules from predefined building blocks. In this way we overcome time-consuming, inefficient trial and error cycles in molecular design. We unveil the black-box machinery usually connected to methods of artificial intelligence by presenting all important evolutionary processes. In addition, we identify general features that characterize well-performing molecules. Our genetic algorithm provides a systematic and powerful way to search chemical space and to identify the most promising molecular candidates.

Towards cavity-mediated molecule-molecule coupling — •André Pscherer[1], Jahangir Nobakht[1], Tobias Utikal[1], Stephan Götzinger[2,1,3], and Vahid Sandoghdar[1,2] — [1]Max Planck Institute for the Science of Light, Erlangen, Germany — [2]Department of Physics, Friedrich- Alexander University Erlangen-Nürnberg (FAU), Erlangen, Germany — [3]Graduate School in Advanced Optical Technologies (SAOT), Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany

We recently demonstrated that a single molecule coupled to a Fabry-Pérot cavity reacts nonlinearly to light at the single-photon level. This was shown in four-wave mixing, optical switching and photon number sorting experiments [1]. We aim to exploit this level of control to couple two molecules to each other via the cavity mode and to explore two-photon transitions that become possible in such a system. We gain access to the excited state population through spectrally tailored cavity mirrors which transmit red-shifted fluorescence. In this contribution, we will report on our progress, challenges, and intermediate results.

TT 27: Focus Session: Unconventional Transport Phenomena in Low-Dimensional Superconducting Heterostructures

The investigation of new superconducting systems and effects is key to the development of superconducting electronics and quantum technologies. Recent studies have demonstrated that systems of low dimensionality in particular offer enormous possibilities for the realization of unconventional superconducting phases and quantum states. An effect hosted by low-dimensional superconducting systems is the supercurrent diode effect. The supercurrent diode effect was experimentally observed in 2020 and has since then been intensively investigated worldwide. The effect has been seen in a variety of low-dimensionality hybrid systems, such as two-dimensional van der Waals heterostructures, in magnetic proximity systems as well superlattices. The origin of the effect, however, is still under debate and several explanations have been proposed for its underlying mechanism including lack of inversion symmetry, spin-orbit coupling and screening effects. This Focus session will bring together the most recent developments in the field of superconducting effects in low-dimensionality systems and update the community on their physics and perspective applications, with particular attention to recent results related to the supercurrent diode effect.

Superconducting diode effect in Rashba superlattice — •Teruo Ono — Kyoto University, Japan

The diode effect is fundamental to electronic devices and is widely used in rectifiers and AC-DC converters. However, conventional diodes have an energy loss due to finite resistance. We found the superconducting diode effect (SDE) in Nb/V/Ta superlattices with a polar structure, which is the ultimate diode effect exhibiting a superconducting state in one direction and a normal state in the other [1-3]. SDE can be considered as the nonreciprocity of the critical current for the metal-superconductor transition. We also found the reverse effect, i.e., the nonreciprocal critical magnetic field under the application of the supercurrent [4]. We also found that the polarity of the superconducting diode shows a sign reversal as a magnetic field is increased, which can be considered as the crossover and phase transitions of the finite-momentum pairing states predicted theoretically [5]. SDE in Nb/V/Ta superlattices needs an application of an external magnetic field to break the time reversal symmetry, which is a disadvantage in applications. We recently succeeded in demonstrating SDE in a zero-field by introducing ferromagnetic layers in superlattices [6]. The polarity of the SDE is controlled by the magnetization direction of the ferromagnetic layer, leading to development of novel non-volatile memories and logic circuits with ultralow power consumption.

Invited Talk   TT 27.2   Wed 10:00   HSZ 03
Quasiparticle-based and Cooper-pair based superconducting diodes — •Maria Spies[1], Stefan Ilić[2], Sebastián Bergeret[2], Francesco Giazotto[1], and Elia Strambini[1] — [1]NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, I-56127 Pisa, Italy — [2]Centro de Física de Materiales (CFM-MPC) Centro Mixto CSICUPV/ EHU, E-20018 Donostia-San Sebastián, Spain

Diodes are key elements for electronics, optics, and detection. Their evolution towards low dissipation electronics has lead to the hybridization with superconductors (S) and the realization of non-reciprocal transport of both quasiparticles and Cooper pairs. That occurs when both spatial inversion and time-reversal symmetries are broken.

Here, we review both effects comparing their efficiencies and basic principles. The quasi-particle diode is a superconducting tunnel junction with zero conductance in only one direction. The directionselective propagation of the charge has been obtained through the broken electron-hole symmetry induced by the spin selection of a ferromagnetic tunnel barrier made of a EuS thin film separating a superconducting Al and a normal metal Cu layer. It achieves a large rectification of up to 40%.

On the other hand, supercurrent diodes made with hybrid S/spinorbit/ S Josephson Junctions or with two-dimensional Rashba superconductors have been demonstrated to show zero resistance in only one direction. We describe the equation of the supercurrent diode effect in a generic formalism that may inspire novel devices based on helical magnetism induced in conventional superconductors.

Invited Talk   TT 27.3   Wed 10:30   HSZ 03
Non-reciprocal superconductivity and the field free Josephson diode — •Mazhar Ali — TU Delft, Delft, Netherlands

Nonreciprocal transport is incredibly important in technology; for example, asymmetry in the current-voltage response in semiconductor junctions has been the cornerstone of computing technology for half a century. The diode effect is a very basic demonstration of nonreciprocity. Nonreciprocal superconductivity, however, proved elusive, and only in 2020 was the superconducting diode effect (superconducting in one direction while normal conducting in the other) discovered for the first time in a bulk alloy of V/Nb/Ta. By breaking both inversion and time reversal symmetry (using an applied magnetic field), a difference in the critical superconducting current (I) for positive vs negative voltages (V) was seen. Recently, we demonstrated a Josephson diode (JD), created in a quantum material Josephson junction (QMJJ, a junction made up of two superconductors separated by a barrier comprised of a quantum material). A diodic effect was seen without an applied magnetic field; a puzzling result for theoretical physicists but an important advance for potential technological application. Using an inversion symmetry breaking heterostructure of $NbSe_2/Nb_3Br_8/NbSe_2$, half-wave rectification of a square-wave excitation was achieved with low switching current density, high rectification ratio, and high robustness. Future directions for optimizations and novel explorations, as well as a broader impact of using other quantum materials will be discussed.

Investigating the mechanism behind the Josephson Diode Effect in   TT 27.4   Wed 11:15   HSZ 03
$NiTe_2$**/superconductor Devices** — •Emily C. McFarlane[1], Jonas A. Krieger[1], Mihir Date[1], Banabir Pal[1], Procopios C. Constantinou[2], Vladimir N. Strocov[2], Stuart S. P. Parkin[1], and Niels B. M. Schröter[1] — [1]Max Planck Institute of Microstructure Physics, Halle, Germany — [2]Swiss Light Source, Paul Scherrer Institute, Villigen, Switzerland

The Josephson diode - recently realized in NiTe2/superconductor devices in the presence of an external magnetic field [1] - has many potential uses in new superconducting memory and logic devices. These $NiTe_2$/Ti/Nb devices are the first Josephson diodes where the Josephson diode effect (JDE) was concluded to arise from finite momentum Cooper pairing. However, the role of the Ti layer directly at the $NiTe_2$ interface is not yet fully understood. Ti-doped $NiTe_2$ is seen to be superconducting [2], so here we investigate the possibility of intrinsic superconductivity at the $NiTe_2$/Ti interface by investigating its electronic structure with angle-resolved photoelectron spectroscopy. In isostructural $PdTe_2$, a van Hove singularity (vHS) near the Fermi level was linked to intrinsic superconductivity [3]. We find a similar vHS in the vicinity of the Fermi level in the electronic structure of $NiTe_2$, which can be shifted in energy at the interface due to a doping effect by aluminium.

Reversal of the AC and DC supercurrent diode effect in ballistic Josephson junctions — Andreas Costa[1], Christian Baumgartner[1], Simon Reinhardt[1], Sergei Gronin[2], Geoffrey C. Gardner[2], Tyler Lindemann[2], Michael J. Manfra[2], Denis Kochan[1], Jaroslav Fabian[1], •Nicola Paradiso[1], and Christoph Strunk[1] — [1]University of Regensburg — [2]Purdue University

Recent experiments [1,2] have demonstrated that the supercurrent diode effect (SDE), –i.e., a nonreciprocal supercurrent– can be obtained by applying a Zeeman field in the presence of spin-orbit coupling. The effect consists in a finite difference ΔI_c between positive I_c^+ and negative $|I_c^-|$ critical current (DC SDE), and an asymmetry in the Josephson inductance as a function of current (AC SDE). In this work, we show that, at high in-plane fields, the AC and DC SDE both change sign. Based on a minimal and analytical model, we clearly identify the origin of this sign change in terms of a 0-π-like transition –an effect predicted in the literature [3] but so far never experimentally observed. Thanks to our inductance measurements we can directly link the AC SDE reversal to the modification of the CPR induced by the Zeeman field. Our results illustrate the power of the Josephson inductance as a probe of phase transitions in unconventional superconductors.

Theoretical study of the supercurrent diode effect in 2DEG Josephson junctions — •Andreas Costa[1], Denis Kochan[1,2], and Jaroslav Fabian[1] — [1]University of Regensburg, Germany — [2]Slovak Academy of Sciences, Slovakia

Superconducting junctions exhibit fascinating physical phenomena, making them promising building blocks for quantum computing. The competition between the two fundamental spin interactions—ferromagnetic exchange and spin-orbit interaction (SOI)—and superconductivity has already been demonstrated to substantially modify the spectroscopic and transport signatures of these junctions, and potentially results in topological superconductivity.

In this talk, we will focus on 2DEG-based S-N-S Josephson junctions that combine intrinsic SOI with proximity-induced superconductivity originating, e.g., from top Al islands. We will demonstrate that turning the nonsuperconducting (N) weak link additionally ferromagnetic—e.g., through a magnetic field—can imprint a strong direction dependence on the current-phase relation, which finally rises a substantial difference between positive and negative critical currents, and thereby a pronounced supercurrent diode effect. Motivated by pioneering experimental studies [1–3], we will elaborate on powerful theoretical approaches—such as numerical tight-binding simulations [2, 3] and analytical studies of the Andreev spectrum—to characterize and understand the features of this Josephson supercurrent diode effect.

Plasmons and dynamical screening in layered superconducting heterostructures — •Yann in 't Veld[1], Mikhail Katsnelson[1], Andrew Millis[2,3], and Malte Rösner[1] — [1]Radboud University, Nijmegen, the Netherlands — [2]Flatiron Institute, New York, USA — [3]Columbia University, New York, USA

Layered metals host low-energetic plasmonic and phononic excitations, which both strongly couple to electrons. At the same time these excitations hybridize with each other, which can be tuned by the surrounding material, resulting in a complex interplay of different bosons. Here we investigate how this interplay affects superconductivity in layered materials and how it is affected by the substrate material. To this end we use a one-loop theory which consistently treats phonons, plasmons, their mutual interaction and environmental screening on the same footing. We find two regimes with large transition temperatures, controlled by the substrate screening. One is mediated by conventional phonon pairing, which shows a significantly reduced transition temperature due to consistent screening. The other regime is dominated by the unconventional electron-plasmon interaction, where we find strong effects of normal-state renormalization on the superconducting state. These results show how crucial a consistent treatment of all pairing and screening channels is for low-dimensional superconductivity.

Investigation of Nb gate-controlled superconducting nanoscale devices. — •Leon Ruf, Elke Scheer, and Angelo Di Bernardo — 78464 Konstanz, Konstanz Germany

The electrical conductance in nanoscale devices can be modulated by an applied electric field (EF). In semiconductors the charge density is low, and the EF can penetrate deeply. However, in superconductors the charge carrier density is high and the external EF decays exponentially over a short distance. In 2018, it was reported [1] that the superconducting state can be partially and fully suppressed in gated nano constrictions by a strong applied EF which they attribute to an EF induced perturbation of the superconducting state. Since then, the observations were controversially discussed attributing them to an EF effect [1], high-energy quasiparticle injection [2], low-energy-mediated phonon excitation [3] or hot-spot generation [4]. Here, we are studying Nb gated Dayem bridges. Our observations show reversible full suppression of the supercurrent for Nb devices made by lift off, not for geometrically comparable etched devices. We discuss our observations in the light of the suggested mechanisms [1-4].

Gate-controlled switching in non-centrosymmetric superconducting devices — •Jennifer Koch, Leon Ruf, Elke Scheer, and Angelo Di Bernardo — Universität Konstanz, Konstanz, Germany

Gate-controlled superconducting devices have become of great interest for the development of energy-efficient hybrid superconductor/semiconductor computing architectures. The idea behind this technology stems from the recent discovery that superconducting devices can be controlled electrically with the application of a gate voltage [1-3].

We investigate gate-controlled switching devices made of the non-centrosymmetric superconductor $Nb_{0.18}Re_{0.82}$ for different gate-to-wire distances. This material promises a low switching voltage due to its disordered structure and should therefore be more suitable for the realization of devices compatible with CMOS transistors.

Microscopic theory of gate-voltage mediated surface pair breaking and its impact on a superconducting wire — •Subrata Chakraborty, Danilo Nikolic, and Wolfgang Belzig — Fachbereich Physik, Universität Konstanz, D-78457 Konstanz, Germany

Gate-induced supercurrent suppression in a superconducting nano-bridge is a hot topic for research in present days. Recent experiments find supercurrent suppression in this nano-bridge for high gate electric fields [1-3]. The microscopic understanding of this effect is not clear till now. According to many experimental findings, there are three distinct tentative mechanisms, which could be responsible for this event, at high gate fields. In our work, we theoretically investigate the role of gate-mediated surface pair breaking on the supercurrent suppression. We show that in presence of a small concentration of magnetic impurities on the surface of the bridge, large gate-fields result in strong spin-flip scattering at the surface. Using microscopic modelling based on the quasiclassical Usadel equation we present the full phase diagram of the wire, that shows a supercurrent suppression very similar to some experiment. We speculate, that our generic theoretical predictions based on this microscopic effect can be tested experimentally by modifying the surface.

TT 28.1   Wed 9:30   HSZ 103

Fermi surface study of the putative spin-triplet superconductor UTe_2 — •Alexander Eaton[1], Theodore Weinberger[1], Zheyu Wu[1], Alexander Hickey[1], Nicholas Popiel[1], and Michal Valiska[2] — [1]Cavendish Laboratory, University of Cambridge, UK — [2]MGML, Charles University, Prague

The unconventional superconductor UTe_2 exhibits numerous properties indicative of spin-triplet pairing, including an upper critical field far in excess of the Pauli paramagnetic limit, and re-entrant superconductivity at high magnetic fields > 40 T. However, a detailed understanding of the material's Fermi surface remains a key open question hampering efforts to attain a more detailed theoretical picture of the microscopic pairing mechanism(s) at play.

Here, we report a detailed de Haas-van Alphen study of the Fermi surface of UTe_2. We measured quantum oscillations in the magnetic torque and contactless resistivity of several high quality samples (RRR ~ 900, Tc = 2.1 K) in a dilution refrigerator at temperatures down to 19 mK and magnetic fields up to 28 T, through two orthogonal rotation planes. Importantly, access to field strengths this high allowed us to measure directly along the [001] direction, which has previously been proposed to run parallel to the axis of cylindrical Fermi surface sections.

We present a summary of our angle- and temperature-dependent results performed to date, and compare to DFT and DMFT calculations that we find to capture the majority of the observed behaviour.

TT 28.2   Wed 9:45   HSZ 103

High pressure study of the unconventional superconductor $CeRh_2As_2$ — •Meike Pfeiffer[1], Konstantin Semeniuk[2], Seunghyun Khim[2], and Elena Hassinger[1] — [1]Technische Universität Dresden Institut für Festkörper- und Materialphysik, 01069 Dresden — [2]Max Planck Institute for Chemical Physics of Solids, 01187 Dresden

The heavy-fermion superconductor $CeRh_2As_2$ hosts two distinct superconducting states which are currently understood as even- and odd-parity states. The compound crystallizes in a layered lattice that is globally centrosymmetric but lacks local inversion symmetry at the Ce sites. This results in a strong spin-orbit coupling, believed to lead to a very high ratio of upper critical field (> 15 T) to critical temperature (T_c = 0.26 K). The normal state of the compound hosts an additional phase below 0.4 K, believed to be a quadrupole-density wave (QDW) order. We present a high-pressure electrical resistivity study of $CeRh_2As_2$ across different generations of samples. The QDW order is highly sensitive to lattice compression and gets fully suppressed at $P_c \approx 0.6$ GPa. The superconducting transition temperature T_c decreases at a significantly lower rate, and both superconducting phases persist well above 2 GPa. Thus, we confirm that the QDW is not responsible for the phase switching from even- to odd-parity state. At the same time, the in-plane magnetic field peaks at P_c, suggesting a different kind of interplay between the two orders.

TT 28.3   Wed 10:00   HSZ 103

Superconductivity versus quadrupole density wave in $CeRh_2As_2$ — •Konstantin Semeniuk[1], Daniel Hafner[1], Pavlo Khanenko[1], Javier Landaeta[1], Thomas Lühmann[1], Christoph Geibel[1], Seunghyun Khim[1], Elena Hassinger[2], and Manuel Brando[1] — [1]MPI-CPfS, Dresden, Germany — [2]TU Dresden, Dresden, Germany

A heavy-fermion superconductor $CeRh_2As_2$ ($T_c \approx 0.3$ K) undergoes a phase transition at the temperature $T_0 \approx 0.5$ K, proposed to be a quadrupole density wave (QDW) instability. The compound hosts two distinct superconducting (SC) phases, presumably of different parity. These are separated by a first order phase boundary at magnetic field $\mu_0 H^* = 4$ T, applied along the c axis of the tetragonal lattice. Recent studies suggest that the QDW phase boundary could meet the $T_c(H)$ line at exactly at H^*. This would imply that the SC phase switching is driven by the field-induced suppression of the QDW order coexisting with the superconductivity. Inability to reliably track T_0 near 4 T has left the question standing.

We present a study of a new generation of $CeRh_2As_2$ crystals, showing sharper signatures of phase transitions. From our measurements of heat capacity and electrical resistivity in c-axis magnetic field, we produce a more detailed phase

diagram which shows that the QDW and SC phase boundaries meet at 6 T. We conclude that the QDW state is not responsible for the SC phase switching at H^* and discuss the possible interplay between the two orders with reference to the Fermiology of $CeRh_2As_2$ as well as thermodynamic considerations.

TT 28.4 Wed 10:15 HSZ 103

Exploring the unconventional superconducting state in Ce_3PtIn_{11} — •Jan Fikáček[1], Sarah R. Dunsiger[2], Sébastien Laughrea[3], Andrea D. Bianchi[3], Shinsaku Kambe[4], Hironori Sakai[4], Yo Tokunaga[4], Manuel Brando[5], and •Jeroen Custers[1] — [1]Charles University, Faculty of Mathematics and Physics, Department of Condensed Matter Physics, Ke Karlovu 5, 121 16 Prague 2, Czech Republic — [2]Centre for Molecular and Materials Science, TRIUMF, Vancouver, British Columbia, Canada V6T 2A3 — [3]Département de Physique, Université de Montréal, Montréal, Canada — [4]Advanced Science Research Center, Japan Atomic Energy Agency, Tokai-mura, Ibaraki 319-1195, Japan — [5]Max Planck Institute for Chemical Physics of Solids, Nöthnitzer Strasse 40, D-01187, Dresden, Germany

The properties of the heavy fermion compound Ce_3PtIn_{11} are certainly enigmatic. At ambient pressure, the compound displays two consecutive magnetic transitions into antiferromagnetic (AFM) states at $T_{N1} = 2.2$K and $T_N = 2.0$K, respectively. Below $T_c = 0.32$K superconductivity (SC) is found. It has been speculated that AFM and SC coexist because the compound harbors two inequivalent Ce sites each having a specific environment favoring either a magnetic or superconducting state. We focus on the SC state and present specific heat, ^{115}In NQR and recent μSR experiments at ambient pressure and down to 20mK. The results sketch a picture of an unusual unconventional SC state.

TT 28.5 Wed 10:30 HSZ 103

Surface-acoustic-wave-induced unconventional superconducting pairing — •Viktoriia Kornich — Julius-Maximilians-Universität Würzburg

Exotic materials, topological states, and quantum collective phenomena are of high interest for fundamental science and technology, because they provide complex and stable performance even at a very small scale. The field of unconventional superconductivity investigates new features and phenomena occurring in superconducting materials and setups. However, the exact processes, which lead to unconventional superconducting states are usually not clear and subject to numerous hypotheses and attempts to experimentally verify them. Here, I will discuss how to use externally applied acoustic waves in order to induce unconventional superconducting pairing of different types in solid state matter, primarily in thin films and 2D materials. I will consider a simple setup consisting of a solid state material with conduction electrons and an applied surface acoustic wave, that breaks spatial translation symmetry. I will show that the symmetries of the possible surface-acoustic-wave-induced order parameters depend on the shape of the applied wave. As an example, I will show that even-frequency spin-triplet odd-parity order parameter can occur due to Rayleigh surface acoustic wave.

Invited Talk TT 28.6 Wed 10:45 HSZ 103

Studying the Fulde-Ferrell-Larkin-Ovchinnikov order parameter in quasi-2D organic superconductors — •Tommy Kotte[1], S. Molatta[1], D. Opherden[1], G. Koutroulakis[2], S. E. Brown[3], J. A. Schlueter[4,5], H. Kühne[1], G. Zwicknagl[6], and J. Wosnitza[1,7] — [1]Hochfeld-Magnetlabor Dresden, HZDR — [2]UC Santa Barbara, USA — [3]UC Los Angeles, USA — [4]NSF, Alexandria, USA — [5]ANL, Argonne, USA — [6]IMP, TU Braunschweig — [7]IFMP, TU Dresden

The Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state can emerge in superconductors for which the orbital critical field exceeds the Pauli limit. This unconventional superconducting state is characterized by a spatial modulation of the superconducting order parameter. Although evidence of the formation of an FFLO state has been found in various classes of materials, it is still theoretically debated and experimentally unexplored how the superconducting order parameter evolves within the FFLO phase. Here, we present two fundamental studies concerning this question in quasi-2D organic superconductors, which are well established to host an FFLO state: (i) By means of ^{13}C NMR spectroscopy on β"-$(ET)_2SF_5CH_2CF_2SO_3$, we were able to quantify the modulation amplitude of the spin polarization throughout the FFLO state. This quantity is related to the modulated superconducting gap, hence representing the order parameter. (ii) By means of angular-resolved specific-heat measurements on κ-$(ET)_2Cu(NCS)_2$, we furthermore show how the FFLO order parameter becomes unstable against orbital interactions, leading to a crossover from the FFLO into Abrikosov-like states of higher-order Landau levels.

TT 29: Frustrated Magnets: General

Time: Wednesday 9:30–13:15 Location: HSZ 201

TT 29.1 Wed 9:30 HSZ 201

Possible stress-driven spiral-to-Néel transition in the triangular antiferromagnet $PdCrO_2$ — •Nina Stilkerich[1,2], Seunghyun Khim[2], Andrew Mackenzie[2,3], Jochen Geck[1], and Clifford Hicks[2,4] — [1]Institut für Festkörper- und Materialphysik, Technische Universität Dresden, 01062 Dresden, Germany — [2]Max Planck Institute for Chemical Physics of Solids, Nöthnitzer Str. 40, 01187 Dresden, Germany — [3]Scottish Universities Physics Alliance (SUPA), School of Physics and Astronomy, University of St. Andrews, St. Andrews KY16 9SS, United Kingdom — [4]School of Physics and Astronomy, University of Birmingham, Birmingham B15 2TT, United Kingdom

$PdCrO_2$ is a triangular antiferromagnet that undergoes a transition from a double-q to single-q magnetic structure under moderate uniaxial stress [1]. Due to a high sensitivity of the magnetic anisotropy to uniaxial stress, another transition from spiral order to a linear antiferromagnetic structure is predicted for higher stress of about 1 GPa [1].

We performed stress-strain measurements on $PdCrO_2$ and were able to identify the double- to single-q transition as a jump in strain. We report the discovery of an additional transition under higher stress, which might be the spin spiral to Néel transition suggested previously. [1] D. Sun et al., New J. Phys. 23, 123050 (2021)

TT 29.2 Wed 9:45 HSZ 201

Thermodynamic study of the partially polarized state of the sawtooth chain atacamite, $Cu_2Cl(OH)_3$ — Leonie Heinze[1], Tommy Kotte[2], Albin de Muer[3], Sven Luther[2,4], Andrew Ammerlaan[5], Uli Zeitler[5], Anja U.B. Wolter[6], Bernd Büchner[6], Kirrily C. Rule[7], Hannes Kühne[2], and •Stefan Süllow[1] — [1]TU Braunschweig, Braunschweig, Germany — [2]HLD, HZ Dresden-Rossendorf, Germany — [3]LNCMI, CNRS, Grenoble, France — [4]TU Dresden, Dresden, Germany — [5]HFML, Radboud University, Nijmegen, The Netherlands — [6]ANSTO, Lucas Heights, Australia — [7]IFW Dresden, Dresden, Germany

Recently, the natural mineral atacamite, $Cu_2Cl(OH)_3$, has been established as a unique model compound of the $S = 1/2$ quantum sawtooth chain with a dominant magnetic exchange $J \sim 360$ K along the chain spine and $J' \sim 102$ K within the sawteeth [1]. Residual interchain couplings of a few Kelvin drive atacamite into an antiferromagnetic (AFM) ground state below $T_N = 8.4$ K. The AFM phase is suppressed in magnetic fields of ~ 30 T. Upon suppression of AFM order,

the magnetization becomes plateau-like close to $M_{sat}/2$.

By now, we have been able to study the magnetic phase diagram up into the unusual partially polarized state by means of specific heat. Here, we present a corresponding study and present evidence for quantum critical behavior occuring upon suppression of AFM order.
[1] L. Heinze et al., Phys. Rev. Lett. **126**, 207201 (2021).

TT 29.3 Wed 10:00 HSZ 201

Weakly coupled triangles forming a star lattice in an organic-inorganic copper sulfate — •Oleg Janson[1], Ulrich K. Rössler[1], and Hajime Ishikawa[2] — [1]Leibniz IFW Dresden, Germany — [2]ISSP, University of Tokyo, Japan

The recently synthesized organic-inorganic copper sulfate $[(CH_3)_2(NH_2)]_3$ $[Cu_3(OH)(SO_4)_4]\cdot0.24H_2O$ has been proposed as a material realization of the $S = \frac{1}{2}$ star lattice model [1]. We report high-field magnetization measured on powder samples showing a broad plateau at $\frac{1}{3}$ of the saturation magnetization. Full saturation was reached at about 105 T in a destructive pulsed-field experiment. Low-field and low-temperature measurements on single crystals show no indications of magnetic ordering and reveal a sizable anisotropy of magnetization. Density-functional-theory (DFT) calculations indicate the relevance of two inequivalent exchanges J_T and J_D with $J_T \gg J_D$, placing this material in the limit of weakly coupled triangles. Anisotropic components of J_T were estimated by noncollinear DFT+U calculations. We demonstrate that a simple model of isolated triangles accounts for the thermodynamic behavior of this compound.

TT 29.4 Wed 10:15 HSZ 201

Temperature-dependent transitions of the rare-earth delafossite $NaGdS_2$ — •Justus Grumbach[1], Mathias Doerr[1], Ellen Haeussler[2], and Sergey Granovsky[1] — [1]Institut für Festkörper- und Materialphysik, Technische Universität Dresden, 01062 Dresden, Germany — [2]Fakultät für Chemie und Lebensmittelchemie, Technische Universität Dresden, 01062 Dresden, Germany

Rare-earth delafossites are materials containing ideal triangular magnetic planes, which are frustrated. Due to their properties, rare-earth delafossites are promising candidates for a QSL ground state. In recent years this state occured in some $S=\frac{1}{2}$-delafossites with transitions in the mK range.
Now a number of own new measurements were made on $NaGdS_2$ single crystals. This delafossite with magnetic Gd^{3+} ions, which has been extensively in-

vestigated for the first time, is of special interest due to the pure spin moment J=S=$\frac{7}{2}$. Measurements of several different thermodynamic and magnetic properties were performed on very small samples (size ~ μm) down to lowest temperatures (40 mK).

Essential physical data could be extracted, which show correspondingly a AFM-groundstate below ~250 mK, which is kind of expected. An additionally investigated modification at 60 K, indicating an anisotropy in the system, is still under theoretical debate and will form a main part of the talk.

TT 29.5   Wed 10:30   HSZ 201

Study of CoNb$_2$O$_6$ magnetic properties from first principles — •Amanda Konieczna[1], Kira Riedl[1], Roser Valenti[1], and Radu Coldea[2] — [1]Goethe-Universität, Frankfurt am Main, Germany — [2]University of Oxford, Oxford, England

The quasi-one-dimensional ferromagnet CoNb$_2$O$_6$ offers an interesting playground to investigate the interplay of anisotropic magnetic interactions in real materials. A variety of magnetic models was proposed for this material, including longer-range Heisenberg exchange, dominant anisotropic Ising and bond-dependent Kitaev-type magnetic interactions.

In this talk, we discuss our theoretical approach to extract the magnetic exchange in CoNb$_2$O$_6$. We first obtain material-specific hoppings from ab-initio methods and proceed by moving from a description in terms of the Hubbard model to the Spin Hamiltonian using exact diagonalization and perturbation theory. Finally, we will discuss how our results fit into the picture of available results for this system, both on the theoretical and experimental side.

We gratefully acknowledge funding by the DFG (German Research Foundation): QUAST-FOR5249 - 449872909 (Project TP4).

TT 29.6   Wed 10:45   HSZ 201

Valence bond solid state in explicitly dimerized chain with magnetic frustration — •Jędrzej Wardyn[1], Satoshi Nishimoto[1,2], and Cliò Efthimia Agrapidis[3] — [1]IFW Dresden, 01069 Dresden, Germany — [2]TU Dresden, 01062 Dresden, Germany — [3]Faculty of Physics, University of Warsaw, Pasteura 5, 02093 Warsaw, Poland;

We consider the spin-1/2 dimerized frustrated ferromagnetic (FM) $J_1-J_1'-J_2$ model, with J_1, $J_1'<0$ FM first neighbours coupling and $J_2>0$ antiferromagnetic second neighbors coupling. This model serves as a minimal model for LiCuSbO$_4$ and Rb$_2$Cu$_2$Mo$_3$O$_{12}$. We introduce the frustration parameter $J_2/|J_1|=\alpha$ and the dimerization parameter $J_1'/J_1=\beta$. There are two special limits of dimerization: fully dimerized at $\beta=0$ and the undimerized J_1-J_2 model at $\beta=1$. Earlier studies have identified phases featured in the special limits as valence bond solid with a finite spin gap for $\beta=1$ and a Haldane-like state for $\beta=0$. For our model, the spin gap and phase diagram was investigated in a 2017 study by Agrapidis *et al.* [1]. Thanks to new insight, we revisit these results with applying new boundary conditions, which allow us to correctly estimate the spin gap which was previously underestimated. We compute the spin gap, the string order parameter (SOP), and dimer-dimer correlations using the density matrix renormalization group method (DMRG). We prove that the model features a VBS state. Our results allow us to determine this state as $\mathscr{D}_3$-VBS state adiabatically connected to the Haldane-like state in the limit of $\beta=0$.

[1] C. E. Agrapidis *et al.*, Phys. Rev. B, 95, 220404 (2017).

TT 29.7   Wed 11:00   HSZ 201

The effect of nonlocal electronic correlations on different lattice geometries - A dynamical vertex approximation study — •Marvin Leusch[1], Andreas Hausoel[2], Alessandro Toschi[3], Giorgio Sangiovanni[4], and Georg Rohringer[1] — [1]Universität Hamburg, Hamburg, Germany — [2]IFW Dresden, Germany — [3]Julius-Maximilians-Universität Würzburg, Würzburg, Germany — [4]TU Wien, Vienna, Austria

In the last decades, dynamical mean-field theory (DMFT) has become a standard tool for describing strongly correlated electron systems. It captures all purely local correlations effects and, hence, provides exact results in the limit of infinite coordination number and thus spacial dimensions. For finite dimensional systems, it neglects nonlocal correlation effects which are captured by diagrammatic extensions of DMFT such as the dynamical vertex approximation (DΓA). In our work, we analyze the three dimensional Hubbard model on various lattice types to investigate the effect of different coordination numbers on local and nonlocal correlations. In particular, we study the magnetic phase diagram of the Hubbard model on a simple cubic (sc), body-centered cubic (bcc) and face-centered cubic (fcc) lattice within DΓA and compare their transition temperatures to magnetically ordered states to corresponding DMFT results. Our numerical findings demonstrate, that the nonlocal correlations of DΓA generally reduce the size of the ordered region with respect to DMFT while the actual magnitude of this reduction depends on the specific lattice type and, in particular, on the coordination number.

TT 29.8   Wed 11:30   HSZ 201

Systematic analysis of diagonal ordering patterns in bosonic lattice models with algebraically decaying density-density interactions — •Jan Alexander Koziol[1], Antonia Duft[1], Giovanna Morigi[2], and Kai Phillip Schmidt[1] — [1]Department of Physics, Staudtstraße 7, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Theoretical Physics, Saarland University, Campus E2.6, D-66123 Saarbrücken, Germany

We propose a general approach to analyse diagonal ordering patterns in bosonic lattice models with algebraically decaying density-density interactions on arbitrary lattices. The key idea is a systematic search for the energetically best order on all unit cells of the lattice up to a given extent. Using resummed couplings we evaluate the energy of the ordering pattern in the thermodynamic limit using finite unit cells. We apply the proposed approach to the atomic limit of the extended Bose-Hubbard on a triangular lattice at fillings $f = 1/2$ and $f = 1$. We investigate the ground-state properties of the antiferromagnetic long-range Ising model on the triangular lattice and determine a six-fold degenerate plain-stripe phase to be the ground state for finite decay exponents. We also probe the classical limit of the Hamiltonian describing Rydberg atom arrangements on the sites and links of the Kagome lattice.

TT 29.9   Wed 11:45   HSZ 201

Phases of the spin-1/2 Heisenberg antiferromagnet on the diamond-decorated square lattice in a magnetic field — •Nils Caci[1], Katarína Karl'ová[2], Taras Verkholyak[3], Jozef Strečka[2], Stefan Wessel[1], and Andreas Honecker[4] — [1]Institute for Theoretical Solid State Physics, RWTH Aachen University, Germany — [2]Department of Theoretical Physics and Astrophysics, P.J. Šafárik University, Košice, Slovakia — [3]Institute for Condensed Matter Physics, National Academy of Sciences of Ukraine, L'viv, Ukraine — [4]Laboratoire de Physique Théorique et Modélisation, CNRS UMR 8089, CY Cergy Paris Université, France

The spin-1/2 Heisenberg antiferromagnet on the highly frustrated diamond-decorated square lattice is a spin system of orthogonal spin dimers that features various ground-state phases, consisting of extended monomer-dimer and dimer-tetramer ground states as well as a ferrimagnetic regime. By using a combination of density matrix renormalization group (DMRG), exact diagonalization, as well as unbiased sign-problem free quantum Monte Carlo (QMC) methods, we investigate this system in the presence of a finite magnetic field. We find at high magnetic fields the emergence of a spin-canted phase, with continuously rising magnetization, as well as the fully polarized paramagnetic phase. At intermediate field strength, we identify the presence of a first-order quantum phase transition line between a ferrimagnetic phase and the monomer-dimer regime, which extends to finite temperatures and terminates in a line of critical points belonging to the Ising universality class.

TT 29.10   Wed 12:00   HSZ 201

Ground-state degeneracy and magneto-thermodynamics of the spin-1/2 Heisenberg antiferromagnet on the diamond-decorated square lattice — •Andreas Honecker[1], Nils Caci[2], Taras Verkholyak[3], Katarína Karl'ová[4], Stefan Wessel[2], and Jozef Strečka[4] — [1]Laboratoire de Physique Théorique et Modélisation, CNRS UMR 8089, CY Cergy Paris Université, France — [2]Institute for Theoretical Solid State Physics, RWTH Aachen University, Germany — [3]Institute for Condensed Matter Physics, National Academy of Sciences of Ukraine, L'viv, Ukraine — [4]Department of Theoretical Physics and Astrophysics, P.J. Šafárik University, Košice, Slovakia

The spin-1/2 Heisenberg antiferromagnet on the diamond-decorated square lattice exhibits a rich ground-state phase diagram in a magnetic field [1]. We investigate the thermodynamic properties of this model using a combination of analytical and numerical methods, including full diagonalization up to effectively $N = 30$ sites. We focus in particular on the vicinity of a "dimer-tetramer" phase at low magnetic fields that maps to a classical dimer model on the square lattice and retains a macroscopic ground-state ddegeneracy in a magnetic field. We discuss the consequences of this degeneracy for the thermodynamic and magnetocaloric properties of the system.

TT 29.11   Wed 12:15   HSZ 201

Thermodynamics of the frustrated Heisenberg model on the truncated hexagonal lattice — •Adrien Reingruber[1], Nils Caci[2], and Stefan Wessel[2] — [1]Institut für Theoretische Physik und Astrophysik, Universität Würzburg, Germany — [2]Institut für Theoretische Festkörperphysik, RWTH Aachen University, Aachen, Germany

The thermodynamical properties of the spin-1/2 Heisenberg antiferromagnet on the truncated hexagonal lattice are studied using trimer-based cluster quantum Monte Carlo simulations. The system consists of an arrangement of spin-trimers on a honeycomb lattice with dimer couplings interconnecting neighboring trimers. The physics of this frustrated quantum spin system is investigated for different spin-coupling strengths. The severeness of the quantum Monte Carlo sign problem with respect to the single-site, dimer and trimer basis is exam-

ined. In the parameter regime of weakly coupled trimers an effective spin-1/2 Hamiltonian can be derived to describe the low-temperature physics. This effective model yields antiferromagnetic effective spin-1/2 trimer-spin interactions with bond-dependent coupling strengths. Unbiased quantum Monte Carlo simulations confirm the validity of the effective model within the low-temperature regime.

Another exact ground state of a 2D quantum antiferromagnet — Pratyay Ghosh, •Tobias Müller, Jannis Seufert, and Ronny Thomale — Julius-Maximilians-Universität, Würzburg, Germany

We present the exact dimer ground state of a quantum antiferromagnet on the maple-leaf lattice. A coupling anisotropy for one of the three inequivalent nearest-neighbor bonds is sufficient to stabilize the dimer state. Together with the Shastry-Sutherland Hamiltonian, we show that this is the only other model with an exact dimer ground state for all two-dimensional lattices with uniform tilings. We futhermore discuss the stability of this ground state from the perspective of perturbation theory.

TT 29.13　Wed 12:45　HSZ 201

Bound states and plateaus: Magnetization behavior of the maple leaf lattice — •Jannis Seufert, Pratyay Ghosh, Tobias Müller, and Ronny Thomale — Julius-Maximilians-Universität, Würzburg, Germany

Recently, the maple leaf lattice equipped with a Heisenberg-Hamiltonian was shown to exhibit an analytically exact antiferromagnetic dimer ground state analogous to the better known Shastry-Sutherland model. Anticipating that its even stronger frustration will lead to both familiar and exotic magnetic behav-

ior, we present the calculation of magnetization plateaus in the maple leaf model with Ising- and Heisenberg-spins. For the latter, this is achieved within a perturbation theory of magnetic excitations incorporating triplet-triplet interactions and correlated hopping, which promotes the emergence of bound states.

TT 29.14　Wed 13:00　HSZ 201

Exact analytical solutions of a distorted spin-1/2 tetrahedron with ring exchange — Rolf Schumann[1] and •Stefan-Ludwig Drechsler[2] — [1]TU-Dresden, D-1169 Dresden, Germany — [2]IFW-Dresden, D-1169 Dresden, Germany

We present exact analytical solutions for the eigenvalues of a general spin-1/2 Hamiltonian with 6 bilinear (Heisenberg) J_i and 3 ring exchange K_i couplings. Focusing on the experimentally interesting orthorhombically, tetragonally, trigonally and non-distorted ideal tetrahedra (ITH) we consider their thermodynamic properties as the magnetization M, susceptibility, entropy, and specific heat at any temperature T and external magnetic field H and derive from the magnetization steps $M(H)$ at high-fields and low-T the saturation field H_s, the critical ferrimagnetic field H_{c1}, and the width of the corresponding plateau as a function of the cyclicity . As a result we find enhanced H_s and lowered H_{c1} values with increasing ring exchange $K > 0$ due to the reduced frustration. We present exact mapping equations to extract the relevant exchange integrals J_i and K_i from experimentally observed transition energies and provide an analytical mapping of the single-band Hubbard model on the ITH valid at any coupling strength U/t, where U is the onsite Coulomb repulsion and t the NN-hopping integral. The experimental situations with respect to the magnitude and sign of $\kappa = J/K$ for $Cu_2Te_2OBr_2$, Cu_2OSeO_3, and $Cu_4X_6L_4$ with X=Cl,Br and L being various ligands are briefly discussed.

Planar superconducting resonators on $SrTiO_3$ and $KTaO_3$: GHz properties of quantum paraelectrics — Vincent T. Engl, Nikolaj G. Ebensperger, Lars Wendel, Marius Tochtermann, Ilenia Neureuther, Ishan Sarvaiya, Cenk Beydeda, and •Marc Scheffler — 1. Physikalisches Institut, Universität Stuttgart, Stuttgart, Germany

$SrTiO_3$ is a common substrate for perovskite thin films, and it hosts a superconducting interface when covered with $LaAlO_3$. Recently, similar superconducting interfaces based on $KTaO_3$ were realized. Any cryogenic electronics application using $SrTiO_3$ or $KTaO_3$ faces the quantum-paraelectric nature of both materials: upon cooling to temperatures of a few K, their very large real part ϵ_1 of the dielectric function complicates high-frequency device design, while the imaginary part ϵ_2 indicates rather high losses for $SrTiO_3$ at GHz frequencies.

Overcoming the challenges of the high ϵ_1, we present coplanar superconducting Nb microwave resonators on $SrTiO_3$ and $KTaO_3$ substrates, which we operate at temperatures down to 25 mK. For $SrTiO_3$ with $\epsilon_1 \approx 20000$ at low temperatures, we couple the coplanar resonator to a conventional 50 Ω feedline using a distant-flip-chip geometry.[1,2] With loaded quality factors exceeding 800 for $SrTiO_3$ and 8000 for $KTaO_3$ we advance the prospects of these quantum paraelectrics towards applications in oxide-based superconducting quantum circuitry.

Revsisiting magnetic and orbital ordering in V_2O_3 — Louis-Victor Schäfer and •Maria Daghofer — Institut für funktionelle Materie und Quantentechnologien, Universität Stuttgart

We revisit the correlated bands of V2O3 using the variational cluster approximation. Starting from various sets of one-particle parameters discussed in the literature, double counting of correlations turns out to be relevant here, as also reported in the literature. Settling onto consistent parameters, we then find that a careful treatment of inter-layer dimers is crucial to reproduce the experimentally observed magnetic ordering. Additionally, bonds in the planes orthogonal to the dimers affects orbital densities. Antiferromagnetic ordering is the found to go in hand with orbital symmetry breaking within the e_g sector. We find any models that reproduce the measured a_{1g} orbital densities also leads to active orbital degrees of freedom above the Neel transition.

TT 30.3　Wed 10:00　HSZ 204

Direct imaging of valence orbitals using hard x-ray photoelectron spectroscopy — •Daisuke Takegami[1], Laurent Nicolaï[2], Yuki Utsumi[1], Anna Meléndez-Sans[1], Daria A. Balatsky[1], Cariad-A. Knight[1], Connor Dalton[1], Shao-Lun Huang[1], Chi-Sheng Chen[1], Li Zhao[1], Alexander C. Komarek[1], Yen-Fa Liao[3], Ku-Ding Tsuei[3], Ján Minár[2], and Liu Hao Tjeng[1] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany —

[2]University of West Bohemia, Pilsen, Czech Republic — [3]National Synchrotron Radiation Research Center, Hsinchu, Taiwan

It was hypothesized already more than 40 years ago that photoelectron spectroscopy should in principle be able to image atomic orbitals. If this can be made to work for orbitals in crystalline solids, one would have literally a different view on the electronic structure of a wide range of quantum materials. Here, we demonstrate how hard x-ray photoelectron spectroscopy can make direct images of the orbitals making up the band structure of our model system, ReO3 [1]. The images are energy specific and enable us to unveil the role of each of those orbitals for the chemical bonding and the Fermi surface topology. The orbital image information is complementary to that from angle-resolved photoemission and thus completes the determination of the electronic structure of materials.

TT 30.4　Wed 10:15　HSZ 204

Orbital imaging of the spin state transition in $LaCoO_3$ — Brett Leedahl[1], Daisuke Takegami[1], Martin Sunderamnn[1,2], Hlynur Gretarsson[1,2], Alexander Komarek[1], Arata Tanaka[3], Maurits Haverkort[4], and •Liu Hao Tjeng[1] — [1]MPI-CPfS, Dresden, Germany — [2]DESY/PETRA-III, Hamburg, Germany — [3]Department of Quantum Matter, Hiroshima University, Japan — [4]Institute for Theoretical Physics, Heidelberg University, Germany

Here we have investigated the Co 3d orbital occupation in LaCoO3 across the spin state transition using the recently developed x-ray-based orbital-imaging method. The images collected allow for a direct determination of the amount of the Co t_{2g} and e_g holes. We find that, at the lowest temperatures, the low-spin state with the nominally $t_{2g}^6 e_g^0$ electron configuration *does* have holes in the t_{2g} subshell which we attribute to the presence of spin-orbit interaction. The hole amount, however, sets limits to the minimum energy gap between the lattice-frozen low-spin and high-spin states. At high temperatures, we find that the high-spin state occupation is about *half* (!) of the value reported in the most recent literature. Implications for the ab-initio modeling of the spin-state transition process are discussed.

TT 30.5　Wed 10:30　HSZ 204

Directional ballistics in ultra-pure delafossite metals — •Michal Moravec[1,2], Graham Baker[3], Maja D. Bachmann[1,2], Philippa H. McGuinness[1,2], Markus König[1], Seunghyun Khim[1], and Andrew P. Mackenzie[1,2] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]School of Physics and Astronomy, University of St Andrews, St Andrews, United Kingdom — [3]University of British Columbia, Vancouver, Canada

Studying electrical transport in extremely pure materials has led to the discovery of novel phenomena. The delafossite metals, with their two-dimensional electronic structure and mean free paths in excess of 20 μm, are a recent addition to

the ultra-pure materials class. Here we study electrical transport in bars of varied width in delafossite metals $PdCoO_2$ and $PtCoO_2$. The bar-like structures are sculpted in two crystal orientations using the focused ion beam and sequentially narrowed across the width corresponding to the mean free path. We observe a cross-over from Ohmic to ballistic transport and gradual increase in resistivity anisotropy between the two orientations, as the channel is narrowed. This anisotropy is not allowed by the symmetry of the bulk crystal lattice; it is an example of symmetry lowering due to the imposition of shapes of finite size and the Fermi surface anisotropy [1]. We also complement our measurements with numerical solutions to the Boltzmann equation including the ARPES Fermi surface parametrisation. We obtain a good qualitative agreement with resistivity data.

Hiroshima 739-8530, Japan
Iron tungstate ($FeWO_4$) is one of the rare oxide compounds with a nearly pure
divalent iron valence state. We investigate the electronic structure of $FeWO_4$
experimentally by X-ray photoelectron spectroscopy. Using various photon energies, cross-section effects allow to identify the individual contributions of the
Fe and W states to the valence band. A comparison with band structure and full
atomic multiplet configuration interaction calculations yields important insights
into the correlations in the material.

TT 30.7   Wed 11:00   HSZ 204

Imaging the orbital-switching in Ti_2O_3 across the metal-insulator transition — •Paulius Dolmantas[1], Chun-Fu Chang[1], Martin Sundermann[1,2],
Brett Leedahl[1], Andrea Amorese[1], Hlynur Gretarsson[1,2], Alexander
Komarek[1], Arata Tanaka[3], Maurits W. Haverkort[4], and Liu Hao Tjeng[1]
— [1]MPI-CPfS, Dresden, Germany — [2]DESY/PETRA-III, Hamburg, Germany
— [3]Department of Quantum Matter, Hiroshima University, Japan — [4]Institute
for Theoretical Physics, Heidelberg University, Germany
Using the recently developed x-ray-based *orbital-imaging* method, we have
been able to observe a switching of the Ti $3d$ orbital occupation across the metal-
insulator transition in Ti_2O_3. We find that in the insulating state only the a_{1g} of
the t_{2g} subshell is occupied, while in the metallic state also the e_g^π gets filled at
the expense of the a_{1g}. The insulator-metal transition may then be viewed as
a transition from a solid of isolated Ti-Ti c-axis singlet dimers into a solid of
electronically partially broken dimers, where the Ti ions acquire additional hopping in the a-b plane via the e_g^π channel. These findings have implications for the
ab-initio modeling of the metal-insulator transition.

Anomalous magnetotransport in $SrIrO_3$ (111) films — •Ji Soo Lim[1],
Merit Spring[1], Martin Kamp[1], Louis Veyrat[1,2], Axel Lubk[2], Bernd
Büchner[2], Michael Sing[1], and Ralph Claessen[1] — [1]Physikalisches Institut and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg,
Würzburg, Germany — [2]Leibniz Institute for Solid State and Materials Research
and Würzburg-Dresden Cluster of Excellence ct.qmat, Dresden, Germany
Complex oxides provides an inexhaustible playground for the study of interactions between charge, spin, orbital, and lattice degrees of freedom. In particular,
spin-orbit coupling can be of comparable magnitude to electron correlations in

5d iridates, leading to exotic quantum phases such as spin liquids and correlated topological semimetals [1]. Perovskite $SrIrO_3$ (SIO) films grown along the
<111> direction exhibit a buckled honeycomb lattice, and are predicted to be
topological crystalline insulators with a relatively large band gap [2].

Here we report on the epitaxial growth of ultrathin SIO films on $SrTiO_3$ (111)
that display a twinned perovskite-like superlattice structure with a periodicity of
3 unit cells and the observation of unusual magnetotransport properties, namely
the anomalous Hall effect. We observe a sign change of the magnetoresistance
and hysteresis loops with increasing coercive fields below 10 K. By comparing
with theoretical results, we discuss the origin of the unusual transport behavior.

Magnetoelectric coupling of terbium orthotantalates — •Xiaotian Zhang[1],
Nicola Kelly[2], Cheng Liu[1], Sian Dutton[1], and Siddharth Saxena[1] —
[1]Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom
— [2]Department of Chemistry, University of Oxford, Oxford, United Kingdom
Quantum multiferroic materials form a new and emerging area of physics where
one expects to find emergence of novel quantum phases induced by subtle coupling between spin and charge degrees of freedom at low temperatures. Experimental study of such phenomena is limited by the lack of model materials where
magnetism and dielectric properties can be tuned using magnetic fields at low
temperatures.

In a recent breakthrough, we found that $TbTaO_4$ exhibits enhancement in dielectric response below 2 K on application of magnetic field, indicating magnetoelectric coupling. Previously, using susceptibility and heat capacity measurements we showed that $TbTaO_4$ orders at $T_N = 2.25$ K; powder neutron diffraction
(PND) was used to solve the magnetic structure, which is A-type antiferromagnetic.

These rare-earth tantalates $LnTaO_4$ (Ln = Y, La-Lu) are of wide interest as a
result of their luminescent, proton-conducting, oxide-ion-conducting and dielectric properties. In addition, in the monoclinic M polymorph of the tantalates with Ln = Nd-Er, the magnetic Ln^{3+} ions are arranged on an elongated
diamond lattice. Materials with such a magnetic lattice have the potential for
unusual magnetic behaviour owing to the interplay of the crystal electric field
with the (possibly competing) J1 and J2 interactions.

Chennai, India — [7]MPI for Chemical Physics of Solids, Dresden, Germany —
[8]Bennett University, Greater Noida, India
Dimerized quantum magnets provide a unique possibility to investigate the
Bose-Einstein condensation of magnetic excitations in crystalline systems at low
temperature. Here, we model the low-temperature magnetic properties of the
recently synthesized spin $S = 1$ dimer system $K_2Ni(MoO_4)_2$ and propose it as
a candidate material for triplon and quintuplon condensation. Based on a first-
principles analysis of its electronic structure, we derive an effective spin dimer
model that we first solve within a mean-field approximation to refine its parameters in comparison to experiment. Finally, the model is solved by employing
a numerically exact quantum Monte Carlo technique which leads to magnetic
properties in good agreement with experimental magnetization and thermodynamic results. We discuss the emergent spin model of $K_2Ni(MoO_4)_2$ in view of
the condensation of magnetic excitations in a broad parameter regime. Finally,
we comment on a geometrical peculiarity of the proposed model and discuss
how it could host a supersolid phase upon structural distortions.

TT 30.12   Wed 12:30   HSZ 204

The crucial influence of side groups on magnetic superexchange - a modification of the Goodenough-Kanamori-rules — Dijana Milosavljevic[1],
Oleg Janson[2], Stefan-Ludwig Drechsler[2], and •Helge Rosner[3] — [1]Max-
Planck-Institut für Mikrostrukturphysik, 06120 Halle, Germany — [2]IFW Dresden, 01069 Dresden, Germany — [3]Max-Planck-Institut für Chemische Physik
fester Stoffe, 01187 Dresden, Germany
According to the famous Goodenough-Kanamori-Anderson rules, the key structural feature that determines the magnetic exchange coupling constant for superexchange in magnetic insulators is the magnetic ion-ligand-magnetic ion
bond angle. Here, we demonstrate that this angle is not the only determining
factor. An at least equally important influence on the exchange coupling has
the presence of side groups attached to the ligands. Applying density functional
calculations and subsequently derived realistic parameters for a multiband tight-
binding model, we provide a quantitative analysis for the example case of edge-
sharing Cu-O chains with bond angles near 90 degrees. We find that a single
parameter, the difference in onsite-energies of the ligand orbitals parallel and

perpendicular to the Cu-O chain, is at least as important as the bond angle for sign and size of the superexchange. This parameter strongly depends on the position of side groups outside the superexchange pathway. For a fixed bond angle, changes of a side group position, only, can cause changes in the superexchange of several hundred Kelvin and thus dramatic changes in the magnetic properties.

TT 30.13　Wed 12:45　HSZ 204

A consistent microscopic magnetic model of the edge-sharing chain cuprate $CuSiO_3$ — •Dijana Milosavljevic[1,2], Andrei Gippius[3], Oleg Janson[4], Michael Baenitz[1], Yurii Prots[1], Johannes Richter[5], and Helge Rosner[1] — [1]MPI for Chemical Physics of Solids, Dresden — [2]MPI of Microstructure Physics, Halle — [3]Moskow, Russia — [4]IFW, Dresden — [5]MPI Physics of Complex Systems, Dresden

A unique place in the family of low-dimensional magnets occupies the Cu^{2+} compounds featuring a series of square-planar CuO_4 plaquettes connected via their edges, forming in this way a chain. The edge-shared plaquettes in Li_2CuO_2 show ferromagnetic ordering [1], whereas similar chains with increased Cu-O-Cu bond angle bridging neighboring Cu atoms in $CuGeO_3$, undergo a spin-Peierls transition [2]. A compound with a Cu-O-Cu angle essentially identical to the one in Li_2CuO_2 and isostructural to the famous Spin-Peierls system $CuGeO_3$ is spin-1/2 cuprate $CuSiO_3$ [3]. In a combined experimental-theoretical approach, we derive a new magnetic model of $CuSiO_3$, consistent with all reported experimental results.

TT 31: Topology: Majorana Physics

Time: Wednesday 9:30–12:45　　　　　　　　　　　　　　　　　　　　　　　　　　　　　Location: HSZ 304

TT 31.1　Wed 9:30　HSZ 304

Photonic noise as a probe of Majorana bound states — •Lena Bittermann[1], Fernando Dominguez[1], and Patrik Recher[1,2] — [1]Institut für Mathematische Physik, Technische Universität Braunschweig, D-38106 Braunschweig, Germany — [2]Laboratory for Emerging Nanometrology Braunschweig, D-38106 Braunschweig, Germany

We propose a route to detect Majorana bound states (MBSs) by coupling a topological superconductor to a quantum dot (QD) in a pn-junction. Here, two MBSs are coherently coupled to electrons on the QD, which recombine with holes in situ to photons. Importantly, the polarization of the emitted photons provides direct information on the spin structure [1,2] and nonlocality [2,3] of the MBSs. Here, we focus on the shot noise of the emitted photons which allows to clearly distinguish the cases of well separated MBSs at zero energy from overlapping MBSs. In addition, we show that quasiparticle poisoning changes the shot noise from super-Poissonian to sub-Poissonian [4]. Furthermore, this setup can be extended by coupling a second QD close to the second MBS which gives rise to nonlocal shot noise correlations leading to additional signatures of MBSs.

Statistical Majorana bound state spectroscopy — •Alexander Ziesen[1], Alexander Altland[2], Reinhold Egger[3], and Fabian Hassler[1] — [1]JARA Institute for Quantum Information, RWTH Aachen University, Aachen, Germany — [2]Institut für Theoretische Physik, Universität zu Köln, Köln, Germany — [3]Institut für Theoretische Physik, Heinrich-Heine-Universität, Düsseldorf, Germany

Tunnel spectroscopy data for the detection of Majorana bound states (MBS) is often criticized for its proneness to misinterpretation of genuine MBS with low-lying Andreev bound states. Here, we suggest a protocol removing this ambiguity by extending single shot measurements to sequences performed at varying system parameters. We demonstrate how such sampling, which we argue requires only moderate effort for current experimental platforms, resolves the statistics of Andreev side lobes, thus providing compelling evidence for the presence or absence of a Majorana center peak.

TT 31.3　Wed 10:00　HSZ 304

Disentanglement, disorder lines, and Majorana edge states in a solvable quantum chain — Gennady Y. Chitov[1], •Karun Gadge[2,3], and Pavel N. Timonin[4] — [1]Département de Physique, Institut Quantique, Université de Sherbrooke, Sherbrooke, Québec J1K 2R1, Canada — [2]Institute for Theoretical Physics, Georg-August-University Göttingen, Friedrich-Hund-Platz 1, D-37077 Göttingen, Germany — [3]School of Basic Sciences, Indian Institute of Technology Mandi, Mandi 175005, India — [4]Rostov-on-Don, Russia

We study the exactly solvable one-dimensional model: the dimerized XY chain with uniform and staggered transverse fields, equivalent upon fermionization to the noninteracting dimerized Kitaev-Majorana chain with modulation. The criticality is controlled by the properties of zeros of model's partition function, analytically continued onto the complex wave numbers. In the ground state they become complex zeros of the spectrum of the Hamiltonian. The analysis of those roots yields the phase diagram which contains continuous quantum phase transitions and weaker singularities known as disorder lines (DLs) or modulation transitions. The salient property of zeros of the spectrum is that the ground state is shown to be separable (factorized), and the model is disentangled on a subset of the DLs. From analysis of those zeros we also find the Majorana edge states and their wave functions. Reference: PRB 106, 125146 (2022)

TT 31.4　Wed 10:15　HSZ 304

Unifying the theoretical description of Andreev, Majorana, quasi-Majorana bound states — •Pasquale Marra[1,2] and Angela Nigro[3] — [1]Graduate School of Mathematical Sciences, The University of Tokyo, 3-8-1 Komaba, Meguro, Tokyo 153-8914, Japan — [2]Department of Physics, and Research and Education Center for Natural Sciences, Keio University, 4-1-1 Hiyoshi, Yokohama, Kanagawa 223-8521, Japan — [3]Dipartimento di Fisica 'E. R. Caianiello', Università degli Studi di Salerno, 84084 Fisciano (Salerno), Italy

In one-dimensional topological superconductors systems, zero-energy Majorana edge modes localize at the domain walls between topologically distinct phases, similar to the case of Jackiw-Rebbi solitons, which are solutions of the Majorana-Dirac equation on an inhomogeneous background. On the other hand, topologically trivial Andreev states below the particle-hole gap can originate from disorder or spatial inhomogeneities. Distinguishing between Majorana and Andreev states is an ongoing challenge that generated intense debate in the scientific community. Indeed, there is a continuous crossover between topologically nontrivial Majorana and trivial Andreev states induced by smooth inhomogeneities, which can occur without closing the bulk gap. Here, we describe nontrivial Majorana and Andreev bound states induced by spatial inhomogeneities and disorder, Shockley states, and Jackiw-Rebbi solitons in a unifying framework, introducing a characteristic length scale that can unambiguously distinguish between different regimes.

TT 31.5　Wed 10:30　HSZ 304

Majorana zero modes in fermionic wires coupled by Aharonov-Bohm cages — •Niklas Tausendpfund[1,2], Sebastian Diehl[2], and Matteo Rizzi[1,2] — [1]Peter Grünberg Institut 8, Forschungszentrum Jülich, Germany — [2]Institute for Theoretical Physics, University of Cologne, Germany

We devise a number-conserving scheme for the realization of Majorana Zero Modes in an interacting fermionic ladder coupled by Aharonov-Bohm cages. The latter provide an efficient mechanism to cancel single-particle hopping by destructive interference. The crucial parity symmetry in each wire is thus encoded in the geometry of the setup, in particular, its translation invariance. A generic nearest-neighbor interaction generates the desired correlated hopping of pairs. We exhibit the presence of an extended topological region in parameter space, first in a simplified effective model via bosonization techniques, and subsequently in a larger parameter regime with matrix-product-states numerical simulations. We demonstrate the adiabatic connection to previous models, including exactly-solvable ones, and we briefly comment on possible experimental realizations in synthetic quantum platforms, like cold atomic samples.

Tunable coupling of quantum dots via Andreev bound states - towards a Kitaev chain — Chun-Xiao Liu, Guanzhong Wang, Tom Dvir, and •Michael Wimmer — Qutech and Kavli Institute for nanophysics, TU Delft, Niederlande

We show that the coupling between two quantum dots can be effectively mediated by Andreev bound states in a central superconducting segment. This gives rise to an effective superconducting and normal coupling between quantum dot states. Both coupling strengths can be independently controlled by changing the properties of the Andreev bound states, e.g. by a gate voltage. This allows to implement a Kitaev chain that can easily be tuned to a topological phase [1]. We will also discuss first experimental results implementing a two-site Kitaev chain [2, 3].

Odd-frequency pairing in Floquet topological superconductors — •Eslam S. Ahmed, Shun Tamura, and Yukio Tanaka — Department of Applied Physics, Nagoya University, Japan

Time-periodic (Floquet) Hamiltonians offer a unique and tunable way to engineer topological systems with intriguing edge modes. In particular, Floquet superconductors can possess multi-Majorana edge modes at energies $E = 0$ and $E = \pi$.

It is well-established that there is a direct relationship between odd-frequency Cooper pairing amplitudes and the topological invariants in the static superconductors. In our study, we discuss this relationship in the time-periodic regime.

We consider a Kitaev chain alternating in time between two different values for chemical potential. By tuning the time-periodicity of the alternating chemical potential, we show that the chain admits multiple zero and π energy Majorana modes at the edge of the chain. Furthermore, We show that odd-frequency Cooper pairing amplitude at the edge of the chain is correlated to the presence of Zero and π Majorana modes.

Phase diagram of an extended parafermion chain — Jurriaan Wouters[1], Fabian Hassler[2], Hosho Katsura[3], and •Dirk Schuricht[1] — [1]Institute for Theoretical Physics, Center for Extreme Matter and Emergent Phenomena, Utrecht University — [2]JARA-Institute for Quantum Information, RWTH Aachen University — [3]Department of Physics, Graduate School of Science, The University of Tokyo

We study the phase diagram of an extended parafermion chain, which, in addition to terms coupling parafermions on neighbouring sites, also possesses terms involving four sites. Via a Fradkin–Kadanoff transformation the parafermion chain is shown to be equivalent to the non-chiral $\mathbb{Z}_3$ axial next-nearest neighbour Potts model. We discuss a possible experimental realisation using heteronanostructures. The phase diagram contains several gapped phases, including a topological phase where the system possesses three (nearly) degenerate ground states, and a gapless Luttinger-liquid phase.

TT 31.10   Wed 12:00   HSZ 304

Multiplicative Majorana zero modes — •Adipta Pal — Max Plank Institute for the Physics of Complex Systems, Dresden, Germany

Topological qubits composed of unpaired Majorana zero-modes are under intense experimental and theoretical scrutiny in efforts to realize practical quantum computation schemes. In this work, we show the minimum four 'unpaired' Majorana zero-modes required for a topological qubit according to braiding schemes and control of entanglement for gate operations are inherent to multiplicative topological phases, which realize symmetry-protected tensor products—and maximally-entangled Bell states—of unpaired Majorana zero-modes known as multiplicative Majorana zero-modes. We introduce multiplicative Majorana zero-modes as topologically-protected boundary states of both one and two-dimensional multiplicative topological phases, using methods reliant on multiplicative topology to construct relevant Hamiltonians from the Kitaev chain model. We furthermore characterize topology in the bulk and on the boundary with established methods while also introducing techniques to overcome challenges in characterizing multiplicative topology. In the process, we explore the potential of these multiplicative topological phases for an alternative to braiding-based topological quantum computation schemes, in which gate operations are performed through topological phase transitions.

TT 31.11   Wed 12:15   HSZ 304

Controlling Majorana modes via Fulde-Ferrell-Larkin-Ovchinnikov phases in topological superconductors and superfluids — •Pasquale Marra[1,2], Daisuke Inotani[2], Takeshi Mizushima[3], and Muneto Nitta[2] — [1]Graduate School of Mathematical Sciences, The University of Tokyo, 3-8-1 Komaba, Meguro, Tokyo 153-8914, Japan — [2]Department of Physics, and Research and Education Center for Natural Sciences, Keio University, 4-1-1 Hiyoshi, Yokohama, Kanagawa 223-8521, Japan — [3]Department of Materials Engineering Science, Osaka University, Toyonaka, Osaka 560-8531, Japan

The next milestones in the route to topological quantum computation with Majorana modes are demonstrating their nonabelian braiding statistics and realizing Majorana-based topological qubits. To achieve this, most proposals require the manipulation of electric gates or magnetic fields in networks of proximitized semiconducting nanowires. Here, we focus on an alternative platform to obtain Majorana modes by employing inhomogeneous Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) phases in topological superconductors and superfluids. The FFLO state spontaneously breaks translational symmetry, inducing a periodic and spatial modulation of the superconducting pairing. We explore the interplay between FFLO order, nontrivial topology, and emergent quantum-mechanical supersymmetry and consider possible routes to realize nonabelian braiding in these platforms.

TT 31.12   Wed 12:30   HSZ 304

Time-reversal invariant topological superconductor in the Coulomb blockade regime — •Steffen Bollmann[1], Elio König[1], and Jukka Väyrynen[2] — [1]Max Planck Institute for Solid State Research, Stuttgart — [2]Purdue University, West Lafayette, Indiana USA

Floating topological superconductors coupled to conduction electrons can realize unconventional O(N), Sp(2N), or multi-channel Kondo effects. Here, we introduce a new topological superconducting mesoscopic device, a time-reversal invariant version of the Majorana Cooper pair box in the Coulomb blockade regime. In this setup of Cartan-Altland-Zirnbauer class DIII, spinful Majorana zero modes appear at the edges of a topological triplet superconductor with fluctuating Cooper pair spin and charge. We study the Kondo effect in the limit of dominating charging energy and in the limit of both small and large spin fluctuations. Beyond its value in the context of exotic mesoscopic Kondo effects, our study sheds light on the intricate interplay of band topology and strong quantum fluctuations of non-Abelian order parameter fields.

TT 32: Molecular Electronics and Excited State Properties (joint session CPP/TT)

Strong Solvatochromism in a Two Metal Center Photocatalyst Molecule — •Miftahussurur Hamidi Putra[1] and Axel Gross[1,2] — [1]Universität Ulm Institut für Theoretische Chemie Mez-Starck-Haus Oberberghof 7 89081 Ulm Deutschland — [2]Helmholtz Institute Ulm (HIU) Electrochemical Energy Storage, 89069 Ulm, Deutschland

In the theoretical study presented here, we show that the electronic and optical properties of a molecular photocatalyst can strongly depend on the solvent it is dissolved in [1]. Ground-state density functional theory and linear response time dependent density functional theory calculations are applied in order to investigate the influence of implicit solvents on the structural, electronic and optical properties of a two metal center molecular photocatalyst $[(tbbpy)_2Ru(tpphz)PtI_2]^{2+}$ (RuPtI$_2$) [2]. These calculations predict a significant dependence of the HOMO-LUMO gap of the photocatalyst on the dielectric constant of the solvent. We elucidate the electronic origins of this strong solvatochromic effect and sketch the consequences of these insights for the use of photocatalysts in different environments.

Dynamic Charge-Transport and Charge-Transfer Regimes for Electron-Phonon-Coupled Molecular Systems — •Michel Panhans, Sebastian Hutsch, and Frank Ortmann — Department of Chemistry, TU München

Different approaches for charge transport in organic solids exist but they differ significantly in the described physics of the electron-phonon coupling. In our recent work, we investigate the charge-transfer dynamics, the fading of transient localization (TL) and the formation of polarons for a large range of vibration frequencies and temperatures in the phase space of the two-site Holstein model. The combined numerical and analytical method is based on the time-domain Kubo formula of electrical conductivity to describe the highly correlated

electron-phonon dynamics from femtoseconds to very large time scales, reaching nanoseconds. We identify three charge-transport regimes, which are TL, soft gating, and polaron transport. Of particular interest is the built up of correlations between the electronic motion and the nuclei manifesting in the crossover between TL and polaron transport. We find, that the transition between these two limiting cases is seamless at all temperatures and all adiabatic ratios even for the low-frequency vibrational modes that were often considered to be frozen.

TT 32.3   Wed 10:00   GÖR 226

Multichromophore Macrocycles of Perylene Bisimide Dyes as Fluorescent OLED Emitters — •Björn Ewald[1], Ulrich Müller[1], Peter Spenst[2], Philipp Kagerer[1], Theodor Kaiser[1], Matthias Stolte[2], Frank Würthner[2], and Jens Pflaum[1] — [1]Experimental Physics VI, University of Würzburg, 97074 Würzburg — [2]Institut für Organische Chemie and Center for Nanosystems Chemistry, University of Würzburg, 97074 Würzburg

Highly efficient electroluminescence from Organic Light Emitting Diodes (OLEDs) is limited by the non-radiative character of triplet states for conventional fluorophores. While fluorescent emitters benefit from high radiative recombination rates on the order of 10^9 s^{-1}, they lack from dark triplet states with lifetimes up to several μs or ms. Here we elucidate the potential of perylene bisimide macrocycles as a novel class of fluorescent OLED emitters by applying photon-correlation studies. The correlation experiments unfold additional excitonic relaxation pathways shortening the dark state lifetime for the covalently linked perylene bisimide chromophores. A trimeric chemical design leads to efficient single-photon emission from optically excited thin film samples and even under electrical operation in OLEDs. To the best of our knowledge this is the first indication of electrically-driven single-photon emission from a fluorescent molecule [1]. Therefor we consider our work to constitute an important step towards the design of state-of-the art fluorescent OLED emitters that might also feature a high potential for application in non-calssical single-photon sources.

TT 32.4   Wed 10:15   GÖR 226

A Tool Kit for Analyzing Emission Spectra of Multi-Molecular States — •Sebastian Hammer[1,4], Theresa Linderl[2], Kristofer Tvingstedt[1], Wolfgang Bruetting[2], and Jens Pflaum[1,3] — [1]Experimental Physics VI, University of Würzburg, 97074 Würzburg — [2]Institute of Physics, University of Augsburg, 86135 Augsburg, Germany — [3]Bayerisches Zentrum für Angewandte Energieforschung (ZAE Bayern), 97074 Würzburg — [4]Departments for Physics and Chemistry, McGill University, Montreal, Canada

The performance of opto-electronic devices is often crucially impacted by multi-molecular excited states such as charge-transfer (CT) states or excimers. Hence, the spectroscopic analysis of these states is a common tool in the characterization of such systems. Due to the many parameters at play full quantum mechanical interpretations are tedious and therefore the analysis is often performed on a phenomenological level only. Here we present a tool kit to analyze temperature dependent emission spectra using a Franck-Condon based approach with a single effective inter-molecular vibrational mode and discuss the implications of considering different potentials for the ground and excited state harmonic oscillators [1]. Finally, we show that fundamental parameters of the potential energy landscape can be extracted from temperature dependent steady state emission spectra using the example of a tetraphenyldibenzoperiflanthene:C_{60} CT heterostructure [2]. Funding from the DFG (Project 490894053) is greatfully acknowledged.

Singlet Fission search in polyacene molecules in gas-phase and on rare-gas clusters using ab initio methods — •Selmane Ferchane and Michael Walter — Institute of Physics, University of Freiburg, Germany

Singlet fission (SF), is a spontaneous photo-excited splitting phenomenon. Where an organic chromophore dimer, converts its singlet exciton into a pair of triplet excitons. A great promise for future photon-to-current conversion of solar energy using organic materials with high efficiency. To get more insight into these processes of SF, we employed different ab initio theories and approaches in our investigation, namely, density functional theory (DFT), TD-DFT, MCTDH, and CASPT2/CASSCF. Since the spatial orientation is crucial to whether the molecule will go SF and the rate of it due to the orbital coupling of both molecules, based on recent studies. We calculate the most favorable orientation of the chromophores with the binding energies in the gas phase and adsorbed on Argon and Neon surfaces. Then we calculate the lowest-lying excited states that contribute to the singlet and triple transition plus the search for the possible conical intersection that crosses the surface potential energies.

TT 32.6   Wed 10:45   GÖR 226

Template-Designed Organic Electronics — •Klaus Meerholz — Chemistry Department, University of Cologne, Greinstr. 4-6, 50939 Cologne, Germany

Worldwide, organic electronic devices such as OLEDs and solar cells have rev-

olutionized the field of electronics; however, technological progress has been largely made by empirical research and development, while fundamental knowledge is often still incomplete.

This presentation will report results from the DFG-funded Research Training Group Template-Designed Organic Electronics addressing the question, how structural order influences the optoelectronic properties of pi-conjugated materials, and how these properties can be improved via the use of templates for the optimization of devices. Our approach spans all the way from the design of appropriate pi-conjugated molecular building blocks and surface-active templates, investigation of surfaces and interfaces by different spectroscopies, fabrication of optoelectronic devices, and finally theoretically modelling.

TT 32.7   Wed 11:00   GÖR 226

Optically detected magnetic resonance of TADF OLED emitters — •Pascal Schady, Mona Löther, Fabian Binder, Vladimir Dyakonov, and Andreas Sperlich — Experimental Physics VI, Julius Maximilian University of Würzburg, 97074 Würzburg

Thermally activated delayed fluorescence (TADF) is an efficient triplet harvesting mechanism for organic light-emitting diodes (OLED). Molecular TADF Donor-Acceptor type emitters are limited by low reverse intersystem crossing (rISC) rates and broad spectra, making them less suitable for potential OLED devices. In contrast, so-called multiple resonance (MR) effect emitters, are very promising as they show narrowband emission, even for deep blue wavelengths. MR-TADF emitters consist mostly of planar and rigidly bound benzyl groups with boron and nitrogen substituents for HOMO and LUMO pinning. As a result, the exchange integral is small, therefore the energy gap between singlet and triplet states is low enough to efficiently populate emissive singlet states by up-converting long-lived triplet states via thermal excitation, even at room temperature. However, many MR-TADF materials, like the DABNA-series behave differently in solution or as a solid. We therefore are investigating the spin system of those emitters by optically detected magnetic resonance (ODMR) in order to shed light on spin-dependent efficiency limiting pathways and how to address them to improve future OLED devices.

TT 32.8   Wed 11:30   GÖR 226

Influence of Fluorination on the Temperature Dependent Optical Transition in β- Phase ZnPc Single Crystals — •Lisa Schraut-May[1], Kilian Strauss[1], Sebastian Hammer[2], Kilian Frank[3], Bert Nickel[3], and Jens Pflaum[1] — [1]Experimental Physics VI, University of Würzburg — [2]Departments of Physics and Chemistry, McGill University, Montreal, Canada — [3]Department of Physics, LMU Munich

The possibility of fluorination renders zinc phthalocyanine (ZnPc) an excellent model system to study the interplay between molecular packing and optoelectronic properties [1]. Here, we conduct temperature as well as polarisation dependent photoluminescence (PL) studies on β-phase ZnPc single crystals with different degrees of fluorination to modify the microscopic packing and, thus, the interaction between the molecules. For plain ZnPc an exceptionally sharp PL peak can be observed at temperatures below 100 K, which can be attributed to a superradiant enhancement [2]. Since this coherent coupling between several molecules strongly depends on the intermolecular spacing, we show, that this phenomenon can be steered by the fluorination of the molecules involved. We interpret the resulting PL signal and its temperature dependence in combination with X-ray studies by a model based on coupled excitons whose coupling is affected by the spatial anisotropy of the thermal contraction of the crystal lattice.

We thank the Bavarian research network SolTech for financial support. [1] Rödel et al., J. Phys. Chem. C (2022) [2] Hestand et al., Chem. Rev. (2018)

Charge Delocalization and Vibronic Couplings in Quadrupolar Squaraine Dyes — Daniel Timmer[1], Fulu Zheng[2], Moritz Gittinger[1], Thomas Quenzel[1], •Daniel C. Lünemann[1], Katrin Winte[1], Yu Zhang[3], Mohamed E. Madjet[2], Jennifer Zablocki[4], Arne Lützen[4], Jin-Hui Zhong[1], Antonietta De Sio[1], Thomas Frauenheim[2], Sergei Tretiak[3], and Christoph Lienau[1] — [1]University of Oldenburg, Germany — [2]University of Bremen, Germany — [3]Los Alamos National Laboratory, USA — [4]University of Bonn, Germany

Squaraines are prototypical quadrupolar charge-transfer chromophores. Their optical properties are often rationalized using an essential state model, predicting that optical transitions to the lowest excited state (S1) are one-photon allowed and to the next higher state (S2) are only two-photon-allowed and that vibronic coupling to high-frequency modes is greatly reduced. Here, we combine time-resolved spectroscopy techniques and quantum-chemical simulations to test and rationalize these predictions. We find the one-photon-allowed S1 and two-photon-allowed S2 states to be energetically well-separated. Also, we find small Huang-Rhys factors, especially for the high-frequency modes. The resulting concentration of the oscillator strength in a narrow spectral region around the S1 transition makes squaraines almost perfect optical two-level. Thus, these

molecules and their aggregates are exceptionally interesting for e.g. strong coupling applications. [1]: Timmer, Daniel, et al., J. Am. Chem. Soc., 144, 41, 19150-19162 (2022)

In-operando observation of polaron formation in SAMFETs using NEXAFS spectroscopy — Manuel Johnson, •Andreas Späth, Baolin Zhao, Marcus Halik, and Rainer H. Fink — FAU Erlangen-Nürnberg, Erlangen, Germany

We present an in-operando near-edge x-ray absorption fine structure (NEXAFS) study on p-type BTBT-based self-assembled monolayer (BTBT-SAM) films. As a 2D-model system, the BTBT-SAM offers direct electron spectroscopic insight into the active organic semiconductor layer without interfering bulk contributions. This optimized geometry allows for the first time the observation of polaronic states caused by charged species at the dielectric/organic interface using a core-level spectroscopic tool. Linear NEXAFS dichroism is employed to derive the molecular orientation of the BTBT subunit. In addition to the conventional C K-edge NEXAFS resonances, we observe modifications in the density of unoccupied states. The spectral changes are affected by the strength and polarity of the applied gate voltage. Furthermore, the related energies match the energy levels of polaronic states. Thus, we have clear indications to interpret the data in the context of polaron formation due to charge accumulation induced by the applied electric field in our ultrathin device.[1] The study has been funded by the

DFG within GRK 1896 and the SolTECH initiative. [1] M. Johnson et al., Appl. Phys. Lett.121 (2022) 183503.

TT 33: Many-Body Quantum Dynamics (joint session DY/TT)

Time: Wednesday 9:30–13:00　　　　　　　　　　　　　　　　　　　　　　Location: MOL 213

Invited Talk　　　　　　　　TT 33.1　Wed 9:30　MOL 213

Many-body localization from Hilbert- and real-space points of view — •Ivan Khaymovich[1], Giuseppe De Tomasi[2], Frank Pollmann[3], and Simone Warzel[3] — [1]Nordic Institute for Theoretical Physics, Stockholm, Sweden — [2]University of Illinois Urbana-Champaign, USA — [3]Technical University Munich, Germany

Many-body localization (MBL), known as a generic mechanism to break quantum ergodicity, has been recently shown to be not the Hilbert-space Anderson localization. Instead, the MBL eigenstate occupies a fractal support [1-2], with extensive number of configurations. On the other hand, the well-established and accepted by the community picture of an emergent set of local integrals of motion [3] provides the structure of the MBL in the real space.

In this talk, I will provide the observable (later measured in the experiment [4]) which combines the fractality in the Hilbert space with the presence of local integrals of motion [2]. This observable, being the radial profile of the eigenstate over the Hamming distance, keeps the information about both the Hilbert-space fractal dimensions and the real-space localization lengths and uncovers the structure of these measures across the MBL transition. Phenomenological picture behind this behavior is consistent with the Kosterlitz-Thouless scenario of the MBL transition, suggested in the literature.

Bridging classical and quantum many-body information dynamics — •Andrea Pizzi[1,2], Daniel Malz[3,4], Andreas Nunnenkamp[5], and Johannes Knolle[6,4,7] — [1]Department of Physics, Harvard University, Cambridge 02138, Massachusetts, USA — [2]Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, United Kingdom — [3]Max-Planck-Institute of Quantum Optics, Hans-Kopfermann-Str. 1, 85748 Garching, Germany — [4]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany — [5]Faculty of Physics, University of Vienna, Boltzmanngasse 5, 1190 Vienna, Austria — [6]Department of Physics, Technische Universität München, James-Franck-Stra. 1, 85748 Garching, Germany — [7]Blackett Laboratory, Imperial College London, London SW7 2AZ, United Kingdom

The fundamental question of how information spreads in closed quantum many-body systems is often addressed through the lens of the bipartite entanglement entropy. Among its most striking features are unbounded linear growth in the thermodynamic limit, asymptotic extensivity in finite-size systems, and measurement-induced phase transitions. Here, we show that these key qualitative features emerge naturally also for the classical bipartite mutual information, the natural classical analogue of the quantum entanglement entropy. Key for this observation is treating the classical many-body problem on par with the quantum one, that is, explicitly accounting for the exponentially large probability distribution. Our analysis is supported by extensive numerics on prototypical cellular automata and Hamiltonian systems.

TT 33.3　Wed 10:15　MOL 213

Performance boost of a collective qutrit refrigerator — •Dmytro Kolisnyk[1] and Gernot Schaller[2] — [1]Jacobs University Bremen, Campus Ring 1, 28759 Bremen, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, 01328 Dresden, Germany

A single qutrit with transitions selectively driven by weakly-coupled reservoirs can implement one of the world's smallest refrigerators. We analyze the performance of N such fridges that are collectively coupled to the reservoirs. We observe a quantum boost, manifest in a quadratic scaling of the steady-state cooling current with N. As N grows further, the scaling reduces to linear, since the transitions responsible for the quantum boost become energetically unfavorable. Fine-tuned inter-qutrit interactions may be used to maintain the quantum boost for all N and also for not-perfectly collective scenarios.

TT 33.4　Wed 10:30　MOL 213

Hidden Phase of the Spin-Boson Model — •Florian Otterpohl[1,2], Peter Nalbach[3], and Michael Thorwart[2,4] — [1]Center for Computational Quantum Physics, Flatiron Institute, New York, New York 10010, USA — [2]I. Institut für Theoretische Physik, Universität Hamburg, Notkestraße 9, 22607 Hamburg, Germany — [3]Fachbereich Wirtschaft und Informationstechnik, Westfälische Hochschule, Münsterstraße 265 46397 Bocholt, Germany — [4]The Hamburg Centre for Ultrafast Imaging, Luruper Chaussee 149, 22761 Hamburg, Germany

A quantum two-level system immersed in a sub-Ohmic bath experiences enhanced low-frequency quantum statistical fluctuations which render the nonequilibrium quantum dynamics highly non-Markovian. Upon using the numerically exact time-evolving matrix product operator approach, we investigate the phase diagram of the polarization dynamics. In addition to the known phases of damped coherent oscillatory dynamics and overdamped decay, we identify a new third region in the phase diagram for strong coupling showing an aperiodic behavior. We determine the corresponding phase boundaries. The dynamics of the quantum two-state system herein is not coherent by itself but slaved to the oscillatory bath dynamics.

Exploring anomalies by many-body correlations — •Klaus Morawetz — Münster University of Applied Sciences, Stegerwaldstrasse 39, 48565 Steinfurt, Germany — International Institute of Physics- UFRN, Campus Universitário Lagoa nova,59078-970 Natal, Brazil

The quantum anomaly can be written alternatively into a form violating conservation laws or as non-gauge invariant currents seen explicitly on the example of chiral anomaly. By reinterpreting the many-body averaging, the connection to Pauli-Villars regularization is established which gives the anomalous term a new interpretation as arising from quantum fluctuations by many-body correlations at short distances. This is exemplified by using an effective many-body quan-

tum potential which realizes quantum Slater sums by classical calculations. It is shown that these quantum potentials avoid the quantum anomaly but approaches the same anomalous result by many-body correlations. A measure for the quality of quantum potentials is suggested to describe these quantum fluctuations in the mean energy. Consequently quantum anomalies might be a short-cut way of single-particle field theory to account for many-body effects. This conjecture is also supported since the chiral anomaly can be derived by a completely conserving quantum kinetic theory. [Eur. Phys. J. B 92 (2019) 176, Phys. Lett. A 383 (2019) 1362, Phys. Status Solidi B (2021) 2100316]

Non-Markovian Stochastic Schrödinger Equation: Matrix Product State Approach to the Hierarchy of Pure States — XING GAO[1], JIAJUN REN[2], ZHI-GANG SHUAI[2], and •ALEXANDER EISFELD[3] — [1]Sun Yat-sen University, Shenzhen, Guangdong, China — [2]Tsinghua University, Beijing, China — [3]MPI-PKS, Dresden

We derive a stochastic hierarchy of matrix product states (HOMPS) for non-Markovian dynamics in open quantum system at finite temperature, which is numerically exact and efficient. HOMPS is obtained from the stochastic hierarchy of pure states (HOPS) by expressing HOPS in terms of formal creation and annihilation operators. The resulting stochastic first order differential equation is then formulated in terms of matrix product states and matrix product operators. In this way the exponential complexity of HOPS can be reduced to scale polynomial with the number of particles. The validity and efficiency of HOMPS is demonstrated for the spin-boson model and long chains where each site is coupled to a structured, strongly non-Markovian environment.

TT 33.7   Wed 11:15   MOL 213

ultrafast gap dynamics near the zone boundary in a cuprate superconductor — •QINDA GUO, MACIEJ DENDZIK, MAGNUS BERNTSEN, CONG LI, WANYU CHEN, YANG WANG, DIBYA PHUYAL, and OSCAR TJERNBERG — Department of Applied Physics, KTH Royal Institute of Technology, Hannes Alfvéns väg 12, 114 19 Stockholm, Sweden

The time- and angle- resolved photoemission spectroscopy (tr-ARPES) is a powerful technique to directly probe the ultrafast electron dynamics in the momentum space. Our recently developed narrow-bandwidth tr-ARPES setup enabled us to access the ultrafast dynamics of the quasiparticle population as well as the superconducting gap, in the whole surface Brillouin zone of the photoexcited cuprate superconductor (Bi2212). The results show non-trivial dynamics at the d-wave antinode and provide new insights into the enigma of the Cooper-pair formation process and condensation that takes place in the high-temperature cuprate superconductor.

Controlling Many-Body Quantum Chaos — •LUKAS BERINGER[1], STEVEN TOMSOVIC[1,2], JUAN DIEGO URBINA[1], and KLAUS RICHTER[1] — [1]Institut für Theoretische Physik, Universität Regensburg, D-93040 Regensburg, Germany — [2]Department of Physics and Astronomy, Washington State University, Pullman, WA USA

Targeting in classical chaos control problems makes optimal use of the system's exponential instabilities to direct a given initial state to a predetermined final target state. A generalization to chaotic quantum systems in the semiclassical regime is possible [1], but also requires controlling an initially localized evolving quantum state's spreading. A coherent procedure of this kind enables directing highly excited, far-out-of-equilibrium states from an initial to some final target quantum state. Such methods have been successfully developed and applied to initially minimum uncertainty wave packets in a quantum kicked rotor system. The aim of our work is to extend those procedures to bosonic many-body systems. More specifically, we demonstrate how to make a localized quantum initial state follow special chaotic mean-field solutions of a Bose-Hubbard system toward an arbitrary localized target final state.

TT 33.9   Wed 12:00   MOL 213

Environment-induced decay dynamics of antiferromagnetic order in Mott-Hubbard systems — •GERNOT SCHALLER[1], FRIEDEMANN QUEISSER[1,2], NIKODEM SZPAK[3], JÜRGEN KÖNIG[3], and RALF SCHÜTZHOLD[1,2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, 01328 Dresden, Germany — [2]Institut für Theoretische Physik, Technische Universität Dresden, 01062 Dresden, Germany — [3]Fakultät für Physik and CENIDE, Universität Duisburg-Essen, Lotharstraße 1, 47057 Duisburg, Germany

We study the dissipative Fermi-Hubbard model in the limit of weak tunneling and strong repulsive interactions, where each lattice site is tunnel-coupled to a Markovian fermionic bath. For cold baths at intermediate chemical potentials, the Mott insulator property remains stable and we find a fast relaxation of the particle number towards half filling. On longer time scales, we find that the antiferromagnetic order of the Mott-Néel ground state on bipartite lattices decays, even at zero temperature. For zero and nonzero temperatures, we quantify the different relaxation time scales by means of waiting time distributions, which can be derived from an effective (non-Hermitian) Hamiltonian and obtain fully analytic expressions for the Fermi-Hubbard model on a tetramer ring.

TT 33.10   Wed 12:15   MOL 213

Arrow of time concept based on properties of Lanczos coefficients — •CHRISTIAN BARTSCH, MATS H. LAMANN, ROBIN HEVELING, LARS KNIPSCHILD, JIAOZI WANG, ROBIN STEINIGEWEG, and JOCHEN GEMMER — Fachbereich Physik, Universität Osnabrück, Barbarastraße 7, DE-49076 Osnabrück

We introduce an arrow of time concept based on a specifically defined class of arrow of time functions (ATF) consisting of a limited number of Krylov space generating observables. These ATF'S are found to be essentially monotonously decaying in time which is measured by some quantifying parameter. The ATF's are constructed to be upper bounds for pertinent autocorrelation functions. Employing certain features of the Lanczos coefficients and the wave package-like excitation moving on the Krylov chain, we find reasonable agreement with corresponding numerics.

TT 33.11   Wed 12:30   MOL 213

Fast Time-Evolution of Matrix-Product States using the QR decomposition — •JAKOB UNFRIED[1,2], JOHANNES HAUSCHILD[1], and FRANK POLLMANN[1,2] — [1]Department of Physics, TFK, Technische Universität München, James-Franck-Straße 1, D-85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany

Numerical simulations of quantum many-body dynamics in and out of equilibrium is essential for the understanding of a wide range of physical phenomena. Efficient matrix product state simulation techniques, such as time evolution block decimation (TEBD), are widely successful in extracting experimentally relevant signatures, such as dynamical correlation functions. We propose and benchmark a modified TEBD algorithm that uses a truncation scheme based on the QR decomposition instead of the singular value decomposition (SVD). The modification reduces the scaling with the dimension of the physical Hilbert space d from d^3 down to d^2. Unlike the SVD, the QR decomposition allows for highly efficient implementations on GPU hardware. In a benchmark simulation of a global quench in a quantum clock model, we observe a speedup of orders of magnitude comparing the QR based scheme on a GPU to the SVD based TEBD on CPU.

TT 33.12   Wed 12:45   MOL 213

Simulating infinite temperature spin dynamics by a dynamic mean-field theory — •TIMO GRÄSSER[1], KRISTINE REZAI[2], ALEXANDER O. SUSHKOV[2], and GÖTZ S. UHRIG[1] — [1]Condensed Matter Theory, TU Dortmund University, Otto-Hahn Straße 4, 44221 Dortmund, Germany — [2]Department of Physics, Boston University, Boston, MA 02215, USA

We develop a dynamic mean-field theory for spin systems at infinite temperature (spinDMFT) [1]. The idea is to replace the large environment of a spin by a dynamic mean-field which displays a random Gaussian temporal evolution. Its autocorrelations are self-consistently linked to the quantum mechanic expectation values of spin-spin correlations. This approach becomes exact in the limit of large lattice coordination numbers. We improve the approach by considering spin clusters quantum-mechanically (cluster spinDMFT). The extended model is able to describe dynamic spin correlations measured in recent experiments [2] where an inhomogeneous spin-$\frac{1}{2}$ ensemble on a diamond surface is probed using nitrogen-vacancy centers as sensors.

TT 34.1   Wed 11:30   HSZ 103

Efficient tuning of the superconductor BaNi$_2$As$_2$ by Calcium substitution - Single crystal Growth and Characterization — •Fabian Henssler, Kristin Willa, Mehdi Frachet, Tom Lacmann, Christoph Meingast, Michael Merz, Amir-Abbas Haghighirad, and Matthieu Le Tacon — Institut für Quantenmaterialien und Technologien, KIT Karlsruhe, Deutschland

BaNi$_2$As$_2$ is a highly tunable superconductor, which is non-magnetic and isostructural to the Fe-based parent compound BaFe$_2$As$_2$. Beyond superconductivity, recent publications reinforce the strong interplay between nematicity, charge density waves (CDW), and structural distortions [1,2,3]. At about 145 K, an incommensurate CDW forms, which coincides with a small lattice distortion ($\delta \sim 10^{-4}$) [4]. At slightly lower temperatures (T_S), the system undergoes a first-order transition, which can be suppressed e.g. by P- or Sr-substitution. Thereby, the superconducting transition temperature T_c can be enhanced by a factor of six [5]. In the case of Sr substitutions, however, a concentration as large as $x_{Sr} \sim 0.7$ is required. As an alternative, we report on the growth of Ca-substituted single crystals with Ca content up to $x_{Ca} \sim 0.1$. Specific heat and electrical transport measurements indicate that Ca is about eight times more efficient than Sr to suppress T_S.

Electronic theory for FFLO state in KFe$_2$As$_2$ superconductor — •Luka Jibuti and Ilya Eremin — Ruhr Universität Bochum, Bochum, Germany

Following the experimental observation of the Frude-Ferrel-Larnik-Ovchinnikov (FFLO) state in heavily hole-doped KFe$_2$As$_2$, we develop a microscopic theory of multi-orbital FFLO phase in this system, based on the microscopic low-energy model consisting of two Γ-centered hole pockets created by xz and yz orbitals and the sizeable spin-orbit coupling between them. We use the leading angular harmonics approximation (LAHA) to write down the general form of the interaction, that involves both s-wave and d-wave channels. By decomposing the interaction into s- and d-wave channels, employing the mean-field approximation and solving the self-consistent equations for the order parameters, we analyse the creation of the FFLO phase, with the appearance of the non-zero, symmetry preserving q vector for the nodal d-wave state and s-wave with accidental nodes. We also discuss the role of spin-orbit coupling and possible orbital FFLO state, discussed recently in the context of Ising superconductors.

TT 34.3   Wed 12:00   HSZ 103

Superconductivity of CaKFe$_4$As$_4$ under anisotropic strains — B. Zúñiga Céspedes[1], A. Valadkhani[2], S. Mandloi[1], M. Xu[3,4], J. Schmidt[3,4], S. L. Bud'ko[3,4], P. C. Canfield[3,4], A. P. Mackenzie[1,5], R. Valentí[2], and •E. Gati[1] — [1]MPI CPfS, 01187 Dresden, DE — [2]Inst. for Theor. Physics, Goethe University, 60438 FFM, DE — [3]Ames Lab, US DOE, Ames, IA 50011, USA — [4]Dept. of Physics and Astronomy, Iowa State Uni, Ames, IA 50011, USA — [5]Scottish Universities Physics Alliance, School of Physics and Astronomy, Uni of St Andrews, UK

CaKFe$_4$As$_4$ is an exceptional member of the family of Fe-based superconductors. First, it is a stochiometric superconductor at ambient pressure with high critical temperature $T_c \sim 35$ K. Second, this superconducting phase can be found in close proximity to a so-called hedgehog vortex magnetic order (SVC), which does preserve tetragonal symmetry. This is in contrast to the ubiquitous stripe-type magnetic order (SSDW) in the Fe-based superconductors that is accompanied by a vestigial nematic phase. Thus, CaKFe$_4$As$_4$ is an important testbed to

investigate the interplay of superconductivity with different magnetic orders and nematicity. Here, we will discuss the impact of anisotropic strains, which couple directly to the nematic order parameter, on superconductivity. To this end, we present measurements of T_c as well as results of DFT calculations of the stability of SVC vs. SSDW order under large strains. Our results support the notion that nematic fluctuations contribute to superconducting pairing in this high-T_c superconductor. *Funded through the SFB/TRR288 (Elasto-Q-mat).*

TT 34.4   Wed 12:15   HSZ 103

The resistive anisotropy of FeSe in the nematic state — •Clifford Hicks[1,2], Jack Bartlett[2], Alexander Steppke[2], Suguru Hosoi[3], Takasada Shibauchi[4], and Andrew Mackenzie[2] — [1]University of Birmingham, U.K. — [2]Max Planck Institute for Chemical Physics of Solids, Dresden — [3]Osaka University, Japan — [4]University of Tokyo, Japan

We employed strain tuning to adjust the degree of twinning of samples of FeSe. By doing so, we were able to measure the resistive anisotropy in the nematic state. The resistive anisotropy of the nematic state, along with the dependence of the resistivity and the superconducting critical temperature on biaxial strain suggest a strong role for the yz orbital in electronic scattering in FeSe.

TT 34.5   Wed 12:30   HSZ 103

The low-temperature specific heat and thermal expansion of YFe$_2$Ge$_2$ — •Pavlo Khanenko[1,2], Jiasheng Chen[2], Jacinta Banda[1], Thomas Luehmann[1], F. Malte Grosche[2], and Manuel Brando[1] — [1]Max Planck Institute for Chemical Physics of Solids, Germany — [2]Cavendish Laboratory, University of Cambridge, Cambridge, UK

We present specific heat and thermal expansion coefficient measurements of the layered iron-based superconductor YFe$_2$Ge$_2$ down to 40 mK and in magnetic field. A new generation of crystals [1] with residual resistivity ratios larger than 500 and $T_c = 1.2$ K have been investigated. These crystals display a sharp superconducting anomaly in both specific heat and thermal expansion. From the jump magnitudes and using the Ehrenfest relation we derive a small positive pressure dependence of T_c, $dT_c/dp = 24.4$ mK/GPa. Despite the high purity of the crystals, the residual Sommerfeld coefficient $\gamma_0 \approx 40$ mJ/K^{2}mol is relatively large, i.e., less than about half of the value in the normal state (100 mJ/K^{2}mol). The field dependences of $\gamma_0(B)$ and its respective coefficient in thermal expansion $\alpha_0(B)$ are analyzed within the frame of two gap scenario.

Spin-density-wave order and evidence for superconductivity in single-crystal LuFe$_2$Ge$_2$ — •Jiasheng Chen and F. Malte Grosche — Cavendish Laboratory, Cambridge, UK

The discovery of unconventional superconductivity in YFe$_2$Ge$_2$ [1, 2] has encouraged the search for more iron-based superconductors in the germanide family. The isostructural and isoelectronic compound, LuFe$_2$Ge$_2$, exhibits physical properties that closely resemble those of YFe$_2$Ge$_2$. Despite the additional spin-density-wave order observed below 9 K in LuFe$_2$Ge$_2$, the overall shape and magnitude of the resistivity and susceptibility above 10 K, and the similarly enhanced Sommerfeld coefficient $C/T > 70$ mJ/molK^2 suggest a similar underlying physics in the two systems [3]. Using the liquid transport flux growth method [2], we investigated the effect of changing growth conditions on the crystal quality and on the spin-density-wave order in LuFe$_2$Ge$_2$. In the best samples with RRR reaching 170, we observe evidence of superconductivity, making it the second iron-germanide superconductor discovered to date.

TT 35: Focus Session: Correlations in Moiré Quantum Matter I

Topological quantum phenomena and breakthroughs in time-resolved spectroscopy pose new challenges for many-body theory: Spatio-temporal electronic correlations often strongly impact topological and dynamical material properties but at the same time hinder an unambiguous interpretation of experiments, let alone a reliable quantitative prediction of material properties. Moiré quantum matter, i.e. systems where fundamental electronic properties and correlation phenomena emerge beyond the atomic scale exemplify these challenges. This Focus Session brings together the most recent developments in the field.

Organizers: Roser Valentí (Goethe-Universität Frankfurt) and Tim Wehling (Universität Hamburg)

Time: Wednesday 15:00–18:15   Location: HSZ 03

Invited Talk   TT 35.1   Wed 15:00   HSZ 03

Strongly correlated excitons in atomic double layers — •Phuong Nguyen[1], Liguo Ma[1], Raghav Chaturvedi[1], Kenji Watanabe[2], Takashi Taniguchi[2], Kin Fai Mak[1,3,4], and Jie Shan[1,3,4] — [1]School of Applied and Engineering Physics, Cornell University, Ithaca, NY, USA — [2]National Institute for Materials Science, Tsukuba, Japan — [3]Laboratory of Atomic and Solid State Physics, Cornell University, Ithaca, NY, USA — [4]Kavli Institute at Cornell for Nanoscale Science, Ithaca, NY, USA

Excitons (bound electron-hole pairs) in solids have been proposed as a platform to achieve high temperature Bose-Einstein condensation. The small exciton binding energy in conventional semiconductors has limited the condensation temperature to about 1 K. In the past several years, a new class of two-dimensional semiconductors with much larger exciton binding energy has emerged. In this talk, we discuss the development of transition metal dichacogenide double layer structures and electrical injection of interlayer excitons up to 10^{12} cm^{-2}. We establish electrical control of the chemical potential of interlayer excitons and probe their thermodynamic properties by capacitance measurements. We present experimental evidence for an excitonic insulating state and discuss the possibility of probing exciton superfluidity in the atomic double layer system.

Invited Talk   TT 35.2   Wed 15:30   HSZ 03

The Quantum Twisting Microscope — •Shahal Ilani — Weizmann Institute

In this talk I will present a fundamentally new type of scanning probe microscope, the Quantum Twisting Microscope (QTM), capable of performing local quantum interference measurements at a twistable interface between two quantum materials. Its working principle is based on a unique tip, made of an atomically-thin two-dimensional material. This tip allows electrons to coherently tunnel into a sample at many locations at once, with quantum interference between these tunneling events, making it a scanning electronic interferometer. With an extra twist degree of freedom, our microscope becomes a momentum-resolving local probe, providing powerful new ways to study the energy dispersions of interacting electrons. I will present various experiments performed with this microscope, demonstrating quantum interference at room temperature, probing the conductance of in-situ twisting interfaces, and imaging local energy dispersions in a variety of quantum materials.

Invited Talk   TT 35.3   Wed 16:00   HSZ 03

Light-driven phenomena in two-dimensional and correlated quantum materials — •Angel Rubio — Max Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, Germany — Center for Computational Quantum Physics Flatiron Institute, Simons Foundation, 10010 NY, USA

We will introduce our newly developed quantum electrodynamics density-functional formalism (QEDFT) as a first principles framework to predict, characterize and control the appearance of ordered phases of strongly interacting light-matter hybrid. We will pursue whether it is possible to create these new states of materials as ground-states of the system. To this end we will show how the emerging (vacuum) dressed states resembles Floquet states in driven systems. Strong light*matter coupling in cavities provides a pathway to break fundamental materials symmetries, like time-reversal symmetry in chiral cavities. We will discuss how to realize non-equilibrium states of matter that have so far been only accessible in ultrafast and ultrastrong laser-driven materials. We illustrate the realization of those ideas in molecules and 2D materials and show that the combination of cavity-QED and 2D twisted vdW heterostructures provides a novel and unique platform for the seamless realization of a plethora of interacting quantum phenomena, including exotic and elusive correlated and topological phases of matter.

15 min. break

Invited Talk   TT 35.4   Wed 16:45   HSZ 03

Cascade of transitions in twisted and non-twisted graphene layers within the van Hove scenario — •Laura Classen[1], Dmitry Chichinadze[2], Yuxuan Wang[3], and Andrey Chubukov[2] — [1]Max Planck Institute for Solid State Research, Stuttgart, Germany — [2]University of Minnesota, Minneapolis, USA — [3]University of Florida, Gainesville, USA

Fermions in layered graphene structures are described by both spin and valley degrees of freedom. Due to weak coupling between valleys, this can lead to an approximate SU(4) symmetry made from combined spin and valley transformations, which plays out differently depending on filling and interactions. Motivated by measurements of compressibility and STM spectra in twisted bilayer graphene, we analyze the pattern of symmetry breaking for itinerant fermions near a van Hove singularity. Making use of the approximate SU(4) symmetry of the Landau functional, we show that the structure of the order parameter changes with increasing filling via a cascade of transitions. We compute the feedback from different spin/valley orders on fermions and argue that each order splits

the initially 4-fold degenerate van Hove peak in a particular fashion, consistent with the STM data and compressibility measurements, providing a unified interpretation of the cascade of transitions in twisted bilayer graphene. Our results follow from a generic analysis of an SU(4)-symmetric Landau functional and are valid beyond a specific underlying fermionic model. We argue that an analogous van Hove scenario explains the cascade of phase transitions in non-twisted Bernal bilayer and rhombohedral trilayer graphene.

Invited Talk   TT 35.5   Wed 17:15   HSZ 03

Topology and strong correlation: From twisted bilayer graphene to the boundary zeros of Mott insulators — •Giorgio Sangiovanni[1], Niklas Wagner[1], Gautam Rai[2], Lorenzo Crippa[1], Tim Wehling[2], and Roser Valentí[3] — [1]Institut für Theoretische Physik und Astrophysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg — [2]I. Institut für Theoretische Physik, Universität Hamburg — [3]Institut für Theoretische Physik, Goethe-Universität Frankfurt am Main

Strong electronic correlations drive materials towards atomic-like Mott phases. How to topologically classify these many-body insulators is an open and highly debated question. In this talk I am going to start from twisted bilayer graphene, an example of the interplay between low-energy protection of single-particle eigenvalues and non-perturbative effects of electron-electron interactions. From this, I plan to move to a broader concept which has been spelled out in rather different ways in the recent literature: topological Mott insulators. Most of the proposed realizations rely either on Hartree-Fock approximations or on appropriately defined auxiliary degrees of freedom. I am going to present a novel, remarkably simple way of describing a topological Mott insulator without long-range order, based on the topological properties of their Green's function zeros in momentum space. After discussing the fate of the bulk-boundary correspondence in these systems, I will show how the zeros can be seen as a form of "topological antimatter" with distinctive features associated to the annihilation with conventional topologically protected edge modes.

     TT 35.6   Wed 17:45   HSZ 03

Transport and electron correlations in magic-angle twisted bilayer graphene: A dynamical mean field theory study — •Gautam Rai[1], Lorenzo Crippa[2], Giorgio Sangiovanni[2], Roser Valentí[3], and Tim Wehling[1] — [1]I. Institut für Theoretische Physik, Universität Hamburg, Hamburg, Germany — [2]Institute for Theoretical Physics and Astrophysics, Julius-Maximilians-Universität Würzburg, Würzburg, Germany — [3]Institut für Theoretische Physik, Goethe-Universität Frankfurt am Main, Frankfurt am Main, Germany

Fully characterising the low-temperature phase diagram of magic-angle twisted bilayer graphene (MATBG) has proven to be one of the most compelling challenges in recent condensed matter physics. Correlation effects dominate due to the flatness of the low-energy bands. By varying doping and temperature, one can tune between superconductor, correlated-insulator, and strange metal phases. It has been difficult to apply standard strong-correlation computational techniques because of a topological obstruction, which precludes the existence of exponentially localized, symmetry-preserving Wannier functions for the flat bands. Recently, a heavy Fermion model has been proposed that successfully treats the hybrid localised-delocalised nature of MATBG [1]. We apply dynamical mean field theory (DMFT) to the heavy Fermion model to describe electron correlation effects in MATBG. In particular, we demonstrate how filling commensurability affects transport at low temperatures.

     TT 35.7   Wed 18:00   HSZ 03

Moiré minibands of twisted MoS$_2$ heterostructures — •Chithra H. Sharma[1,2], Marta Prada[1], Jan-Hendrick Schmidt[1], Lars Tiemann[1], Tobias Stauber[3], Takashi Taniguchi[4], Kenji Watanabe[4], Robert Zierold[1], Kai Rossnagel[2], and Robert H. Blick[1,5] — [1]Universität Hamburg, Luruper Chaussee 149, 22761 Hamburg — [2]CAU Kiel, Leibnitzstrasse 19, 24118 Kiel — [3]ICMM-CSIC, Sor Juana Inés de la Cruz 3, Madrid 28049 Spain — [4]Research Center for Functional Materials, National Institute for Materials Science, Namiki 1-1, Tsukuba, 305-0044, Ibaraki, Japan — [5]Material Science and Engineering, University of Wisconsin-Madison, University Ave. 1550, Madison, 53706, Wisconsin, USA

In the last decade, the evolution of van der Waals material systems has provided a multitude of options to manipulate, control, and engineer materials properties to various needs by combination, proximity, and twisting. Moiré superlattices formed as a result of lattice mismatch or twist angle modify the electronic structure to create flat bands and host exotic correlated electron phases. Here we observe the existence of low-dispersing mini-bands near the conduction band edge of MoS$_2$ twisted devices. We employ transport measurements and resolve discrete states within the band gap at low temperatures, in agreement with first-principles density functional theory calculations. We could also infer that the mini-bands correspond to iso-spin flavors as a result of interaction in the system coherent with our temperature dependence.

TT 36: Topological Insulators

Time: Wednesday 15:00–17:45   Location: HSZ 103

TT 36.1   Wed 15:00   HSZ 103

In-plane magnetic field induced asymmetric magnetoconductance in topological insulator kinks — •Gerrit Behner[1,2], Abdur Rehman Jalil[1,2], Kristof Moors[1,2], Erik Zimmermann[1,2], Peter Schüffelgen[1,2], Detlev Grützmacher[1,2], and Thomas Schäpers[1,2] — [1]Peter Grünberg Institut (PGI-9), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]JARA-Fundamentals of Future Information Technology, Jülich-Aachen Research Alliance, Forschungszentrum Jülich and RWTH Aachen University, Germany

The study of the transport properties of quasi one-dimensional topological insulator (TI) nanostructures under the application of an in-plane magnetic field is crucial for the later realization of topological quantum computation building blocks. We present low temperature measurements of selectively grown TI-kinks under the application of an in-plane magnetic field. A dependence of the TI-kink resistance on the the in-plane magnetic field angle is visible in the magnetotransport data resulting in a π-periodic change of the conductance. This phenomenon originates from an orbital effect, leading to a periodic alignment of the phase-coherent states on the bottom and top surface of the topological insulator. Respectively, once the states are aligned an increased conductance in the device is observed. The measurement results are supported theoretically by an analysis of a surface Rashba-Dirac model and tight-binding calculations of an effective three-dimensional model.

TT 36.2   Wed 15:15   HSZ 103

Topological quantum chemistry with a twist — •Axel Fünfhaus, Marius Möller, and Roser Valentí — Goethe Uni Frankfurt, Frankfurt am Main, Germany

It is well known that many topological phases can be indicated by the symmetry behavior of their band structure at high symmetry points, which culminated in the development of topological quantum chemistry. This approach becomes problematic once interactions are added, as this does not permit conserved particle occupation numbers in reciprocal space. We face this challenge by generalizing the Brillouin zone for translation invariant many-body wave functions via a torus of twisted boundary conditions. This allows for a symmetry analysis of the ground state wave function in twisted boundary space. We apply this ansatz to detect topological phases in interacting Chern insulators and fractional Chern insulators as well as Mott insulating systems that cannot adiabatically be connected to atomic limits.

TT 36.3   Wed 15:30   HSZ 103

Phonon-induced breakdown of Thouless pumping in the Rice-Mele-Holstein model — •Suman Mondal, Eric Bertok, and Fabian Heidrich-Meisner — Institut für Theoretische Physik, Georg-August-Universität Göttingen, D-37077 Göttingen, Germany

Adiabatic and periodic variations of the lattice parameters can make it possible to transport charge through a system even without net external electric or magnetic fields, known as Thouless charge pumping. The amount of charge pumped in a cycle is quantized and entirely determined by the system's topology, which is robust against perturbations such as disorder and interactions. However, coupling to the environment may play a vital role in topological transport in many-body systems. In this talk, we will discuss the topological Thouless pumping, where the charge carriers interact with local optical phonons. The semi-classical multi-trajectory Ehrenfest method is employed to treat the phonon trajectories classically and charge carriers quantum mechanically. We find a breakdown of the quantized charge transport in the presence of phonons. It happens for any finite electron-phonon coupling strength at the resonance condition when the pumping frequency matches the phonon frequency, and it takes finite phonon coupling strength away from the resonance. Moreover, there exist parameter regimes with non-quantized negative and positive charge transport. The modified effective pumping path due to electron-phonon coupling accurately explains the underlying physics.

Large thermal Hall effect in a disordered topological insulator — •Rohit Sharma, Mahasweta Bagchi, Oliver Breunig, Yoichi Ando, and Thomas Lorenz — II. Physikalisches Institut, Universität zu Köln, Zülpicher Straße 77, D-50937 Köln, Germany

Topological insulators mother compounds (Bi_2Se_3, Bi_2Te_3) are notorious for their high thermoelectric figure of merit and to quantify that, they have been under scrutiny in the past for their longitudinal thermal transport. Surprisingly no attention has been paid on the transverse part of heat transport. Motivated by the recent findings of thermal Hall effect in some oxide and magnetic insulators[1], we have experimentally observed a large thermal Hall effect in disordered topological insulator $TlBi_{0.15}Sb_{0.85}Te_2$[2]. By comparing thermal conductivity κ_{xx} and thermal Hall effect κ_{xy} data with the electrical counterparts (σ_{xx} & σ_{xy}), we

study a possible influence of phonon drag on thermal transport. Electrical hall conductivity (σ_{xy}) shows multi-band behaviour in the whole temperature range (4-300K). Electronic contribution to thermal transport κ_e was calculated by using Wiedemann-Franz law and then compared with the measured thermal transport data, where it was found that both κ_{xx} and κ_{xy} shows phonon dominated behaviour. When compared κ_{xy} and κ_e, former shows an order of magnitude higher signal then the latter one.Possible reasons for large thermal Hall effect in $TlBi_{0.15}Sb_{0.85}Te_2$ will be discussed.

Mixed higher-order topology: boundary non-Hermitian skin effect induced by a Floquet bulk — •Hui Liu and Ion Cosma Fulga — Leibniz Institute for Solid State and Materials Research, Dresden

We show that anomalous Floquet topological insulators generate intrinsic, non-Hermitian topology on their boundary. As a consequence, removing a boundary hopping from the time-evolution operator stops the propagation of chiral edge modes, leading to a non-Hermitian skin effect. This does not occur in Floquet Chern insulators, however, in which boundary modes continue propagating. By evaluating the local density of states, we found that the resulting non-Hermitian skin effect is critical, i.e. scale-invariant, due to the nonzero coupling between the bulk and the edge. Further, it is a consequence of the nontrivial topology of the bulk Floquet operator, which we show by designing a real-space topological invariant. Our work introduces a form of 'mixed' higher-order topology, where a bulk system characterized by Floquet topology produces a boundary system characterized by non-Hermitian topology, without the need for any added perturbations. This opens an alternate direction in the study of topological classifications, and provides a route towards generating non-Hermitian skin effects by means of periodic driving.

PT-symmetric photonic topological insulator — •Alexander Fritzsche[1,2], Tobias Biesenthal[2], Lukas Maczewsky[2], Karolin Becker[2], Max Erhardt[2], Matthias Heinrich[2], Ronny Thomale[1], Yogesh Joglekar[3], and Alexander Szameit[2] — [1]Fakultät für Physik und Astronomie, Julius-Maximilians-Universität Würzburg, Würzburg, Germany — [2]Institut für Physik, University of Rostock, Rostock, Germany — [3]Department of Physics, Indiana University-Purdue University Indianapolis (IUPUI), Indianapolis, Indiana, USA

Gain and loss are characteristic features of open or non-Hermitian systems and lead, in general, to instable, exponentially increasing and decreasing states. However, these instabilities can be avoided when parity-time (PT) symmetry is added to such arrangements. Because of its unique properties it has been tried to combine PT symmetry with the unrivalled robustness of transport in topological insulators. In this work we propose and experimentally realize a periodically driven topological insulator with two counterpropagating boundary states where gain and loss are distributed not only spatially but also temporally using photonic waveguides as the experimental platform. Here, the periodic driving allows us to circumvent the problems that have so far hindered the combination of PT symmetry and topological insulators thereby providing the missing link between these two realms.

Time-reversal invariant finite-size topology — •Rafael Alvaro Flores Calderon, Roderich Moessner, and Ashley Cook — Max Planck Institut for the Physics of Complex Systems, Dresden,Germany

We report finite-size topology in the quintessential time-reversal (TR) invariant systems, the quantum spin Hall insulator (QSHI) and the three-dimensional, strong topological insulator (STI): previously-identified helical or Dirac cone boundary states of these phases hybridize in wire or slab geometries with one open boundary condition for finite system size, and additional, topologically-protected, lower-dimensional boundary modes appear for open boundary conditions in two or more directions. For the quasi-one-dimensional (q(2-1)D) QSHI, we find topologically-protected, quasi-zero-dimensional (q(2-2)D) boundary states within the hybridization gap of the helical edge states, determined from q(2-1)D bulk topology characterized by topologically non-trivial Wilson loop spectra. We show this finite-size topology furthermore occurs in 1T'-WTe2 in ribbon geometries with sawtooth edges, based on analysis of a tight-binding model derived from density-functional theory calculations, motivating experimental investigation of our results. In addition, we find quasi-two-dimensional (q(3-1)D) finite-size topological phases occur for the STI, yielding helical boundary modes distinguished from those of the QSHI by a non-trivial magneto-electric polarizability linked to the original 3D bulk STI.

Spectral functions of a topological Fermi-Hubbard model in one dimension — •David Mikhail and Stephan Rachel — School of Physics, University of Melbourne, Parkville, VIC 3010, Australia

We study the effects of electron-electron interactions on the charge excitation spectrum of the spinful Su-Schrieffer-Heeger model, a prototype of a one-dimensional bulk obstructed topological insulator. In light of recent progress in the fabrication of dopant-based quantum simulators we focus on experimentally detectable signatures of interacting topology in finite lattices. Importantly, these semiconductor platforms allow for local high-precision measurements using scanning tunnelling spectroscopy (STS). To this end we use Lanczos-based exact diagonalization to calculate the single-particle spectral function in real space which generalizes the local density of states to interacting systems. Its spatial and spectral resolution allows for the direct investigation and identification of edge states. While the non-trivial topology is manifested in zero-energy spin-like edge excitations for any finite interaction strength, our analysis of the spectral function shows that the single-particle charge excitations are gapped out on the boundary. Despite the loss of topological protection, we find that these edge excitations are quasiparticle-like as long as they remain within the bulk gap and as such serve as an indicating signature of the correlated topological phase measurable in single-particle measurement techniques such as STS. Our results are available at Phys. Rev. B 106, 195408 (2022).

TT 36.9   Wed 17:15   HSZ 103

Topological phases of one and two Su-Schrieffer-Heeger wires on a semiconducting substrate — •Keshab Sony[1], Anas Abdelwahab[2], and Eric Jeckelmann[3] — [1]Leibniz universität, Hannover, Germany — [2]Leibniz universität, Hannover, Germany — [3]Leibniz universität, Hannover, Germany

Atomic wires deposited on semiconducting substrates attracted lots of attention in the last two decades as a platform of quasi one-dimension (1D) properties. The Su-Schrieffer-Heeger (SSH) model is one of the simplest models that manifests the typical features of topological phases in quasi 1D characterized by topological invariant (winding number) and corresponding number of zero edge states. In this study, we consider models of one and two SSH wires coupled to semiconducting three-dimensional (3D) substrates and investigate the topological phases of these models with respect to the model parameters, eg. dimerization, wire-wire coupling, wire-substrate hybridization. The phase diagram of single wire coupled to the substrate shows stability of the existing phases without substrate but with changing effectively the wire parameters. We also address the issue of how the presence of the substrate change or preserve the phase diagrams of the two-leg ladders without substrate. We discuss the local density of states for different cases we consider.

TT 36.10   Wed 17:30   HSZ 103

Thermal diode effect in Dirac hybrid junctions — •Phillip Mercebach and Pablo Burset — Autonomous University of Madrid, Madrid, Spain

Thermo-electric devices are utilized for nano-scale refrigeration or to harness waste heat to produce electric power in electronic circuits. These devices usually require semiconductor materials or complex geometries to induce thermo-electric effects which may suffer from a narrow range of operation or poor efficiency. To counteract these shortcomings, we propose a simple device consisting of a ferromagnet (F) in proximity to a Dirac semi-metal (N) creating a ballistic NFN junction with a large operating window. We theoretically study the heat and electric currents through the junction and show strong Seebeck and Peltier effects arising from the Dirac physics and Klein tunneling in the ballistic junction. We use the device's high tunability to create a thermal diode allowing for refrigeration of a hot reservoir or for power production induced by a temperature gradient. Finally, we discuss refrigeration efficiency and the effective electron cooling temperature taking into account the phonon contribution in quasi-two-dimensional materials, like graphene or topological insulators.

Elastocaloric determination of the phase diagram of Sr_2RuO_4 — •You-Sheng Li[1], Markus Garst[2,3], Jörg Schmalian[3,4], Sayak Ghosh[5], Naoki Kikugawa[6], Dmitry Sokolov[1], Clifford Hicks[1,7], Fabian Jerzembeck[1], Matthias Ikeda[8], Zhenhai Hu[1], Brad Ramshaw[5], Andreas Rost[9], Michael Nicklas[1], and Andrew Mackenzie[1,9] — [1]Max Planck Institute for Chemical Physics of Solids — [2]Institut für Theoretische Festkörperphysik, Karlsruher Institut für Technologie — [3]Institut für Quantenmaterialien und -technologien, Karlsruher Institut für Technologie — [4]Institut für Theorie der Kondensierten Materie, Karlsruher Institut für Technologie — [5]Laboratory of Atomic and Solid State Physics, Cornell University — [6]National Institute for Materials Science — [7]School of Physics and Astronomy, University of Birmingham — [8]Department of Applied Physics, Stanford University — [9]School of Physics and Astronomy, University of St Andrews

Uniaxial pressure has shown the capabilities of tuning the electronic structures of Sr_2RuO_4 across a Van Hove singularity (VHS). By performing high precision ac-elastocaloric effect (ECE) measurements under uniaxial strain along <100> direction, we mapped out the phase diagram of Sr_2RuO_4 in detail. Similar to many unconventional superconductors, Sr_2RuO_4 has a SC dome in proximity to a magnetic phase. Besides, we observe a strong reversal of the ECE around the VHS upon entering the SC state. Together with a model calculation, these results strongly suggest a node-less gap opening at the VHS and, thus, put a strong constraint on possible SC order parameters.

TT 37.2   Wed 15:15   HSZ 201

High-resolution elastocaloric effect measurement of 110-Sr_2RuO_4 — •Zhenhai Hu[1,2], You-Sheng Li[1], Fabian Jerzembeck[1], Michael Nicklas[1], Andrew P. Mackenzie[1,2], and Clifford W. Hicks[1,3] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]Scottish Universities Physics Alliance, School of Physics and Astronomy, University of St Andrews, St Andrews, UK — [3]School of Physics and Astronomy, University of Birmingham, Birmingham, UK

The symmetry of the order parameter of superconducting Sr_2RuO_4 remains an undetermined question. Whether the order parameter has more than one component is still under debate. If the superconducting order parameter is degenerate and protected by lattice symmetry, the degeneracy will be lifted when the lattice symmetry is broken. Uniaxial pressure, which can continuously break the lattice symmetry, is thus a powerful tool to distinguish whether there is a degeneracy. However, the second transition was not observed in the previous heat capacity and elastocaloric effect measurements with strain applied along <100>. Although stringent constraints on the nature of superconducting states at zero strain were placed by the absence of the second transition with <100> strain, there remains a possibility that a second transition exists under <110> strain. Here we report the latest progress on elastocaloric measurement of Sr_2RuO_4 crystal with strain applied along <110>. Within our experimental precision, no signal indicating a second phase transition below T_c is observed.

TT 37.3   Wed 15:30   HSZ 201

Strain dependence of the superconducting state of Sr_2RuO_4 under <110> uniaxial pressure: No evidence for multi-component order parameter — •Fabian Jerzembeck[1], You-Sheng Li[1], Zhenhai Hu[1], Naoki Kikugawa[2], Dmitry Sokolov[1], Yoshiteru Maeno[3], Michael Niklas[1], Andrew Mackenzie[1], and Clifford Hicks[4] — [1]Max Planck Institute for Chemical Physics of Solids, D-01187 Dresden, Germany — [2]National Institute for Materials Science, Tsukuba 305-0003, Japan — [3]Department of Physics, Kyoto University, Kyoto 606-8502, Japan — [4]School of Physics and Astronomy, University of Birmingham, Birmingham B15 2TT, United Kingdom

After more than 25 years of intense research, the order parameter of the unconventional superconductor Sr_2RuO_4 is still unknown. Recent experiments suggest that the order parameter is even-parity and multi-component [1,2], which would result in distinct features in the strain dependence of the superconducting state, such as a kink in the strain dependence of T_c around zero strain [3]. Here, we present uniaxial pressure results along the crystallographic <110>-axis and find no evidence for a discontinuity in T_c, predicted for a multi-component order parameter. However, we can place tight constraints on the thermodynamics of several discussed two-component order parameters.

TT 37.4   Wed 15:45   HSZ 201

Giant lattice softening at a Lifshitz transition in the normal state of Sr_2RuO_4 — •Hilary M. L. Noad[1], Kousuke Ishida[1], You-Sheng Li[1], Veronika Stangier[2], Naoki Kikugawa[3], Dmitry A. Sokolov[1], Bongjae Kim[4], Igor I. Mazin[5], Markus Garst[2], Jörg Schmalian[2], Andrew P. Mackenzie[1,6], and Clifford W. Hicks[1,7] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]Karlsruhe Institute of Technology, Karlsruhe, Germany — [3]National Institute for Materials Science, Tsukuba, Japan — [4]Kunsan National University, Gunsan, Korea — [5]George Mason University, Fairfax, USA — [6]University of St Andrews, St Andrews, UK — [7]University of Birmingham, Birmingham, UK

The interplay between lattice and electronic degrees of freedom is a central theme in condensed matter physics. In Sr_2RuO_4, the quasi-two-dimensional Fermi surface can be tuned through a Lifshitz transition—a change in its topology—with

uniaxial pressure along the ⟨100⟩ direction. We investigated the influence of this electronic transition on the lattice by using a piezo-based uniaxial pressure cell to measure the stress-strain relation of Sr_2RuO_4 across the Lifshitz transition. We find a large and strongly temperature-dependent softening of the [100] Young's modulus at the Lifshitz transition. From thermodynamic arguments and comparison to a tight-binding model, we establish that the softening is indeed driven by conduction electrons.

TT 37.5　Wed 16:00　HSZ 201

Effect of superconductivity on the stress-strain relationships of Sr_2RuO_4 — •Kousuke Ishida[1], Hilary Noad[1], You-sheng Li[1], Veronika Stangier[2], Naoki Kikugawa[3], Dmitry Sokolov[1], Michael Nicklas[1], Markus Garst[2], Jörg Schmalian[2], Andrew Mackenzie[1,4], and Clifford Hicks[1,5] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]Karlsruhe Institute of Technology, Karlsruhe, Germany — [3]National Institute for Materials Science, Tsukuba, Japan — [4]University of St. Andrews, St. Andrews, United Kingdom — [5]University of Birmingham, Birmingham, United Kingdom

In the unconventional superconductor Sr_2RuO_4, applying uniaxial stress along a ⟨100⟩ crystalline direction induces a Lifshitz transition. Here we report on measurement of the stress-strain relationships across this transition down to temperatures below the superconducting transition. In the normal state, the Young's modulus softens by $\approx$ 10 % in the vicinity of the Lifshitz transition, indicating that this is a local maximum in the electronic free energy. We find that the onset of superconductivity causes a slight hardening of the lattice, though the electronic free energy remains a local maximum at the Lifshitz transition.

TT 37.6　Wed 16:15　HSZ 201

Effect of strain and momentum dependent spin-orbit coupling on the superconducting phase of Sr_2RuO_4 — •Jonas Hauck[1,2], Sophie Beck[1], Dante Kennes[2,3], Antoine Georges[1,4,5,6], and Olivier Gingras[1] — [1]Center for Computational Quantum Physics, Flatiron Institute, NY 10010, USA — [2]Institut für Theorie der Statistischen Physik, RWTH Aachen, 52056 Aachen, Germany and JARA - Fundamentals of Future Information Technology — [3]Max Planck Institute for the Structure and Dynamics of Matter, Center for Free Electron Laser Science, 22761 Hamburg, Germany — [4]Collège de France, 75005 Paris, France — [5]CPHT, CNRS, École Polytechnique, Institut Polytechnique de Paris, 91128 Palaiseau, France — [6]DQMP, Université de Genève, CH-1211 Genève, Switzerland

The nature of Sr_2RuO_4's superconducting order parameter is a long-standing puzzle. First proposed to be a triplet superconductor, the current preferred picture is that of a degenerate singlet order parameter. The main driving force behind this development is the unification of experimental measurements and theoretical predictions. In this talk, we will employ a functional renormalization group approach to first-principles derived tight binding models to study the behavior of the leading order parameter under strain. Additionally, we examine the influence of momentum dependent spin-orbit coupling. Our results suggest the possible pairing candidates should be restricted to combinations of a d-wave pseudospin singlet with another order parameter whose critical temperature is not influenced by strain.

TT 37.7　Wed 16:45　HSZ 201

Gate-controlled superconductivity in Sr_2RuO_4 — •Priyana Puliyappara Babu[1], Roman Hartmann[1], Rosalba Fittipaldi[2], Antonio Vecchione[2], Elke Scheer[1], and Angelo Di Bernardo[1] — [1]University of Konstanz, 78457 Konstanz, Germany — [2]University of Salerno, I-84084 Fisciano, Italy

The electrical field effect was believed to be inapplicable for superconductors until 2018 when it was found that the supercurrent I_c in nanowires can be controlled by the application of strong enough voltages to gate electrodes, which has been interpreted as field effect. This discovery has great potential in the future to build hybrid superconductor/semiconductor architectures which might serve reducing the increasing energy demands of modern supercomputers. The majority of observations of such gate effects have been made for BCS superconductors like Ti, Va, Nb, Al etc. Here we report gate control of I_c in transistors made of Sr_2RuO_4 flakes. Sr_2RuO_4 is an unconventional superconductor found in 1994 which has been intensively studied to understand the nature of its superconducting order parameter. Single crystals of Sr_2RuO_4 were mechanically exfoliated to produce flakes which were then patterned into gated nanodevices using a gallium focused ion beam. Total suppression of I_c was observed for gate voltages V_G above 8.3 V. The V_G dependence of I_c at different temperatures and different fields were also investigated. We will also discuss the role of leakage currents between wire and gate and possibilities to further minimize them.

TT 37.8　Wed 17:00　HSZ 201

Non-local electrodynamics and field angle dependence of the superfluid density in Sr_2RuO_2 — •Javier Landaeta[1], Konstantin Semeniuk[1], Joost Aretz[1], Ismardo Bonalde[2], and Elena Hassinger[1] — [1]Max Planck Institute

for Chemical Physics of Solids, 01187 Dresden, Germany — [2]Centro de Física, Instituto Venezolano de Investigaciones Científicas, Caracas 1020-A, Venezuela

Although being extensively studied for more than 25 years, the nature of the superconducting order parameter (SOP) of the weak type II superconductor Sr_2RuO_4 is still strongly debated. To get insight into the nodal structure of the SOP, we carried out a comprehensive study of the temperature dependence of the superfluid density n_s at various field orientations. By measuring the superconducting lower critical field $H_{c1}(T)$ in a spherical sample with ac-susceptibility, we obtained the temperature dependence of $n_s = H_{c1}(T)/H_{c1}(0)$ down to 0.03 T_c. Our results show that follows a low-temperature power law of T^2 up to 0.7T_c irrespective of the field angle. The observed behavior is in excellent agreement with what is expected of a type II superconductor with vertical nodes, with a strong influence of non-local electrodynamics. The discussed mechanisms are highly relevant for all weak type II superconductors.

TT 37.9　Wed 17:15　HSZ 201

Propagating charge carrier plasmon in Sr_2RuO_4 — Martin Knupfer[1], Fabian Jerzembeck[2], Naoki Kikugawa[3], Friedrich Roth[4], and •Jörg Fink[1] — [1]Leibniz Institute of Solid State an Materials Research, Dresden — [2]MPI for Chemical Physics of Solids, Dresden — [3]National Institute for Material Science, Tsukuba, Japan — [4]Institute of Exp. Physics, TU Bergakademie Freiberg

We report on studies of charge carrier plasmon excitations in Sr_2RuO_4 by transmission Electron Energy-Loss Spectroscopy. In particular, we present results on the plasmon dispersion and its width as a function of momentum transfer. The dispersion can be qualitatively explained in the framework of RPA calculations, using an unrenormalized tight-binding band structure. The constant long-wavelength width of the plasmon indicates, that it is caused by a decay into inter-band transition and not by quantum critical fluctuations. The results from these studies on a prototypical highly correlated metal system show that the long-wavelength plasmon excitations near 1 eV are caused by resilient quasiparticles and are not influenced by correlation effects.

TT 37.10　Wed 17:30　HSZ 201

Transport and structural characterisation of the metal to insulator transition in Ca_2RuO_4 nanoflakes — •Roman Hartmann[1], Anita Guarino[2], Rosalba Fittipaldi[2], Mario Cuoco[2], Elke Scheer[1], Antonio Vecchione[2], Gerardina Carbone[3], and Angelo di Bernardo[1] — [1]Department of Physics, Universität Konstanz, Konstanz, Germany — [2]CNR-Spin, Salerno, Italy — [3]Max IV Laboratory, Lund, Sweden

The Mott-insulator Ca_2RuO_4 (CRO) has attracted considerable attention due to its insulator to metal transition (IMT) with a transition temperature of 357 K (insulating below, metallic above) and the ability to trigger the IMT using pressure, current or an electric field of just 40 V/cm [1,2]. Unfortunately, stress from a structural transition (orthorhombic to tetragonal) during the IMT with an increase in unit cell volume [1] generally breaks bulk crystals. To overcome this limitation we have developed a method to fabricate CRO nanoflakes (despite it not being a layered material) that we can contact using standard lithographic methods. In these nanoflakes we can reversibly trigger the IMT thousands of times by passing current without breaking the sample. The robustness of the devices also enabled us to perform spatially resolved nano-diffraction measurements showing the current-dependent local formation of the metallic phase, confirming the reversibility and giving first insights in the timescale of the IMT.

Tuning van Hove singularities in strontium ruthenate with isovalent Barium doping — •Caitlin I O'Neil[1,2], Maximillian T Pelly[1,2], Ben Gade[1], Alexandra S Gibbs[1,3,4], and Andreas W Rost[1,2] — [1]SUPA, School of Physics and Astronomy, University of St Andrews, St Andrews, UK — [2]MPI for Chemical Physics of Solids, Dresden, Germany — [3]MPI for Solid State Research, Stuttgart, Germany — [4]ISIS Neutron and Muon Source, STFC Rutherford Appleton Laboratory, Harwell Campus, Didcot, OX11 0QX, UK

Controlling a van Hove singularity (VHS) close the Fermi energy (E_F) of a compound allows control of the low temperature phases as shown for example in recent experiments in single layer ruthenates [1,2]. This study pursues a new direction of structural doping of $Sr_3Ru_2O_7$ by the substitution of barium onto the strontium site. Powder samples of $(Sr_{1-x}Ba_x)_3Ru_2O_7$ were synthesised from x=0.0 - 0.12. The samples were analysed with X-ray and neutron diffraction, magnetic susceptibility and heat capacity measurements. The unit cell volume changes linearly with doping with the primary structural change being an adjustment of the RuO_6 octahedral rotation mode magnitude. Using heat capacity we map the evolution of the VHS towards the E_F, crossing it at x=0.08. Intriguingly, heat capacity shows that the strength of the singularity is decreased, contrary to standard scenarios. In combination with DFT calculations we trace this back to the primary role of the rotation mode in controlling the VHS in ruthenates.

TT 37.12   Wed 18:00   HSZ 201

Imaging of compass-like control of the electronic structure in $Sr_3Ru_2O_7$ — •Masahiro Naritsuka[1], Izidor Benedičič[1], Luke Rhodes[1], Carolina Marques[1], Christopher Trainer[1], Zhiwei Li[2], Alexander Komarek[2], and •Peter Wahl[1] — [1]SUPA, School of Physics and Astronomy, University of St Andrews, North Haugh, St Andrews, Fife, KY16 9SS, United Kingdom — [2]Max Planck Institute for Chemical Physics of Solids, Nöthnitzer Straße 40, 01178 Dresden, Germany

Electronic nematicity results in a surprisingly strong symmetry-breaking reconstruction of electronic states without a significant lattice distortion. An enigmatic example of a nematic state is found in $Sr_3Ru_2O_7$, where a large resistivity anisotropy is stabilized by external magnetic field. The direction of the anisotropy can be controlled by the in-plane component of the magnetic field. Recently, STM measurements have revealed symmetry breaking of the electronic structure at the surface of $Sr_3Ru_2O_7$ even in zero magnetic field. Here, we use low-temperature scanning tunnelling microscopy to study the electronic structure in $Sr_3Ru_2O_7$ in vector magnetic fields. We find that the electronic structure is strongly affected even by relatively small external field when applied in the crystallographic a-b-plane, and is evolving continuously as a function of in-plane field direction. Our result establishes compass-like control over the electronic structure in the surface layer of $Sr_3Ru_2O_7$. We can rationalise the continuous

evolution of the electronic structure with field direction through the interplay of magnetism and spin-orbit coupling.

TT 37.13   Wed 18:15   HSZ 201

Optical study of domains and domain walls in $Ca_3Ru_2O_7$ as a function of temperature and uniaxial pressure tuning — •Simli Mishra[1], Fei Sun[1], Elena Gati[1], Hilary Noad[1], Andrew P Mackenzie[1,2], and Veronika Sunko[1,3] — [1]Max Planck Institute, Chemical Physics of Solids, 01187, Dresden, Germany — [2]School of Physics and Astronomy, University of St. Andrews, St. Andrews, KY16 9SS, UK — [3]Department of Physics, University of California, Berkeley, California, 94720, USA

Using optical methods to investigate a material is a powerful non-contact method to explore fundamental physics. In our experiment, we use optics as a versatile microscope to investigate birefringence as well as thermal transport with micron-scale spatial resolution. It can be combined with an in-situ controllable uniaxial pressure device, which has recently been shown to be a powerful tuning parameter to control lattice symmetries in quantum materials. In this contribution, we present the birefringence of an anisotropic material, $Ca_3Ru_2O_7$, which has structural domains at room temperature and can be tuned through a structural phase transition by lowering the temperature at ambient pressure. We will discuss the spatial evolution of its domains as a function of temperature and uniaxial pressure.

Hilbert space fragmentation in open quantum systems — •Yahui Li, Pablo Sala, and Frank Pollmann — Department of Physics, TFK, Technische Universität München, James-Franck-Straße 1, D-85748 Garching, Germany

Several mechanisms have been identified that can lead to a breakdown of thermalization in closed quantum systems-including integrability and many-body localization. Recently, a novel mechanism for ergodicity breaking has been discovered in systems with certain dynamical constraints, where the Hilbert space fragments into exponentially many disconnected subspaces. An open question is how such systems evolve when they are coupled to a dissipative bath.

We find that the Hilbert space fragmentation can be utilized to preserve coherence in the presence of dissipation. We study a quantum fragmented model, which fragments in an entangled basis due to unconventional non-Abelian symmetries. We investigate the Lindblad dynamics under two different couplings, which either preserves or destroys the quantum fragmentation structure. At sufficiently large couplings, the operator space entanglement is suppressed, which allows for an efficient numerical simulation using tensor networks. Surprisingly, under the structure-preserving noise, we observe finite Renyi negativity, indicating non-vanishing quantum correlations. Using an analytic approach, we derive the stationary states under both couplings, which explains the long-time behaviors observed in numerical simulations.

Hilbert space fragmentation and interaction-induced localization in the extended Fermi-Hubbard model — •Philipp Frey, Lucas Hackl, and Stephan Rachel — University of Melbourne

We study Hilbert space fragmentation in the extended Fermi-Hubbard model with nearest and next-nearest neighbor interactions. Using a generalized spin/mover picture and saddle point methods, we derive lower bounds for the scaling of the number of frozen states and for the size of the largest block preserved under the dynamics. We find fragmentation for strong nearest and next-nearest neighbor repulsions as well as for the combined case. Our results suggest that the involvement of next-nearest neighbor repulsions leads to an increased tendency for localization. We then model the dynamics for larger systems using Markov simulations to test these findings and unveil in which interaction regimes the dynamics becomes spatially localized. In particular, we show that for strong nearest and next-nearest neighbor interactions random initial states will localize provided that the density of initial movers is sufficiently low.

Rate functions and the approach to adiabaticity in quantum many body systems — •Vibhu Mishra, Salvatore Manmana, and Stefan Kehrein — Institute for Theoretical Physics, Georg-August-Universität Goettingen, Friedrich-Hund-Platz 1, 37077 Goettingen

The quantum adiabatic theorem is a fundamental result in quantum mechanics with applications ranging from quantum adiabatic computation to topological systems, while also serving as a theoretical foundation to many body perturbation theory via the Gell-Mann Low theorem.

We establish an inherent competition between ramp times T for an adiabatic process vs the system size N, in the behavior of relevant many body overlaps. We study this interplay between T and N by analyzing the properties of rate functions which are defined to be intensive quantities that give us a quantitative measure of the deviation from adiabaticity in the thermodynamic limit.

We analyze the Transverse Field Ising Model and the XXZ chain in $1D$ using exact diagonalization. We find that the rate functions show algebraic decay with increasing ramp time T. The decay exponent of the rate function for ramps within the gapped phase is 2, for ramps across Ising critical point it is 0.5 and within the Luttinger Liquid phase it is 1. The immediate implication is that the many body adiabatic time scales grow unavoidably with system size, namely as the $\sqrt{N}$ for ramps within the gapped phase, and with N within the Luttinger Liquid phase.

TT 38.4   Wed 15:45   HSZ 204

Classical route to ergodicity and scarring phenomena in a two-component Bose-Josephson junction — Debabrata Mondal[1], Sudip Sinha[1], •Sayak Ray[2], Johann Kroha[2], and Subhasis Sinha[1] — [1]Indian Institute of Science Education and Research Kolkata, Mohanpur, Nadia 741246, India — [2]Physikalisches Institut, Rheinische Friedrich-Wilhelms-Universität Bonn, Nußallee 12, 53115 Bonn, Germany

We consider a Bose-Josephson junction (BJJ) formed by the binary mixture of ultracold atoms to investigate the manifestation of coherent collective dynamics on ergodicity and quantum scars, unfolding the connection between them. By tuning the inter and intra-species interaction, we demonstrate a rich variety of Josephson dynamics and transitions between them, which plays a crucial role in controlling the overall ergodic behaviour. The signature of underlying classicality is revealed from the entanglement spectrum, which also elucidates the formation of quantum scars of unstable steady states and of periodic orbits leading to athermal behaviour in a reduced Hilbert space. We show how the degree of ergodicity across the energy band and the scarring phenomena can be probed from the auto-correlation function as well from the phase fluctuation of the condensates, which has relevance in cold atom experiments. The model can also be realized in spin systems with application to information processing and lattice-gauge simulation.

TT 38.5   Wed 16:00   HSZ 204

Ultrafast dynamics of cold Fermi gas after a local quench — Nikolay Gnezdilov[1], •Andrei Pavlov[2,3], Vladimir Ohanesjan[4], Yevheniia Cheipesh[4], and Koenraad Schalm[4] — [1]Department of Physics, University of Florida, Gainesville, USA — [2]The Abdus Salam International Centre for Theoretical Physics (ICTP) Strada Costiera 11, Trieste, Italy — [3]Institut für QuantenMaterialien und Technologien, Karlsruhe Institute of Technology, Hermann-von-Helmholtz-Platz 1, Eggenstein-Leopoldshafen, Germany — [4]Instituut-Lorentz, Universiteit Leiden, Leiden, The Netherlands

We consider energy dynamics of two initially independent reservoirs A and B filled with a cold Fermi gas coupled and decoupled by two quantum quenches following one another. The energy change in the system adds up the heat trans-

ferred between A and B and the work done by the quench to uncouple the reservoirs. In case when A and B interact for a short time, we find an energy increase in both reservoirs upon decoupling. This energy gain results from the quenches' work and does not depend on the initial temperature imbalance between the reservoirs. We relate the quenches' work to the mutual correlations of A and B expressed through their von Neumann entropies. Utilizing this relation, we show that once A and B become coupled, their von Neumann entropies grow (on a timescale of the Fermi time) faster than thermal transport within the system. For a metallic setup, this implies the characteristic timescale of correlations' growth to be in the femtosecond range, while for the ultracold atoms, we expect it to be in the millisecond range.

TT 38.6   Wed 16:15   HSZ 204

A conjecture regarding the overlap of different ground states within the same phase — •Sarah Damerow and Stefan Kehrein — Georg-August Universität Göttingen

An extension of the adiabatic theorem to quantum quenches, i.e. non-adiabatic changes, is presented. Using exact diagonalisation, we numerically study the Transverse Field Ising Model (TFIM) and the Axial Next Nearest Neighbour Ising Model (ANNNI). We numerically test the following conjecture: Within the same phase, the overlap between the initial ground state and the ground state of the quenched Hamiltonian is the largest possible eigenstate overlap. In the TFIM, this conjecture is confirmed for both the paramagnetic (PM) and the ferromagnetic (FM) phases. In the ANNNI model results are ambiguous in some phases, due to both numerical errors and finite size effects.

Charge, spin, and heat shot noises in the absence of average currents — •Ludovico Tesser, Matteo Acciai, Christian Spånslätt, Juliette Monsel, and Janine Splettstoesser — Chalmers University of Technology, Gothenburg, Sweden

Shot noise in electronic conductors occurs when the system is brought out of equilibrium, e.g., by a stationary bias. However, nonequilibrium does not imply that an average current flows. Indeed, the situation where selected currents are suppressed is of interest in fields like thermoelectrics and spintronics, raising the question of how the related noises behave.

I will present results on zero-current charge, spin, and heat noises in two-terminal mesoscopic conductors induced by voltage, spin and temperature biases. The nonequilibrium shot noises can be arbitrarily large, even if the respective average currents vanish. However, as soon as a temperature bias is present, additional equilibrium (thermal-like) noise necessarily occurs. This equilibrium noise sets an upper bound on the zero-current nonequilibrium charge and spin shot noise [1,2]. We have shown that the bound on the charge noise for strictly two-terminal conductors even extends into the finite-frequency regime. By contrast, these bounds can be overcome for heat transport by breaking the spin and electron-hole symmetries, respectively.

Maximally chaotic to Fermi liquid crossover in a generalized SYK model — •Nick von Selzam and Stefan Kehrein — Institute for Theoretical Physics, University of Göttingen, Germany

We consider a generalized Sachdev-Ye-Kitaev (SYK) model: Majorana fermions on $\mathcal{N}$ sites with random $\frac{q}{2}$-body all to all interactions plus a kinetic energy term.

The SYK model can be seen as a toy model for quantum chaos and does not allow for a quasiparticle description. We discuss the continuous crossover between the Fermi liquid regime, dominated by the kinetic term, and the maximally chaotic regime, dominated by the SYK interaction, by studying the quantum Lyapunov exponents.

For fixed interaction strength there exists a crossover temperature for which the Lyapunov exponent becomes maximal. For lower temperatures the Lyapunov exponent is exponentially small. For larger temperatures the behaviour is close to indistinguishable from the pure SYK term.

TT 38.9   Wed 17:15   HSZ 204

Vibrationally-coupled electron transport in a quantum shuttle: A study using the hierarchical equations of motion approach — •Salvatore Gatto, Christoph Kaspar, and Michael Thoss — Institute of Physics, Albert-Ludwigs-Universität Freiburg

A quantum shuttle is an archetypical nanoelectromechanical device, in which the coupling of electronic and mechanical degrees of freedom is crucial [1]. In this contribution, we investigate transport properties of quantum shuttles, with a particular focus to the so-called shuttling regime, in which the transport of electrons is synchronized with the mechanical motion. The transport characteristics

are strongly influenced by the interplay of electronic and vibrational degrees of freedom, which manifests itself in step structures of the current-voltage characteristics. An effective molecule-lead coupling results in an increase of the current with respect to the tunneling regime. The study uses the hierarchical equations of motion approach, which allows a numerically exact simulation of nonequilibrium transport in general open quantum systems involving multiple bosonic and fermionic environments [2].

Effective form factors for finite temperature correlation functions — •Oleksandr Gamayun — University of Warsaw, ul. Pasteura 5, 02-093 Warsaw, Poland

The behavior of dynamical correlation functions in one-dimensional quantum systems at zero temperature is now very well understood in terms of linear and non-linear Luttinger models. The "microscopic" justification of these models consists in exactly accounting for the soft-mode excitations around the vacuum state and at most few high-energy excitations. At finite temperature, or more generically for finite entropy states, this direct approach is not strictly applicable due to the different structure of soft excitations. To address these issues we study the asymptotic behavior of correlation functions in one-dimensional free fermion models. On the one hand, we obtain exact answers in terms of Fredholm determinants. On the other hand, based on "microscopic" resummations, we develop a phenomenological approach that introduces the effective form factors and reduces the problem to the zero temperature case. The information about the initial state is transferred into the scattering phase of the effective fermions. I will demonstrate how this works for correlation functions in the XY model, mobile impurity, and the sine-kernel Fredholm determinants.

TT 38.11   Wed 17:45   HSZ 204

Transfer-matrix summation of path integrals for transport through nanostructures — Simon Mundinar, •Alexander Hahn, Jürgen König, and Alfred Hucht — Theoretische Physik, Universität Duisburg-Essen and CENIDE, 47048 Duisburg, Germany

On the basis of the method of iterative summation of path integrals (ISPI), we develop a numerically exact transfer-matrix method to describe the nonequilibrium properties of interacting quantum-dot systems. For this, we map the ISPI scheme to a transfer-matrix approach [1], which is more accessible to physical interpretation, allows for a more transparent formulation of the theory, and substantially improves the efficiency. In particular, the stationary limit is directly implemented, without the need of extrapolation. The resulting new method, referred to as "Transfer-matrix Summation of Path Integrals" (TraSPI), is then applied to resonant electronic transport through a single-level quantum dot [2].

Quasi-particle excitations at Mott-metal interfaces — •Jan Verlage[1], Friedemann Queisser[2,3], Peter Kratzer[1], and Ralf Schützhold[2,3] — [1]Fakultät für Physik, Universität Duisburg-Essen — [2]Institut für Theoretische Physik, Helmholtz-Zentrum Dresden-Rossendorf — [3]Institut für Theoretische Physik, Technische Universität Dresden

We investigate excitations at the interface between a metallic bulk and a strongly correlated Mott insulator. Employing a hierarchy of correlations we identify effective quasi-particle and hole excitations in the heterostructure. To leading order in the hierarchy, the modes satisfy an effective two-component evolution equation. This allows the investigation of evanescent modes at the interface and tunneling through a Mott insulating layer.

The project is funded by the DFG, grant # 278162697 (CRC 1242).

TT 38.13   Wed 18:15   HSZ 204

Configuration interaction based nonequilibrium steady state impurity solver — •Daniel Werner, Jan Lotze, and Enrico Arrigoni — ITPCP, Graz, Austria

We present a solver for correlated impurity problems out of equilibrium based on a combination of the so-called auxiliary master equation approach (AMEA) and the configuration interaction (CI) expansion. Within AMEA one maps the original impurity model onto an auxiliary open quantum system with a restricted number of bath sites which can be addressed by numerical many-body approaches such as ED or MPS. While the mapping becomes exponentially more accurate with increasing number of bath sites, ED implementations are severely limited due to the fast increase of the Hilbert space dimension for open systems, and the MPS solver typically requires rather long runtimes. Here, we propose to adopt a CI approach to solve numerically the correlated auxiliary open quantum system. This allows access to a larger number of bath sites at lower computational costs than for ED. We benchmark the approach with NRG results in equilibrium and with MPS out of equilibrium. We evaluate the current, the con-

ductance as well as the Kondo peak and its splitting. We obtain a rather accurate scaling of the conductance as a function of the bias voltage and temperature rescaled by TK for moderate to strong interactions in a wide range of parame-

ters. The approach combines the fast runtime of ED with an accuracy close to the one achieved by MPS making it an attractive solver for nonequilibrium DMFT. (arXiv: 2210.09623)

TT 39: Superconducting Electronics

Sensing and control of MHz photons with microwave photon-pressure — Ines C. Rodrigues[1,2], Gary A. Steele[1], and •Daniel Bothner[1,3] — [1]Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands — [2]Department of Physics, ETH Zürich, Switzerland — [3]Physikalisches Institut, Center for Quantum Science (CQ) and LISA+, Universität Tübingen, Germany

Superconducting microwave circuits have emerged as one of the leading platforms for quantum information science and quantum sensing in the recent decade. In 2018, a new type of interaction between a superconducting microwave circuit and a low frequency (LF) circuit has been realized, so called photon-pressure coupling, which is the all-circuit analogue of the radiation-pressure interaction between a mechanical oscillator and an optical cavity in optomechanics. Since 2020, several milestone experiments with photon-pressure circuits have been reported, such as the interferometric thermometry of an LF circuit, the observation of parametric strong-coupling or sideband-cooling of an LF mode into its quantum groundstate. Quite recently, we have realized a series of experiments in these circuits, for which we add a strong parametric drive to the Kerr-nonlinear high-frequency mode. This approach allows for parametrically enhanced interaction strengths, for the observation of nonreciprocal heat flow and for the implementation of photon-pressure with a "negative mass" microwave mode that inverts dynamical backaction and sideband-cooling effects. In our presentation, we will give an overview of photon-pressure circuits, discuss the most recent developments and possible future directions.

TT 39.2　Wed 15:30　HSZ 304
Waveguide quantum electrodynamics in high impedance networks — •Miriam Resch[1], Ciprian Padurariu[1], Björn Kubala[1,2], Frank Grossmann[3], and Joachim Ankerhold[1] — [1]ICQ and IQST, Ulm University, Ulm, Germany — [2]Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany — [3]Institut für Theoretische Physik, Technische Universität Dresden, Dresden, Germany

The emerging field of high impedance quantum circuits aims to exploit the extraordinary properties of high kinetic inductance materials, such as granular superconductors. The low propagation speed of electromagnetic excitations in such devices enables to strongly couple various types of qubits or resonators and waveguides. Theoretical description of such strongly coupled systems is challenging as the localized modes of the sub-unit couple to many waveguide modes simultaneously so that many common approximation schemes break down. Furthermore for a more realistic description of the system, Kerr nonlinearities are included in the model of the granular superconductor. To tackle this challenging regime in a numerically efficient way, we use the multi Davydov-Ansatz [1], where the wave function of the full system is described by a superposition of coherent states. As a first step we investigate how Kerr nonlinearities modify properties of qubit decay or readout, with the ultimate goal of identifying strong-coupling signatures in those observables, which are accessible to our experimental collaborators.

High-impedance resonators based on granular aluminum — •Mahya Khorramshahi, Martin Spiecker, Patrick Paluch, Nicolas Zapata, Ritika Dhundhwal, Ioan M. Pop, and Thomas Reisinger — Karlsruhe Institute of Technology, Germany

Superconductors with characteristic impedance larger than the resistance quantum are a valuable resource in superconducting circuits. They enable the design of protected qubits such as Fluxoniums or 0-pi qubits and can improve the coupling to small-dipole-moment objects, which may be useful for interfacing to spin-qubits, donor spins, etc. Here we present compact resonators in the lower GHz regime with a high characteristic impedance given by a high-kinetic-inductance material, namely granular aluminum, with spurious modes above 10GHz. We fabricated the resonators with an electron-beam lithography lift-off process, and we coupled them using a 50 Ohm coplanar waveguide architecture. Measurements performed in a dilution cryostat reveal that the resonators maintain high-quality factors in the single photon regime, a valuable resource for future quantum hardware implementations.

Surface acoustic wave resonators on thin film piezoelectric substrates for quantum acoustics — •Thomas Luschmann[1,2,3], Alexander Jung[1,2], Stephan Geprägs[1,2], Rudolf Gross[1,2,3], and Hans Huebl[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]Technische Universität München, TUM School of Natural Sciences, Physics Department, Garching, Germany — [3]Munich Center for Quantum Science and Technology, Munich, Germany

Lithium Niobate (LNO) is a well established material for Surface Acoustic Wave (SAW) devices including resonators, delay lines and filters. Recently, multi-layer substrates based on LNO thin films have become commercially available. Here, we present a systematic study of the performance of SAW devices fabricated on LNO-on-Insulator (LNOI) and LNO-on-Silicon substrates and compare them to bulk LNO devices. Our study aims at applications of these substrates for quantum acoustics, i.e. the integration with superconducting circuits operating in the quantum regime. To this end, we design SAW resonators with a target frequency of 5 GHz and perform our experiments at millikelvin temperatures and microwave power levels corresponding to single photons or phonons. We investigate the device quality factors as a function of the excitation power and temperature and model the observed losses by the coupling of the resonator to a bath of two-level-systems (TLS). Our results suggest that SAW devices on thin film LNO on Silicon have sufficient performance to be used in future SAW based quantum acoustic devices.

Towards hybrid quantum systems coupling superconducting qubits to cold atoms — •Benedikt Wilde, Nicolas Albenge, Manuel Kaiser, Conny Glaser, Malte Reinschmidt, Andreas Günther, József Fortágh, Dieter Koelle, Reinhold Kleiner, and Daniel Bothner — Physikalisches Institut, Center for Quantum Science (CQ) and LISA+, Universität Tübingen

Coupling superconducting quantum circuits to ultracold atom clouds promises the possibility of exploiting the advantages of both systems, enabling new advances in both fundamental research and potential technological applications. One can realize such a hybrid quantum system by using a superconducting microwave resonator that is simultaneously coupled to both sub-systems. While coupling superconducting resonators to superconducting qubits is state-of-the-art, several challenges arise when trying to couple cold atoms to the integrated circuit. These challenges include achieving the required microwave field homogeneity, engineering a sufficiently large interaction strength and keeping a high resonator quality factor despite environmental factors suitable to deteriorate the performance of superconducting circtuits, such as laser beams or magnetic atom traps. We present our recent developments and advances, discussing design considerations, simulations and intermediate results.

Parameter spread in Josephson traveling-wave parametric amplifiers: Vulnerabilities and tolerances — •Christoph Kissling, Victor Gaydamachenko, Fabian Kaap, Marat Khabipov, Ralf Dolata, Alexander B. Zorin, and Lukas Grünhaupt — Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany

Josephson traveling-wave parametric amplifiers (JTWPAs) hold great promise for wideband amplification of few-photon-level signals at microwave frequencies. These devices typically consist of thousands of nominally identical circuit elements, which are subject to fabrication variations. We analyse the effect of circuit parameter variation on the performance of a JTWPA using transient circuit simulations. Using this tool, we analyze two dispersion engineering concepts, resonant phase matching and periodic capacitance modulation, and compare their parameter spread tolerances. We identify circuit elements, which are critical concerning parameter spread, and explore ways to mitigate the impact of spread. Furthermore, we present the status of our practical implementation of rf-SQUID based JTWPAs and show experimental results.

TT 39.7　Wed 17:00　HSZ 304

Fabrication of low-loss Josephson parametric circuits — •Kedar E. Honasoge[1,2], Yuki Nojiri[1,2], Daniil E. Bazulin[1,2], Leon Koch[1,2], Thomas Luschmann[1,2], Niklas Bruckmoser[1,2], Maria-Teresa Handschuh[1], Florian Fesquet[1,2], Michael Renger[1,2], Fabian Kronowetter[1,2,4], Achim Marx[1], Rudolf Gross[1,2,3], and Kirill G. Fedorov[1,2] — [1]Walther-Meißner-Institut, 85748 Garching, Germany — [2]Physik- Department, Technische Universität München, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), 80799 München, Germany — [4]Rohde & Schwarz GmbH, 81671 München, Germany

The emergence of quantum information processing with superconducting circuits has stimulated the development of various interest in Josephson parametric devices. The latter offer a wide range of applications ranging from quantum-limited amplification to the generation of entangled squeezed states of light. We fabricate low-loss devices by employing careful cleaning steps during the fabrication of the superconducting circuits. Upon optimization, we fabricate Josephson parametric devices with internal quality factors in excess of 10^5. We characterize bandwidth, gain, noise, dynamic range, and other properties of the realized devices. Based on these investigations, we derive useful criteria for the development of more intricate devices incorporating Josephson parametric circuits.

Nb SQUIDs patterned by He and Ne focused ion beams — •Simon Koch[1], Timur Griener[1], Simon Pfander[1], Julian Linek[1], Thomas Weimann[2], Reinhold Kleiner[1], Oliver Kieler[2], and Dieter Koelle[1] — [1]Physikalisches Institut, Center for Quantum Science (CQ) and LISA[+], Universität Tübingen, Germany — [2]Department Quantum Electronics, Physikalisch-Technische Bundesanstalt (PTB), Braunschweig, Germany

Nanopatterning of superconducting thin film structures with focused He or Ne ion beams (He/Ne-FIB) offers a flexible tool for creating constriction-type Josephson junctions (cJJs) which can be integrated into strongly miniaturized superconducting quantum interference devices (nanoSQUIDs) for magnetic sensing on the nanoscale. We present our attempts to use He/Ne-FIB for fabricating Nb cJJs and nanoSQUIDs which shall provide ultra-low noise and high spatial resolution for their application in scanning SQUID microscopy (SSM). Moreover, we address the possibility to implement multiterminal, multi-JJ SQUIDs that provide flexibility in SQUID readout. The nanoSQUIDs are designed as sensors for magnetic flux and dissipation. They shall be integrated on custom-made Si cantilevers, which will provide the possibility of simultaneous conventional topographic imaging by atomic force microscopy (AFM). We will discuss the status of this project and challenges that have to be met on the way to combine SSM and AFM on the nanoscale.

TT 39.9　Wed 17:30　HSZ 304

Synchronization in Josephson photonics devices in the presence of shot noise — Florian Höhe[1], Ciprian Padurariu[1], Brecht Donvil[1], Lukas Danner[1,2], Joachim Ankerhold[1], and •Björn Kubala[1,2] — [1]ICQ and IQST, Ulm University, Ulm, Germany — [2]Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany

For many quantum sources the exploitation and characterization of their quantum properties, such as entanglement and squeezing, is hampered by phase instability. Josephson photonics devices, where microwave radiation is created by inelastic Cooper pair tunneling across a *dc-biased* Josephson junction in-series with a microwave resonator are particularly vulnerable lacking the reference phase provided by an ac-drive. To counter this issue, sophisticated measurement schemes have been used in [1] to prove entanglement, while in [2] a weak ac-signal was put in to lock phase and frequency of the emission. Intrinsic shot noise of the Josephson-photonics device inevitably diffuses the oscillators phase and requires an extension of classical synchronization theories to the quantum regime.

Performing multi-time scale perturbation theory we derive an effective Fokker-Plank equation for the phase to analyze quantum locking and synchronization in an Adler-type equation. Injection locking and synchronization lead to a narrowing of the photon emission statistics, while the shot noise induces phase slips.

Mitigating losses in NbTiN superconducting circuits under magnetic fields. — •Arne Bahr, Matteo Boselli, Benjamin Huard, and Audrey Bienfait — Laboratoire de Physique - École normale supérieure de Lyon, France

Quantum superconducting circuits enable quantum information processing as well as quantum sensing at microwave frequencies. One predominant factor limiting their performance is the presence of impurities creating microwave losses, triggering intense research effort for their identification and mitigation[1]. Here we probe these impurities in the context of using superconducting circuits under magnetic fields, which has application for coupling to other spin systems[2] and also detecting electron spin resonance (ESR) at the few spin levels[3].

We report continuous wave ESR measurements on spin impurities in resonators fabricated in NbTiN on a sapphire substrate. A simple etch through a resist layer process results in the presence of many spin impurities, preventing any ESR measurement near the spin 1/2 line. Following the characterization and identification of these spin signals, we improve our fabrication process to remove these spurious spin signals so that the resonators exhibit internal quality factors above $5 \cdot 10^5$ that remain constant up to 350 mT.

Pressure drop measurements and flow simulations of different regenerator fillings in a single stage GM-type pulse tube cryocooler — •Bernd Schmidt[1,2], Elias Eisenschmidt[1,3], Jack-André Schmidt[1,2], Jens Falter[1], Hardy Weisweiler[3], and André Schirmeisen[1,2] — [1]TransMIT-Center for Adaptive Cryotechnology and Sensors, Giessen, Germany — [2]Institute of Applied Physics, Justus-Liebig-University Giessen, Germany — [3]Technische Hochschule Mittelhessen, Friedberg, Germany

Although pulse tube cryocoolers (PTCs) reaching liquid Helium temperature were already presented in the 1990s[1], they are still subject to vivid development in many directions. Much of this development is done with the help of simulations and empirical values. A crucial part of a PTC is the regenerator, which is usually filled with multiple layers of porous materials with high heat capacity. These porous materials come in different shapes, mainly packed spheres and wire meshes.

In this talk we present measurements and simulations of pressure drop and gas flow through different regenerator fillings. We show the differences between the different kinds of fillings from the fluid mechanics point of view.

Der Sachunterricht in der Primarstufe ist ein Konglomerat aus allen Natur- und Gesellschaftswissenschaften, erst in der Sekundarstufe findet eine Aufspaltung in die einzelnen Fächer statt. Zudem unterrichten viele Grundschul-Lehrkräfte fachfremd. Auch der Zeitaufwand für die Vorbereitung von Experimenten ist

nicht unerheblich. Wie also kann man trotz dieser Hürden kindgerechte physikalische und chemische Experimente bereits in der Grundschule einführen?

Ich berichte aus 10 Jahren Erfahrung mit dem Projekt experimentamus!. Dabei handelt es sich um einen Kanon aus ca. 40 Experimenten für die Klassen 2 bis 4, welcher die Themen Licht, Wärme, Magnetismus, Wasser, Luft, Feuer und Elektrizität mit einem kindgerechten Alltagsbezug abdeckt. Anstelle des darlegenden Lernens wird auf das Forschende Lernen gesetzt: Frage - Hypothese - Experiment - Beobachtung - Erklärung; diese fünf Stationen des wissenschaftlichen Erkenntnisprozesses werden immer wieder durchlaufen. Ganz im Sinne Martin Wagenscheins wird dabei nach der exemplarischen und sokratischen Methode vorgegangen. Die praktische Implementierung umfasst 1. Materialkisten für alle Themen, 2. kompakte und leicht verständliche Informationshefter für die Lehrkräfte, sowie 3. Lernheftchen für alle SuS. Am Ende möchte ich über Erfahrungen und Herausforderungen im Rahmen dieses Projektes berichten und Ideen für eine mögliche weitere Verbreitung vorstellen.

TT 40.2   Wed 15:30   POT 81
Internal interfaces - goals and realisation of a scientific image film — •Ulrich Höfer[1,2] and Michael Dürr[2,3] — [1]Fachbereich Physik, Philipps-Universität Marburg — [2]SFB 1083, www.internal-interfaces.de — [3]Institut für Angewandte Physik, Justus-Liebig-Universität Giessen, Germany
Funded by the German Science Foundation (DFG), a professional film maker has produced an image film about the research conducted in the Collaborative Research Center SFB 1083 "Structure and Dynamics of Internal Interfaces". The six-minute video clip takes the non-specialist on a journey down to atomic scale to show the progress at the forefront of research at solid/solid interfaces. It is not a demanding educational film. Rather, it is a visually stunning piece that looks like science fiction taken straight out of a movie, with tracking shots that take the viewer down to the nanometer scale, with flights through luminous molecules, exotic excitons, and space-filling laser labs. The film also has a very impressive soundtrack. Gustav Holst's (1874-1934) composition "The Planets" was re-orchestrated especially for this film. It is available on the youtube channel of the DFG (https://www.youtube.com/watch?v=_-mDt0NzHrc). Visitors of Chemikum Marburg can watch the German version on a 4K OLED screen, a device actually based on microscopic processes at interfaces investigated by SFB 1083.

The idea behind the creation of a professional film, its conceptional design and the necessary steps towards its realization will be outlined.

TT 40.3   Wed 15:45   POT 81
Outreach activities of SFB 1083 @ Chemikum Marburg — •Christof Wegscheid-Gerlach, Luise Cleres, Ina Budde, Karl-Heinz Muth, and Marion Enssle — Chemikum Marburg / SFB1083
The diffusion of concepts, methods, and visions of the SFB 1083 on Structure and Dynamics of Internal Interfaces into the general public is our general goal. To this end project Ö makes use of the institution Chemikum Marburg e.V., whose basic idea is to fascinate the public excited about natural sciences. The experiments offered here, stand for chemical, biological, pharmaceutical, and physical subjects related with daily phenomena or beyond. We will give an overview about the introduction of basic ideas and methods of SFB 1083 to the public as well as the institution Chemikum Marburg. The contents of the individual offers, such as experiments within the regular workspace, the workshops for the Girls' Day and the compilation of special workshops that are offered to give high-school students an understanding of the research content of the SFB 1083 are presented. An additional topic is the linking of basic research to applications for regenerative energy resources. Hydrogen fuel cells are well-known to the general public and rely on functional internal interfaces. An additional workshop which was prepared in cooperation with the district Marburg-Biedenkopf gives an overview about production, storage, and application of hydrogen as a new energy resource. We will also share various occasions at Chemikum Marburg where further outreach activities represent SFB 1083.

Under the Microscope – spotlighting materials and nano science — •Svenja Lohmann and Pranoti Kshirsagar — The Science Talk, Germany
Real Scientists Nano is a science communication project dedicated to materials and nano science. Despite the widespread relevance of materials science to everyday life, we feel that dedicated science communication in this area is much rarer than in other fields. Our aim is to provide a platform for active materials and nano scientists to directly communicate their science and life as a scientist to the public. The use of social media thereby provides a very low threshold to science communication as basically the only requirement is to have an account. We have the goal to showcase the scientific community in all its diversity, and so far (12/2022) had guest scientists from more than 30 countries of origin as well as various fields and career stages. The two main pillars of the Real Scientists Nano project are the @RealSci_Nano Twitter account and the Under the Microscope podcast. Our guest scientists are interviewed for one podcast episode, and subsequently get to tweet from the account for one week following the rotation curation concept. We let curating scientist decide for themselves what they would like to tweet about. The form and content therefore vary greatly. Many of

our scientists report from their everyday life, and are for example live-tweeting from a conference, uploading videos or photos from the lab or sending the occasional "stuck in meetings, will return later" tweet. Science communication on social media thus gives the opportunity to open a direct and real-time window into the scientist's life.

Phyphox – A pocketful of physics — •Christoph Stampfer — JARA-FIT and 2nd Institute of Physics, RWTH Aachen University, 52074 Aachen, Germany — Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich, 52425 Jülich, Germany
Most smartphones are used to make phone calls, to write short messages, surf the Internet or check e-mails. However, they can do much more: With the help of the integrated sensors and the free app "phyphox" (abbreviation for Physical Phone Experiments), pupils, students, and teachers and interested others can independently perform and develop physics experiments. For example, the app can use the accelerometer to record pendulum movements and determine the rotational acceleration in a salad spinner, or the air pressure sensor to determine time-resolved differences in altitude and thus the speed of an elevator. The didactic potential of the app is great, as the students are picked up on ground that is very familiar and attractive to them (smartphones) and are introduced to experimental natural sciences in a playful way and with an extremely low barrier (zero cost, i.e. only one click away). The app helps to get students excited about scientific and technical questions and contexts at an early age. The app is available free of charge for Android and iOS (more information can be found at www.phyphox.org). In my presentation, I will go into the concept of phyphox, introduce the range of functions and show a number of application examples.

Chair PR representative as a doctoral student's secondary task: A field report — •Paula M. Weber, Felix Friedrich, and Manuel Seitz — Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany
Especially in recent years, it has become more important to communicate one's scientific work and methods to the public in order to show that in the scientific world, knowledge can only be created through research and the scientific process. Yet, extra time besides research is often limited and it is thus difficult to get into science communication. In this talk, I would like to present how PhD students can use their interest in science communication to benefit their own research group as a part-time PR representative.

In the first part of my talk, I will report on our efforts to attract new bachelor and master students. This advertising is focused on an audience with a scientific background, such that lab tours and advertising posters may contain scientific language and references. The second part is about communication with the general public, who usually know physics from their school days. Here, I will report on how we presented our research activities at the Night of Science in Physics and at the "Highlights der Physik" in Würzburg.

Working part-time as a PR representative could encourage doctoral students to try their hand at science communication and develop the associated communication skills.

TT 40.7   Wed 17:45   POT 81
Real or Fake - A format in science communication that encourages critical thinking — •Tobias Löffler — Institut für Angewandte Physik Düsseldorf
The outreach format "Real or Fake" aims to train the audience in an critical approach to credible-sounding facts.

It is aimed at the general public and specifically at young people. At the same time, it offers an easy introduction for scientists to audience-oriented communication of science on stage. The format can be performed in front of a live audience or as an interactive online event. It has been proven to work as implemented into science festivals, nights of sciences, as a public individual event and also as part of events with constrained settings - such as outreach events at schools or as part of conferences.

"Real or Fake" was developed in 2017 by scientists around the Berlin March for Science who later founded Besserwissen e.V. with the goal to promote the format and support new organisers. I do cooprate with them since 2019 and have organized more than ten "Real or Fake" events since then.

In my talk, I will present the concept and its origins, give an overview of successful events and show what to do and what support one can get, if one wants to organize a "Real or Fake" event.

Invited Talk   TT 40.8   Wed 18:00   POT 81
Physics for school and the public at the LMU — •Dr. Cecilia Scorza-Lesch — Fakultät für Physik der LMU, München
Germany lives from research and technology. Physics, as the basis of all empirical sciences and technologies, has a very special, fundamental role to play. The Faculty of Physics at LMU, the largest in Germany, comprises nine research areas,

three centres and two excellence clusters. In this talk we will present the approach we use to successfully communicate our various topics of modern research, the role of physics in our daily lives and in the fight against global warming to the schools and the public in a participatory way.

TT 41: Quantum Transport and Quantum Hall Effects II (joint session HL/TT)

Time: Wednesday 15:00–17:00   Location: POT 251

TT 41.1   Wed 15:00   POT 251

Aharonov-Bohm-type oscillations in phase-pure core/shell GaAs/InAs nanowires — •Farah Basaric[1,2], Anton Faustmann[1,2], Erik Zimmermann[1,2], Gerrit Behner[1,2], Alexander Pawlis[1,2], Christoph Krause[1,2], Hans Lüth[1,2], Detlev Grützmacher[1,2], and Thomas Schäpers[1,2] — [1]Peter Grünberg Institut (PGI-9), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]JARA-Fundamentals of Future Information Technology, Jülich-Aachen Research Alliance, Forschungszentrum Jülich and RWTH Aachen University, Germany

Epitaxially grown phase-pure GaAs/InAs core/shell nanowires offer uniformity in their electrical, mechanical and optical properties due to the absence of a crystallographic disorder. Magnetotransport measurements were carried out at variable temperatures and for different gate voltages, under an applied in-plane magnetic field. Pronounced Aharonov-Bohm-type oscillations in the conductance are observed for this nanowire type. In measurements at different gate voltages, significantly higher oscillation amplitudes are observed in comparison to the corresponding measurements on polymorphic core/shell nanowires. Furthermore, measurements at different temperatures show robustness of these oscillations against high temperatures as a result of reduced disorder. Finally, strong indications of a quasi-ballistic transport regime could be recognized for the phase-pure nanowire type. Obtained results indicate a strong effect of disorder reduction in GaAs/InAs nanowire transport properties, manifested in superior transport properties.

TT 41.2   Wed 15:15   POT 251

Spin valves based on bilayer graphene quantum point contacts — •Eike Icking[1,2], Christian Volk[1,2], Christopher Schattauer[3], Luca Banszerus[1,2], Kenji Watanabe[4], Takashi Taniguchi[5], Florian Libisch[3], Bernd Beschoten[1], and Christoph Stampfer[1,2] — [1]RWTH Aachen University, Germany — [2]Forschungszentrum Jülich, Germany — [3]TU Vienna, Austria — [4]Research Center for Functional Material, Japan — [5]International Center for Materials Nanoarchitectonics, Japan

Bernal bilayer graphene (BLG) is a unique material as it allows opening and electrostatically tuning a sizeable band gap by applying a perpendicular electric field. Recently, charge carriers have been confined successfully in one dimension to form quantum point contacts (QPC) based on split gates separated by a channel of a few hundred nanometers. Moreover, spin-polarized quantum transport through such structures has been demonstrated up to 6 e^2/h using a high in-plane magnetic field. The threshold magnetic field at which the lowest modes become spin-polarized depends on the subband spacing and thus on the width of the split gate channel. In this work, we combine two QPCs of different geometric widths, resulting in different threshold magnetic fields, to spin-polarize the first QPC and use it as a filter for the second QPC. In particular, we report on a spin-valve achieving spin-polarized channels with a total conductance of up to 10 e^2/h.

TT 41.3   Wed 15:30   POT 251

Optical and electrical tuning between the normal insulating and topological insulating phase of InAs/GaSb bilayer quantum wells — •Manuel Meyer[1], Tobias Fähndrich[1], Sebastian Schmid[1], Sebastian Gebert[1], Gerald Bastard[1,2], Fabian Hartmann[1], and Sven Höfling[1] — [1]Technische Physik, Physikalisches Institut and Würzburg-Dresden Cluster of Excellence ct.qmat, Am Hubland, D-97074 Würzburg, Germany — [2]Physics Department, École Normale Supérieure, PSL 24 rue Lhomond, 75005 Paris, France

Topological insulators (TI) based on InAs/GaSb bilayer quantum wells (BQW) are appealing due to their rich phase diagram with a TI and normal insulating (NI) phase[1]. The switching between both phases can be achieved by external electric fields using a top and back gate (TG and BG)[2]. However, especially a fully functional BG is difficult to realize in antimonides due to leakage issues. To overcome this bottleneck we present another tuning knob using optical excitation to switch from the NI to the TI phase over the TI gap[3]. By monitoring the charge carrier densities we can identify the hybridized band structure and in-plane magnetic field measurements evidence the TI gap. Furthermore, a top-gated sample is investigated. Without a back gate we find properties from both phases for magnetotransport measurements which points to a mixing of NI and TI states. This is further indicated by the resistance peak evolutions with temperature for both samples.

Transport in high mobility HgTe heterostructures — •Michael Kick, Lena Fürst, Johannes Kleinlein, Saquib Shamim, Hartmut Buhmann, and Laurens W. Molenkamp — Experimentelle Physik III, Physikalisches Institut, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany

The Fractional Quantum Hall Effect (FQHE) has not yet been observed in the material system of HgTe. Due to recent progress in MBE growth, routinely charge carrier mobilities of HgTe heterostructures of over $\mu > 1 \cdot 10^6$ cm^2/Vs are obtained which is in the same order of magnitude as in the first reported experimental observation of the FQHE in GaAs/GaAlAs heterostructures. This opens up new prospects for transport investigations into the long time still open question of fractional states in this material system.

In 2-dimensional HgTe quantum wells, transport measurements show well pronounced quantum Hall plateaus for all filling factors, but no indication of any fractional state. High magnetic field measurements show a prolonged $\nu = 1$ plateau and a transition to an insulating state. Intriguingly, the $\nu = 1$ plateau exhibits a transition to an insulating state for filling factor $\nu = 1/2$.

Another possibility to observe the FQHE in HgTe is provided by the 2D surface states of a 3D topological insulator. High mobility layers, $\mu > 1 \cdot 10^6$ cm^2/Vs, of tensil strained HgTe are subject of extensive magneto-transport investigations. First results reveal a good and detailed correspondence to recent k.p band structure calculations for non-interacting electron systems.

Electron Density Depended Giant Negative Magnetoresistance — •Lina Bockhorn and Rolf J. Haug — Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany

Ultra-high mobility two-dimensional electron gases not only show an increasing number of new fractional filling factors, but also an astonishing robust negative magnetoresistance at zero magnetic field [1 -5]. The theoretical description of this negative magnetoresistance is still an open issue due to its complex dependencies on several parameters.

The behavior of the giant negative magnetoresistance is affected by different scattering events, e. g. interface roughness, oval defects, background impurities and remote ionized impurities, which leads to a strong dependence on different parameters. Here, we take a closer look on the temperature dependence of the giant negative magnetoresistance for different electron densities. At low temperatures we observe the predicted temperature dependence of $T^{1/2}$ [6].

TT 41.6   Wed 16:45   POT 251

Massless Dirac fermions on a space-time lattice with a topologically protected Dirac cone — •Michal Pacholski[1], Alvaro Donís Vela[3], Gal Lemut[3], Jakub Tworzydlo[2], and Carlo Beenakker[3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Warsaw University, Warsaw, Poland — [3]Lorentz Institute, Leiden, The Netherlands

The symmetries that protect massless Dirac fermions from a gap opening may become ineffective if the Dirac equation is discretized in space and time, either because of scattering between multiple Dirac cones in the Brillouin zone (fermion doubling) or because of singularities at zone boundaries. Here we introduce an implementation of Dirac fermions on a space-time lattice that removes both obstructions. The quasi-energy band structure has a tangent dispersion with a single Dirac cone that cannot be gapped without breaking both time-reversal and chiral symmetries. We show that this topological protection is absent in the familiar single-cone discretization with a linear sawtooth dispersion, as a consequence of the fact that there the time-evolution operator is discontinuous at Brillouin zone boundaries.

Time: Wednesday 15:00–18:00   Location: P2/OG2

TT 42.1   Wed 15:00   P2/OG2

Single crystal growth and characterization of CeCoIn$_5$ and Ce$_2$IrIn$_8$ — •Anja Philipp, Kristin Kliemt, and Cornelius Krellner — Max-von-Laue-Straße 1

The heavy-fermion series Ce$_n$T$_m$In$_{3n+2}$ (n=1,2; T = Co, Rh, Ir) with the unique tetragonal crystal structure, leading to a quasi-two dimensional Fermi surface, received growing attention over the past decades [1],[2],[3]. In these compounds, there are strong electronic interactions between conduction electrons and localized 4f-electrons of the Ce ions, which lead to a variety of interesting phenomena like spin and valence fluctuations, Kondo effect, magnetic order, non Fermi-liquid behaviour and unconventional superconductivity [3].

In this contribution, the results of the self-flux growth of CeCoIn$_5$ and Ce$_2$InIr$_8$ single crystals are shown. The crystallographic orientation of the single crystals was determined using microscopy and Laue X-ray diffraction. The physical properties like resistivity, heat capacitiy and magnetic susceptibility down to 2K were measured for both compounds and were analyzed in this work.

Search for superconductivity in CeSb$_2$ under chemical pressure — •Jan Weber, Kristin Kliemt, and Cornelius Krellner — Max-von-Laue Straße 1, 60438 Frankfurt am Main, Physikalisches Institut

Recently, an unconventional superconducting state was discovered at a pressure-induced magnetic quantum critical point in the Kondo-lattice system CeSb$_2$ [1]. Under normal pressure CeSb2 crystallizes in the orthorombic SmSb$_2$ structure (Space group 64) [2]. At high pressures, the crystal structure changes and CeSb$_2$ adopts the ZrSi$_2$ - structure (Space group 63)[1]. This change in structure precedes the superconductivity around the magnetic quantum critical point. In this contribution, we present first attempts to replace the physical pressure using adequate substituents to reproduce the high-pressure structure at ambient pressure.

TT 42.3   Wed 15:00   P2/OG2

Searching for the critical endpoint in cobalt-doped EuRh$_2$Si$_2$ — •Franziska Walther, Alexej Kraiker, Kristin Kliemt, and Cornelius Krellner — Physikalisches Institut, Goethe-Universität Frankfurt, 60438 Frankfurt/Main, Germany

The ternary europium-based intermetallic compounds with the ThCr$_2$Si$_2$-type structure show a variety of intriguing physical properties due to the coupling between lattice and electronic degrees of freedom. Eu ions can be present in a magnetic divalent or non-magnetic trivalent state. Under variation of temperature and pressure, it's possible to enforce a valence transition associated with a change of the unit cell volume [1]. At ambient pressure, EuRh$_2$Si$_2$ orders antiferromagnetically below T$_N$ = 24 K in a stable divalent state [2], whereas the isoelectronic related compound EuCo$_2$Si$_2$ is nearly trivalent und indicates no magnetic ordering [1]. EuRh$_2$Si$_2$ undergoes a pressure-induced first order valence transition [3]. We expect the second order critical endpoint in the pressure range from 1.7 to 2.1 GPa, where the first-order phase transition terminates and critical elasticity may occur. We want to approach the critical endpoint by applying chemical pressure through substituting Rh in EuRh$_2$Si$_2$ with Co. We report on the growth of samples of the Eu(Rh$_{1-x}$Co$_x$)$_2$Si$_2$ -system and the characterization of their physical and chemical properties.

TT 42.4   Wed 15:00   P2/OG2

Symmetry-broken low-temperature state in the Kondo system Ce$_2$Rh$_2$Ga — •Sajal Naduvile Thadathil^{1,2}, J Stirnat^{1,2}, P Devi^1, M Baenitz^3, A Strydom^4, D Soholov^4, J Wosnitza^{1,2}, and T Helm^1 — ^{1}Dresden High Magnetic Field Laboratory (HLD-EMFL), HZDR, Germany — ^{2}Institute of Solid State and Materials Physics, TU Dresden, Germany — ^{3}Max Planck Institute for Chemical Physics of Solid, Dresden, Germany — ^{4}University of Johannesburg, South Africa

Cerium-based heavy-fermion conductors often exhibit unconventional transport and thermodynamic properties related to 4f-electron physics. Ce$_2$Rh$_2$Ga exhibits a structural phase transition around $T_p \approx 130$ K from an orthorhombic to monoclinic crystal structure accompanied by an extreme anisotropy in its electrical conduction. Recent nuclear quadrupole resonance studies on polycrystals found evidence for the emergence of two inequivalent Ce ions below 2 K with different electronic environments that may provide grounds for multi-ion Kondo physics [1]. Here, we present results from magnetotransport studies on

micron-sized devices cut from single crystals. We investigated the anisotropy between 0.3 and 300 K in fields up to 16 T. Below 5 K, the angular dependence of the magnetoresistance exhibits a significant change in its rotational anisotropy, indicating a broken symmetry. These findings may provide further evidence for multi-ion Kondo physics in Ce$_2$Rh$_2$Ga.

[1] Sh. Yamamoto et al., Phys. Rev. B 106, 115125 (2022)

TT 42.5   Wed 15:00   P2/OG2

Spin excitations in the field-induced phase of Ce$_2$Bi — •Nikolai Pavlovskii^1, Anton Kulbakov^1, Aleksandr Sukhanov^1, Michael Smidman^2, Federico Mazza^3, and Dmytro Inosov^1 — ^{1}TU Dresden, Dresden, Germany — ^{2}Zhejiang University, Hangzhou, China — ^{3}Vienna University of Technology, Austria

The compound Ce$_2$Bi represents a rare example of the heavy fermion materials that exhibit the coexistence of an antiferromagnetic magnetic (AFM) order and a tricritical point (TCP) in their temperature-magnetic field phase diagram. This combination is unusual because the TCP typically occurs in the ferromagnetic (FM) heavy fermion materials. In AFMs, the magnetic order can in many cases be continuously suppressed to zero temperature at a quantum critical point (QCP) by tuning pressure, magnetic fields, or chemical substitution. In the case of FMs, the situation is usually different. There, a QCP is generally avoided by changing the character of the magnetic phase transition from the second order to the first order, which induces a TCP. Using neutron time-of-flight spectroscopy, we observed two weakly-dispersed magnetic excitations modes in Ce$_2$Bi below Neel temperature that seem to show a nontrivial response to the applied magnetic field.

TT 42.6   Wed 15:00   P2/OG2

Transverse-field susceptibility of spin freezing at the mesoscale quantum phase transitions in LiHoF$_4$ — •Michael Lampl, Andreas Wendl, Felix Rucker, and Christian Pfleiderer — Physik-Department, Technical University of Munich, 85748 Garching, Germany

The perhaps best understood example of a quantum critical point is the response of the dipolar Ising ferromagnet LiHoF$_4$ under a transverse field [1-3]. When tilting the magnetic field away from the hard axis such that the Ising symmetry is always broken, a line of well-defined phase transitions emerges from the transverse-field quantum critical point, characteristic of further symmetry breaking, and in stark contrast to a crossover expected microscopically [4]. Detailed theoretical modelling in excellent agreement with experiment identifies this line of phase transitions as mesoscale quantum criticality. We report an experimental study of the transverse-field susceptibility of this mesoscale quantum criticality into a regime of spin freezing under large field tilting angles. Our observations will be compared with the characteristics of spin freezing, kinetic arrest, and quantum annealing observed in heavily diluted LiHo$_x$Y$_{1-x}$F$_4$.

Phase diagram study of the Falicov-Kimball model on the two-dimensional Kagome lattice — Younes Javanmard^1 and •Ammar Nejati^2 — ^{1}Leibniz Universität Hannover, Hannover, Germany — ^{2}Jülich Centre for Neutron Science (JCNS), Forschungszentrum Jülich

The Falicov-Kimball Model (FKM) is a relatively simple model of coupled quantum and classic degrees of freedom, in the middle of the spectrum between the Hubbard and the Anderson models. A number of studies have revealed its rich phase diagram in two-dimensional lattices, e.g. square and triangular lattices [1,2]. In a square lattice with half-filling, depending on the interaction strength and temperature, FKM exhibits a rich variety of phases: At sufficiently low temperatures, there is a charge density wave (CDW) phase; at high temperatures and weak interactions, a weakly localized phase appears which becomes an Anderson-localized phase in the thermodynamic limit; at high temperatures and strong interactions, a Mott insulating phase emerges [1]. In addition, there are two other phases called "quantum liquid" and "classical liquid" in triangular lattices and away from half-filling at sufficiently low temperatures and weak interactions [2].

We set up a Monte Carlo algorithm for the two-dimensional FKM away from the half-filling regime on a Kagome lattice to study this model's rich phase diagram, and to extend the previous studies regarding the consequences of geometry on the emegent quantum phases and the corresponding phase transitions.

Quantum-critical properties of random transverse-field Ising models extracted by quantum Monte Carlo methods — •Calvin Krämer, Anja Langheld, Jan Koziol, Max Hörmann, and Kai Phillip Schmidt — Lehrstuhl für Theoretische Physik I, Staudtstraße 7, Universität Erlangen-Nürnberg, D-91058 Erlangen, Germany

The transverse-field Ising model with quenched disorder is studied in one and two dimensions at zero temperature by stochastic series expansion quantum Monte Carlo simulations. Using a sample-replication method we are able to determine distributions of pseudo-critical points, from which critical shift and width exponents $\nu_{s/w}$ are extracted by finite-size scaling. The scaling of the averaged magnetisation at the critical points is used further to determine the order-parameter critical exponent β. The dynamical scaling in the Griffiths phase is investigated by measuring the local susceptibility in the disordered phase and the critical exponent z' is extracted.

TT 42.9   Wed 15:00   P2/OG2

Numerical investigation of the Ising model in a light-induced quantized transverse field — •Anja Langheld and Kai Phillip Schmidt — Lehrstuhl für Theoretische Physik I, Staudtstraße 7, Friedrich-Alexander Universität Erlangen-Nürnberg, D-91058 Erlangen, Germany

We investigate the Ising model in a light-induced quantized transverse field [1] with a particular focus on antiferromagnetic, potentially frustrated Ising interactions. Using exact diagonalization, we provide data for the antiferromagnetic chain in a longitudinal field that is inconsistent with earlier results coming from mean-field considerations [2]. In order to study the model on frustrated, two-dimensional lattice geometries, we extend the mean-field calculation and develop a quantum Monte Carlo update based on the recently introduced wormhole update [3], for which the photons are integrated out. By this means, the photons induce a retarded spin-spin interaction in imaginary time that is also non-local in space in contrast to the Ising interaction inherent to the model.

TT 42.10   Wed 15:00   P2/OG2

High-order series expansions and crystalline structures for Rydberg atom arrays — •Antonia Duft, Jan Koziol, Matthias Mühlhauser, Patick Adelhardt, and Kai Phillip Schmidt — Friedrich-Alexander-Universität Erlangen-Nürnberg

We investigate a model of hardcore bosons on the links of a Kagome lattice subject to a long-range decaying van-der-Waals interaction. This model is known to be the relevant microscopic description of Rydberg atom arrays excited by a detuned laser field which has been realized in experiments recently. Particular interest lies on this system as it is an engineerable quantum platform which has been predicted to to host a topological phase. We investigate the quantum phase diagram for different limiting cases with a main focus on the low interaction-strength limit where we apply high-order linked cluster expansions.

TT 42.11   Wed 15:00   P2/OG2

Superexchange and spin-orbit coupling in the half-filled t_{2g} shell — •Marco Schönleber, Daniel Pranjic, and Maria Daghofer — Insitut für Funktionelle Materie und Quantentechnologien, Universität Stuttgart

Strongly correlated and spin-orbit coupled t_{2g} systems have been extensively investigated. By coupling orbital and spin angular momentum into one quantity, spin-orbit coupling (SOC) tends to reduce orbital degeneracy, e.g. for the widely studied case of one hole in the t_{2g} shell. However, the opposite has to be expected at half filling. Without spin-orbit coupling, all orbitals are half filled, no orbital degree of freedom is left and coupling to the lattice can be expected to be small. At dominant spin-orbit coupling, in contrast, one of the $j = 3/2$ states is empty and the system couples to the lattice. We investigate this issue. One finding is that the low-energy manifold evolves smoothly from the four $S = 3/2$ states in the absence of SOC to the four $j = 3/2$ states with dominant SOC. These fur states are always separated from other states by a robust gap. We then discuss relevant superexchange models.

TT 42.12   Wed 15:00   P2/OG2

From linear to circular polarized light - Floquet engineering in Kitaev-Heisenberg materials with Lissajous figures — •Pascal Strobel[1] and Maria Daghofer[1,2] — [1]Institute for Functional Matter and Quantum Technologies, University of Stuttgart, 70550 Stuttgart, Germany — [2]Center for Integrated Quantum Science and Technology, University of Stuttgart, Pfaffenwaldring 57, 70550 Stuttgart, Germany

Floquet engineering is a promising tool for tuning magnetic interactions in the candidate Kitaev material α-RuCL$_3$. Amplitude and frequency of the time periodic light field are able to modulate both sign and strength of Kitaev-, Heisenberg-, and Γ-interactions present in α-RuCl$_3$. This paves the way for possibly driving α-RuCL$_3$ into the sought after Kitaev spin-liquid phase.

We want to discuss possibilities of Floquet engineering with arbitrary polar-ized light in α-RuCl$_3$. In order to do so, we describe the influence of arbitrary polarization via an effective model including Lissajous figures. This model is derived via perturbation theory up to fourth order. Starting from linear and circular polarized light we bridge the gap between those two limiting cases. Moreover we study more complex Lissajous figures and general trends arising for them.

TT 42.13   Wed 15:00   P2/OG2

Complete field-induced spectral response of the spin-1/2 triangular-lattice antiferromagnet CsYbSe$_2$ — •Stanislav Nikitin[1], T. Xie[2], A. A. Eberharter[7], J. Xing[2], S. Nishimoto[3,4], M. Brando[5], P. Khanenko[5], J. Sichelschmidt[5], A. A. Turrini[1], D. G. Mazzone[1], P. G. Naumov[1], L. D. Sanjeewa[2], A. S. Sefat[2], B. Normand[1,6], A. M. Lauchli[1,6], and A. Podlesnyak[2] — [1]Paul Scherrer Institut, Switzerland — [2]Oak Ridge National Laboratory, USA — [3]TU Dresden, Germany — [4]IFW, Germany — [5]MPI CPfS, Germany — [6]EPFL, Switzerland — [7]Universitat Innsbruck, Austria

The spin 1/2 triangular lattice Heisenberg antiferromagnet remains on of the most attractive models to explore highly entangled quantum spin states in proximity to magnetic order. In my presentation I will discuss our recent results on CsYbSe$_2$. This materials exhibits strong two-dimensional magnetic behavior in absence of exchange and structural disorder and its spin Hamiltonian is well described by J_1–J_2 AFM Heisenberg model. We performed comprehensive INS measurements over the whole field scale starting from zero field up to the saturation and observed that corresponding excitation spectra evolve from continuum-like to relatively sharp spin-wave modes in the up-up-down phase, then back to continua and back to spin waves. We further support our observation by cylinder MPS calculation, which reproduce all observed features with semi-quantitative accuracy. Thus our comprehensive experimental and theoretical analysis of the field-induced spin excitations in the CsYbSe$_2$ provides valuable insight into the dynamics of a broad class of quantum many-body systems.

TT 42.14   Wed 15:00   P2/OG2

Low energy, mobile excitations in herbertsmithite revealed by magnetothermal conductivity — •Ralf Claus, Jan Bruin, Yosuke Matsumoto, Jürgen Nuss, Masahiko Isobe, and Hidenori Takagi — Max Planck Institute for Solid State Research, Stuttgart, Germany

We report the magnetothermal conductivity k(B) of the Kagome quantum spin liquid candidate herbertsmithite (ZnCu$_3$(OH)$_6$Cl$_2$) in the temperature range from 100 mK to 70 K with applied magnetic fields up to 12 T for heat flow parallel and perpendicular to the Kagome planes. We identify both phonon and magnetic contributions to k and find that the latter is only present for heat flow within the Kagome planes. These 2D magnetic contributions persist down to at least 200 mK, consistent with the presence of low-lying quantum spin liquid excitations with a gapless excitation spectrum.

TT 42.15   Wed 15:00   P2/OG2

Field-tuned critical fluctuations in the triangular-lattice delafossite NaYbO$_2$ probed by ^{23}Na NMR — •S. Luther[1,2], K. M. Ranjith[3,4], D. Opherden[1], S. Khim[3], H. Yasuoka[3], J. Wosnitza[1,2], M. Baenitz[3], and H. Kühne[1] — [1]Hochfeld-Magnetlabor Dresden, HZDR — [2]Institut für Festkörper- und Materialphysik, TU Dresden — [3]MPI-CPfS, Dresden — [4]IFW Dresden

The frustrated triangular-lattice delafossite NaYbO$_2$ is a promising candidate for realizing a quantum spin liquid (QSL) ground state. The combination of a strong spin-orbit coupling and crystalline-electric-field effects leads to a magnetic anisotropy and a pseudospin-1/2 state of the Yb^{3+} ions at low temperatures. The absence of magnetic order and emergence of pronounced low-energy spin fluctuations have been shown by several experimental techniques, such as specific heat, inelastic neutron scattering, and muon spin relaxation. We present ^{23}Na NMR investigations of the low-temperature spin correlations by means of spectroscopy and $1/T_1$ measurements of polycrystalline NaYbO$_2$. At small magnetic fields and low temperatures, a strongly increased $1/T_1$ rate, as well as the absence of significant spectral line broadening suggest the presence of a QSL ground state with critical fluctuations at the verge of a magnetic instability. Above about 1 T, a crossover regime with persistent strong spin fluctuations and an onset of static magnetic ordering is observed. For fields above about 2 T, the formation of field-induced long-range magnetic order yields a strongly suppressed $1/T_1$ rate and an inhomogeneously broadened spectral lineshape.

TT 42.16   Wed 15:00   P2/OG2

Disorder effects in spiral spin liquids — •Pedro Monteiro Cônsoli and Matthias Vojta — Institut für Theoretische Physik, TU Dresden

Spiral spin liquids are a special kind of paramagnetic state that features a subextensive classical ground-state degeneracy related to a family of spin spirals whose ordering wave vectors form a submanifold of momentum space. As the number of their theoretical and experimental realizations grows, there is cumulative evidence that, under additional perturbations, spiral spin liquids constitute a promising platform for the emergence of exotic phases of matter and excitations, including quantum spin liquids, multiple-q states, and skyrmions. However, little is known about their response to quenched disorder. In this poster, we investigate how various types of defects affect the classical ground-state manifold

of a spiral spin liquid on the honeycomb lattice. Among our results, we describe how different order-by-disorder mechanisms can arise, compete among themselves, and lead to spin-glass physics in these systems.

TT 42.17   Wed 15:00   P2/OG2

Second-harmonic generation in the Kitaev model — •Olesia Krupnitska[1,2] and Wolfram Brenig[1] — [1]Institute for Theoretical Physics, Technical University Braunschweig, D-38106 Braunschweig, Germany — [2]Institute for Condensed Matter Physics, National Academy of Sciences of Ukraine, 1 Svientsitskii Street, Lviv, 79011, Ukraine

Optical spectroscopies are important probes for elementary excitations of quantum magnets. In the present study, we investigate second-harmonic generation in the hexagonal Kitaev model induced by external electric fields. The prime interest is to identify fingerprints of fractionalization as has been shown to exist in this model in terms of Majorana particles and gauge excitations. For that purpose second order response functions are calculated within the equation of motion approach. Analytical results for the spectrum will be presented in the homogeneous gauge sector and exchange anisotropy and temperatures of Majorana fermions will be analyzed. The impact of gauge flux excitation will be speculated upon.

TT 42.18   Wed 15:00   P2/OG2

Magnetostriction in frustrated planar quantum magnets — •Alexander Schwenke and Wolfram Brenig — Institute for Theoretical Physics, Technical University Braunschweig, D-38106 Braunschweig, Germany

Using the numerical linked cluster expansion (NLCE) focussing on the single-site representation, we study the field-induced thermodynamic and magnetoelastic properties of paradigmatic frustrated planar spin models. Results are presented for the energy, the specific heat and the magnetization. Employing simple magnetoelastic modelling we calculate the linear magnetostriction coefficient versus temperature and external magnetic field. In particular we consider magnetostriction at field-induced quantum phase transitions. Results obtained for the generalized Kitaev honeycomb model are extended to include findings on the anisotropic triangular Heisenberg antiferromagnet.

TT 42.19   Wed 15:00   P2/OG2

Continuous similarity transformation for critical phenomena: bilayer antiferromagnetic Heisenberg-model and $J_1 - J_2$-model — •Matthias R. Walther[1], Dag-Björn Hering[2], Götz S. Uhrig[2], and Kai P. Schmidt[1] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Institut für Theoretische Physik I, Staudtstraße 7, 91058 Erlangen — [2]Technische Universität Dortmund, Department of Physics, Condensed Matter Theory, Otto-Hahn-Str. 4, 44227 Dortmund

We apply continuous similarity transformations (CSTs) to the bilayer antiferromagnetic Heisenberg model and the antiferromagnetic $J_1 - J_2$ model on the square lattice. The bilayer Heisenberg model features a well studied, continuous phase transition in the O(3) universality class between a gapless Néel phase and a gapped paramagnetic dimer phase (valence bond solid). The $J_1 - J_2$ features a gapless Néel phase for $J_1 \gg J_2$, a gapless columnar phase for $J_2 \gg J_1$ and an intermediate phase whose nature is still under debate. We start in both models from the magnetically ordered, collinear phases and approach the quantum phase transitions indicating the breakdown of these long-range ordered phases. The CST flow equations are truncated in momentum space by the scaling dimension d so that all contributions with $d \leq 2$ are taken into account. We determine critical points by studying the breakdown of the ordered phases and try to determine critical exponents from the flow of the couplings, the ground-state magnetization and the ground-state energy.

TT 42.20   Wed 15:00   P2/OG2

Continuous similarity transformation for critical phenomena: easy-axis antiferromagnetic XXZ model — •Dag-Björn Hering[1], Matthias R. Walther[2], Kai P. Schmidt[2], and Götz S. Uhrig[1] — [1]Technische Universität Dortmund, Department of Physics, Condensed Matter Theory, Otto-Hahn-Str. 4, 44227 Dortmund — [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Institut für Theoretische Physik I, Staudtstraße 7, 91058 Erlangen

We apply continuous similarity transformations (CSTs) to the easy-axis antiferromagnetic XXZ-model on the square lattice. The CST flow equations are truncated in momentum space by the scaling dimension d so that all contributions with $d \leq 2$ are taken into account. The resulting quartic magnon-conserving effective Hamiltonian is analyzed in the zero-, one-, and two-magnon sector. In this way, a quantitative description of the ground-state energy, the one-magnon dispersion and its gap as well as of two-magnon bound states is gained for anisotropies ranging from the gapped Ising model to the gapless Heisenberg model. We discuss the critical properties of the gap closing as well as the evolution of the one-magnon roton mininum. The excitation energies of two-magnon bound states are calculated and their decay into the two-magnon continuum is determined via the inverse participation ratio.

TT 42.21   Wed 15:00   P2/OG2

Quantum criticality of the frustrated transverse-field Ising model on a triangular lattic using enhanced perturbative continous unitary transformations — •Lukas Schamriss[1], Matthias R. Walther[1], Dag-Björn Hering[2], and Kai P. Schmidt[1] — [1]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Staudtstraße 7, 91058 Erlangen, Germany — [2]Condensed Matter Theory, Technische Universität Dortmund, Otto-Hahn-Straße 4, 44221 Dortmund, Germany

Ising models in a transverse field are paradigmatic models for quantum phase transitions of various universality classes which occur depending on the lattice geometry and the choice of antiferromagnetic of ferromagnetic coupling. We investigate the quantum phase diagram of the bilayer antiferromagnetic transverse field Ising model on a triangular lattice with an Ising-type interlayer coupling. Without a field, the model is known to host a classically disordered ground state, and in the limit of decoupled layers it exhibits the 3dXY transition of the corresponding single layer model. Our starting point for the unknown parts of the phase diagram is a high-order perturbative calculation from the limit of isolated dimers. Enhanced perturbative continuous unitary transformations (epCUTs) are used to derive series expansions for the ground state and the energy gap. These are refined by directly evaluated epCUTs (deepCUTs) which provide estimates which coincide with the perturbative series up to its respective order and add a non-perturbative correction. These allow to draw conclusions about the nature of occurring phase transitions.

TT 42.22   Wed 15:00   P2/OG2

Quantum simulation of transverse field Ising model using numerical linked cluster expansions with variational quantum eigensolver — •Sumeet Sumeet, Max Hörmann, and Kai P. Schmidt — Institut für Theoretische Physik I Friedrich-Alexander-Universität Erlangen-Nürnberg

With the advancements in quantum technologies it has become inevitable to investigate the potential existence of quantum advantage for the paradigmatic models of quantum-many body physics. One of the very basic models is the transverse field Ising model that can be simulated on a quantum computer to compute properties such as the ground-state energy of a spin system. This problem, when tackled on a classical computer, leads to an exponential surge in the cost of computation with increasing system size. The advent of classical-quantum hybrid algorithms has shifted the focus to investigate the solution to this problem with algorithms such as the variational quantum eigensolver (VQE) which is considered reasonably good for obtaining the ground-state energies of quantum many-body systems in the NISQ era. In this work, we exploit the Hamiltonian variational ansatz for calculating the ground-state energy and fidelity of the transverse-field Ising model on one- and two-dimensional geometries. We devise strategies to compute the ground-state energy in the thermodynamic limit on quantum computers. In that regard, we apply numerical linked cluster expansions (NLCE) to VQE in order to simulate infinite spin systems using calculations on finite graphs. Further, we extend this approach to geometrically frustrated systems.

TT 43.1   Wed 15:00   P2/OG3

Interplay between order-by-disorder and long-range interactions — •Jan Alexander Koziol and Kai Phillip Schmidt — Department of Physics, Staudtstraße 7, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany

We study the ground-state properties of the antiferromagnetic long-range transverse-field Ising model in the limit of small transverse fields. We present degenerate perturbation theory calculations on the extensively degenerate nearest-neighbour ground-state space for finite systems, treating the long-range inter-action and the transverse field perturbatively. The long-range interaction breaks the degeneracy and stabilises a gapped six-fold degenerate plain stripe phase in the absence of a transverse field. An infinitessimal transverse-field leads to an order-by-disorder emergent six-fold degenerate gapped clock-ordered phase in the nearest-neighbour case. We demonstrate a level crossing transition between the plain stripe phase and clock ordered phase for finite transverse fields and long-range interactions.

TT 43.2 Wed 15:00 P2/OG3

Magnetic dilution of a frustrated triangular-lattice spin system — •Florian Bärtl[1,2], Ellen Häussler[3], Thomas Doert[3], Jörg Sichelschmidt[4], Sven Luther[1,2], Tommy Kotte[1], Jochen Wosnitza[1,2], Michael Baenitz[4], and Hannes Kühne[1] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden — [2]Institut für Festkörper- und Materialphysik, TU Dresden — [3]Fakultät für Chemie und Lebensmittelchemie, TU Dresden — [4]Max-Planck-Institut für Chemische Physik fester Stoffe, Dresden

Among the Yb-based triangular-lattice magnets, the delafossite $NaYbS_2$ is one of the promising candidates for realizing a quantum-spin-liquid (QSL) ground state. The magnetic phase diagram was probed by several experimental methods, such as specific-heat, magnetization, and NMR measurements. The proposed QSL ground state of $NaYbS_2$ is suppressed at fields of several tesla, and long-range order with various spin configurations is manifested. As a next step, we investigated possible changes to this phenomenology by diluting the magnetic lattice of $NaYbS_2$ by means of Lu substitution. A series of $NaYb_{1-x}Lu_xS_2$ single crystals, with $0 \le x \le 1$, were synthesized and characterized by various probes, including ESR spectroscopy. The ESR data reveal a systematic reduction of the Weiss temperature as x is increased. Further, we present recent specific-heat measurements for samples with $x \le 0.5$, which reveal a systematic suppression of the transition temperatures to long-range order in magnetic fields with increasing Lu substitution.

We acknowledge the support of the SFB 1143.

TT 43.3 Wed 15:00 P2/OG3

Dynamic flash method for probing heat transport of quantum magnets — •Maximilian Schiffer[1], Xiaochen Hong[1], Martin Valldor[2], Christian Hess[1,3], and Bernd Büchner[3] — [1]Fakultät für Mathematik und Naturwissenschaften, Bergische Universität Wuppertal, 42097 Wuppertal, Germany — [2]Centre for Materials Science and Nanotechnology (SMN), Department of Chemistry, University of Oslo, P.O. Box 1033 Blindern, N-0315 Oslo, Norway — [3]Leibniz-Institute for Solid State and Materials Research (IFW-Dresden), 01069 Dresden, Germany

Transport experiments in principle provide access to the investigation of exotic entropy carrying quasiparticles in quantum magnets, such as spinons in spin chains, triplons in spin ladders and Majorana fermions and visons in spin liquids. Generally, the thermal conductivity of an insulating, magnetic compound consists of phononic and magnetic contributions: $\kappa_{xx} = \kappa_{xx,ph} + \kappa_{xx,mag}$. Thus, measurement of κ_{xx} can offer a fine grasp of the above mentioned quasiparticles, which are currently under hot debate in the field of solid state physics.

Here we address heat transport experiments at elevated temperature which becomes important in materials with sizeable exchange interactions $J/k_B \gtrsim 100$ K. It is well known that standard steady state heat transport measurements are difficult for $T \ge 200$ K due to inevitable radiation losses. We present Laser Flash Analysis as a method for avoiding this problem. The method will be introduced, and initial results on various quantum materials will be discussed.

TT 43.4 Wed 15:00 P2/OG3

Modified nanoparticles of Prussian Blue metal organic frameworks — •Sascha A. Bräuninger and Hermann Seifert — Institute of General Radiology and Medical Physics, University of Veterinary Medicine Foundation, Hannover, Germany

Prussian Blue compounds (PBC), e.g. soluble $AFe^{3+}[Fe^{2+}(CN)_6] \cdot xH_2O$ (A = K, Na, NH_4), have shown a huge potantial of applications in physics, chemistry, medicine and radioecology, e.g., PBC acting as efficient ion exchanger extracting the radioistope ^{137}Cs in solutions. For potassium, proposed ferromagnetism by superexchange is discussed between Fe(III) with $S = 5/2$ and an effective magnetic moment of $\mu_{eff} \approx 5.98\mu_B$ consistent with a spin-only value of Fe(III) high-spin. Powder neutron diffraction studies showed a Curie temperature $T_C \approx 5.6$ K consistent with susceptibility measurements. Here, we are presenting the synthesis and low-energy investigation of modified magnetic Prussion-blue nanoparticles protected by PVP (polyvinylpyrrolidene).

TT 43.5 Wed 15:00 P2/OG3

Experimental studies of phase diagram of compound $Ni(2aepy)_2Cl(H_2O)]Cl \cdot H_2O$ - a spin-1 antiferromagnetic chain — •Mariia Holub[1], Slavomíra Šterbinská[2], Marc Uhlarz[3], Juraj Černák[2], and Erik Čižmár[1] — [1]Institute of Physics, Faculty of Science, P.J. Šafárik University, Park Angelinum 9, Košice, Slovakia — [2]Institute of Chemistry, Faculty of Science, P.J. Šafárik University, Moyzesova 11, Košice, Slovakia — [3]Dresden High Magnetic Field Laboratory (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße, Dresden, Germany

We present the study of compound $Ni(2aepy)_2Cl(H_2O)]Cl \cdot H_2O$ (2aepy = 2-aminoethylpyridine) identified as a spin-1 antiferromagnetic chain with ratio of D/J=1.14 (D is the single-ion anisotropy, J is the intrachain exchange interaction). It represents a unique experimental example of a system close to the quantum critical point (QCP), which is a topological phase transition that separates Haldane and Large-D gapped phases for spin-1 chains. In this work, we observed the presence of field-induced crossover into the gapless Tomonaga-Luttinger liq-

uid phase using low-temperature specific heat measurements. A very low first critical field is in good agreement with the small energy gap predicted close to QCP. Estimation of saturation field (second critical field) using D and J parameters was confirmed by high-field magnetic measurements at ≈ 12.5 T.

TT 43.6 Wed 15:00 P2/OG3

Electrical and thermal transport properties of delafossite oxide $CuCr_{1-x}FexO_2$ — •Mithun Kumar Majee[1], Ratnamala Chatterjee[1], and Preeti Bhobe[2] — [1]Department of Physics, Indian Institute of Technology Delhi, Hauz Khas, New Delhi 110016, India — [2]Department of Physics, Indian Institute of Technology Indore, Khandwa Road, Simrol, Indore-453552, India

In order to improve the thermoelectric property of a material the effect of phonon/magnon drag, and spin fluctuations are other central parameters apart from carrier concentration, and lower thermal conductivity. It is known from the literature that $CuCrO_2$ has a large Seebeck value of around 350 μV/K at room temperature, but its electronic concentration is low, hence the thermoelectric figure-of-merit (ZT) turns out to be quite poor. Hence to better its ZT, we attempt to replace some Cr ions with Fe in the series, $CuCr_{1-x}Fe_xO_2$ (0<x<1) and study its electrical and thermal conductivity, heat capacity, and Seebeck coefficient. Our results exhibit a large and complex Seebeck coefficient in 20 K<T<380 K. The low-temperature electrical conduction is observed to obey 3D variable range hopping mechanism. Unlike, nonmagnetic Cu-based Delafossites, we show that the thermal conductivity is strongly affected by spin-phonon scattering in $CuCr_{1-x}FexO_2$ compositions. The heat capacity measurements identify the Debye temperature and effects due to magnetic ordering temperatures. Out of the different contributed processes, the role of the phonon drag effect and complexity in temperature dependence is observed in the Cr-rich compositions.

TT 43.7 Wed 15:00 P2/OG3

Influence of lattice strain on the electronic and magnetic properties of $SrRuO_3/SrTiO_3$ heterostructures — •Robin Heumann, Robert Gruhl, and Philipp Gegenwart — Experimentalphysik VI, Universität Augsburg, 86159 Augsburg, Germany

Layered ruthenate Sr_2RuO4, consisting of strontium- and ruthenium-oxide stacks along the c-axis, is a prototype unconventional superconductor and continues to attract strong interest. Artificial heterostructures composed of layers of $SrRuO_3$ (SRO) and $SrTiO_3$ (STO) were recently considered by band-structure calculations [1,2]. It is predicted that SRO_1/STO_1 bilayers show a variety of emergent quantum states tunable by lattice strain, including ferro- and checkerboard-type antiferromagnetism, spin-density waves [1] and even unconventional superconductivity [2].

Utilizing metal-organic aerosol deposition $[SRO_n/STO_n]_m$ epitaxial heterostructures were grown. The superlattices show sharp interfaces and an atomically smooth surface morphology. Different substrates were used to study the effect of tensile and compressive lattice strain. Besides structural studies by x-ray diffraction, reciprocal space mapping and TEM imaging we utilized Hall- and magnetoresistance as well as magnetization measurements to investigate the electronic and magnetic properties.

TT 43.8 Wed 15:00 P2/OG3

Manipulating the metal-insulator transition in ultrathin oxide films by strain engineering — •Sizhao Huang, Philipp Scheiderer, Judith Gabel, Michael Sing, and Ralph Claessen — Physikalisches Institut and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany

The relationship between metal-insulator transition (MIT) and strain relaxation in films of strongly correlated perovskite oxides has been intensively studied. The oxide films can emerge numerous phenomena when the film thickness is reduced towards the 2D limit, such as SrVO3 (SVO). In our previous studies on SrTiO3 (STO) capped SVO films, a transition from the Mott insulating state at 6 u.c. to metallic behaviour at 10 u.c. film thickness has been found. In order to further explore the relationship between MIT transition and orbital occupation, we have grown coherently strained SVO thin films on various substrates with different lattice constants by pulsed laser deposition (PLD) in an Ar gas background. Using x-ray photoelectron spectroscopy and transport measurements, we have found that the MIT in SVO thin films can be fine-tuned by both film thickness and strain.

TT 43.9 Wed 15:00 P2/OG3

Towards noise spectroscopy at the Mott critical endpoint — •Tim Thyzel[1], Harald Schubert[1], Michael Lang[1], Takahiko Sasaki[2], and Jens Müller[1] — [1]Institute of Physics, Goethe-Universität Frankfurt, Frankfurt (Main), Germany — [2]Institute of Materials Research, Tohoku University, Sendai, Japan

Quasi-two-dimensional organic charge-transfer salts are ideal model systems for studying strongly correlated electrons due to their chemical variability, good physical tunability and rich phase diagrams.

Of special interest has been the family of Mott-Insulators κ-$(ET)_2Cu[N(CN)_2]Z$ where Z is Br or Cl, which exhibit superconductivity and an insulator-to-metal transition in an easily accessible temperature-pressure window. In particular, we focus on the critical endpoint of the Mott transition, where a breakdown of Hooke's law of elasticity has been observed [1], as well as indications of ergodicity breaking [2].

We employ resistance noise spectroscopy as a powerful method to detect slow dynamics in charge transport near the Mott endpoint, which we access in a cryogenic hydrostatic gas pressure setup. Using this technique, we search for a slowing-down of carrier dynamics, as well as the appearance of non-stationary fluctuations hinting at critical behaviour. Details on the experimental setup will be presented, as well as initial spectroscopy scans of the phase diagram.

TT 43.10   Wed 15:00   P2/OG3

Thermal-history-dependent electronic properties of κ-(BEDT-TTF)$_2$Cu[N(CN)$_2$]Br close to the Mott metal-insulator transition — •Florian Kollmannsberger[1,2], Shamil Erkenov[1,2], Natalia Kushch[1], Toni Helm[3], Werner Biberacher[1], and Mark Kartsovnik[1] — [1]Walther-Meißner-Institut, 85748 Garching, Germany — [2]Technische Universität München Fakultät Physik, 85748 Garching, Germany — [3]Hochfeld-Magnetlabor Dresden, HZDR, 01328 Dresden, Germany

The partially deuterated organic charge-transfer salt κ-(BEDT-TTF)$_2$Cu-[N(CN)$_2$]Br (shortly, κ-Br) can be tuned over the Mott-metal-insulator transition (MIT) by rapid cooling through the temperature interval around $T_g \simeq 75$ K where a glassy ordering of the BEDT-TTF ethylene endgroups occurs. It was suggested [1,2] that this tuning happens due to a change of the conduction bandwidth, an effect similar to that induced by hydrostatic pressure. We investigated the influence of the ethylene group ordering in purely hydrogenated κ-Br. To this end, we have studied the resistance as a function of temperature and magnetic field for samples cooled through the glass transition at different rates. In particular, we have studied the variation in the behavior of magnetoresistance quantum oscillations. This allows us to trace the change in the Hubbard model parameter U/t extracted from the renormalized effective cyclotron mass.

Tetragonal CuO : Suppression of nearest-neighbour correlations in a strongly correlated material — •Benjamin Bacq-Labreuil[1], Max Bramberger[2], Martin Grundner[2], Silke Biermann[3], Ulrich Schollwöck[2], Sebastian Paeckel[2], and Benjamin Lenz[4] — [1]Institut Quantique, Université de Sherbrooke, Sherbrooke, Canada — [2]Arnold Sommerfeld Center of Theoretical Physics, University of Munich, Munich, Germany — [3]CPHT, Ecole Polytechnique, Palaiseau, France — [4]IMPMC, Sorbonne Université, Paris, France

Since tetragonal CuO (t-CuO) is composed of well separated 2D CuO planes, it appears as an ideal candidate to connect model calculations with real materials in the quest of understanding the nature of high-temperature superconductivity. In this work [1], we investigate the low-energy electronic properties of t-CuO by means of Cellular Dynamical Mean Field Theory (CDMFT) using a 2D Hubbard model. From experiment it was proposed that single layers of t-CuO can be viewed as two weakly interconnected sublattices. Our calculations support this assumption: we find a suppression of the nearest-neighbour (NN) correlations for the benefit of the next-nearest neighbour (NNN) ones. The calculated spectral function is in remarkable agreement with photoemission experiments, showing that a one-band model is sufficient to capture the low-energy physics of t-CuO. Finally, we study the transition from the paramagnetic to antiferromagnetic phase at finite temperature and elucidate the nature of the insulating regime in both phases.

Thermal expansion measurements at low temperatures of a valence fluctuating system close to a critical endpoint. — •Arif Ata, Bernd Wolf, Jan Zimmermann, Marius Peters, Kristin Kliemt, Cornelius Krellner, and Michael Lang — PI, SFB/TRR288, Goethe Univ., Frankfurt/M., Germany

Thermodynamic investigations of highly correlated electron systems at low-temperatures are of general interest. Especially strong-coupling effects between lattice- and electronic degrees of freedom, which are expected around second-order critical endpoints [1], have become topics of current interest. These include phenomena such as critical softening and deviations from Hooks law of elasticity [1]. The intermetallic compound EuPd$_2$Si$_2$ and its Ge-doped variants, which show different kinds of phase transitions such as valence- and magnetic- transitions, are promising target materials for such investigations [2]. Of particular interest is the possibility to approach the critical regime by the combination of chemical pressure (Ge-doping) and He-gas pressure. In this work we present results of thermal expansion measurements on single crystalline EuPd$_2$(Si$_{1-x}$Ge$_x$) as a function of temperature for 4.2 K ≤ T ≤ 300 K and He-gas pressure P ≤ 12

kbar The data have been obtained by using a strain gauge, enabling measurements of thermal expansion and compressibility to be performed at high pressure, i.e., in P-T parameter ranges where He is in its solid phase.

TT 43.13   Wed 15:00   P2/OG3

Probing the electron-lattice coupling near the valence transition in YbLn$_{1-x}$Ag$_x$Cu$_4$ — •Jan Zimmermann, Bernd Wolf, Michelle Ocker, Kristin Kliemt, Cornelius Krellner, and Michael Lang — PI, SFB/TR288, Goethe Univ., Frankfurt/M,. Deutschland

The recently proposed phenomenon of *critical elasticity* is linked to a nonperturbatively strong coupling between lattice- and critical electronic degrees of freedom [1]. Intermetallic compounds that show various types of phase transitions such as valence- or structural instabilities that make it possible to study such collective phenomena, are currently a field of high interest. It has been shown that doping can be used in EuPd$_2$(Si$_{1-x}$Ge$_x$)$_2$ to generate chemical pressure which may open up the possibility to experimentally access directly the area around the critical endpoint [2]. It is expected to find similar effects for the valence transition in the doped intermetallic compound YbLn$_{1-x}$Ag$_x$Cu$_4$ [3]. We are investigating the elasticity of YbLn$_{1-x}$Ag$_x$Cu$_4$ using ultrasound-wave-propagation. In addition to measurements performed under variable temperature, we have developed a new setup that allows ultrasonic measurements to be performed under variable He-gas pressure. We will discuss first results on the elasticity, in comparison with data on the magnetic susceptibility, and highlight the additional experimental possibilities the new setup offers.

TT 43.14   Wed 15:00   P2/OG3

Order from disorder phenomena in BaCoS$_2$ — •Benjamin Lenz[1], Michele Fabrizio[2], and Michele Casula[1] — [1]IMPMC, Sorbonne Université, CNRS, MNHN, 4 Place Jussieu, 75005 Paris, France — [2]International School for Advanced Studies (SISSA), Via Bonomea 265, I-34136 Trieste, Italy

We investigate different nematic and orbital ordered instabilities in the antiferromagnetic insulating phase of BaCoS$_2$, which shows a Néel transition at a surprisingly high temperature of $T_N \sim 300$ K. Based on *ab initio* simulations, we discuss several competing orders in terms of magnetic order, orbital composition and structural distortions to identify a set of nematic and orbital ordered states as possible candidates for the ground state. From these considerations we derive an effective spin model of $J_1 - J_2 - J_3$ type and discuss the consequences of the most probable, orbital ordered ground state for its parametrization. We finally identify a driving mechanism which allows to explain the high Néel temperature by C_4-symmetry breaking through orbital order and draw parallels to other quasi-2D materials such as pnictides.

TT 43.15   Wed 15:00   P2/OG3

Basis dependence of the Mott transition in Ba$_2$IrO$_4$ within Dynamical Mean Field Theory — •Francesco Cassol[1], Léo Gaspard[2], Cyril Martins[2], Michele Casula[1], and Benjamin Lenz[1] — [1]L'Institut de Minéralogie, de Physique des Matériaux et de Cosmochimie (IMPMC) , Sorbonne Université, Paris, France — [2]Laboratoire de Chimie et Physique Quantiques, Université Toulouse III Paul Sabatier, Toulouse, France

Among strongly correlated materials Sr$_2$IrO$_4$ is often presented as a paradigmatic system for the complex competition that takes place between ligand field, spin-orbit coupling (SOC), Coulomb correlation and structural distortion. Ba$_2$IrO$_4$ has recently attracted some interest being simpler in view of the absence of structural distortion and being isostructural to La$_2$CuO$_4$. Normally, the physics of iridates has been described within a $j_{eff} = \frac{1}{2}$ basis representation solved by means of Dynamical Mean Field Theory (DMFT). This picture however, while it partially alleviates the sign problem of Quantum Monte Carlo solver, often goes in hands with some approximation that prevent the application of a fully Ab initio DFT+DMFT scheme. In this work, we will go beyond standard approximation comparing the usual schemes to the orbital picture.

TT 43.16   Wed 15:00   P2/OG3

Calculating moments for many-electrons systems — •Elaheh Adibi and Erik Koch — Institute for Advanced Simulation, Forschungszentrum Jülich, 52425 Jülich, Germany

We present a technique for computing the moments $\langle E^M \rangle = \mathrm{Tr}\, H^M$ of the many-electron spectrum. Taking the trace over a basis of Slater determinants $|I\rangle$ and expressing the Hamiltonian in the same orbital basis, matrix elements $\langle I|H^M|I \rangle$ can only be non-zero when the orbital indices of the creation operators are a permutation of those of the annihilation operators. Writing the permutations in cycle notation and realizing that the trace over a cycle with different orbital indices only depends on the number of descends, we can write the trace as a sum over products of Eulerian numbers times binomial factors involving the number of orbitals and electrons.

TT 43.17   Wed 15:00   P2/OG3

Exact diagonalization with twisted boundary conditions — •Benjamin Heinrich — Institut für funktionelle Materie und Quantentechnologie, Universität Stuttgart

When using exact diagonalization, using twisted instead of periodic boundary conditions gives access to additional momentum points. We investigate here in detail flavour-specific twisted boundary conditions, where each spin and /or orbital can have different boundary conditions. One goal is to assess whether and to which extent this improves estimates of observables (e.g. the ground-state energy). As increased momentum resolution is of particular interest in excitation spectra, a second aim is to estimate the quality of these additional data. We investigate the method for one- and two-dimensional one- and two-band Hubbard models. First results suggest that the additional momenta work well where the relevant physics is to a large extent captured by one quasiparticle (e.g. the magnon in case of magnetic spectra), but are less reliable in more complex scenarios (e.g. two spinons).

TT 43.18   Wed 15:00   P2/OG3

Symmetries and independent parameters of Coulomb matrix elements — •Coraline Letouzé, Guillaume Radtke, Benjamin Lenz, and Christian Brouder — Sorbonne Université, Muséum National d'Histoire Naturelle, UMR CNRS 7590, IRD, Institut de Minéralogie, de Physique des Matériaux et de Cosmochimie, IMPMC, 75005 Paris, France

In realistic (DFT+DMFT) calculations of correlated materials, the matrix of the partially-screened electron-electron Coulomb interaction is usually approximated in spherical symmetry and parameterized by Slater integrals (or, equivalently, Racah parameters). Few works have considered the real point-group symmetry of the Coulomb matrix. We suggest parameterizing the Coulomb matrix by its eigenvalues on the irreducible representations of the point group: this respects the point-group symmetry of the system and, compared to other approaches, is completely basis-independent. The permutation symmetry of the 1-electron states in the Coulomb matrix is also taken into account in the two cases of real and complex wavefunctions, to further reduce the number of independent parameters. Finally we apply this method to 3d-transition-metal monoxides.

TT 43.19   Wed 15:00   P2/OG3

Phase diagram of the SU(3) Fermi-Hubbard model with next-neighbor interactions — •Arturo Pérez Romero[1,2], Jereson Silva Valencia[2], and Roberto Franco Peñaloza[2] — [1]Institut for Theoretical Physics, Georg-August-Universität Göttingen, D-37077 Göttingen, Germany — [2]Departamento de Física, Universidad Nacional de Colombia, A. A. 5997 Bogotá, Colombia.

We explore the zero-temperature phase diagram of a one-dimensional gas composed of three-color fermions, which interact locally and with their next neighbors. Using the density matrix renormalization group method and considering one-third filling, we characterize the ground state for several values of the parameters, finding diverse phases, namely: phase separation, spin density wave, pairing phase, a metallic phase, two different charge-density waves, and a non-separable state with modulation of charge. We show that the von Neumann block entropy and the fidelity susceptibility are useful for estimating the borders between the phases.

TT 43.20   Wed 15:00   P2/OG3

Spatiotemporal dynamics of classical and quantum density profiles in low-dimensional spin systems — Tjark Heitmann[1], Jonas Richter[2], Fengping Jin[3], Kristel Michielsen[3], Hans De Raedt[4], and •Robin Steinigeweg[1] — [1]University of Osnabrück, DE — [2]University College London, UK — [3]FZ Jülich, DE — [4]University of Groningen, NL

We provide a detailed comparison between the dynamics of high-temperature spatiotemporal correlation functions in quantum and classical spin models. In the quantum case, our large-scale numerics are based on the concept of quantum typicality, which exploits the fact that random pure quantum states can faithfully approximate ensemble averages, allowing the simulation of up to 40 spin-1/2 spins. Due to the exponentially growing Hilbert space, we find that for such system sizes even a single random state is sufficient to yield results with extremely low noise. In contrast, a classical analog of typicality is missing. In particular, in order to obtain data with a similar level of noise in the classical case, extensive averaging over classical trajectories is required, no matter how large the system size. Focusing on (quasi-)one-dimensional spin chains and ladders, we find a remarkably good agreement between quantum and classical dynamics. Comparing space-time profiles of the spin and energy correlation functions, the agreement is found to hold not only in the bulk but also in the tails of the resulting density distribution. The mean-squared displacement of the density profiles is found to exhibit similar scaling for quantum and classical models.

TT 43.21   Wed 15:00   P2/OG3

Probing real-time broadening of nonequilibrium density profiles via a local coupling to a Lindblad bath — •Tjark Heitmann[1], Jonas Richter[2], Jacek Herbrych[3], Jochen Gemmer[1], and Robin Steinigeweg[1] — [1]University of Osnabrück, Germany — [2]University College London, UK — [3]Wroclaw University of Science and Technology, Poland

The Lindblad master equation is one of the main approaches to open quantum systems. While it has been widely applied in the context of condensed matter systems to study properties of steady states in the limit of long times, the actual route to such steady states has attracted less attention yet. Here, we investigate the nonequilibrium dynamics of spin chains with a local coupling to a single Lindblad bath and analyze the transport properties of the induced magnetization. Combining typicality and equilibration arguments with stochastic unraveling, we unveil for the case of weak driving that the dynamics in the open system can be constructed on the basis of correlation functions in the closed system, which establishes a connection between the Lindblad approach and linear response theory at finite times. In this way, we provide a particular example where closed and open approaches to quantum transport have to agree strictly. We demonstrate this fact numerically for the spin-1/2 XXZ chain at the isotropic point and in the easy-axis regime, where superdiffusive and diffusive scaling is observed, respectively.

TT 43.22   Wed 15:00   P2/OG3

Configuration interaction based nonequilibrium steady state impurity solver for the Anderson-Holstein model — •Daniel Werner and Enrico Arrigoni — ITPCP, Graz, Austria

Recently we developed a non-equilibrium impurity solver based on the Auxiliary Master Equation Approach using Configuration Interaction (CI). This allowed us to treat a larger auxiliary system, which can more accurately model physical environments with more challenging hybridization functions, as compared to ED. Due to the promising results we obtained, we extended the solver to include phonons, since this gives access to interesting physical phenomena. In particular we are investigating the vibrational steps in the differential conductance in the Kondo regime. We limited ourselves to a single phonon mode, i.e. Holstein phonons, which we again treated with CI to keep the increase of the state space low. Preliminary results, as well as possible extensions for a more complicated treatment of phonons are being discussed.

TT 43.23   Wed 15:00   P2/OG3

Hilbert space fragmentation in open quantum systems — •Yahui Li, Pablo Sala, and Frank Pollmann — Department of Physics, TFK, Technische Universität München, James-Franck-Straße 1, D-85748 Garching, Germany

Several mechanisms have been identified that can lead to a breakdown of thermalization in closed quantum systems-including integrability and many-body localization. Recently, a novel mechanism for ergodicity breaking has been discovered in systems with certain dynamical constraints, where the Hilbert space fragments into exponentially many disconnected subspaces. An open question is how such systems evolve when they are coupled to a dissipative bath.

We find that the Hilbert space fragmentation can be utilized to preserve coherence in the presence of dissipation. We study a quantum fragmented model, which fragments in an entangled basis due to unconventional non-Abelian symmetries. We investigate the Lindblad dynamics under two different couplings, which either preserves or destroys the quantum fragmentation structure. At sufficiently large couplings, the operator space entanglement is suppressed, which allows for an efficient numerical simulation using tensor networks. Surprisingly, under the structure-preserving noise, we observe finite Renyi negativity, indicating non-vanishing quantum correlations. Using an analytic approach, we derive the stationary states under both couplings, which explains the long-time behaviors observed in numerical simulations.

TT 43.24   Wed 15:00   P2/OG3

Floquet engineering in tilted lattices — •Melissa Will[1], Pablo Sala[2,3], and Frank Pollmann[1] — [1]Department of Physics, T42, Technische Universität München, James-Franck-Straße 1, D-85748 Garching, Germany — [2]Department of Physics and Institute for Quantum Information and Matter, California Institute of Technology, Pasadena, California 91125, USA — [3]Walter Burke Institute for Theoretical Physics, California Institute of Technology, Pasadena, California 91125, USA

Quantum many-body systems out of equilibrium can exhibit very rich and exciting phenomena. A particularly important question is whether and how a quantum system thermalizes under unitary evolution. In this context three classes of systems have been identified: ergodic, localized and an intermediate regime exhibiting so called quantum many-body scars. In this talk we discuss whether a time-periodic, local drive can induce thermalization of a localized system. We consider interacting hard-core bosons in an one dimensional, tilted system with periodic driving. We find that the system becomes ergodic for resonant driving frequencies. In contrast, if the tilt is not close to a multiple of driving frequency, the system stays localized. This observation can theoretically be understood by deriving an effective Hamiltonian using a Magnus expansion. Using large scale

numerical methods, we explore entanglement entropy and imbalance over time. Our theoretical predictions are in good agreement with numerics.

TT 43.25 Wed 15:00 P2/OG3

Impact of decoherence on the route to equilibrium — •Jiaozi Wang and Jochen Gemmer — University of Osnabrück, Osnabrück, Germany

We study the time evolution of a small quantum system when coupling to a quantum chaotic bath, within the framework of projection operator techniques. We study this problem by employing a different approach which also take the so called pure-dephasing term as a part of the unperturbed Hamiltonian. With this method, a new formula of the relaxation rate is derived analytically in a random matrix model, which is also confirmed by numerical results. We find that, the relaxation process is slowed down by decoherence, which is in consistent with the quantum zeno effect.

TT 43.26 Wed 15:00 P2/OG3

Nonequilibrium steady-states in photodoped Mott insulators — •Fabian Künzel — Universität Hamburg, Hamburg, Germany

Photodoped states in Mott insulators are peculiar states which simultaneously host strongly correlated electron and hole-like carriers, and can show instabilities into various non-thermal orders. Here we stabilize a stationary photodoped state in a Mott insulator using Dynamical-Mean-Field-Theory (DMFT) in the nonequilibrium steady-state formalism. This formalism provides a description of the longtime dynamics of microscopic models with well separated timescales. The photodoping can be established by coupling the Hubbard model with external baths that pump holon and doublon excitations in the Hubbard bands. In particular, we develop an algorithm to stabilize DMFT solutions with a prescribed nonthermal distribution function in the local Green's functions. This formulation may allow for a nonperturbative solution of the DMFT impurity model, using methods like Quantum Monte Carlo, and it opens the possibility to study the dynamics of photodoped states using a Quantum Boltzmann equation.

TT 43.27 Wed 15:00 P2/OG3

Quantum oscillations beyond the Onsager relation in a doped Mott insulator — •Valentin Leeb[1,2] and Johannes Knolle[1,2,3] — [1]Technical University of Munich, Germany; TUM School of Natural Sciences, Department of Physics, TQM — [2]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany — [3]Blackett Laboratory, Imperial College London, London SW7 2AZ, United Kingdom

The kinetic energy of electrons in a magnetic field is quenched resulting in a discrete set of highly degenerate Landau levels (LL). This gives rise to fascinating phenomena like quantum oscillations or the integer and fractional quantum Hall effect. The latter is a result of interactions partially lifting the degeneracy within a given LL while inter-LL interactions are usually assumed to be unimportant. Here, we study the LL spectrum of the Hatsugai–Kohmoto model, a Hubbard-like model which is exactly soluble on account of infinite range interactions. For the doped Mott insulator phase in a magnetic field we find that the degeneracy of LLs is preserved but inter-LL interactions are important leading to a non-monotonous reconstruction of the spectrum. As a result, strong interactions lead to aperiodic quantum oscillations of the metallic phase in contrast to Onsager's famous relation connecting oscillation frequencies with the Fermi surface areas at zero field. In addition, we find unconventional temperature dependencies of quantum oscillations and effective mass renormalizations. We discuss the general importance of inter-LL interactions for understanding doped Mott insulators in magnetic fields.

TT 43.28 Wed 15:00 P2/OG3

Magnetism of graphene beyond half filling using a mean-field approach — •Maxime Lucas, Andreas Honecker, and Guy Trambly de Laissardière — Laboratoire de Physique Théorique et Modélisation, CY Cergy Paris Université / CNRS, France

The discovery of correlations between electronic flat-band states due to a Moiré pattern in twisted bilayers of graphene [1] or other 2D materials has recently stimulated studies of their magnetic properties. It is shown experimentally and theoretically that the filling of the flat bands is an essential parameter for understanding their properties. However, the behavior of a simple graphene layer is still unclear. Indeed, its half-filled case is well known and it has been studied by various theoretical approaches (mean-field theories (MFT), Monte Carlo) [2], but beyond half filling its magnetic properties are still unknown. Here, we present a detailed study of graphene magnetism using a combination of the Hubbard model and MFT. We focus on non half-filling cases, taking into account non-collinear magnetic moments.

Spectral densities of quantum magnets with quenched disorder using the coherent potential approximation and perturbative continuous unitary transformations — •Max Hörmann and Kai Phillip Schmidt — Institut für Theoretische Physik I, Universität Erlangen-Nürnberg, Staudtstraße 7, 91058 Erlangen

We combine perturbation theory by means of perturbative continuous transformations together with the coherent potential approximation to derive approximations for the averaged spectral density of the antiferromagnetic dimer-diluted Heisenberg bilayer model and the spin-diluted transverse-field Ising model on the square latttice. To this end, we calculate a dilution dependent series for the real and imaginary part of the one quasi-particle self-energy. While the real part shifts the extremal energy of the spectral density for fixed momentum the imaginary part reflects the finite-lifetime of momentum modes. Using extrapolations we study the applicability of this approach to critical behaviour and derive approximations for averaged spectral densities in non-perturbative regimes.

TT 43.30 Wed 15:00 P2/OG3

The influence of continuous electric bias fields on the dielectric loss of atomic tunneling systems — •Jan Blickberndt, Christian Ständer, Lukas Münch, Marcel Haas, Andreas Reiser, Andreas Fleischmann, and Christian Enss — Kirchhoff-Institute for Physics, Heidelberg, Germany

The low temperature properties of amorphous solids are dominated by atomic tunneling systems (TSs), which are known to act as a major source of noise and decoherence in superconducting quantum devices. We investigate the non-equilibrium dielectric loss of atomic tunneling systems under the influence of continuous electric bias fields at very low temperatures. The dielectric loss of an amorphous sample is obtained by measuring the quality factor of a microfabricated superconducting resonator. Simultaneously, an electric bias field can be applied via a cover electrode, which allows us to sweep TSs through the resonance frequency by modulating their energy splitting. Experimentally, we found that for slow changing bias fields, TSs are saturated by the driving field leading to a constant loss. For faster bias rates, more and more TSs are swept through resonance and therefore contribute to an increasing loss. In the limit of fast continuous bias sweeps, relaxation in between consecutive crossings diminishes and multiple coherent Landau-Zener transitions are possible, reducing the loss back to the saturation limit. We are able to verify these experimental results with a Monte Carlo based numerical simulation that shows good qualitative agreement.

TT 43.31 Wed 15:00 P2/OG3

Electrically and acoustically biased resonators for investigations of dielectric low temperature properties of amorphous solids — •Christian Ständer, Jan Blickberndt, Joyce Glass, Benedikt Frey, Andreas Reifenberger, Andreas Fleischmann, Andreas Reiser, and Christian Enss — Kirchhoff-Institute for Physics, Heidelberg University, D-69120 Heidelberg

The low temperature properties of amorphous solids are governed by atomic tunnelling systems, which can be described as two-level systems (TLS) with a distribution of their energy splitting E, as assumed by the phenomenological standard tunnelling model. Recent interest in these systems due to their deteriorative effects on the performance of superconducting quantum devices lead to novel experimental investigations of atomic tunnelling systems driven by novel measurement techniques.

We use newly designed microfabricated superconducting LC-resonators to study the dielectric rf-response of the amorphous sample in the presence of an electric bias field. A novel method of applying this electrical bias field was introduced to the resonators. Compared to previous experiments, the bias field is applied via an electrode placed above the resonator chip. We present first results of this new way of introducing a bias, which modifies the energy splitting E of a TLS.

In addition we tried to achieve a similar effect as with the electrical bias field with a mechanical strain field. To induce such a strain field, the amorphous substrate of the resonator chip was flexed by a piezo-actuator.

TT 43.32 Wed 15:00 P2/OG3

Investigating the Non-Equilibrium Dynamics of Two-Level Systems at Low Temperatures — •Marcel Haas, Mareike Dinger, Lukas Münch, Jan Blickberndt, Andreas Reiser, Andreas Fleischmann, and Christian Enss — Kirchhoff-Institute for Physics, Heidelberg, Germany

The dielectric loss of amorphous materials along with noise and decoherence is the major limiting factor in many applications like superconducting circuits, Josephson junctions and quantum computing. It is mainly determined by atomic tunneling systems described by quantum mechanical two-level systems (TLS), which are broadly distributed low-energy excitations in the sample. The spontaneous phonon emission of an excited TLS gives rise to a relaxation time T_1 and the interaction between TLSs with their thermally excited surrounding induces a decoherence time T_2. These effects mainly determine the measurable dielectric loss in the observed material, which we ascertain by measuring the quality factor of a bridge type superconducting LC-resonator. The dielectric medium in between the capacitor plates is a sputter deposited a-SiO_2 film. The setup shows a unique property when two off-resonant pump tones are applied symmetrically.

In this limit, the resonator is emitting at the intermediate frequency of the driving fields. The underlying mechanism can therefore be explained by a nonlinear interaction of the rf-field with the TLSs and the res- onator which is creating additional lines in the frequency spectrum. We present measurements and a phenomenological describtion of the effect for a frequency of 1 GHz.

TT 43.33   Wed 15:00   P2/OG3
Machine learning stochastic dynamics of order parameters — •Francesco Carnazza[1], Federico Carollo[1], Igor Lesanovsky[1], Georg Martius[2], Sabine Andergassen[1], and Miriam Klopotek[3] — [1]University of Tuebingen — [2]Max Planck Institute for Intelligent Systems — [3]University of Stuttgart
The dynamics of coarse-grained observables, or of order-parameters, in many-body systems is usually rather intricate due to emergent nonlinearities and collective effects. In fact, except for few exactly solvable models, it is typically not possible to find the form of the differential equation describing the dynamics of these observables. Here, we address this problem exploiting a machine learning approach. We consider single trajectories of the thermal dynamics of a two-dimensional Ising model and feed these to a neural network. These trajectories, simulated by Monte Carlo methods, are intrinsically stochastic. Their dynamics can be approximated by a stochastic differential equation parametrised by a smooth term, the drift, and one multiplied by the differential of a Wiener process, that is, the diffusion.

In [1] a neural solver for stochastic differential equation was introduced, by means of which the drift and diffusion terms are approximated by neural networks. A classical integration method, e.g., Euler-Maruyama, is then adopted to recover full trajectories. We adopt this method to learn the drift and diffusion terms and infer the properties of the Ising model.

TT 44: Focus Session: Superconducting Nickelates I

The discovery of superconductivity in hole-doped infinite-layer nickelates in 2019 has brought a breath of fresh air to the research on unconventional superconducting materials. These nickel oxides structurally closely resemble high-T_c cuprates and show a formally analogous nickel $d^{9-\delta}$ electronic configuration. Other striking similarities with cuprates have been recently reported, such as a dome-like doping dependence of the superconducting phase, sizeable antiferromagnetic exchange couplings, and a charge order instability in the underdoped region of the phase diagram. Likewise, a number of studies identified clear differences, e.g. concerning selected transport behavior as well as magnetic properties, and with regard to the relevance of oxygen-$2p$ states. It is precisely this combination of strong similarities and specific differences that promises new, game-changing insights into the origin of high-temperature superconductivity. The goal of this focus seesion is to bring together the latest results for low-valence nickelates from studies of structure, electronic structure, magnetism, charge density waves and superconductivity, and thus setting the stage for a coherent picture of these complex quantum materials.

Invited Talk   TT 44.1   Thu 9:30   HSZ 03
Atomic-scale insights to lattice and electronic structure in superconducting nickelates — •Berit Goodge — School of Applied and Engineering Physics, Cornell University — Kavli Institute at Cornell for Nanoscale Science, Cornell University — Max Planck Institute for Chemical Physics of Solids
Although the synthesis of superconducting nickelates [1,2] remains notoriously challenging [3,4], many materials realities including epitaxial strain, extended defects, impurities, and secondary phases are largely undiscussed in the context of understanding their measured properties. As direct probes of lattice and electronic structure down to the atomic scale, scanning transmission electron microscopy (STEM) and electron energy loss spectroscopy (EELS) offer unique insights to build a holistic understanding of both the intrinsic physical properties in these materials as well as more extrinsic features and their consequences, many of which arise from their multistep synthesis. Here, we discuss how quantitative lattice-scale measurements can disentangle many of these effects, revealing, for example, multi-band hole interactions [5], nontrivial interface reconstruction [6], and the impact of epitaxial strain [2, 7].

Nickelate and cuprate superconductors: Similar yet different — •Vamshi Mohan Katukuri — Max Planck Institute for Solid State Research, Stuttgart, Germany
The discovery of superconductivity in hole-doped infinite-layer $NdNiO_2$ – a transition metal oxide that is both isostructural and isoelectronic to cuprate superconductors – has lead to renewed enthusiasm in the hope of understanding the origin of unconventional superconductivity. In this talk, I will present and discuss the similarities and differences in the electronic structure of nickelates and cuprates from the perspective of *ab initio* many body wavefunction analysis derived from state-of-the-art quantum chemistry calculations. After highlighting the main differences in the parent (undoped) infinite-layered $NdNiO_2$ and $CaCuO_2$ compounds, I will discuss the character of the doped hole by analyzing the electron-removal (which mimics hole-doping) states in the two compounds. In the end, I will discuss the evolution of the electronic structure of nickelates under pressure.

Invited Talk   TT 44.3   Thu 10:30   HSZ 03
Superconducting instabilities in strongly-correlated infinite-layer nickelates — •Andreas Kreisel — Niels Bohr Institute, University of Copenhagen, Denmark
Unconventional superconductivity is often referred to as originating from a pairing mechanism different from electron-phonon interactions and connected to an anisotropic superconducting order parameter with sign change of the Cooper pair wavefunction. In this talk, I will start from a discussion of the mechanism of spin-fluctuation mediated pairing that can lead to d-wave states as evidenced in the cuprate superconductors, but also the sign-changing $s_\pm$ state that seems to be realized in Fe-based superconductors. The discovery of superconductivity in infinite-layer nickelates has immediately posed the question about the pairing mechanism and the pairing symmetry in this system and sparked proposals of analogs towards well studied families of materials in the class of unconventional superconductors. To connect to this open question, the leading superconducting instability is computed from magnetic fluctuations relevant for infinite-layer nickelates incorporating the strongly correlated multi-orbital nature of the low-energy electronic degrees of freedom. Observing the interplay between the Ni $d_{x^2-y^2}$ and d_{z^2} orbitals as well as the self-doping band, a transition from d-wave pairing symmetry to nodal $s_\pm$ superconductivity is uncovered. This is driven by strong fluctuations in the d_{z^2}-dominated orbital states. As probe of the detailed superconducting gap structure, we discuss the properties of the resulting superconducting condensate in light of tunneling and penetration depth experiments.

Infinite-layer nickelate thin films: From synthesis to spectroscopy — •Daniele Preziosi — Université de Strasbourg, CNRS, IPCMS UMR 7504, F-67034 Strasbourg, France
In the last three decades, special efforts were devoted to the realization of nickelates mimicking the electronic structure of cuprates. These efforts led to the realization of infinite-layer nickelates characterized by a stable $Ni-3d^9$ configuration and reduced dimensionality. A superconducting state below 15 K was reported for $Nd_{0.8}Sr_{0.2}NiO_2$ thin films deposited onto (001) $SrTiO_3$ (STO). Soon after this discovery, x-ray absorption spectroscopy (XAS) and resonant inelastic x-ray scattering (RIXS) experiments on undoped ($LaNiO_2$, $NdNiO_2$) and doped ($Nd_{1-x}Sr_xNiO_2$) samples showed that infinite-layer nickelates show some important differences compared to layered cuprates, in particular a larger charge transfer energy and an important Nd 5d-Ni 3d hybridization. In this talk, after introducing our efforts to stabilize the infinite-layer phase, I will show that some

of those aforementioned differences depend also on the presence/absence of a STO-capping-layer. A robust charge order is observed in undoped capping-free thin films, while strong magnetic excitations around 200 meV energy-loss characterize capped samples. Polarization-resolved RIXS measurements unambiguously demonstrated that also the low-energy excitations for uncapped samples are magnetic in nature, but largely damped. The 'altered' doping effect as observed from the enlarging of the XAS feature at the NiL_3-edge combined to a strong $Ni3d - Nd5d$ hybridization for uncapped samples, may speak in favor of this extra softening.

Superconducting layered square-planar nickelates: Synthesis, properties, and progress — •Grace Pan[1], Dan Ferenc Segedin[1], Harrison LaBollita[2], Qi Song[1], Berit Goodge[3], Lena Kourkoutis[3], Charles Brooks[1], Antia Botana[2], and Julia Mundy[1] — [1]Harvard University, Cambridge, MA, USA — [2]Arizona State University, Tempe, AZ, USA — [3]Cornell University, Ithaca, NY, USA

Since the discovery of high-T_c superconductivity in the cuprates, there have been sustained efforts to both understand the origins of this phase and discover new cuprate-like superconductors. One prime materials platform has been the rare-earth nickelates; indeed, superconductivity was discovered in the doped compound $Nd_{0.8}Sr_{0.2}NiO_2$ in 2019. Undoped $NdNiO_2$ belongs to a series of layered square-planar nickelates with chemical formula $Nd_{n+1}Ni_nO_{2n+2}$ and is known as the infinite-layer (n=∞) nickelate. Here, we describe the synthesis of the quintuple-layer (n=5) member, $Nd_6Ni_5O_{12}$, in which optimal cuprate-like electron filling ($d^{8.8}$) is achieved without chemical doping. We observe a superconducting transition beginning at ~13 K. Electronic structure calculations fortified with experiments suggest that $Nd_6Ni_5O_{12}$ interpolates between cuprate-like and infinite-layer nickelate-like behaviour. By engineering a distinct superconducting nickelate, we identify the square-planar nickelates as a new family of superconductors that can be tuned via both doping and dimensionality. In this talk, I will further discuss ongoing experimental progress on the synthesis and characterization of these layered nickelates.

TT 44.6　Thu 12:15　HSZ 03
Nickelate superconductors: One-band Hubbard model plus decoupled A pocket picture — •Karsten Held[1], Motoharu Kitatani[2], Liang Si[1,3], and Paul Worm[1] — [1]Institute for Solid State Physics, TU Wien, Austria — [2]University of Hyogo , Japan — [3]Northwest University, Xi'an, China

At first glance, nickelate superconductors appear to be more complicated than their cuprate peers. Based on density functional theory (DFT) plus dynamical mean-field theory (DMFT) we however arrived at a picture that the physics of nickleate superconductors is dominated by the Ni $d_{x^2-y^2}$-band and the pockets are, in many respects, merely passive bystanders [1]. Other groups have argued instead for the importance of the Ni d_{z^2}-band based, e.g., on self-interaction corrected (sic)DFT+DMFT [2].

Taken the premise of a $d_{x^2-y^2}$-band Hubbard model description, we have predicted the phase diagram, superconducting critical temperature T_c vs. doping x

[1]. Later experiments synthesizing high-quality films are in excellent qualitative and even quantitative agreement [3], as is the resonant inelastic x-ray (RIXS) spectrum. Also the pentalayer nickelate superconductor which has no pockets in DFT+DMFT and the increase T_c with pressure nicely match this picture [4].

Synthesis and physical properties of perovskite and infinite-layer nickelate crystals — •Pascal Puphal[1], Vignesh Sundaramurthy[1], Valentin Zimmermann[1], Björn Wehinger[2], Gaston Garbarino[2], Kathrin Küster[1], Ulrich Starke[1], Jürgen Nuss[1], Bernhard Keimer[1], Masahiko Isobe[1], and Matthias Hepting[1] — [1]Max Planck Institute for Solid State Research — [2]European Synchrotron Radiation Facility

Infinite-layer (IL) nickelates are an emerging family of superconductors whose synthesis in thin film form is an established process by now, whereas the growth of their bulk counterparts remains a formidable challenge. In a previous study, we achieved the reduction of perovskite La1-xCaxNiO3 single-crystals grown by a flux method under high external pressure to the IL phase $La_{1-x}Ca_xNiO_2$ [1]. The typical lateral dimension of these crystals was 150 μm. As an advanced approach, we recently accomplished the reduction of millimeter-sized $LaNiO_3$ crystals obtained by optical floating zone growth under high oxygen gas pressure to the IL phase $LaNiO_2$ [2]. We will present our characterization of the crystalline, magnetic, and electronic properties of the $LaNiO_2$ crystals, and give an outlook on the synthesis of millimeter-sized crystals of pure $LaNiO_3$ and $PrNiO_3$ as well as ones with hole- and electron doping.

On the alternating spin chain with continuous spectrum of scaling dimensions — Mouhcine Azhari and •Andreas Klümper — Universität Wuppertal

We investigate the low-lying spectrum of an integrable staggered Heisenberg spin-1/2 chain possessing in the large length (L) limit a CFT structure with logarithmic corrections $(1/(\log L)^2)$. This realizes a continuous spectrum of conformal weights similar to that of for instance the $SL(2,R)/U(1)$ black hole sigma model.

The quantum spin chain is exactly "solvable" by Bethe ansatz and other techniques from the theory of integrability. However, the analysis of the resulting Bethe Ansatz equations is challenging and manageable by numerical techniques only for relatively small sizes L. Integral equations for the distribution functions of the Bethe roots suffer from singularities of the kernel functions.

Due these phenomena and challenges the model attracted interest by several groups of authors (Ikhlef, Jacobsen, Saleur 08, 12; Frahm, Martins 12; Candu, Ikhlef 13; Frahm, Seel 14; Bazhanov, Kotousov, Koval, Lukyanov 20).

In our contribution we report on recent progress allowing us to rewrite already existing non-linear integral equations (NLIE) with a singular, i.e. long-ranged kernel in a novel form without such problems. We present results for the lowest lying excitations for system sizes $L = 10, 10^2, 10^3, ..., 10^9, ...$

TT 45.2　Thu 9:45　HSZ 103
Electron spin resonance as a direct probe of spinon interactions in a $S = 1/2$ chain — •Kirill Povarov[1,2], Timofei Soldatov[3], Ren-Bo Wang[4], Andrey Zheludev[1], Alexander Smirnov[3], and Oleg Starykh[4] — [1]Laboratory for Solid State Physics, ETH Zürich — [2]Dresden High Magnetic Field Laboratory (HLD), Helmholtz-Zentrum Dresden-Rossendorf (HZDR) — [3]P.L. Kaptiza Institute for Physical Problems RAS — [4]Department of Physics and Astronomy, University of Utah

The presence of well-hidden backscattering between the fractionalized spinon excitations was known to be a somewhat exotic part of the $S = 1/2$ chain physics. However, its dramatic consequences for the dynamics were realized recently [1]. They are challenging for observation, as applied field and nonzero momenta are simultaneously required. We have succeeded in the experimental verification of these effects using electron spin resonance as probe [2]. Our observations are enabled by the specific pattern of Dzyaloshinskii–Moriya interactions in our target material $K_2CuSO_4Br_2$. Description of the observed spectrum requires accounting for the backscattering on a qualitative level. Quantitative analysis allows us to estimate the backscattering constant as $2.4J$ (intrachain exchange), in agreement with the renormalization group predictions. This work has been supported by SNSF Division II (ETHZ), the NSF CMMT grant DMR-1928919 (U. Utah), and the RSF Grant 17-12-01505 (IPP).

Dominant superconducting correlations in a Luttinger liquid induced by spin fluctuations — •Niels Henrik Aase and Asle Sudbø — Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, NO-7491 Trondheim, Norway

In the last decades, heterostructures of magnetic materials and various conductors have received much attention. Several studies have focused on the emergent interfacial phenomena and their possible application in spintronic devices. Motivated by this, we study the simplest equivalent heterostructure in one dimension: an interacting metallic chain coupled to a spin chain. Confining interacting electrons to one dimension causes the breakdown of Fermi liquid theory, so our study provides insight into how spin fluctuations can induce superconductivity in a strongly correlated non-Fermi liquid with repulsive electronic interactions only.

Treating the system using bosonization, we calculate the correlation functions of the electrons in the metal. Based on the non-universal power-law decay of different order parameters, we outline the electron phase diagram as a function of the interchain coupling and the interactions in the metal. The coupling favors triplet pairing, suggesting that the metal chain can sustain a spin-polarized supercurrent. In some parameter regimes, the superconducting triplet correlations persist in the case of repulsive interactions in the metal. The spin chain is thus an essential ingredient for overcoming electron repulsion in a Luttinger liquid.

TT 45.4   Thu 10:15   HSZ 103

The role of electron-electron interactions in electron emission from arrays of nanotubes — •Naira Grigoryan[1] and Piotr Chudzinski[1,2] — [1]Institute of Fundamental Technological Research, Polish Academy of Sciences, Adolfa Pawinskiego 5b, 02-106 Warsaw, Poland — [2]School of Mathematics and Physics, Queen's University Belfast, University Road, Belfast, NI BT7 1NN, United Kingdom

Nanotubes and nanorods have been recently established as very good materials to build electron sources in the cold emission process. These are 1D materials where electron-electron interactions are known to play a crucial role in their physics. The interactions in 1D systems lead to a collective modes' physics that is usually described using Tomonaga-Luttinger liquid (TLL) formalism. The advantage is that within this method all correlation functions are known and can be expressed in terms of power laws with non-universal, interaction dependent, exponents. To capture this situation we generalize a canonical Fowler-Northeim theory of field emission to solve the case of a barrier described by any power-law potential. With this generalization, expressed in terms of a confluent hypergeometric function, we are able to compute currents from arrays of carbon nanotubes. We shall present results showing an influence of various interaction terms, as encoded in varying TLL parameters, as well as effects of a finite temperature.

TT 45.5   Thu 10:30   HSZ 103

Delta-T noise for weak tunneling in one-dimensional systems: interactions versus quantum statistics — Gu Zhang[1], Igor V. Gornyi[2], and •Christian Spanslatt[3] — [1]Beijing Academy of Quantum Information Sciences, 100193 Beijing, China — [2]Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76021 Karlsruhe, Germany — [3]Department of Microtechnology and Nanoscience (MC2), Chalmers University of Technology, S-412 96 Göteborg, Sweden

Delta-T noise - excess charge noise at zero charge current but due to a finite temperature bias - has recently emerged as a novel transport spectroscopy tool for mesoscopic systems. In this talk, I present recent work [1] on delta-T noise for weak tunneling in one-dimensional, interacting systems. We show that the sign of the delta-T noise is generically determined by the scaling dimensions of the dominating tunneling process. Importantly, we clarify how this sign can be related to the quantum exchange statistics of the tunneling quasiparticles.

In systems with interacting and chiral channels, we find that when the delta-T noise is negative, the tunneling particles are boson-like, revealing their tendency towards bunching. Thus, one might expect that negative delta-T noise is a smoking gun for detecting "intrinsic anyons". Here, we find that this is not the case, since boson-like particles do not necessarily produce negative delta-T noise. Our findings clarify how delta-T noise can be used to probe the nature of collective excitations in interacting one-dimensional systems.

TT 45.6   Thu 10:45   HSZ 103

Terminable transitions in a topological fermion ladder — Yuchi He[1,2], Dante Kennes[2,3], Christoph Karrasch[4], and •Roman Rausch[4] — [1]Rudolf Peierls Centre for Theoretical Physics, Clarendon Laboratory, Parks Road, Oxford OX1 3PU, United Kingdom — [2]Institut für Theorie der Statistischen Physik, RWTH Aachen University and JARA - Fundamentals of Future Information Technology, 52056 Aachen, Germany — [3]Max Planck Institute for the Structure and Dynamics of Matter, Center for Free Electron Laser Science, 22761 Hamburg, Germany — [4]Technische Universität Braunschweig, Institut für Mathematische Physik, Mendelssohnstraße 3, 38106 Braunschweig, Germany

Interacting fermion ladders are important platforms to study quantum phases of matter including various Mott-insulators with different symmetry properties, such as the D-Mott and S-Mott phase. The latter hold pre-formed electron pairs and become paired liquids (d-wave and s-wave) upon doping. We show that the D-Mott and S-Mott phases are in fact two facets of the same topological phase and that the transition between them is terminable. With this, we provide a quantum analog of the well-known terminable liquid-gas transition. However, the phenomenology we uncover is even richer, as in contrast to the liquid-gas transition, the order of the transition can be tuned by the interaction and bears relevance for the topological properties of the system. The numerical results are obtained using the variational uniform matrix-product state (VUMPS) formalism, and are complemented by analytical field-theoretical explanations.

TT 45.7   Thu 11:15   HSZ 103

Critical and topological phases of a dimerized Kitaev chain in the presence of a quasiperiodic potential — •Saurabh Basu[1], Sk Noor Nabi[2], and Shilpi Roy[1] — [1]Department of Physics, Indian Institute of Technology Guwahati-Guwahati, 781039 Assam, India — [2]Department of Physics, Indian Institute of Technology Kharagpur, Kharagpur - 721302, West Bengal, India

We investigate the localization and topological properties of a dimerized Kitaev chain with p-wave superconducting correlations and a quasiperiodically modulated chemical potential. In the localization studies, we illustrate the existence of distinct phases, such as, the extended phase, the critical (intermediate) phase, and the localized phase that arise due to the competition between the dimerization and the onsite quasiperiodic potential. Most interestingly, the critical phase comprises of two distinct phase transitions that are found to exist between the extended to the localized phase, and between the critical (multifractal) and localized phases. Furthermore, we study the topological properties of the zero-energy edge modes via computing the real-space winding number and number of the Majorana zero modes present in the system. We specifically demonstrate that our model undergoes a phase transition from a topologically trivial to a non-trivial phase (topological Anderson phase) beyond a critical dimerization strength under the influence of the quasiperiodic potential strength. Finally, in presence of a large potential, we demonstrate that the system undergoes yet another transition from the topologically non-trivial to an Anderson localized phase.

TT 45.8   Thu 11:30   HSZ 103

Statistics induced phase transitions in the extended bosonic anyon Hubbard model — •Imke Schneider[1], Kevin Jägering[1], Martin Bonkhoff[1], Shijie Hu[2], Axel Pelster[1], and Sebastian Eggert[1] — [1]Department of Physics and Research Center Optimas, Technical University of Kaiserslautern, 67663 Kaiserslautern, Germany — [2]Beijing Computational Science Research Center, Beijing 100193, China

We study a 1D extended Hubbard model of anyons with statistical exchange phases ranging from bosons to pseudo-fermions. The model can be realized in optical lattice experiments implementing occupation-dependent hopping amplitudes. We enforce a two-body hard-core constraint and numerically determine the full phase diagram including attractive on-site interactions. Surprisingly, the symmetry protected topological Haldane phase remains robust up to large statistical angles close to the pseudo-fermionic limit. However, for a critical angle the phase diagram qualitatively changes involving a dimer phase while the Haldane phase disappears. This behavior is analytically described by an adapted bosonization approach.

TT 45.9   Thu 11:45   HSZ 103

Fractonic Luttinger liquids and supersolids in a constrained Bose-Hubbard model — •Philip Zechmann[1,2], Ehud Altman[3], Michael Knap[1,2], and Johannes Feldmeier[1,2,4] — [1]Department of Physics, Technical University of Munich, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany — [3]Department of Physics, University of California, Berkeley, CA 94720 — [4]Department of Physics, Harvard University, Cambridge, MA 02138, USA

Quantum many-body systems with fracton constraints are widely conjectured to exhibit unconventional low-energy phases of matter. In this work, we demonstrate the existence of a variety of such exotic quantum phases in the ground states of a dipole-moment conserving Bose-Hubbard model in one dimension. For integer boson fillings, we perform a mapping of the system to a model of microscopic local dipoles, which are composites of fractons. We apply a combination of low-energy field theory and large-scale tensor network simulations to demonstrate the emergence of a novel dipole Luttinger liquid phase. At non-integer fillings our numerical approach shows an intriguing compressible state described by a quantum Lifshitz model in which charge density-wave order coexists with dipole long-range order and superfluidity - a 'dipole supersolid'. While this supersolid state may eventually be unstable against lattice effects in the thermodynamic limit, its numerical robustness is remarkable. We discuss potential experimental implications of our results.

TT 45.10   Thu 12:00   HSZ 103

Phase diagram detection via Gaussian fitting of number probability distribution — Daniele Contessi[1,2,3], Alessio Recati[1], and •Matteo Rizzi[2,3] — [1]Università di Trento & INO-CNR Pitaevskii BEC Center, Povo, Italy — [2]Peter-Grünberg-Institut 8, FZ Jülich, Germany — [3]Institute for Theoretical Physics, University of Cologne, Germany

In recent years, methods for automatic recognition of phase diagrams of quantum systems have gained large interest in the community: Among others, machine learning analysis of the entanglement spectrum has proven to be a promis-

ing route. Here, we discuss the possibility of using an experimentally readily accessible proxy, namely the number probability distribution that characterizes sub-portions of a quantum many-body system with globally conserved number of particles. We put forward a linear fitting protocol capable of mapping out the ground-state phase diagram of the rich one-dimensional extended Bose-Hubbard model: The results are quantitatively comparable with more sophisticated traditional numerical and machine learning techniques. We argue that the studied quantity should be considered among the most informative and accessible bipartite properties.

Magnetic and elastic properties of spin ice materials in high magnetic fields — •Nan Tang[1,2], Masaki Gen[3], Mingxuan Fu[2], Huiyuan Man[4], Akira Matsuo[5], Koichi Kindo[5], Akihiko Ikeda[5,6], Yasuhiro H. Matsuda[5], Kazuyuki Matsuhira[7], Yoshimitsu Kohama[5], and Satoru Nakatsuji[2,5] — [1]Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg, Augsburg, Germany — [2]Department of Physics, University of Tokyo, Tokyo, Japan — [3]Riken Center for Emergent Matter Science, Saitama, Japan — [4]Geballe Laboratory for Advanced Materials, Stanford University, California, U.S.A. — [5]ISSP, University of Tokyo, Chiba, Japan — [6]Department of Engineering Science, University of Electro-Communications, Tokyo, Japan — [7]Department of Engineering, Kyushu Institute of Technology, Fukuoka, Japan

Spin ice is a prototypical state of frustrated magnets, in which Ising spins form a short-range "2-in, 2-out" correlation instead of a long-range order due to geometrical frustrations of pyrochlore lattice. Local Ising anisotropy induced by the competition between crystal electric field (CEF) effect and magnetic interactions play important roles to stabilize such spin-ice correlations. Generally, frustrated magnets show characteristic magnetostrictive responses and in this study, we measured both magnetization and magnetostriction of classical spin ice $Ho_2Ti_2O_7$ and quantum spin ice $Pr_2Zr_2O_7$ under high magnetic fields to explore the regime beyond the Ising limit. In the talk, we will discuss the influences of CEF splitting and exchange-striction on the magnetostrictive responses in the two spin ice materials.

TT 46.2   Thu 9:45   HSZ 201

XMCD studies of honeycomb lattice compound $RuBr_3$ — •Sahana Roessler[1], X. Wang[1], S. Agrestini[2], Z. Hu[1], C. Guillemard[3], J. Herrero-Martin[3], U. Schwarz[1], M. W. Haverkort[4], and L. H. Tjeng[1] — [1]Max-Planck Institute for Chemical Physics of Solids, Dresden Germany — [2]Diamond Light Source, Oxfordshire, United Kingdom — [3]ALBA Synchrotron Light source, Barcelona, Spain — [4]Institute of theoretical physics, Heidelberg University, Germany.

The high-pressure phase of $RuBr_3$ consisting of a honeycomb lattice [1] is structurally essentially isotypic to the Kitaev quantum spin liquid candidate α-$RuCl_3$. As in α-$RuCl_3$, Ru^{3+} ion in $RuBr_3$ is in $4d^5$ electronic configuration and expected to be in a spin-orbit coupled $J_{eff} = 1/2$ doublet ground state. Here, we will present the results of X-ray magnetic circular dichroism (XMCD) measurements on $RuBr_3$ performed at the Ru $L_{2,3}$ absorption edges. The spin and orbital moments were determined using the sum rule analysis. In addition, the XMCD spectra were simulated using the full atomic-multiplet cluster calculations within the configuration interaction approach. By comparing the experimental spectra with the theoretical simulations, we determined the ratio of spin to orbital moments along with the values of the crystal field splitting and the spin-orbit coupling in $RuBr_3$. Our results indicated the $J_{eff} = 1/2$ ground state for $RuBr_3$, which is one of the requisites for the Kitaev quantum spin-liquid behavior. [1] Imai et al., Phys. Rev. B 105, L041112 (2022).

TT 46.3   Thu 10:00   HSZ 201

Structural transition in single crystals of Kagome compound $Y_3Cu_9(OH)_{19}Cl_8$ — •Katharina M. Zoch[1], Pascal Puphal[2], and Cornelius Krellner[1] — [1]Physikalisches Institut, Goethe-Universität Frankfurt, 60438 Frankfurt am Main, Germany — [2]Max-Planck-Institute for Solid State Research, 70569 Stuttgart, Germany

Kagome systems serve as the ideal candidates to obtain an experimental realization of a quantum spin liquid, a class of matter where the spins strongly fluctuate down to lowest temperatures, thus preventing order. $Y_3Cu_9(OH)_{19}Cl_8$ presents a distorted Kagome lattice with a rich magnetic phase diagram [1]. The improved synthesis of phase-pure single crystals crystals via an external gradient method lead to the evidence of subtle structural instabilities at 33 K and 13 K in thermodynamic measurements while preserving the magnetic model of the system. The compound shows a magnetic phase transition at 2.2 K with persistent spin

dynamics below the ordered state in powder samples [2]. We present the single crystal growth as well as thermodynamic and magnetic measurements of this compound.

TT 46.4   Thu 10:15   HSZ 201

Thermodynamics of the spin liquid candidate $KYbS_2$ — •Franziska Grussler[1], Sebastian Bachus[1], Noah Winterhalter-Stocker[1], Mamoun Hemmida[2], Hans-Albrecht Krug von Nidda[2], Yurii Skourski[3], Philipp Gegenwart[1], and Alexander Tsirlin[4] — [1]Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg — [2]Experimental Physics V, Center for Electronic Correlations and Magnetism, University of Augsburg — [3]High Magnetic Field Laboratory, Helmholtz-Zentrum Dresden-Rossendorf — [4]Felix Bloch Institute for Solid-State Physics, University of Leipzig

Triangular antiferromagnets with competing nearest-neighbor and next-nearest-neighbor interactions offer a promising playground for realizing quantum spin liquid behavior. However, detailed nature of this state and its manifestations in real materials remain heavily debated. Here, we show that a quantum disordered, potentially spin liquid state can be realized in the disorder-free triangular antiferromagnet $KYbS_2$ and report its temperature-field phase diagram using heat capacity, dilatometry, magnetocaloric and magnetization measurements down to below 0.1 K. The phase diagram reveals an additional phase between the up-up-down and putative spin liquid phases, so far not observed in other members of the same structural family. Following a systematic analysis of the nuclear contribution and its evolution in the applied field, we conclude that at zero field the magnetic specific heat shows quadratic behavior in the low-T limit in accordance with the expectations for a gapless Dirac spin liquid.

Anisotropic phonon-spin scattering in the quantum spin liquid canidate $NaYbS_2$ — •Matthias Gillig[1,2], Xiaochen Hong[1,3], Ellen Häussler[2], Philipp Schlender[2], Thomas Doert[2], Bernd Büchner[1,2], and Christian Hess[1,3] — [1]IFW Dresden — [2]TU Dresden — [3]Bergische Universität Wuppertal

A perfect triangular spin lattice and absence of long-range magnetic order down to $T = 260$ mK make the delafossite material $NaYbS_2$ a prime candidate to host a quantum spin liquid ground state. We present the results of heat transport experiments on $NaYbS_2$ in the low-temperature limit ($T < 1$ K), where the in-plane thermal conductivity κ_{ab} shows a peculiar temperature dependence mimicking a potential residual linear term that decays below 500 mK. Application of in-plane magnetic field drastically enhances the thermal conductivity until it saturates in the field polarized limit. This behavior hints at phonon dominated heat transport with very strong magnetic phonon scattering where magnetic field suppresses the phonon scattering off spin fluctuations and the phonon thermal conductivity recovers at high field. In the field-dependence of κ broad features appear that indicate possible field-induced phase transitions in the magnetic system. Within this framework no clear evidence for magnetic heat transport due to spin excitations is observed. The investigation of the anisotropy of κ reveals that the phonon-spin scattering is strongly anisotropic and the out-of-plane coupling of phonons to spin excitations is weakened.

Thermodynamics studies on RE_3BWO_9 (RE = Nd and Pr) spin-liquid candidate systems — •Ahmed Elghandour[1], P Khuntia[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Heidelberg, Germany — [2]Department of Physics, IIT Madras, Chennai 600036, India

Boratotungstates exhibit a distorted Kagome structure of rare-earth ions (RE), thereby providing a platform to unveil the pure Kagome physics fully dominated by magnetic frustration of RE moments while avoiding the influence of conduction electrons. We report the thermodynamic properties of poly crystals of RE_3BWO_9 (RE = Nd and Pr) by means of means of DC magnetometry (0.4 - 350

K) and heat capacity studies (0.4 - 270 K). In Nd_3BWO_9, our dc magnetization and c_p data indicate a possible transition at $T = 1\ K$ while there is no evidence of long-range order at higher temperatures. This yields $\frac{\theta}{T_N} = 45$. Isotherm magnetization measured at $T = 400\ mK$, demonstrates saturation up to 7 T at half of the expected saturation magnetization, which we attribute to crystal-field effects. In addition, there are two low field anomalies at $\frac{1}{4}$ and $\frac{1}{8}$ of the theoretical saturation field. In contrast, Pr_3BWO_9 does not signal long-range order down to $T = 90\ mK$ [5] (i.e., $\frac{\theta}{T_N} > 300$) and M vs B only shows smooth right bending at $T = 400\ mK$ again with reduced saturation moment (0.8 μ_B/Pr at $B = 7\ T$). The data are discussed in terms of an unconventional persistent fluctuating paramagnetic ground state as suggested by recent NMR data [1].

Low temperature phase diagram of $PbCuTe_2O_6$ for magnetic fields $B \parallel$ (110) — •Paul Eibisch[1], Christian Thurn[1], Ulrich Tutsch[1], Arif Ata[1], Abanoub R. N. Hanna[2], A. T. M. Nazmul Islam[2], Shravani Chillal[2], Bella Lake[2], Bernd Wolf[1], and Michael Lang[1] — [1]PI Goethe-University Frankfurt — [2]HZ Berlin

The quantum-spin-liquid (QSL) state shows interesting phenomena such as fractional spin excitations and spin entanglement. Here we investigate the spin-liquid-candidate system $PbCuTe_2O_6$ where antiferromagnetic interactions among $s = 1/2$ spins lead to a 3D network of triangles similar to the hyper-Kagome lattice. While first experiments on polycrystalline samples, were found to be consistent with the QSL state [1], a recent study on single crystals showed a far more complex scenario including a ferroelectric transition at $T = 1$ K with strong lattice distortions and a quantum critical behaviour close to $B = 0$ T [2]. For the present study we combine thermodynamic, dielectric and magnetic experiments to investigate the field- and temperature phase diagram of $PbCuTe_2O_6$ for fields up to $B = 14.5$ T parallel to the [110] direction. In addition to the ferroelectric state we find a structurally distorted phase which coincides with the ferroelectric state at low fields but splits above $B = 6$ T as well as a long-range magnetically ordered phase for fields $B > 11$ T. Based on our experimental results we discuss how the elastic, dielectric and magnetic degrees of freedom are coupled.

Delafossite magnet $AgCrSe_2$: frustration, short range correlations, and field-tuned anisotropic order — •Michael Baenitz[1], S. Luther[2,3], M. Piva[1], J. Sichelschmidt[1], M. Nicklas[1], H. Zhang[1], B. Schmidt[1], H. Rosner[1], D. Khalyavin[4], P. Manuel[4], J. Wosnitza[2,3], H. Kuehne[2], and M. Schmidt[1] — [1]MPI for Chemical Physics of Solids, D-01187 Dresden, Germany — [2]Hochfeld-Magnetlabor Dresden (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — [3]Institut für Festkörper- und Materialphysik, TU Dresden, 01062 Dresden Germany — [4]ISIS Neutron and Muon Source, Rutherford Appelton Laboratory, Chilton, Didcot OX11 OQX, United Kingdom

In contrast to Cr based oxy delafossites (DFs) with predominant antiferromagnetic (afm) nearest neighbor (nn) interaction in the Heisenberg triangular lattice, $AgCrSe_2$ as a non oxy DFs member is characterized by competing interactions (ferromagnetic nn- vs afm third neighbor interaction). Due to this, the magnetism, can be tuned by relatively small magnetic fields, allowing us to probe the H-T phase diagram in great detail. Large single crystals are grown by chemical vapor transport and studied by magnetization, specific heat, and thermal expansion and Cr-electron spin resonance and neutron diffraction as local probes. An anisotropic cycloidal ordering with unusual extended two-dimensional fluctuations is found [1]. The impact of antisymmetric interactions (Dzyaloshinskii-Moriya) due to the noncentrosymmetric polar space group (R3m) is discussed.

Dynamical signatures of symmetry broken and liquid phases in an $S = 1/2$ Heisenberg antiferromagnet on the triangular lattice — •Markus Drescher[1], Laurens Vanderstraeten[2], Roderich Moessner[3], and Frank Pollmann[1,4] — [1]TU München, 85748 Garching, Germany — [2]University of Ghent, 9000 Gent, Belgium — [3]Max-Planck-Institut für Physik komplexer Systeme, 01187 Dresden, Germany — [4]Munich Center for Quantum Science and Technology, 80799 Munich, Germany

We present the dynamical spin structure factor of the antiferromagnetic spin-$\frac{1}{2}$ $J_1 - J_2$ Heisenberg model on a triangular lattice obtained from large-scale matrix-product state simulations. The high frustration due to the combination of antiferromagnetic nearest and next-to-nearest neighbour interactions yields a rich phase diagram. We resolve the low-energy excitations both in the 120°-ordered phase and in the putative spin liquid phase at $J_2/J_1 = 0.125$. In the ordered phase, we observe an avoided decay of the lowest magnon-branch, demonstrating the

robustness of this phenomenon in the presence of gapless excitations. Our findings in the spin-liquid phase chime with the field-theoretical predictions for a gapless Dirac spin liquid, in particular the picture of low-lying monopole excitations at the corners of the Brillouin zone. We comment on possible practical difficulties of distinguishing proximate liquid and solid phases based on the dynamical structure factor.

TT 46.10   Thu 12:00   HSZ 201

Generic interplay of magnetism and structural dimerization in pressured Kitaev materials — •Bin Shen[1], Franziska Breitner[1], Angel M. Arevalo-Lopez[2], Danil Prishchenko[3], Maximilian Seidler[1], Friedrich Freund[1], Anton Jesche[1], Philipp Gegenwart[1], and Alexander A. Tsirlin[1,4] — [1]EP VI, EKM, University of Augsburg, Germany — [2]University of Lille, France — [3]Yekaterinburg, Russia — [4]Felix Bloch Institute, University of Leipzig, Germany

Quantum spin liquids in the Kitaev honeycomb model feature quantum entanglement and exotic fractionalized spin excitations, thus attracting tremendous attention. However, experimental realization of Kitaev quantum spin liquid phases in real materials has been proven difficult due to the presence of competing interactions beyond Kitaev exchange. Almost all known structurally ordered Kitaev candidate materials host a magnetically ordered ground state. Suppression of the order by various tuning parameters is currently subject of extensive investigations. We explore the possibility of suppressing magnetic order by high-pressure magnetization measurements on several Kitaev materials under hydrostatic pressure and reveal a generic interplay of magnetism and structural dimerization: Upon applying hydrostatic pressure, structural dimerization emerges and becomes visible as step in the temperature dependence of the magnetic susceptibility that shifts to higher temperatures upon further compression. We also investigate how magnetic order disappears once dimerization emerges.

TT 46.11   Thu 12:15   HSZ 201

Variational States for the S=3/2 Kitaev spin liquids — •Willian Massashi Hisano Natori[1,2], Hui-Ke Jin[3], Frank Pollmann[3,4], and Johannes Knolle[2,3,4] — [1]Institut Laue-Langevin — [2]Imperial College London — [3]Technische Universität München — [4]Munich Center for Quantum Technology and Science

The lack of a mapping to free fermion models has for a long time prevented the analytical characterization of Kitaev spin liquids (KSLs) for general values of S. The most complicated of these spin liquids was the S=3/2 KSL, which defied both analytical and numerical techniques. This problem importance increased thanks to recent studies pointing out the relevance of Kitaev interactions on chromium-based van der Waals magnets.

We recently uncovered the ground state of the S=3/2 KHM perturbed by a single-ion anisotropy (SIA) using an SO(6) parton mean-field theory that displayed a remarkable quantitative agreement with DMRG simulations (Nat. Comm. 13, 3813). In this follow-up work, we uncover similarities between the S=3/2 KSL and the Majorana quantum spin-orbital liquids that emerge as ground states of exactly solvable Kugel-Khomskii models. We show that expectation values of several observables can be exactly calculated over a set of parton wavefunctions without Gutzwiller-projection, including the own KHM, quadrupolar parameters and correlation functions. The S=3/2 KSLs are then identified to the Gutzwiller projection of the state in this set minimizing the energy.

Linked-cluster expansions of perturbed topological phases — •Viktor Kott, Matthias Mühlhauser, and Kai Phillip Schmidt — FAU, Erlangen-Nürnberg, Deutschland

We investigate the robustness of Kitaev's toric code in a uniform magnetic field on the square and honeycomb lattice by perturbative linked cluster expansions using a full graph decomposition. In particular, the full graph decomposition allows to correctly take into account the non-trivial mutual exchange statistics of the elementary anyonic excitations. This allows us to calculate the ground-state energy and excitation energies of the topological phase which are then used to study the quantum phase transitions out of the topologically ordered phase as a function of the field direction.

TT 46.13   Thu 12:45   HSZ 201

Spin-Peierls instability of the U(1) Dirac spin liquid — •Josef Willsher[1], Urban Seifert[2], and Johannes Knolle[1,3,4] — [1]TU Munich, Germany — [2]Kavli Institute, University of California, Santa Barbara, USA — [3]MCQST, Munich, Germany — [4]Imperial College London, UK

Quantum spin liquids are tantalising phases of quantum matter, but experimental evidence of their existence has remained elusive. Recent theoretical and numerical studies have provided evidence that triangular-lattice Heisenberg magnets may host a U(1) Dirac spin liquid (DSL): a state of matter whose low-energy description is given by compact quantum electrodynamics in 2+1 dimensions coupled to four Dirac fermions, which is believed to flow to a strongly interacting conformal fixed point. Monopole operators constitute a strongly relevant perturbation to this fixed point, driving the spin liquid into magnetically ordered or VBS states, but are forbidden by the microscopic (UV) symmetries on the tri-

The mystery of the missing heavy-fermion weight — •Chia-Jung Yang[1], Oliver Stockert[2], Hilbert v. Löhneysen[3], Shovon Pal[1,4], Johann Kroha[5], and Manfred Fiebig[1] — [1]Department of Materials, ETH Zurich, Switzerland — [2]MPI for Chemical Physics of Solids, Dresden, Germany — [3]KIT Karlsruhe, Germany — [4]School of Physical Science, NISER Bhubaneshwar, India — [5]University of Bonn, Germany

The fermionic quasiparticle weight is one of the keys to understanding the quantum critical scenarios across a quantum phase transition (QPT). In heavy-fermion compounds, $CeCu_{6-x}Au_x$ (CCA), Cu substitution by Au expands the lattice, thereby inducing a QPT at x = 0.1 from a paramagnetic Fermi-liquid state to an antiferromagnetically-ordered ground state. Recently, the evolution of spectral weight has been revealed in CCA at x = 0, 0.1, and 1.0 via terahertz (THz) time-domain spectroscopy [1,2]. Here, we further investigate the spectral weight within the RKKY-dominated region where x = 0.2 and 0.3. In both samples, we find that the spectral weight increases slightly with decreasing temperature (T), but settles at a strongly suppressed, T-independent value already at and below 100 K, about two orders of magnitude above the Néel temperature [3]. This indicates that across QPT in CCA, the Kondo singlet formation is suppressed by the T-independent RKKY interaction, not by the critical magnetic fluctuations, in agreement with theoretical predictions [4].

Phonon softening close to a structural instability at zero temperature — T. Gruner[1,2], S. Lucas[1], C. Geibel[1], K. Kaneko[3], S. Tsutsui[4,5], K. Schmalzl[6], and •O. Stockert[1] — [1]Max-Planck-Institut für Chemische Physik fester Stoffe, 01187 Dresden, Germany — [2]Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, United Kingdom — [3]Materials Sciences Research Center, Japan Atomic Energy Agency, Tokai, Naka, Ibaraki 319-1195, Japan — [4]Japan Synchrotron Radiation Research Institute, SPring-8, Sayo, Hyogo 679-5198, Japan — [5]Institute of Quantum Beam Science, Graduate School of Science and Engineering, Ibaraki University, Hitachi, Ibaraki 316-8511, Japan — [6]Jülich Centre for Neutron Science JCNS, Forschungszentrum Jülich GmbH, Outstation at ILL, 38042 Grenoble, France

The structural transition in $LuPt_2In$ is interesting since it can be tuned to zero temperature upon substituting Pd for Pt in $Lu(Pt_{1-x}Pd_x)_2In$. Of particular interest is the appearance of a superconducting dome around the structural quantum criticality. We combined inelastic neutron and x-ray scattering measurements and studied in detail this structural transition in $Lu(Pt_{1-x}Pd_x)_2In$. As a result we determined the low-energy phonon dispersions and clearly identified the relevant phonon branch becoming soft at the transition. In general, the theoretical calculations broadly agree with the measured dispersion. However, large tails of the superstructure intensity above the structural transition clearly point to a non-mean-field behavior, which might be related to quantum criticality and/or the superconducting dome.

TT 47.3   Thu 10:00   HSZ 204

Search for ferromagnetic quantum phase transitions in CePt — Marc Seifert[1], •Florian Kübelbäck[1], Pau Jorba[1], Michael Schulz[2], Georg Benka[1], Andreas Bauer[1], and Christian Pfleiderer[1] — [1]Physik-Department, Technical University of Munich, D-85748 Garching, Germany — [2]MLZ, Technical University of Munich, D-85748 Garching, Germany

We report an investigation of the ferromagnetic properties and the putative existence of quantum phase transitions in CePt. Tracking the neutron depolarization of polycrystalline samples under pressure by means of bespoke diamond anvil cell and focussing neutron guides [1], we confirm the presence of a ferromagnetic to paramagnetic quantum phase transition at 13 GPa as inferred previously from the resistivity [2]. An additional drop in the depolarization deep in the ferromagnetic state for pressures up to 5 GPa suggests an additional small moment to large moment transition. We explore the nature and possible existence of a second quantum phase transition in the ferromagnetic state of single-crystal CePt grown under ultra-high vacuum compatible conditions. The pressure versus temperature phase diagram of CePt and its magnetic properties will

be compared with the emergence of a Kondo cluster glass in the isostructural sibling CePd of CePt when suppressing ferromagnetic order by substitutional Rh doping [3].

Quantum criticality on a compressible lattice — Saheli Sarkar, •Lars Franke, Nikolas Grivas, and Markus Garst — Institut für Theoretische Festkörperphysik, Karlsruhe, Germany

It is a long standing result in the theory of classical criticality that a second order phase transition when coupled to a compressible lattice will become first order if the Larkin-Pikin criterion[1] is satisfied. More recently the extension of these results to quantum criticality has sparked the interest of the community[2,3]. However, until now a detailed analysis of a microscopic theory describing a quantum phase transition on a compressible lattice and its implications for the nature of the phase transition as well as the consequences for the lattice has been missing. Here we provide this calculation for a Lorentz-invariant ϕ^4-theory with quadratic coupling to strain and analyse it using renormalization group (RG) methods to one-loop order. We find that both critical and phonon velocity flow with RG leading to an additional fixed point where the phonons have a renormalized dynamical exponent. Furthermore, our results show that the quantum version of the Larkin-Pikin criterion[2] holds, but even when the criterion is not satisfied a structural instability can still occur, if the coupling is large enough.

Marginal Fermi liquid at a magnetic quantum critical point from dimensional confinement — •Bernhard Frank[1], Zi Hong Liu[2], Fakher F. Assaad[2], Matthias Vojta[1], and Lukas Janssen[1] — [1]Institut für Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01062 Dresden, Germany — [2]Institut für Theoretische Physik und Astrophysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany

Metallic quantum criticality is frequently discussed as a source for non-Fermi liquid behavior, but controlled theoretical treatments are scarce. Here, we identify and study a novel magnetic quantum critical point in a two-dimensional antiferromagnet coupled to a three-dimensional environment of conduction electrons. By combining an effective field theory analysis and sign-problem-free quantum Monte Carlo simulations, we demonstrate that the quantum critical point exhibits marginal Fermi liquid behavior. In particular, we compute the electrical resistivity for transport across the magnetic layer, which is shown to display a linear temperature dependence at criticality. Experimental realizations in Kondo heterostructures are discussed.

TT 47.6   Thu 10:45   HSZ 204

Transverse-field quantum phase transitions in $CoNb_2O_6$ — •Alexander Engelhardt[1], Andreas Wendl[1], Andreas Bauer[1], Andreas Erb[2], Matthias Vojta[3], and Christian Pfleiderer[1] — [1]Physik-Department, Technical University of Munich, D-85748 Garching, Germany — [2]Walther-Meißner-Institut, D-85748 Garching, Germany — [3]Institut for Theoretical Physics, Technical University of Dresden, D-85748 Garching, Germany

The ferromagnetic Ising chain in a transverse magnetic field displays the perhaps best understood theoretical example of a quantum phase transition. One of the closest realizations has been reported in the columbite compound $CoNb_2O_6$ [1,2,3], in which, however, weak interchain couplings result in incommensurate antiferromagnetism as a function of decreasing temperature, followed by a transition to commensurate antiferromagnetic order. We have grown high-quality single-crystal $CoNb_2O_6$ by means of optical float-zoning. Measuring the transverse magnetic ac susceptibility of a spherical sample down to 90 mK under arbitrary field orientations, we have mapped out the emergence of the quantum phase transitions associated with the incommensurate and commensurate antiferromagnetic order under transverse field, as well as the evolution of the mag-

netic phase diagram when systematically tilting the magnetic field away from the hard magnetic axis.

Non-Fermi liquid behavior at flat hot spots at the onset of density wave order in two-dimensional metals — •Lukas Debbeler and Walter Metzner — Max Planck Institute for Solid State Research, Stuttgart, Germany

We analyze the quantum critical point (QCP) at the transition towards incommensurate charge or spin density wave order with a $2k_F$ wave vector that connects a single pair of hot spots on the Fermi surface. From a theoretical point of view the fate of this QCP is debated. Strong fluctuations might lead to a discontinuously opening gap and therefore a first order transition [1]. On the other hand a fluctuation driven flattening at the hot spots of the Fermi surface has been found [2,3], which could protect the QCP. Hence, we investigate the effect of quantum critical fluctuations for a flat Fermi surface at the nesting points. We report non-Fermi liquid properties and provide numerical values for anomalous exponents.

TT 47.8　Thu 11:30　HSZ 204

Frozen deconfined quantum criticality — •Vira Shyta[1,2], Jeroen van den Brink[1,3], and Flavio Nogueira[1] — [1]Institute for Theoretical Solid State Physics, IFW Dresden, Helmholtzstr. 20, 01069 Dresden, Germany — [2]Kyiv Academic University, 36 Vernadsky blvd., Kyiv 03142, Ukraine — [3]Institute for Theoretical Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, 01069 Dresden, Germany

There is a number of contradictory findings with regard to whether the theory describing easy-plane quantum antiferromagnets undergoes a second-order phase transition. The traditional Landau-Ginzburg-Wilson approach suggests a first-order phase transition, as there are two different competing order parameters. On the other hand, it is known that the theory has the property of self-duality which has been connected to the existence of a deconfined quantum critical point (DQCP). The latter regime suggests that order parameters are not the elementary building blocks of the theory, but rather consist of fractionalized particles that are confined in both phases of the transition and only appear at the critical point. Here we establish from exact lattice duality transformations and renormalization group analysis that the easy-plane CP1 antiferromagnet does feature a DQCP. We uncover the criticality starting from a regime analogous to the zero temperature limit of a certain classical statistical mechanics system which we therefore dub frozen. At criticality our bosonic theory is dual to a fermionic one with two massless Dirac fermions, which thus undergoes a second-order phase transition as well.

TT 47.9　Thu 11:45　HSZ 204

Finite temperature entanglement negativity of fermionic topological phases and quantum critical points — •Wonjune Choi[1,2], Frank Pollmann[1,2], and Michael Knap[1,2] — [1]Department of Physics, Technical University of Munich, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany

In condensed matter physics, topology is vital in describing quantum phases of matter beyond the Ginzburg-Landau paradigm. Two symmetry-preserving quantum states may not be adiabatically connected if the topological structure encoded in the many-body entanglements is distinct. Hence, this talk presents how quantum entanglements can be quantified to unveil the underlying topological nature of the gapped topological phases and the quantum critical points. We demonstrate that the logarithmic negativity between spatially separated disjoint intervals can sharply count the topologically protected edge modes. Notably, the quantized values of the negativity could reveal the topological indices of the gapless quantum states described by the conformal field theories having the same central charge. At finite temperatures, the entanglement negativity for the disjoint intervals is no longer quantized. However, the negativity for the two adjacent intervals leaves the structure similar to the quantum critical fan, which

signals the highly entangled ground state even at a finite temperature window.

Symmetry enriched topological quantum phase transition in projected entangled pair states — •Lukas Haller, Yu-Jie Liu, Wen-Tao Xu, and Frank Pollmann — Department of Physics, Technical University of Munich, 85748 Garching, Germany

Phase transitions between topologically ordered phases can exhibit a rich structure and are generically challenging to study. In this context, we consider the 2D toric code decorated with 1D symmetry protected topological states and construct a family of parametrized projected entangled pair states (PEPS), which describes the ground states of time-reversal (TR) symmetric Hamiltonians. The system can exhibit three distinct phases of matter: (i) A trivial phase; (ii) the toric code phase, where TR symmetry is not fractionalized; (iii) a symmetry enriched topological (SET) phase, where TR symmetry can be fractionalized on anyons. We characterize different phases using topological entanglement entropy and membrane order parameters. By mapping the PEPS to the partition functions of 2D classical models, we show that the trivial phase is separated from the toric code and the SET phases by critical points described by an Ising conformal field theory (CFT) with central charge $c = 1/2$, while the phase transition between the toric code and the SET phase is described by a compactified free-boson CFT with $c = 1$. The model realizes a direct phase transition between the toric code and the SET phases at a microscopic level.

Renormalization group flow of the Yukawa-SYK model — •Niklas Cichutek and Peter Kopietz — Goethe University Frankfurt

We use the functional renormalization group to calculate the global renormalization group flow of the Yukawa-SYK model describing N fermions on a quantum dot which are coupled to M phonons by a disorder-induced Yukawa coupling in the large N and M limit for an arbitrary ratio $\frac{N}{M}$. By determining the fixed-point structure we identify the different phases as well as the quantum critical point and their corresponding anomalous dimensions. The stability analysis of the fixed points sheds light on the self-tuning to criticality of the Yukawa-SYK model.

TT 47.13　Thu 12:45　HSZ 204

Quantum criticality of Heisenberg systems with long-range interactions — •Patrick Adelhardt and Kai Phillip Schmidt — Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU)

The majority of numerical approaches investigating long-range quantum systems is restricted to one-dimensional systems and systems in two dimensions with quickly decaying long-range interactions. While models with discrete symmetries like the long-range transverse-field Ising model have been studied thoroughly, much less is known about long-range models with continuous symmetries where long-range interactions can cricumvent the Hohenberg-Mermin-Wagner theorem in one dimension allowing the spontaneous breaking of continuous symmetries or can give rise to massive excitations violating Goldstone's theorem. We study the breakdown of the rung-singlet phase in the quasi one-dimensional Heisenberg ladders as well as two-dimensional Heisenberg bilayer systems with algebraically decaying long-range interactions. To this end we use the method of perturbative continuous unitary transformations (pCUT) as a white graph expansion with classical Monte Carlo simulations yielding high-order series in the thermodynamic limit about the limit of isolated dimers. This allows us to determine the critical point as well as critical exponents as a function of the decay exponent.

Superconductivity mediated by topological phonons — •ALESSIO ZACCONE — Department of Physics, University of Milan, 20133 Milano, Italy

Topological phononic insulators are the counterpart of three-dimensional quantum spin Hall insulators in phononic systems and, as such, their phononic topological surfaces are characterized by Dirac cone-shaped gapless edge states arising as a consequence of a bulk-boundary correspondence. We proposed [1] a theoretical framework for the possible superconductivity in these materials, where the attractive interaction between electrons is mediated by topological phonons in nontrivial boundary modes. Within the BCS limit, we developed a self-consistent two-band gap equation, whose solutions show that the superconducting T_c has a nonmonotonic behavior with respect to the phononic frequency in the Kramers-like point. This remarkable behavior is produced by a resonance that occurs when electrons and phonons on the topological surfaces have the same energy: this effectively increases the electron-phonon interaction and hence the Cooper pair binding energy, thus establishing an optimal condition for the superconducting phase. With this mechanism, the T_c can be increased by well over a factor 2, and the maximum enhancement occurs in the degenerate phononic flat-band limit.

TT 48.2   Thu 9:45   HSZ 304

Topological superconductivity on the honeycomb lattice: Effect of normal state topology and disorder — •STEPHAN RACHEL — School of Physics, University of Melbourne, Australia

The search for topological superconductors is one of the most pressing and challenging questions in condensed-matter and material research. Despite some early suggestions that doping a topological insulator might be a successful recipe to find topological superconductors, to date there is no general understanding of the relationship of the topology of the superconductor and the topology of its underlying normal state system. Here we present an analysis of doped insulators - topological and trivial. Our approach allows us to study and compare superconducting instabilities of different normal state systems and present rigorous results about the influence of the normal state system's topology. If time permits we will also discuss the influence of disorder on topological superconductivity on the honeycomb lattice.

TT 48.3   Thu 10:00   HSZ 304

Ground state topology of a multiterminal superconducting double quantum dot — •LEV TESHLER, HANNES WEISBRICH, and WOLFGANG BELZIG — Universität Konstanz, Konstanz, Germany

Multiterminal Josephson junctions can provide topological Andreev bound states in the space of the superconducting phases [1]. The topology of the Andreev bound states manifests itself in a quantized transconductance when applying voltages to two terminals. Such systems are candidates to realise higher-dimensional topology and non-Abelian Berry phases using their synthetic dimensions [2]. For practical purposes a linear arrangement of quantum dots coupled to superconductors might be beneficial and was shown to exhibit nontrivial topology [3]. In this work, we study a double quantum dot in which each dot is coupled to two superconductors. This system that depends on three superconducting phase differences already displays non-trivial topology in terms of the first Chern number and is an example that allows to study the fundamental properties of this class of systems. We will study the ground state and the respective topological phase diagram for different sets of parameters of the double quantum dot. Furthermore, we will also discuss the influence of Coulomb interaction and Zeeman splitting on the topological properties of the ground state.

TT 48.4   Thu 10:15   HSZ 304

Fractional transconductance via non-adiabatic topological Cooper pair pumping — •HANNES WEISBRICH[1], RAFFAEL L. KLEES[2], ODED ZILBERBERG[1], and WOLFGANG BELZIG[1] — [1]Universität Konstanz — [2]Universität Würzburg

Many robust physical phenomena in quantum physics are based on topological invariants, which are intriguing geometrical properties of quantum states. A prime example is the 2D quantum Hall effect with its quantized quantum Hall conductance in units of $\frac{e^2}{h}$ protected by the respective 2D topology. A comparable effect in superconducting systems is the appearance of a quantized transconductance in units of $\frac{4e^2}{h}$ for topological Andreev bound states in multiterminal Josephson junctions.

In this work, we theoretically demonstrate how fractional quantized plateaus in the transconductance can be observed as a result of topological Cooper pair pumping in a chain of Josephson junctions. The fractional plateaus in the transconductance are stabilized by non-adiabatic Landau-Zener transitions which even allow for a robustness to disorder in the chain.

TT 48.5   Thu 10:30   HSZ 304

Magnetic-domain mediated topological superconductivity in a Josephson Junction — •IGNACIO SARDINERO[1], RUBÉN SEOANE SOUTO[2,3], and PABLO BURSET[1] — [1]Department of Theoretical Condensed Matter Physics, Condensed Matter Physics Center (IFIMAC) and Instituto Nicolás Cabrera, Universidad Autónoma de Madrid, 28049 Madrid, Spain — [2]Division of Solid State Physics and NanoLund, Lund University, S-221 00 Lund, Sweden — [3]Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, Denmark

Topological superconductors are appealing building blocks for robust and reliable quantum information processing. Most platforms for engineering topological superconductivity rely on a combination of materials with intrinsic spin-orbit coupling and external magnetic fields, which are usually challenging to manipulate. We propose and describe a setup without spin-orbit or magnetic fields where a conventional Josephson junction is linked by a narrow ferromagnetic insulator with multi-domain structure along the interface. Our calculations show that sequences of magnetic domains preserving the net magnetization's rotation direction are sufficient for generating topological superconductivity in a wide range of parameters and degrees of disorder. We find that the topological phase transition strongly depends on the magnitude and period of the net magnetization. Interestingly, a phase bias across the junction can control and tune the formation and localization of a pair of Majorana zero-energy modes along the junction interface, with an observable effect on the current-phase relation.

TT 48.6   Thu 10:45   HSZ 304

Symmetry enriched entanglement properties of chiral Skyrme insulators — •JOE WINTER[1,2,3], BERND BRAUNECKER[3], and ASHLEY COOK[1,2] — [1]Max Planck Institute for Chemical Physics of Solids, Nothnitzer Straße 40, 01187 Dresden, Germany — [2]Max Planck Institute for the Physics of Complex Systems, Nothnitzer Straße 38, 01187 Dresden, Germany — [3]SUPA, School of Physics and Astronomy, University of St. Andrews, North Haugh, St. Andrews KY16 9SS, UK

The expectation value of an observable $\mathcal{O}$ may be computed with a density matrix ρ as $\mathrm{Tr}\left(\rho\mathcal{O}\right)$. In this work, we introduce the symmetry-enriched partial trace operation for density matrices, $\tilde{\rho}_{\mathscr{T}} = \bar{\mathrm{T}}\mathrm{r}_{\mathscr{T}}\left(\rho\right)$, a partial trace performed over $\mathscr{T}$ degrees of freedom on a density matrix as part of partial computation of an expectation value for an observable $\mathcal{O}$. That is, for representation of observable $\mathcal{O}$ after tracing out $\bar{\mathscr{T}}$ being $\mathcal{O}_{\mathscr{T}}$, $\tilde{\rho}_{\mathscr{T}}$ satisfies $\mathrm{Tr}\left(\rho\mathcal{O}\right) = \langle\mathcal{O}\rangle = \langle\mathcal{O}_{\mathscr{T}}\rangle = \mathrm{Tr}\left(\tilde{\rho}_{\mathscr{T}}\mathcal{O}_{\mathscr{T}}\right)$, with symmetry-enrichment deriving from differences in symmetry between $\mathcal{O}$ and $\mathcal{O}_{\mathscr{T}}$. We use this to characterize bulk-boundary correspondence of topological skyrmion phases, by computing the symmetry-enriched reduced density matrix in the 2D bulk of a topological skyrmion phase, and for slab geometries with open boundary conditions in one direction. We show winding of this reduced density matrix matches winding of the spin expectation value vector in the bulk, and the entanglement spectrum of the reduced density matrix for the slab geometry reveals $\mathscr{Q}$ topologically-protected, chiral edge modes for skyrmion number $\mathscr{Q}$ characterizing the bulk topological skyrmion phase.

TT 48.7   Thu 11:00   HSZ 304

Non-Hermitian dimerized interacting Kitaev chain — •SHARAREH SAYYAD[1] and JOSE LADO[2] — [1]MPI for the science of light, Erlangen, Germany — [2]Aalto University, Espoo, Finland

Non-Hermitian models have risen as a new paradigm to manipulate and interpret various emergent quantum phenomena. While numerous studies have been focused on exploring (effective) non-Hermitian non-interacting models. The role of interactions in modifying the non-interacting non-Hermitian physics still needs to be well-explored. In this talk, I will present how incorporating many-body interactions can enrich non-interacting physics. To be more precise, combining our exact analytical results and tensor- network numerical calculations, I will discuss the phase diagram of the non-Hermitian dimerized interacting Kitaev chain. Here, the non-Hermiticity is due to the complex-valued nearest-neighbor density-density interaction strength. I will show that the ground state degeneracy of this system may be fourfold, twofold, or nondegenerate, depending on the parameter regimes. I will further discuss how these degeneracies are lifted in the presence of non-Hermiticity. Elaborating on this behavior clarifies the role of non-Hermiticity in washing out multiple phases in the phase diagram of the Hermitian interacting model.

TT 49: Quantum Coherence and Quantum Information Systems I

TT 49.1   Thu 11:30   HSZ 304

Inter-lab quantum microwave teleportation — •Michael Renger[1,2], Simon Gandorfer[1,2], Wun Kwan Yam[1,2], Florian Fesquet[1,2], Kedar Honasoge[1,2], Fabian Kronowetter[1,2,3], Yuki Nojiri[1,2], Achim Marx[1], Rudolf Gross[1,2,4], and Kirill G. Fedorov[1,2] — [1]Walther-Meißner-Institut, BadW, 85748 Garching, Germany — [2]TUM School of Natural Sciences, Technische Universität München, Garching, Germany — [3]Rohde & Schwarz GmbH & Co. KG, 81671 Munich, Germany — [4]Munich Center for Quantum Science and Technology, 80799 Munich, Germany

Quantum communication enables secure and efficient information exchange among different quantum nodes. To avoid inefficient frequency conversion for data transfer between superconducting quantum processors, we implement our quantum communication protocols with propagating quantum microwave states, directly in the microwave frequency regime which relies on ambient temperatures below 100 mK. To realize such a microwave quantum channel, we connect two dilution refrigerators over a distance of 6.5 m via a cryogenic link, operating at a base temperature of 52 mK. We employ our system to demonstrate inter-lab quantum teleportation of coherent microwave states, where we achieve the teleportation fidelity of 55%, exceeding the classical threshold. We discuss quantum advantage and security of this protocol and provide an outlook into the future of microwave quantum communication.

TT 49.2   Thu 11:45   HSZ 304

A co-design superconducting quantum circuit for quantum simulations — •Daria Gusenkova, Jayshankar Nath, Hsiang-Sheng Ku, Julia Lamprich, Nicola Wurz, Stefan Pogorzalek, Florian Vigneau, Ping Yang, Frank Deppe, Antti Vepsäläinen, Alessandro Landra, Vladimir Milchakov, Caspar Ockeloen-Korppi, Wei Liu, Lan-Hsuan Lee, Seung-Goo Kim, Hermanni Heimonen, Manish Thapa, and Inés de Vega — IQM Germany GmbH, Nymphenburger Str. 86, 80335 Munich

The co-design concept of building application-specific quantum processors is a viable strategy for reaching quantum advantage with noisy intermediate-scale quantum computers. We consider many-body problems which map onto a Hamiltonian with all-to-all interacting qubits. Here, a prototypical example is the simulation of a nanoscale NMR system consisting of an NV center coupled to multiple nuclear spins. We discuss the implementation on a star-topology circuit developed in IQM. Compared to the general-purpose square-grid topology, the star reduces the number of SWAP gates in the algorithm implementation, and thus tolerates higher gate errors for a given computational precision [1]. In order to allow for hardware scaling, we use a distributed-element resonator as a center component in the circuit. To use this resonator as a computational element, we develop qubit-resonator SWAP and CZ gates. In this talk, we present the experimental progress towards digitally simulating the nanoscale NMR problem.

TT 49.3   Thu 12:00   HSZ 304

Showcasing the effective direct interaction between a readout resonator and a strongly coupled junction defect mediated by a transmon qubit — •Alexander K. Händel, Alexander Bilmes, Alexey V. Ustinov, and Jürgen Lisenfeld — Physikalisches Institut, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany

Decoherence from material defects constitutes a principal problem on the way to improve superconducting quantum bits. Strongly coupled defects residing in the Josephson junction pose a particular challenge, demonstrating coupling strengths of multiple MHz. This strong coupling leads to avoided level crossings when qubit and defect come into resonance, and spoils qubit performance. In this work, we reveal an additional decoherence channel that occurs due to the resonant interaction between defects in the qubit's Josephson junction with the qubit's readout resonator, through an interaction mediated by the qubit. We investigate this effect using multi-photon spectroscopy and QuTiP simulations of the tripartite energy level spectrum.

TT 49.4   Thu 12:15   HSZ 304

Modular flip-chip architecture for generalized flux qubits — •Soeren Ihssen[1], Simon Geisert[1], Martin Spiecker[2], Patrick Winkel[2], Wolfgang Wernsdorfer[1,2], and Ioan M. Pop[1,2] — [1]Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, Germany — [2]Physikalisches Institut, Karlsruhe Institute of Technology, Germany

Superconducting circuits are a promising and widely-used platform to implement quantum information processing hardware. However, scaling up to more sophisticated devices requires major engineering efforts due to the complexity of the mandatory coupling, readout and control circuitry. To investigate innovative coupling and scaling strategies, we developed a modular flip-chip architecture, in which the various circuit elements reside on dedicated chips that are capacitively coupled. A unit cell of our architecture consists of a qubit chip that is flipped above a control chip. The qubit chip contains a single generalized flux qubit (GFQ) and a harmonic readout mode, through which dispersive readout is possible. The control chip is used to excite, read out and flux bias the qubit. We tested our architecture by characterizing the GFQs in all conventional flux qubit regimes by modifying the qubit loop inductance as well as the shunt capacitance and the Josephson energy of the alpha junction. This resulted in qubit frequencies between 150 MHz and 7.5 GHz, and dispersive shifts of 60 kHz to 6 MHz. Coupling between unit cells may be achieved through coupler chips, so that our unit cell can be used as a basic building block of a scalable qubit array.

TT 49.5   Thu 12:30   HSZ 304

Improving Fabrication Methods for Highly Coherent Superconducting Qubits — •Niklas Bruckmoser[1,2,3], Leon Koch[1,2,3], David Bunch[1,2,3], Tammo Sievers[1,2,3], Kedar E. Honasoge[1,2,3], Thomas Luschmann[1,2,3], and Stefan Filipp[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

Superconducting qubits and resonators with long coherence times pave the way towards useful quantum processors. Significant improvements in coherence time have already been made over the last years. However, the fidelity is still limited by decoherence due to noise and losses arising in the local environment of the qubit. It is thus an integral endeavor of fabrication efforts to mitigate these effects. Here, we demonstrate that qubit lifetimes well beyond 0.1 ms can be achieved by a combination of substrate cleaning, etching optimization and post-process sample cleaning. By improving on these processes we reach quality factors above 4×10^6 for thin-film niobium coplanar waveguide resonators in the single photon regime and qubit lifetimes of more than 0.2 ms for niobium based transmons.

TT 49.6   Thu 12:45   HSZ 304

Dynamics of superconducting qubit coherence times due to fluctuations of two-level systems — •Ivan Tsitsilin[1,2] and Stefan Filipp[1,2] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [2]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany

Recent studies have shown that the stability of coherence times is strongly affected by two-level systems (TLSs). This is caused by chaotic frequency fluctuations of TLSs, which, when in proximity to the qubit resonance, significantly reduce its T_1 times. Understanding and mitigating this behavior is crucial to realize functional quantum processing devices based on superconducting qubits. In this work, we perform a long-time stability analysis of the qubit T_1 times as a function of qubit frequency utilizing the AC-Stark shifting technique[1]. We present an extensive analysis of the TLS distributions and their impact on T_1 times for different qubit sample materials and RF line configurations. Furthermore, our results provide insight into the effect of the noise spectrum on the behavior and density of TLSs.

TT 50: Focus Session: Superconducting Nickelates II

Time: Thursday 15:00–17:00   Location: HSZ 03

TT 50.1   Thu 15:00   HSZ 03

Fermi liquid on the verge of antiferromagnetism: Non-local correlations in bulk LaNiO$_3$ as seen by SX-ARPES — •Johannes Falke[1], Cheng-En Liu[1,2,3], Keng-Yung Lin[1,4], Chang-Yang Kuo[1,2,3], Hanjie Guo[1], Alexander Komarek[1], Chun-Fu Chang[1], Philipp Hansmann[5], and Liu Hao Tjeng[1] — [1]MPI CPfS, Dresden, Germany — [2]NYCU, Hsinchu, Taiwan — [3]NSRRC, Hsinchu, Taiwan — [4]NTU, Taipei, Taiwan — [5]FAU, Erlangen, Germany

Soft X-ray ARPES measurements were performed on large single crystals of the metallic oxide LaNiO$_3$ along high symmetry directions, revealing the bulk electronic structure of the full valence band. The experimental Fermi surface is accurately reproduced by conventional band theories, whereas the nonzero frequency part of the spectra shows k-dependent renormalizations that cannot be explained by DFT even accounting for octahedral rotations and require true many-body methods to accurately explain.

TT 50.2   Thu 15:15   HSZ 03

Insights into the electronic structure of oxygen reduced and doped nickelates from core-level spectroscopy — •Rebecca Pons — Max-Planck Institut für Festkörperforschung, Stuttgart, Germany — Stewart Blusson Quantum Matter Institute, UBC Vancouver, Canada

With the observation of superconductivity in Sr-doped infinite-layer nickelate $Nd_{0.8}Sr_{0.2}NiO_2$ research interest in this material class intensified. We used ozone assisted molecular beam epitaxy to grow $RNiO_3$ thin films (R=La,Pr) and investigated the subsequent topotactic soft-chemistry reaction, needed to synthesize the square-planar phase, at different stages of reduction by x-ray absorption spectroscopy. We observe the evolution of the Ni oxidation state and that the process is laterally homogeneous down to length scales of 50 nm. To reach the superconducting phase hole doping of the infinite-layer nickelates is required with an optimal doping level around x=0.2. This can be achieved by self-doping in quintuple-layer Ruddlesden-Popper nickelates or alkaline-earth doping, Ca or Sr, in infinite-layer films. Using angle-resolved photoemission spectroscopy (ARPES) we studied changes in the Fermi surface upon alkaline-earth doping in $(La,Ca)NiO_3$.

TT 50.3   Thu 15:30   HSZ 03

Thickness-dependent interface polarity in infinite-layer nickelate superlattices — •Chao Yang[1], Roberto A. Ortiz[1], Yi Wang[2], Wilfried Sigle[1], Hongguang Wang[1], Eva Benckiser[1], Bernhard Keimer[1], and Peter A. van Aken[1] — [1]Max Planck Institute for Solid State Research, Stuttgart, 70569, Germany — [2]Center for Microscopy and Analysis, Nanjing University of Aeronautics and Astronautics, Nanjing, 210016, P.R. China

The interface polarity plays a vital role in the physical properties of oxide heterointerfaces, since it can enforce a reconstruction of the electronic and atomic structure. In the recently discovered superconducting nickelate thin films, interfacial effects could play an important role. This motivated our investigation of the electronic and atomic structure at the atomic scale at interfaces of infinite-layer nickelate thin films. Using four-dimensional scanning transmission electron microscopy (4D-STEM) and electron energy-loss spectroscopy (EELS), we systematically studied the effects of oxygen distribution and site occupancy, polyhedral distortion, elemental intermixing, as well as dimensionality on interface properties of infinite-layer NdNiO2/SrTiO3 superlattices. The oxygen intensity and distribution maps show the local symmetry change from octahedral to square planar induced by the reduction process and a gradual change of the oxygen content in the nickelate layers. Remarkably, we demonstrate spatially controlled interface polarity with accompanying interface reconstructions. Our results provide insights to understand the effects of polarity and dimensionality on the interface properties of infinite-layer nickelates.

TT 50.4   Thu 15:45   HSZ 03

GW+**EDMFT investigation of** $Pr_{1-x}Sr_xNiO_2$ **under pressure** — •Viktor Christiansson, Francesco Petocchi, and Philipp Werner — University of Fribourg, Fribourg, Switzerland

The recent experimental observation of a large pressure effect on T_c in $Pr_{1-x}Sr_xNiO_2$ opens up an interesting prospect for reaching even higher values of T_c in the nickelates. On the theoretical side, systematic changes with pressure also provides a new possibility for probing the single- versus multi-orbital nature of these systems. In this talk, we discuss the electronic structure of this system as a function of pressure and doping, based on numerical calculations using self-consistent GW+EDMFT. We show that the normal state properties demonstrate a non-trivial interplay between physical pressure and chemical doping, and we find small but systematic changes with increasing pressure. The proper treatment of correlation effects, beyond density functional theory, is shown to play an important role in revealing these trends. While the pressure dependent changes of the undoped compound suggest a more single-orbital-like behavior towards the high-pressure regime, a qualitatively different behavior is observed for the doped system with a multi-orbital nature manifesting itself also at high pressures.

TT 50.5   Thu 16:00   HSZ 03

Nature of magnetic coupling in bulk infinite-layer nickelates versus cuprates — •Armin Sahinovic, Benjamin Geisler, and Rossitza Pentcheva — Fakultät für Physik, Universität Duisburg-Essen

In contrast to cuprates, where the proximity of antiferromagnetism (AFM) and superconductivity is well established, first indications for AFM interactions in superconducting infinite-layer nickelates [1] were only recently obtained [2,3]. Here, we explore, based on first-principles simulations, the nature of the magnetic coupling in NdNiO2 as a function of the on-site Coulomb and exchange interaction, varying the explicit hole doping and the treatment of the Nd $4f$

electrons. The U-J phase diagrams for undoped nickelates and cuprates indicate G-type ordering, yet show different U dependency. By either Sr hole doping or explicit treatment of the Nd $4f$ electrons, we find a transition to a Ni C-type AFM ground state. We trace this back to a distinct response of the Ni vs. Cu e_g orbitals to the hole doping. The interaction between Nd $4f$ and Ni $3d$ spin stabilizes C-type AFM order on both sublattices. Though spin-orbit interactions induce a band splitting near the Fermi energy, the bad-metal state is retained under epitaxial strain. The magnetocrystalline anisotropy features an in-plane easy axis, related to the planar NiO2 coordination. These results establish the nickelates as a unique platform to study unconventional superconductivity.

Magnetic interactions in $InNiO_3$ **compared to** $RNiO_3$ — •Alexander Yaresko, Graham McNally, Minu Kim, and Hidenori Takagi — Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany

$RNiO_3$ nikelates undergo with lowering temperature a metal-to-insulator (MIT) transition, accompanied by orthorhombic-to-monoclinic distortion of their crystal structure, and another transition at T_N to a magnetically ordered state with the ordering vector q=(1/2, 0, 1/2). Two Ni sites in the monoclinic unit cell are nonequivalent, with the average Ni_1–O distance being significantly larger than Ni_2–O. In compounds with the large radius of a R^{3+} ion the two transitions occur simultaneously. As the R size decreases, the crystal structure becomes more distorted. As a consequence, the MIT temperature increases while T_N decreases. Recently, a new $InNiO_3$ compound, in which an In^{3+} ion is even smaller than the smallest rare-earth Lu^{3+}, has been synthesized. We performed DFT(+U) calculations for $InNiO_3$ and compare the results to other nikelates. In order to quantify the effect of structural distortions on the magnetic properties we estimated exchange interactions between magnetic Ni_1 ions by mapping the energies of spin-spirals with different wave vectors q to an effective Heisenberg model. We found that the strongest interactions are those along Ni_1-O-Ni_2-O-Ni_1 bonds but their strength decreases with increasing lattice distortions. The experimental q=(1/2, 0, 1/2) order can only be reproduced if a sufficiently small value of Coulomb repulsion U is used for more covalent Ni_2 ion.

Transport properties of $Nd_{1-x}Sr_xNiO_2$ **based on a realistic 3-band model** — •Steffen Bötzel, Ilya Eremin, and Frank Lechermann — Institut für theoretische Physik III, Ruhr-Universität Bochum, Bochum, Germany

Here, we consider theoretically the quasiparticle transport in the superconducting nickelate $Nd_{1-x}Sr_xNiO_2$ based on a realistic 3-band low-energy model derived from a first-principle approach [1]. The transport properties are obtained from the standard Kubo formalism. They depend on the band structure near the Fermi surface and are consequently a probe of the hitherto poorly understood low-energy electronic structure. We find significant contributions from different orbitals and bands depending on temperature and doping. Their interplay gives rise to multi-band characteristics, which are in accordance to available experimental data. This observation is important for the ongoing debate whether the low-energy physics is single- or multi-band like and points towards multi-band physics in these compounds.

High-pressure crystal growth and physical properties of Ruddlesden-Popper trilayer nickelates $La_4Ni_3O_{10}$ — •Ning Yuan, Kaustav Dey, Jan Arneth, Ahmed Elghandour, and Rüdiger Klingeler — Kirchhoff Institute for Physics, Heidelberg University, Germany

Single crystals of $La_4Ni_3O_{10}$ were successfully grown by the high-pressure optical floating-zone method under 20 bar oxygen pressure. We investigate the different growth and post-annealing processes leading to two different polymorphs, namely $P2_1/a$ (No.14) and $Bmab$ (No.64), respectively, and report high-resolution thermal expansion, specific heat and magnetometry data on both of them. Our thermodynamic studies show sharp anomalies associated with the reported Metal-to-Metal Transition (MMT) in $La_4Ni_3O_{10}$ and distinct anisotropy. For the $P2_1/a$ phase, the MMT transition is found at 134 K while it appears at 152 K for $Bmab$. Our thermal expansion data in particular confirm that the MMT transition is associated with strong lattice changes (cf. [1]) but is also reveals clear contradictions to the published XRD data [2].

The zoo of magnetic states in the 2D Hubbard model — •Robin Scholle, Pietro Bonetti, Demetrio Vilardi, and Walter Metzner — MPI FKF Stuttgart

We use real-space Hartree-Fock theory to construct a magnetic phase diagram of the two-dimensional Hubbard model as a function of temperature and doping. We are able to detect various spin- and charge order patterns including Néel, stripe and spiral order without biasing the system towards one of them. For an intermediate interaction strength we predominantly find Néel order close to half-filling, stripe order for low temperatures or large doping, and an intermediate region of spiral order.

I will give a short summary of the method followed by a presentation of our current results and an outlook for possible further applications.

TT 51.2   Thu 15:15   HSZ 103

Effect of higher-order van Hove singularity on the formation of spin density waves — Alkistis Zervou[1], Garry Goldstein[2], Joseph Betouras[1], and •Dmitry Efremov[3] — [1]Department of Physics and Centre for the Science of Materials, Loughborough University, Loughborough LE11 3TU, UK. — [2]Physics Department, Boston University, Boston MA 02215, USA — [3]Leibniz Institute for Solid State and Materials Research Dresden, Helmholtzstrasse 20, D-01069 Dresden, Germany.

Van-Hove singularities in the density of states, which occur due to Lifshitz transitions in electronic band structures, affect different types of ordering in quantum materials. In addition to the usual Van Hove singularities, there are higher-order Van Hove singularities (HOVHS) with DOS divergence according to the power law. We find that the spin wave density and charge density of the phase formation can be enhanced by the presence of a singularity depending on the strength of certain interactions, with the critical temperature increasing by orders of magnitude. We discuss the application of our findings to various experimental systems such as Sr3Ru2O7.

Kinetic theory of charge-density waves — •Viktor Hahn and Peter Kopietz — Institut für Theoretische Physik, Universität Frankfurt, Max-von-Laue Strasse 1, 60438 Frankfurt, Germany

We present a theoretical study of the dynamics of the collective amplitude and phase modes in the charge-density wave (CDW) state of the electronically quasi one-dimensional material $K_{0.3}MoO_3$ (blue bronze). For this purpose we formulate a kinetic theory using the method of expansion in connected equal-time correlations. Our kinetic equations for the CDW order parameter has the same form as the phenomenological equation of motion obtained within a time-dependent Ginzburg-Landau approach. From the numerical solution of our kinetic equations we extract the frequencies and the damping of the collective amplitude and phase modes in the CDW state. We find that the damping is strongly enhanced when the temperature approaches the critical temperature from below, in agreement with recent experiments.

TT 51.4   Thu 16:00   HSZ 103

Collective modes in the quasi one-dimensional charge-density wave material blue bronze — •Max Oberon Hansen — Goethe University, Frankfurt am Main, Germany

We calculate the spectrum of collective modes (amplitude, phase, phonon, and plasmon) in the charge-density wave state of the quasi-one dimensional metal $K_{0.3}MoO_3$, named blue bronze. Using a functional integral approach we derive effective actions for the different types of collective modes in Gaussian approximation and compare our results with experiments. Our approach emphasizes the role of acoustic phonons to guarantee that the phase mode remains gapless in the presence of long-range Coulomb interactions.

TT 51.5   Thu 16:15   HSZ 103

Lattice instability in charge-frustrated CsW_2O_6 — •Pascal Reiss[1], Peter Wochner[1], Armin Schulz[1], Jürgen Nuss[1], Masahiko Isobe[1], and Hidenori Takagi[1,2,3] — [1]Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany — [2]Institute for Functional Matter and Quantum Technologies, University of Stuttgart, Germany — [3]Department of Physics, The University of Tokyo, Bunkyo, Tokyo, Japan

The transition metal compound CsW_2O_6 represents an intriguing example of a pyrochlore structure at quarter filling. Starting from a bad metal with a nominal $W^{5.5+}$ oxidation state, the system suffers a metal-to-insulator transition around $T_c \approx 215$ K. Here, a breathing distortion leads to the formation of regular molecular W_3 trimers with 2 localised electrons each, and a remaining W^{6+} site devoid

of $5d$ electrons [1]. However, the origin of the transition as well as the electronic nature of the low-temperature phase remain unclear [2].

To elucidate the origin of the 215 K transition, we will present our recent structural investigations and transport measurements on CsW_2O_6 conducted under high pressures, where we uncover another structural instability, distinct from the ambient pressure one.

TT 51.6   Thu 16:30   HSZ 103

Pressure-induced stabilization mechanism of molecular orbital crystals in $IrTe_2$ — •Tobias Ritschel[1], Quirin Stahl[1], Maximilian Kusch[1], Gaston Garbarino[2], Volodymyr Svitlyk[2], Mohamed Mezouar[2], Junjie Yang[3], Sang-Wook Cheong[4], and Jochen Geck[1] — [1]Institute of Solid State and Materials Physics, TU Dresden, 01069 Dresden, Germany — [2]ESRF, Grenoble, France — [3]New Jersey Institute of Technology, Newark, New Jersey 01702, USA — [4]Rutgers, New Jersey, USA

Doped $IrTe_2$ is considered a platform for topological superconductivity and therefore receives currently a lot of interest. In addition, the superconductivity in these materials exists in close vicinity to electronic order and the formation of molecular orbital crystals, which we explore here by means of high-pressure single crystal x-ray diffraction in combination with density functional theory. Our crystallographic refinements provide detailed information about the structural evolution as a function of applied pressure up to 42 GPa. Using this structural information for density functional theory calculations, we show that the local multicenter bonding in $IrTe_2$ is driven by changes in the Ir-Te-Ir bond angle. When the electronic order sets in, this bond angle decreases drastically, leading to a stabilization of a multicenter molecular orbital bond. This unusual local mechanism of bond formation in an itinerant material provides a natural explanation for the different electronic orders in $IrTe_2$. It further illustrates the strong coupling of the electrons with the lattice and is most likely relevant for the superconductivity in this material.

TT 51.7   Thu 16:45   HSZ 103

Lifshitz transition at the onset of superconductivity from mismatched nesting in $TiSe_2$ — •Roemer Hinlopen[1], Owen Moulding[1,2], Felix Flicker[3], Charles Sayers[4], Enrico Da Como[4], Jasper van Wezel[5], and Sven Friedemann[1] — [1]University of Bristol, UK — [2]Institut Néel, Grenoble, France — [3]Cardiff University, UK — [4]University of Bath, UK — [5]University of Amsterdam, The Netherlands

Fermi surface reconstructions and topological (Lifshitz) transitions can have a profound effect on the electronic ground state of a metal. For example, reentrant superconductivity (SC) in URhGe may be due to the appearance of a small pocket [1], whereas in Bechgaard salts [2] and doped $BaFe_2As_2$ [3] the appearance of large pockets from mismatched nesting may give rise to SC within the magnetic phase.

Here, we report quantum oscillation measurements and DFT calculations under pressure in the prototypical charge density wave (CDW) compound $TiSe_2$. We observe the emergence of new Fermi surface pockets at 2 GPa within the CDW arising as a result of mismatched nesting. This Lifshitz transition coincides with the emergence of superconductivity [4], suggesting an intimate link between SC and the presence of these Fermi pockets similar to $BaFe_2As_2$. This suggests that SC in $TiSe_2$ might be of extended $s^{\pm}$-wave character - the first such case in a CDW system.

TT 51.8   Thu 17:00   HSZ 103

Spin stripe fluctuations in antiferromagnetic $Pr_{2-x}Sr_xNiO_{4+\delta}$ — •Avishek Maity[1], Rajesh Dutta[2,3], and Werner Paulus[4] — [1]Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, 85747 Garching, Germany — [2]Institut für Kristallographie, RWTH Aachen Universität, 52066 Aachen, Germany — [3]Jülich Centre for Neutron Science (JCNS) at Heinz Maier-Leibnitz Zentrum (MLZ), 85747 Garching, Germany — [4]ICGM, Univ. Montpellier, CNRS, ENSCM, Montpellier, France

Spin and charge stripe correlations and their dynamics have been well explored in the ordered state of RE−based 214-nickelates for last 3 decades. In this regards, what remains less explored is the fluctuating state of the spin stripes from which the long-range spin stripes develop on cooling. In this talk, we present our recent inelastic neutron scattering study of the low energy spin stripe fluctuations in $Pr_{2-x}Sr_xNiO_{4+\delta}$ with magnetic incommensurability ϵ = 0.33 above the spin stripe ordering temperature T_{so} = 190 K [1]. The spin stripe fluctuations measured at the at the incommensurate wave vector show a non-

dispersive character with no detectable anisotropy persisting up to a maximum energy 10 meV, and strongly suppressed already below the charge stripe ordering temperature T_{co} = 255 K. Our results clearly indicate the presence of static charge stripe order is essential for the spin stripe fluctuations in 214-type nickealtes.

TT 51.9   Thu 17:15   HSZ 103

Glass-like transitions in the frustrated charge system θ-(BEDT-TTF)$_2 MM'$(SCN)$_4$ (MM' = CsZn, CsCo, and RbZn) revealed by thermal expansion measurements — •Yohei Saito[1], Tatjana Thomas[1], Yassine Agarmani[1], Tim Thyzel[1], Kenichiro Hashimoto[2], Takahiko Sasaki[2,3], Jens Müller[1], and Michael Lang[1] — [1]Goethe University Frankfurt, Frankfurt (M), Germany — [2]University of Tokyo, Chiba, Japan — [3]Tohoku University, Sendai, Japan

Geometrical frustration causes degenerate states and a frustrated charge system is proposed in organic conductors. It is expected that charge order (CO) is suppressed and is possibly replaced by a charge glass state. In organic condutors, the CO transition accompanies a structural transition. Therefore, investigating their elastic properties is of fundamental interest. We performed thermal expansion measurements on θ-(BEDT-TTF)$_2 MM'$(SCN)$_4$ (MM' = CsZn, CsCo, and RbZn) : whereas the CsZn and CsCo salts exhibit no CO transition, slowly-cooled RbZn salt shows the transition. The thermal expansion coefficient of no-CO salts exhibited a glassy transition at 90-100 K. This behavior is reminiscent of the freezing of the terminal ethylene end-groups on the BEDT-TTF molecules. For the RbZn salt we observe a CO transition at 210 K and also an ethylene-group related glass-like transition at 80-100 K. Therefore, the glass-like anomaly around 90 K appears as a common feature in θ-type salts regardless of whether long-range CO exists. These results point to the importance of the lattice degrees of freedom in the frustrated charge system.

TT 52: Frustrated Magnets: Strong Spin-Orbit Coupling

Time: Thursday 15:00–17:30   Location: HSZ 201

Finite temperature nonlinear optical response of the Kitaev magnet — •Wolfram Brenig[1] and Olesia Krupnitska[1,2] — [1]Institute for Theoretical Physics, Technical University Braunschweig, D-38106 Braunschweig, Germany — [2]Institute for Condensed Matter Physics, NASU, Svientsitskii Str. 1, 79011 Lviv, Ukraine

One of the key properties of a quantum spin liquid is fractionalization. In the spin liquid hosted by the Kitaev model, this occurs in terms of two types of quasiparticles, i.e., itinerant Majorana fermions and localized gapped Z_2 fluxes. A multitude of probes have been suggested to provide evidence for the response and spectral continua related to such fractionalization. Here we report results on the nonlinear optical response of a Kitaev magnet at finite temperature. Our analysis is based on complementary calculations in the low-temperature homogeneous gauge and a mean-field treatment of thermal gauge fluctuations, valid at intermediate and high temperatures.

TT 52.2   Thu 15:15   HSZ 201

Thermal decomposition of the Kitaev material α-RuCl$_3$ and its influence on the low-temperature properties — •Franziska Breitner[1], Anton Jesche[1], Vladimir Tsurkan[2], and Philipp Gegenwart[1] — [1]Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg, 86159 Augsburg, Germany — [2]Experimental Physics V, Center for Electronic Correlations and Magnetism, University of Augsburg, 86159 Augsburg, Germany

Thermally driven decomposition and reduction of honeycomb ruthenium-trichloride has been known long before the material attracted considerable interest as a Kitaev system [1,2]. We systematically explore the effect of heat treatment in argon atmosphere under various temperatures up to 500˚C on single crystals by study of the mass loss, microprobe energy dispersive x-ray spectroscopy, powder x-ray diffraction, as well as low-temperature magnetic susceptibility and specific heat experiments. For annealing temperatures beyond 300˚C we detect clear signatures of dechlorination and oxidation of Ru. The specific heat is consistently described by the sum of a major α-RuCl$_3$ and minor RuO$_2$ volume fraction, whose latter C~T contribution dominates the total specific heat below 1 K. Comparison with measurements on unannealed crystals suggests that even therein a tiny RuO$_2$ metal fraction cannot be excluded, which could be relevant also for other physical properties.

TT 52.3   Thu 15:30   HSZ 201

Spin-phonon dynamics in α-RuCl$_3$ probed by ultrasound — •Andreas Hauspurg[1,2], S. Zherlitsyn[1], T. Helm[1], V. Tsurkan[3], K. Y. Choi[4], S. H. Do[5], W. Brenig[6], N. Perkins[7], and J. Wosnitza[1,2] — [1]Hochfeld-Magnetlabor Dresden, HZDR, Germany — [2]Institut für Festkörper- und Materialphysik, TU Dresden, Germany — [3]Institute of Physics, University of Augsburg, Germany — [4]Department of Physics, Sungkyunkwan University, Republic of Korea — [5]Oak Ridge National Lab, USA — [6]Institute for Theoretical Physics, TU Braunschweig, Germany — [7]School of Physics and Astronomy, University of Minnesota, USA

Among the most studied honeycomb-lattice materials predicted to host Kitaev interactions is the spin-orbit-coupled Mott insulator α-RuCl$_3$. Despite antiferromagnetic ordering at 7 K, α-RuCl$_3$ is considered proximate to the Kitaev quantum spin liquid (QSL) state, which features fractionalized quasiparticle excitations. A promising approach to study such excitations is to investigate the spin-phonon interaction in this material. Our studies of the elastic properties of α-RuCl$_3$ by means of ultrasound pulse-echo technique indicate unconventional physics of the debated QSL phase. Here, we present low-temperature results of the sound velocity and attenuation in external magnetic fields and discuss their behavior with respect to the quasiparticle excitations in α-RuCl$_3$. In our studies we observed a linear temperature dependence of the attenuation beyond the ordered state at 8 T that follows a characteristic C_6 symmetry. Anomalies in the acoustic properties shed new light on the H-T phase diagram.

TT 52.4   Thu 15:45   HSZ 201

Rethinking α-RuCl$_3$ again — •Marius Möller[1], Roser Valentí[1], and Alexander L. Chernyshev[2] — [1]Institute for Theoretical Physics, Goethe University Frankfurt, Max-von-Laue-Strasse 1, 60438 Frankfurt am Main, Germany — [2]Department of Physics and Astronomy, University of California, Irvine, California 92697, USA

The honeycomb Kitaev material α-RuCl$_3$ is widely investigated due to its originally suspected proximity to a spin liquid state suggested by unusual neutron scattering results. The magnetic Hamiltonian was initially formulated as a generalized Kitaev model K_1-J_1-Γ_1-Γ_1'-J_3 in a cubic spin reference orientated along the Ru-Cl bonds. Recent studies, however, suggest that a crystallographic parametrization of the Hamiltonian in a spin-ice-like language $J(XY)$-Δ-$J_{\pm\pm}$-$J_{z\pm}$-J_3 could lead to significant reduction of the parameter space, hinting towards a potential minimal model of α-RuCl$_3$. We present the classical and quantum phase diagram of this $J(XY)$-$J_{z\pm}$-J_3 minimal model candidate obtained by Luttinger-Tisza method (LT), Exact Diagonalization (ED) and Density Matrix Renormalization Group (DMRG). Further, we present the phase diagrams of three interesting parameter regions with constrained anisotropic exchanges K_1, Γ_1, Γ_1' leading to effective J_1-J_3 models which possibly capture the relevant region to describe the essential physics of α-RuCl$_3$.

TT 52.5   Thu 16:00   HSZ 201

Evolution of electronic and magnetic properties of the Kitaev-type compound Ru(Br$_{1-x}$I$_x$)$_3$ — •Jihuan Gu[1], Tomohiro Takayama[1,2], Alexander Yaresko[1], and Hidenori Takagi[1,2] — [1]Max-Planck Institute for Solid State Research, 70569 Stuttgart, Germany — [2]Institut für Funktionelle Materie und Quantentechnologien, University of Stuttgart, 70550 Stuttgart, Germany

Kitaev magnets like α-RuCl$_3$ have attracted great attention in the field of solid-state physics as a potential realization of exotic quantum spin-liquid state. If such Kitaev materials are turned into a metallic state, exotic electronic properties may be realized near the critical phase boundary, such as unconventional superconductivity. So far, carrier doping via intercalation or application of pressure has been attempted to induce a metal-insulator transition (MIT), but no metallic state has been obtained. Recently, the two honeycomb compounds RuBr$_3$ and RuI$_3$, which are isostructural to α-RuCl$_3$, have been reported. While RuBr$_3$ is a Mott insulator with a zigzag magnetic order, RuI$_3$ was reported to be a correlated semimetal, likely induced by the enhanced d-p hybridization. Hence, the MIT phase boundary should be expected between RuBr$_3$ and RuI$_3$. We thus synthesized Ru(Br$_{1-x}$I$_x$)$_3$ with various doping levels x. The successful substitution of Br with I was confirmed by the systematic change of lattice parameters. The MIT phase boundary seems to be at x around 0.7. We will discuss the evolution of electronic and magnetic properties in the series of Ru(Br$_{1-x}$I$_x$)$_3$ and a marginal metallic state near MIT.

TT 52.6   Thu 16:30   HSZ 201

Milli-Kelvin thermal conductivity of YbAlO₃, a quasi-one-dimensional quantum magnet — •Parisa Mokhtari[1,2,3], Ulrike Stockert[1], Stanislav Nikitin[4], Leonid Vasylechko[5], Manuel Brando[2], and Elena Hassinger[1] — [1]Institute of Solid State and Materials, Dresden, Germany — [2]Max-Planck-Institute for Chemical Physics of Solids, Dresden, Germany — [3]Physics Department, Technical University of Munich, Garching, Germany — [4]Paul Scherrer Institute, Villigen, Switzerland — [5]Lviv Polytechnic National University, Lviv, Ukraine

In 2019, Wu *et al.* found the typical excitation spectrum of the fractionalised magnetic excitations, so-called spinons, in the Q-1D material $YbAlO_3$ via neutron scattering at 1 K. $YbAlO_3$ exhibits AFM (J_c=2.3 K) and FM (J_{ab}=0.8 K) exchange interaction along and perpendicular to the chain direction, respectively [1, 2]. In zero field (B), a 3D AFM order is established at 0.88 K. For $B \parallel a$, this order is suppressed and replaced by an incommensurate-AFM state, until the field-polarised state occurs for $B >$1.5 T.

In this work, we investigate the thermal conductivity (κ) of $YbAlO_3$ down to 30 mK in B up to 4 T, with a focus on the magnetic excitations' contribution in thermal transport within different phases and their interactions with lattice vibrations. Notably, our results are in agreement with the previous reports, as well as providing new anomalies compared to thermodynamics' probes and theoretical predictions.

TT 52.7   Thu 16:45   HSZ 201

Thermal expansion and magnetostriction as the probe of exotic magnetism in honeycomb BaCo₂(AsO₄)₂ — •Prashanta K. Mukharjee[1], Bin Shen[1], Anton Jesche[1], Julian Kaiser[1], Philipp Gegenwart[1], and Alexander Tsirlin[2] — [1]Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg, 86159 Augsburg, Germany — [2]Felix Bloch Institute for Solid-State Physics, University of Leipzig, 04103 Leipzig, Germany

The $3d^7$ Co-based honeycomb materials have received wide attention as a possible platform for the experimental realization of the celebrated Kitaev model. Here, we elucidate the thermodynamic properties of the candidate material $BaCo_2(AsO_4)_2$ using high-resolution thermal expansion and magnetostriction measurements. At 2 K, with an increase in field, the linear magnetostriction coefficient shows two well-separated anomalies around critical field $H_{c1} \sim$ 0.2 T and $H_{c2} \sim$ 0.5 T transition around H_{c1} is hysteretic, pointing towards a first-order type transition, whereas the transition at H_{c2} lacks hysteresis, reflecting the second-order nature. The linear thermal expansion coefficient shows a sharp positive peak in 0 T, which decreases, then changes its sign with the rise in the field and smears out entirely above H_{c2}. Below T_N, for $H_{c1} \ll H \ll H_{c2}$, our angle-dependent magnetization shows an apparent six-fold symmetry, whereas significant deviations have been observed below Hc1 and above H_{c2}. We draw the in-plane phase diagram from the above experiments and other complementary techniques and discuss the interplay of first and second-order transitions in this material.

TT 52.8   Thu 17:00   HSZ 201

Phononic-magnetic dichotomy of the thermal Hall effect in the Kitaev-Heisenberg candidate material Na₂Co₂TeO₆ — Matthias Gillig[1], Xiaochen Hong[2,1], Christoph Wellm[1], Vladislav Kataev[1], Weiliang Yao[3], Yuan Li[3], Bernd Büchner[1], and •Christian Hess[2,1] — [1]Leibniz Institute for Solid State and Materials Research, 01069 Dresden, Germany — [2]Fakultät für Mathematik und Naturwissenschaften, Bergische Universität Wuppertal, 42097 Wuppertal, Germany — [3]International Center for Quantum Materials, School of Physics, Peking University, 100871 Beijing, China

We investigate the thermal Hall effect of the Kitaev quantum spin liquid candidate material $Na_2Co_2TeO_6$ in both the magnetically ordered and the paramagnetic phase, with a magnetic field perpendicular to the honeycomb layers of this material. The transversal heat conductivity κ_{xy} is sizeable, but remains at all temperatures investigated significantly smaller than one half of the thermal conductance quantum which has been predicted as fingerprint of topologically protected Majorana edge modes in a Kitaev quantum spin liquid. κ_{xy} is negative in the paramagnetic phase but becomes positive deep in the antiferromagnetically ordered phase suggesting a non-phononic origin. However, distinct similarities are present in κ_{xy} and the longitudinal thermal conductivity κ_{xx} concerning both their temperature and field dependences. Thus our findings imply an at least two-component, i.e. magnetic and phononic origin of the thermal Hall effect in $Na_2Co_2TeO_6$.

TT 52.9   Thu 17:15   HSZ 201

Triple-Q order in Na₂Co₂TeO₆ from proximity to hidden-SU(2)-symmetric point — •Wilhelm Krüger[1], Wenjie Chen[2], Xianghong Jin[2], Yuan Li[2,3], and Lukas Janssen[1] — [1]Institut für Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, 01062 Dresden, Germany — [2]International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China — [3]Collaborative Innovation Center of Quantum Matter, Beijing 100871, China

In extended Heisenberg-Kitaev-Gamma-type spin models, hidden-SU(2)-symmetric points are isolated points in parameter space that can be mapped to pure Heisenberg models via nontrivial duality transformations. Such points generically feature quantum degeneracy between conventional single-Q and exotic multi-Q states. We argue that recent single-crystal inelastic neutron scattering data place the honeycomb magnet $Na_2Co_2TeO_6$ in proximity to such a hidden-SU(2)-symmetric point. The low-temperature order is identified as a triple-Q state arising from the Néel antiferromagnet with staggered magnetization in the out-of-plane direction via a 4-sublattice duality transformation. This state naturally explains various distinctive features of the magnetic excitation spectrum, including its surprisingly high symmetry and the dispersive low-energy and flat high-energy bands. Our result demonstrates the importance of bond-dependent exchange interactions in cobaltates, and illustrates the intriguing magnetic behavior resulting from them.

Andreev and normal reflections processes in gated bilayer graphene — •Panch Ram[1], Detlef Beckmann[2], Romain Danneau[2], and Wolfgang Belzig[1] — [1]Fachbereich Physik, Universität Konstanz, D-78457 Konstanz, Germany — [2]Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, D-76021 Karlsruhe, Germany

We present our theoretical study of the Andreev and normal reflections processes in a bilayer graphene normal-superconductor junction where gate fields are applied (equal and opposite). Gating can induce a gap in the dispersion of the graphene layer. We employ the Dirac-Bogoliubov-de Gennes equation for the low-energy gated bilayer graphene Hamiltonian and calculate the Andreev and normal reflections probabilities using the scattering theory, and also obtain the differential conductance within the Blonder-Tinkham-Klapwijk formalism [1, 2]. We observe the Andreev retro-reflection (specular-reflection) below (above) the Fermi energy when the bias voltage is within the superconducting gap [3]. Interestingly, both retro-reflection as well as specular reflection are strongly modified in the presence of the gate field. For small gate field, they can be tuned to either specular or retro Andreev reflection by changing the Fermi energy. Moreover, we find double Andreev reflections and double normal reflections (specular and retro) when the gate field becomes comparable to the interlayer coupling strength.

Graphene superlattice due to twisted hexagonal boron nitride monolayers — •Ming-Hao Liu — Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan

Stacking of two-dimensional (2D) materials of similar lattice structures on top of each other with a small twist angle leads to the so-called Moiré pattern due to the large-scale lattice inteference. When one of them is a conducting material such as graphene, the Moiré pattern serves as a large-scale periodic potential, turning the host conducting lattice into a superlattice, whose modified electronic properties can be seen in transport experiments and simulations. Graphene placed on a hexagonal boron nitride (hBN) layer is one of the best known graphene superlattices, while twisted bilayer graphene made of two monolayers of graphene is another example under intensive investigations during the past years. Twisted monolayers of hBN also form the Moiré pattern, yet its effect on transport properties of neighboring graphene is less known. Here, we consider graphene put on monolayers of twisted hBN (thBN), and perform quantum transport simulations considering the effect of the charge-polarized superlattice potential [1]. Due to the exceptionally long Moiré wavelength of the twisted hBN, multiple satellite Dirac points emerge in the transmission spectrum within the experimentally accessible range of the carrier density. Possible experiments confirming the model of graphene on thBN as well as further exploring novel transport behaviors due to the thBN will be discussed.

TT 53.3   Thu 15:30   HSZ 204

Transport signatures of Van Hove singularities in mesoscopic twisted bilayer graphene — •Aleksander Sanjuan Ciepielewski[1], Jakub Tworzydło[2], Timo Hyart[1,3], and Alexander Lau[1] — [1]MagTop, IF PAN, Warsaw, Poland — [2]University of Warsaw, Poland — [3]Aalto University, Finland

Magic-angle twisted bilayer graphene (TBG) exhibits quasiflat low-energy bands with Van Hove singularities (VHS) close to the Fermi level. These singularities play an important role in the exotic phenomena observed in this material, such as superconductivity and magnetism, by amplifying electronic correlation effects. In this work [1], we study the correspondence of four-terminal conductance and the Fermi surface topology as a function of the twist angle, pressure, and energy in mesoscopic, ballistic samples of small-angle TBG. We establish a correspondence between features in the wide-junction conductance and the presence of VHS in the density of states. Moreover, we identify additional transport features, such as a large, pressure-tunable minimal conductance, conductance peaks coinciding with nonsingular band crossings, and unusually large conductance oscillations as a function of the system size. Our results suggest that TBG close the magic angle is a unique system featuring simultaneously large conductance due to the quasiflat bands, strong quantum nonlinearity due to the VHS, and high sensitivity to external parameters, which could be utilized in high-frequency device applications and sensitive detectors.

TT 53.4   Thu 15:45   HSZ 204

Coulomb blockade effects in minimally twisted bilayer graphene — •Patrik Wittig[1], Fernando Dominguez[1], Christophe De Beule[2,3], and Patrik Recher[1,4] — [1]Institute for Mathematical Physics, TU Braunschweig, 38106 Braunschweig, Germany — [2]Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg — [3]Department of Physics and Astronomy, University of Pennsylvania, Philadelphia PA19104 — [4]Laboratory of Emerging Nanometrology, 38106 Braunschweig, Germany

In the presence of a finite interlayer electric field, minimally twisted bilayer graphene displays a triangular network of chiral valley Hall states that propagate along the AB/BA interfaces and scatter at the metallic AA regions. Previous studies model the chiral network using a phenomenological scattering matrix approach based entirely on the symmetries of the system [1,3]. So far, the physics of the metallic AA scattering regions has been disregarded, although in the chiral network regime are also flat bands corresponding to a finite density of states in the AA region [2]. Therefore, we include in the phenomenological scattering matrix the AA regions in form of quantum dots: A set of discrete energy levels with Coulomb interaction, which we treat in mean field theory. We study the resulting network through the energy spectrum and magneto-conductance calculations.

Twisted bilayer graphene at charge neutrality: Spontaneous symmetry breaking of SU(4) Dirac electrons — •Nikolaos Parthenios and Laura Classen — Max-Planck Institute for Solid State Research, Stuttgart, Germany

We study possible patterns for spontaneous symmetry breaking in twisted bilayer graphene at charge neutrality. Starting from an effective Dirac Hamiltonian, we show how an SU(4) symmetry emerges that is composed of combined spin, valley and sublattice transformations. We construct the corresponding low-energy model that includes all symmetry-allowed four-fermion interactions and employ a renormalization group treatment to identify the critical points that describe transitions into the different ordered phases. The resulting phase diagram depends on the number of fermion flavours and we argue that for twisted bilayer graphene it is governed by a quantum Hall state or SU(4) manifolds of spin-valley orders with emergent Lorentz symmetry. Due to the large symmetry, small perturbations will determine the final symmetry breaking mechanism.

TT 53.6   Thu 16:15   HSZ 204

Analog gravity in twisted bilayer graphene — •Mireia Tolosa-Simeón[1], Stefan Floerchinger[2], and Michael Scherer[1] — [1]Institut für Theoretische Physik III, Ruhr-Universität Bochum — [2]Theoretisch-Physikalisches Institut, Friedrich-Schiller-Universität Jena

Condensed-matter systems can sometimes be used to emulate and study phenomena from a completely different field of physics, for example, from elementary particle physics or gravity. Such analog condensed-matter models may provide a novel perspective to approach difficult problems in the original systems, and can potentially be realized experimentally in a well-controlled environment.

In this contribution, we will address the problem of cosmological fermion production in expanding universes using twisted bilayer graphene as an analog model. In particular, we study twisted bilayer graphene's Dirac electrons near charge neutrality, which acquire a mass gap through a symmetry-breaking phase transition. Introducing a time-dependent Fermi velocity, we show the emergence

of an analog of cosmological pair production. Our scenario could be scrutinized experimentally in the future.

Quantum transport simulation for graphene on transition-metal dichalcogenides — •Wun-Hao Kang and Ming-Hao Liu — Department of Physics, National Cheng Kung University, Tainan, Taiwan

The strength of spin-orbit coupling (SOC) in pristine graphene was found from first-principles calculations to be in the order of μeV [1], which gives nearly no effects in transport experiments. Subsequent studies showed that the SOC can be significantly enhanced to the order of meV by putting graphene on transition-metal dichalcogenides (TMDC) [2]. Very recently, Tiwari P. et al. reported that the enhanced SOC can be experimentally observed in graphene/WSe2 systems [3]. Here we perform quantum transport simulations for graphene on TMDCs based on real-space tight-binding models [4], considering the Fabry-Pérot interferometer by using a gate-induced potential barrier as the cavity.

TT 53.8   Thu 17:00   HSZ 204

Theory of broken symmetry quantum Hall states in the $N = 1$ Landau level of Graphene — •Nikolaos Stefanidis[1] and Inti Sodemann[2,1] — [1]Max-Planck-Institut für Physik komplexer Systeme, Dresden 01187, Germany — [2]Institut für Theoretische Physik, Universität Leipzig, D-04103, Leipzig, Germany

We study many-body ground states for the partial integer fillings of the $N = 1$ Landau level in graphene, by constructing a model that accounts for the lattice scale corrections to the Coulomb interactions. Interestingly, in contrast to the $N = 0$ Landau level, this model contains not only pure delta function interactions but also some of its derivatives. Due to this we find several important differences with respect to the $N = 0$ Landau level. For example at quarter filling when only a single component is filled, there is a degeneracy lifting of the quantum hall ferromagnets and ground states with entangled spin and valley degrees of freedom can become favourable. Moreover at half-filling of the $N = 1$ Landau level, we have found a new phase that is absent in the $N = 0$ Landau level, that combines characteristics of the Kekulé state and an antiferromagnet. We also find that according to the parameters extracted in a recent experiment, at half-filling of the $N = 1$ Landau level graphene is expected to be in a delicate competition between an AF and a CDW state, but we also discuss why the models for these recent experiments might be missing some important terms.

TT 53.9   Thu 17:15   HSZ 204

Multi-layered atomic relaxation in van der Waals heterostructures — Dorri Halbertal[1], •Lennart Klebl[2], Valerie Hsieh[1], Jacob Cook[3], Stephen Carr[4], Guang Bian[3], Cory Dean[1], Dante M. Kennes[5,6], and Dmitri N. Basov[1] — [1]Department of Physics, Columbia University, United States — [2]1st Institute of Theoretical Physics, University of Hamburg, Germany — [3]Department of Physics and Astronomy, University of Missouri, United States — [4]Physics Department, Brown University, United States — [5]Institut für Theorie der Statistischen Physik, RWTH Aachen University, Germany — [6]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany

When two-dimensional van der Waals materials are stacked to build heterostructures, Moiré patterns emerge from twisted interfaces or from mismatch in lattice constant of individual layers. Relaxation of the atomic positions is a direct, generic consequence of the Moiré pattern, with many implications for the physical properties. Motivated by experimental findings in multi-layered van der Waals heterostructures, we develop a generic continuum approach to model (multi-layered) relaxation processes based on the generalized stacking fault energy functional. The continuum property of the approach enables us to access large scale regimes and achieve agreement with experimental findings. Furthermore, we study the impact of multi-layered relaxation on the local density of states of a twisted graphitic system. We identify measurable implications for the system, experimentally accessible by scanning tunneling microscopy.

TT 53.10   Thu 17:30   HSZ 204

Non-destructive low-temperature contacts to MoS$_2$ nanoribbon and nanotube quantum dots — •Robin T. K. Schock[1], Jonathan Neuwald[1], Konstantin D. Schneider[1], Matthias Kronseder[1], Luka Pirker[2], Maja Remškar[2], and Andreas K. Hüttel[1] — [1]Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Solid State Physics Department, Institute Jožef Stefan, 1000 Ljubljana, Slovenia

Planar TMDCs are at the center of manifold research efforts due to their intrinsic two dimensional nature. Despite detailed studies of their optical parameters, worldwide efforts to reach single level transport in lithographically designed quantum dots at low temperatures have so far been largely unsuccessful. This is due to the requirement for very small confinement potentials as well as disorder

from dangling bonds at the edges of nanoflakes. Both issues can be circumvented by using as-grown MoS_2 nanotubes and nanoribbons. First Coulomb blockade measurements were recently performed on a MoS_2 nanotube[1], so far limited by disorder below the metallic scandium contacts.

Here, we present low temperature measurements on MoS_2 nanotubes and nanoribbons contacted with bismuth[2]. Our data clearly shows the non-

destructive and transparent nature of these contacts to our quantum dots and indicates quantum confinement[3].

Dominant materials losses in superconducting circuits based on tantalum thin films — •Ritika Dhundhwal[1], Haoran Duan[2], Dirk Fuchs[1], Alexander Welle[3], Mahya Khorramshahi, Jasmin Aghassi-Hagmann[2], Ioan M. Pop[1], and Thomas Reisinger[1] — [1]Institut für Quantenmaterialien und technologien — [2]Institut für Nanotechnologie — [3]Institut für Funktionelle Grenzflächen, Karlsruher Institut für Technologie

Superconducting quantum circuits are a promising hardware platform in the fields of quantum computing and detection. To improve their performance, exploring new materials is highly relevant. One promising candidate material is tantalum (Ta), which was recently shown to improve transmon qubit lifetimes[1]. However, the understanding of the dominant loss mechanisms related to Ta is limited. Here, we present a study of losses in epitaxial Ta films deposited using magnetron sputtering, with the aim of relating basic material properties to loss mechanisms. A variation in the deposition parameters (mainly substrate temperature) leads to structurally different films. We characterized these using high-resolution X-ray diffraction, Time-of-Flight secondary-ion mass spectrometry, scanning electron microscopy and superconducting transition temperature measurements. We fabricated lumped element resonators from the films and measured their quality factors as a function of photon number and temperature. In addition, we vary the energy participation ratio of Ta metal-substrate interface to find the dominant loss mechanism.

Many body localization of 2D transmon arrays with a quasi-periodic potential and perturbative Walsh-Hadamard coefficients — •Evangelos Varvelis and David DiVincenzo — JARA, Aachen, Germany

Recently it has been shown that transmon qubit architectures experience a phase transition between many body localized and quantum chaotic. It is crucial for quantum computation that the system remains in the localized regime, yet the most common way to achieve this relies on random disorder. Here we propose a quasi-periodic potential as a substitute for random disorder, with the purpose of localizing a 2D transmon array. We demonstrate, using the Walsh-Hadamard diagnostic, that the quasiperiodic potential is more effective at achieving localization. In order to study the localizing properties of our new potential for experimentally relevant system sizes, we develop a many-body perturbation theory whose computational cost scales only with the non-interacting system dimensions.

Linear response for pseudo-Hermitian Hamiltonian systems: Application to *PT*-symmetric qubits — •Mikhail V. Fistul, Leander Tetling, and Ilya M. Eremin — Ruhr-Universität Bochum, Bochum Germany

We develop the linear response theory formulation suitable for application to various *pseudo-Hermitian Hamiltonian* systems. The analytical expressions for the generalized temporal quantum-mechanical correlation function and the time-dependent dynamic susceptibility, $\chi(t)$, are derived [1].

We apply our results to two *PT*-symmetric non-Hermitian quantum systems: a single qubit and two unbiased/biased qubits coupled by the exchange interaction. For both systems we identify *PT*-symmetry unbroken and broken quantum phases and quantum phase transitions between them. The temporal oscillations of the dynamic susceptibility of the qubits polarization, $\chi(t)$, relate to *ac* induced transitions between different eigenstates, and we analyze the dependencies of the oscillations frequency and the amplitude on the gain/loss parameter γ and the interaction strength g.

Studying the time dependence of $\chi(t)$ we observe different types of oscillations, i.e., undamped, heavily damped and amplified ones, related to the transitions between eigenstates with broken (unbroken) *PT*-symmetry. These predictions can be verified in the microwave transmission experiments.

TT 54.4　Thu 15:45　HSZ 304
High kinetic inductance microstrip networks for integrated quantum information devices — •Niklas Gaiser[1], Ciprian Padurariu[1], Björn Kubala[1,2], Nadav Katz[3], and Joachim Ankerhold[1] — [1]ICQ and IQST, University of Ulm, Ulm, Germany — [2]Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany — [3]The Racah Institute of Physics, The Hebrew University of Jerusalem, Israel

Modern superconducting quantum information devices integrate qubits and readout resonators into complex microwave circuits. Efficient qubit operation and fast readout require relatively strong coupling. This, however, can compromise the qubit lifetime due to spontaneous emission through the resonator. An elegant solution is provided by a Purcell filter, an added circuit element that suppresses transmission at the qubit frequency.

Here, we present a theoretical proposal for circuit architectures that realize qubit readout with Purcell filters, utilizing the highly versatile platform of high-kinetic inductance microstrip networks experimentally realized in [1]. The strongly reduced phase velocities in such materials allow compact filter designs that can be integrated on-chip. We describe band-structure design techniques to build an efficient Purcell filter and provide quantitative estimations for the suppression of unwanted relaxation channels.

Microwave radiation emitted by a phase qubit — •Surangana Sengupta[1], Ciprian Padurariu[1], Bjoern Kubala[1,2], and Joachim Ankerhold[1] — [1]ICQ and IQST, Ulm University, Germany — [2]German Aerospace Center (DLR), Ulm, Germany

Josephson photonics devices consist of a DC-biased Josephson junction in series with a superconducting microwave cavity and are promising sources of bright quantum states of microwave radiation. Such devices realize the regime of strong-coupling circuit quantum electrodynamics, when the effective fine structure constant of the circuit approaches unity. In this case, multi-photon down-conversion processes, where one tunnelling Cooper pair emits k photons in the cavity ($k \leq 6$), have been observed [1].

Here, we propose a new regime for Josephson photonics devices, where both the inductive as well as the capacitive behavior of the Josephson junction is taken into account [2]. Thereby, the Josephson phase is treated as an electronic degree of freedom, characterized by the plasma frequency of the junction, that is independent of the photonic degree of freedom, described by the phase of the cavity. We present a preliminary study of the coupled photonic and electronic dynamics, discuss the nature of the coupling and present a detailed comparison to conventional Josephson photonics dynamics. As an example, we focus on the case when the Josephson junction is operated as a phase qubit and study the resulting statistics of radiation emitted in the cavity.

Heat transport and rectification in an ultrastrongly-coupled qubit-resonator system — •Luca Magazzu[1], Milena Grifoni[1], and Elisabetta Paladino[2] — [1]Regensburg University — [2]University of Catania

Inspired by the recent experimental developments in the field of heat transport in the quantum regime, we consider a flux qubit coupled to a superconducting resonator as a composite open quantum system.

The two elements of this open quantum Rabi system interact with two heat baths held at different temperatures. At the steady state, a heat current is established which is the result of photon exchanges between the system and the baths. Due to the geometry of the setup, the coupling to the heat baths is asymmetric. In turn this entails the presence of a preferred direction for the heat current, to a degree quantified by the heat rectification.

We calculate the heat current and rectification in different coupling regimes and considering a periodic driving applied to the qubit. The rectification displays

the signatures of multi-photon processes that occur when the qubit-resonator coupling enters the nonperturbative regime.

Qubit reset using frequency modulation by AC Stark effect — •Jami Rönkkö, Vasilii Sevriuk, Antti Vepsäläinen, and Fabian Marxer — IQM Quantum Computers, Espoo, Finland

We present a theory for an unconditional reset scheme utilizing qubit's frequency modulation by AC Stark effect and a coupled lossy resonator. In AC Stark effect, off-resonant microwave drive shifts the frequency of a qubit without causing strong Rabi oscillations. Modulating the frequency of this drive creates sidebands around the qubit frequency. By setting the modulation frequency equal to the difference between the qubit and resonator frequencies, one of the sidebands becomes resonant with the resonator frequency. This leads to the transfer of the qubit excitation to the lossy resonator, resulting in a qubit reset. With typical parameters, the reset is achieved in only tens of nanoseconds

TT 54.8　Thu 17:00　HSZ 304

Fabrication of a superconducting transmission line in a planar design on a spin-doped crystalline membrane — •Georg Mair[1,2], Ana Strinic[1,2,3], Niklas Bruckmoser[1,2], Michael Stanger[1], Andreas Erb[1,2], Rudolf Gross[1,2,3], and Nadezhda Kukharchyk[1,2,3] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85747 Garching, Germany — [2]Walther-Meissner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology, 80799 Munich, Germany

Scaling up the density of superconducting qubits on a chip is reaching its limits, and a supplementing microwave quantum memory is a promising way to enhance the computing power [1]. Rare-earth doped crystals are potential candidates to realize such microwave quantum memories, due to the long coherence times of their spin states [2]. For efficient operation, one needs to have precise control over the distribution of strength and orientation of the oscillating magnetic field inside the sample. Here, we introduce a novel, planar superconducting transmission line design based on a thin crystalline $CaWO_4$ membrane. The transmission line is designed to exhibit high transmission in the range of $1 - 8$ GHz, i.e. the frequency range of the hyperfine transitions of the rare-earth ions in near-zero external magnetic field. Fabrication techniques are explained and transmission spectra recorded at cryogenic temperatures are discussed.

TT 54.10　Thu 17:30　HSZ 304

Broadband electron spin resonance spectroscopy of rare earth spin ensembles at mK temperatures — •Ana Strinic[1,2,3], Hans Huebl[1,2,3], Rudolf Gross[1,2,3], and Nadezhda Kukharchyk[2,1,3] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, Garching, Germany — [2]Walther-Meißner-Institut, Bavarian Academy of Sciences, Garching, Germany — [3]Munich Center for Quantum Science and Technologies, Munich, Germany

Rare earth spin ensembles exhibit spin coherence times in the millisecond range and possess transitions at microwave frequencies [1,2]. These properties make them attractive candidates for realizing microwave quantum memories, which can be directly interfaced with superconducting quantum processors. In principle, there are two options for the implementation of spin-based quantum memories: (i) coupling them to resonators, or (ii) interfacing them with an open transmission line. In particular, the latter is considered for multi-modal concepts or the storage of information based on atomic frequency comb protocols. In this work we characterize the electron spin resonance Hamiltonian of an ^{167}Er spin ensemble in a $^7LiYF_4$ host crystal at mK temperatures using a broadband microwave spectroscopy approach. We find good agreement with published g and hyperfine tensors, which is key for the implementation of microwave quantum memory schemes at low magnetic fields.

Imperfect Many-Body Localization in Exchange-Disordered Isotropic Spin Chains — •Julian Siegl and John Schliemann — University of Regensburg

We study many-body localization in isotropic Heisenberg spin chains with the local exchange parameters being subject to quenched disorder. The Hamiltonian is invariant under global SU(2)- rotations and incorporates therefore a non-abelian symmetry. Systems of common spin length 1/2 and 1 are studied numerically using random matrix techniques. In both cases we find a transition from an ergodic phase at small disorder strength to an incompletely localized phase at stronger disorder. The transition is signaled by a maximum of the sample-to-sample variance of the averaged consecutive-gap ratio. The incompletely localized phase found here is distinguished from a fully localized system by the scaling behavior of the sample-to-sample variance.

TT 55.2　Thu 15:15　MOL 213

Magnetic Dipole Clusters - Resurrection of Catastrophe Machines — •Ingo Rehberg and Simeon Völkel — Experimental Physics, University of Bayreuth

Hysteretic transitions between stable configurations of a hexagonal magnetic dipole cluster [1] are set in a broader context by revealing the nature of the corresponding instabilities [2]. Following the animation of this bifurcation scenario [3], we present an experimental setup where the height of the centre dipole serves as the bifurcation parameter. This catastrophe machine demonstrates the two instabilities forming the hysteresis loop, and it might provide a hint to the unresolved puzzle of the slowing down of one of the eigenmodes [4].

Signatures of the interplay between chaos and local criticality on the dynamics of scrambling in many-body systems — Felix Meier[1], •Mathias Steinhuber[2], Juan Diego Urbina[2], Daniel Waltner[1], and Thomas Guhr[1] — [1]University of Duisburg-Essen, Lotharstr. 1, 47048 Duisburg, Germany — [2]University of Regensburg, Universitätsstr. 31, 93040 Regensburg, Germany

Fast scrambling, quantified by the exponential initial growth of Out-of-Time-Ordered-Correlators (OTOCs), is the ability to efficiently spread quantum correlations among the degrees of freedom of interacting systems, and constitutes a characteristic signature of local unstable dynamics. As such, it may equally manifest both in systems displaying chaos or even in integrable systems around criticality. We discuss the results from our recent publication [1], where we go beyond these two well-studied regimes with an exhaustive study of the interplay between local criticality and chaos. We address many-body systems with a well-defined classical (mean-field) limit, as coupled large spins and Bose-Hubbard chains, thus allowing for semiclassical analysis. Our aim is to investigate the dependence of the exponential growth of the OTOCs, defining the quantum Lyapunov exponent λ_q on quantities derived from the classical system with mixed

phase space, specifically the local stability exponent of a fixed point λ_{loc} as well as the maximal Lyapunov exponent λ_L of the chaotic region around it.

Characterizing quantum chaoticity of kicked spin chains — •Tabea Herrmann, Maximilian F. I. Kieler, and Arnd Bäcker — TU Dresden, Institut für Theoretische Physik, Dresden, Germany

Quantum many body systems are commonly considered as quantum chaotic if their spectral statistics, such as the level spacing distribution, agree with those of random matrix theory. Using the example of the kicked Ising chain we demonstrate that even if both level spacing distribution and eigenvector statistics agree well with random matrix predictions, the entanglement entropy deviates from the expected Page curve. We propose a new measure of the effective spin interactions and obtain the corresponding random matrix result. By this the deviations of the entanglement entropy can be understood.

TT 55.5   Thu 16:00   MOL 213

Entanglement Characterization of Measurement-Induced Phase Transition in Fermionic Chains — •Jiangtian Yao[1,2], Sebastian Diehl[1], and Michael Buchhold[1] — [1]Institute for Theoretical Physics, University of Cologne, D-50937 Cologne, Germany — [2]Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany

We report characterization of measurement-induced phase transition in Gaussian fermionic chains. We use various entanglement measures to characterize the two phases as well as the nature of the transition. Through a numerical study on the entanglement spectra, we observe closure of the entanglement gap in the critical phase and relate the scaling of the closure to the effective central charge of the system. In addition, we numerically extract the effective Luttinger liquid parameter of the system and use it to characterize the critical phase. Lastly, we use the scaling behavior of the effective Luttinger liquid parameter as well as the Schmidt gap to estimate the critical point for the phase transition.

Dynamical characterization of the chaotic phase in the Bose-Hubbard model — David Peña Murillo and •Alberto Rodríguez — Departamento de Física Fundamental, Universidad de Salamanca, E-37008 Salamanca, Spain

We study the dynamical manifestation of the Bose-Hubbard model's chaotic phase [1] by analysing the temporal behaviour of connected two-point density correlations on experimentally accessible time scales up to a few hundred tunneling times. The time evolution of initial Mott states with unit density in systems including up to 17 bosons (Hilbert space dimension $\approx 10^9$) reveals that the chaotic phase can be unambiguously identified from the early time fluctuations of the considered observable around its equilibrium value [2]. The emergence of the chaotic phase is also seen to leave an imprint in the initial growth of the time signals. The possibility to discern specific features of this many-body chaotic phase, on top of the universal prediction of random-matrix theory, from these experimentally accessible measures is explored.

Universal Eigenvalue Distribution for Locally Interacting Quantum Systems — •Tobias Helbig, Tobias Hofmann, Ronny Thomale, and Martin Greiter — Institut für Theoretische Physik und Astrophysik, Universität Würzburg, D-97074 Würzburg, Germany

Wigner has shown [1] that the eigenvalue distribution of a Gaussian orthogonal or unitary ensemble of random matrices approaches a semicircle in the thermodynamic limit. Here, we show that the joint eigenvalue distribution of locally interacting quantum systems, that is, ensembles of finite dimensional subsystems with local interactions between them, approaches a Gaussian distribution as the number of subsystems is taken to infinity [2]. In the talk, we present our analytical results supported by numerical data and discuss possible implications of a Gaussian density of states for physical problems.

[1] E. P. Wigner. On the statistical distribution of the widths and spacings of nuclear resonance levels. Mathematical Proceedings of the Cambridge Philosophical Society, 47(4): 790-798 (1951).

[2] T. Hofmann, T. Helbig, R. Thomale, and M. Greiter. In preparation.

TT 55.8   Thu 17:00   MOL 213

Power-law decay of correlations after a global quench in the massive XXZ chain — •Flávia Braga Ramos[1], Andrew Urichuk[2,3], Imke Schneider[1], and Jesko Sirker[3] — [1]Fachbereich Physik und Research Center OPTIMAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany — [2]University of Manitoba, Winnipeg, Canada — [3]Bergische Universität Wuppertal, Wuppertal, Germany

While there have been great advances in understanding the final equilibration of integrable systems after a quantum quench, relatively little is known about their precise relaxation towards the steady state. In this context, the XXZ chain provides a playground for the investigation of interaction effects in out-of-equilibrium properties of quantum many-body systems. We investigate the relaxation dynamics of equal-time correlations in the antiferromagnetic phase of the XXZ spin-1/2 chain following a global quantum quench of the anisotropy parameter. In particular, we focus on the relaxation dynamics starting from an initial Néel state. Using the exact solution of an effective free-fermion model, state-of-art density matrix renormalization group simulations, and the quench-action approach, we show that the late-time relaxation is characterized by a power-law decay $\sim t^{-3/2}$ independent of anisotropy. Overall, we find remarkable agreement in the results obtained from the distinct approaches.

TT 55.9   Thu 17:15   MOL 213

Universal correlations in chaotic many-body quantum states: lifting Berry's Random Wave Model into Fock space — Rémy Dubertrand[1], Juan-Diego Urbina[2], Klaus Richter[2], and •Florian Schöppl[2] — [1]Department of Mathematics, Physics and Electrical Engineering, Northumbria University, NE1 8ST Newcastle upon Tyne, United Kingdom — [2]Institut für Theoretische Physik, Universität Regensburg, 93040 Regensburg, Germany

Using a semiclassical analysis based on Berry's ansatz [1] we investigate the universal statistical features of eigenstate correlations in chaotic mesoscopic many-body quantum systems, focusing on Bose-Hubbard lattices, where the existence of a classical (mean-field) limit allows for the use of many-body semiclassical methods [2]

For this, we first have to lift Berry's ansatz into the many-body space by expanding the microscopic correlations and the conjectured multivariant Gaussian distribution of expansion coefficients into the Fock space of quantum fields. Together with numerical evidence, which supports the extension to multi-point correlations of the known Gaussian distribution for a single expansion coefficient, the universality of eigenstate correlations can be extended well beyond random matrix theory, where these correlations are absent. Our results bring the correlation backbone of eigenfunctions into a precise signature of quantum chaos in many-body mesoscopic systems.

TT 56: Focus Session: Making Experimental Data F.A.I.R. – New Concepts for Research Data Management I (joint session O/TT)

Data have been identified as major resource of the 21st century, unlocking great potential if refined and processed in the right way. In scientific research, particularly modern data science concepts like machine learning or neural networks enable novel types of data analysis with often strong predictive power. This Focus Session aims at providing a framwork for presenting and discussing novel concepts, tools and platforms for managing experimental research data related to surface science and solid-state physics. In particular, in light of the German NFDI initiative, where several consortia are actively working on tackling the imminent challenges of research data management in experimental solid-state physics, this Focus Session will offer an ideal environment for exchange among researchers, and bringing these novel developments into the labs. The intended topics include the description of experimental data and meta data generation workflows, meta data schemas and file formats, electronic lab notebooks, novel tools for handling and analyzing scientific research data, as well as sharing and searching platforms according to F.A.I.R. principles.

Organizers: Martin Aeschlimann (TU Kaiserslautern), Laurenz Rettig (FHI Berlin) and Heiko Weber (U Erlangen)

Time: Thursday 15:00–18:30   Location: WIL A317

Topical Talk   TT 56.1   Thu 15:00   WIL A317

Introducing a FAIR research data management infrastructure for experimental condensed matter physics data — •Christoph Koch — Humboldt-Universität zu Berlin, Department of Physics & IRIS Adlershof, Berlin, Germany

Digitization and an increase in complexity and price of experimental materials characterization techniques, an increase in accuracy and system size of computational solid state physics (or computational materials science), and the maturation of machine learning tools to extract patterns from large amounts of very diverse (annotated) data promise an acceleration of materials development by synergistically combining research data from many sources. While some labs start to upload their (raw) research data to data repositories, this is only a first but not sufficient step in leveraging the above-mentioned potential, since such repositories are typically either specific to a very particular technique or agnostic to the content of the data being uploaded. In both cases the research data cannot easily, and definitely not without significant human effort, be compared to and integrated with experimental data from other sources, or numerical predictions. In this talk I will report on recent progress of the FAIRmat NFDI consortium in extending the novel materials discovery laboratory (NOMAD), the world's largest data base for ab-initio computational materials data, to ingest experimental research data on the synthesis and characterization of materials in a machine-accessible manner, i.e. annotated with well-defined and interoperable metadata, achieved by establishing links between related (experimental and computational) quantities.

TT 56.2   Thu 15:30   WIL A317

Introducing an electronic laboratory notebook in a collaborative research center — •Sebastian T. Weber[1], Aneta Daxinger[1], Philipp Pirro[1], Marek Smaga[1], Christiane Ziegler[1], Mathias Kläui[2], Georg von Freymann[1], Baerbel Rethfeld[1], and Martin Aeschlimann[1] — [1]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau — [2]Institute of Physics, Johannes Gutenberg University Mainz

The basis of a FAIR data management is a well-described and detailed documentation of every single step of the experiment and data analysis. In recent decades, however, the focus has shifted from analog measuring instruments and analytical calculations to computer-based experiments and simulations. This has lead to a large increase in the numbers of measurements and observed quantities and therefore in the amount of data generated. Consequently, traditional paper lab notebooks have reached their limits. Electronic lab notebooks (ELNs) are better suited for storing, indexing, searching and retrieving a large amount of entries. In particular, the automated filling-in of meta data can lead to a reduction in the workload of the scientists in the long term.

We present the lessons learned on challenges and advantages with the introduction of a joint electronic lab notebook within our collaborative research center CRC/TRR173 *Spin+X*. We report on our experiences in the daily work of the scientists and in education in student labs.

TT 56.3   Thu 15:45   WIL A317

An efficient workflow for processing single event dataframes. — •Steinn Ýmir Ágústsson[1], M. Zain Sohail[2,3], David Doblas Jiménez[4], Dmytro Kutnyakhov[3], and Laurenz Rettig[5] — [1]Aarhus University, DK — [2]RWTH, Aachen — [3]DESY, Hamburg — [4]Eu-XFEL, Schenefeld — [5]FHI, Berlin

Single event resolved data streams measured by delay-line-detectors allow to correlate each measured photoelectron with the state of the experimental apparatus. This allows corrections and calibrations to be applied on a shot-to-shot basis and a flexible investigation of correlations between various measurement parameters.

We are developing an open-source python package[1], where highly optimized dataframe management and binning methods enable leveraging the full potential of event-resolved data structures. The flexible design of the pipeline allows processing any event-resolved data stream.

With momentum microscopy as the primary target application, we developed axis calibration and artifact correction methods designed to be agnostic to the experimental apparatus. These methods are tested on data generated by microscopes at FELs (HEXTOF@FLASH) as well as at HHG sources (FHI), but are easily exended to other end-stations using similar detection techniques.

Our aim is to provide tools for the community which will reduce the development time for each end station, as well as an open and accessible data processing pipeline, built around the FAIR data principles.

TT 56.4   Thu 16:00   WIL A317

FAIR Data Infrastructure for Computation: Advanced many-body methods. — •José M. Pizarro[1], Nathan Daelman[1], Joseph F. Rudzinski[1,2], Luca M. Ghiringhelli[1], Roser Valentí[3], Silvana Botti[4], and Claudia Draxl[1] — [1]Institut für Physik und IRIS-Adlershof, Humboldt-Universität zu Berlin — [2]Max-Planck-Institut für Polymer Forschung, Mainz — [3]Institut für Theoretische Physik, Goethe University Frankfurt am Main — [4]Institut für Festkörpertheorie und Optik, Friedrich-Schiller-Universität Jena

Big-data analyses and machine-learning approaches have recently emerged as a new paradigm to study and predict properties of materials. In order to perform these analyses, materials data have to be structured in a FAIR (findable, accessible, interoperable, and reusable) format [1]. While most of the current databases deal with density-functional-theory (DFT) calculations, there is a clear need for developing FAIR-data schema for methodologies going beyond DFT. Methods such as the *GW* approximation, dynamical mean-field theory, and time-dependent DFT allow to calculate excited- and many-body-states properties beyond DFT, thus having a direct quantitative comparison with experiments. In this talk, we will introduce the achievements and challenges undertaken within the FAIRmat consortium towards fully structuring the (meta)data of all these techniques. We demonstrate how users can analyze the data and compare with angle-resolved photoemission spectroscopy.

[1] M. Scheffler et al., Nature **604**, 635 (2022).

TT 56.5   Thu 16:15   WIL A317

Electronic Laboratory Notebooks for FAIR Data Management; Evaluation and Recommendations for Solutions at Research Infrastructures — •Philipp Jordt[1], Wiebke Lohstroh[2], and Bridget Murphy[1] — [1]IEAP, Kiel University, Germany — [2]MLZ, Technische Universität München, Germany

Electronic Laboratory Notebooks (ELN) are the digital counterpart to the classical handwritten paper notebook and play a vital role in the implementation of FAIR data standards. Modern ELN solutions range from simple note taking applications to integrated tools, combining documentation, inventory management, progress tracking and more. Nowadays, ELNs are becoming more prominent in research laboratories around the world, replacing paper notebooks. This evaluation of basic needs was carried out in the context of the DAPHNE4NFDI consortia. Of special interest is the view on ELNs for combined use at large scale facilities and in the home laboratory. Thus, the requirements regarding implementation, deployment, authentication, etc., may differ from those for single or laboratory use at universities. An overview of different concepts and existing solutions is given. Multiple ELNs have been evaluated during test runs at large scale facilities and a survey on existing solutions was held. From these results, a list of ELN specifications is presented, ranging from useful to necessary. These insights may serve as a guideline for evaluating or implementing ELNs in the future.

TT 56.6 Thu 16:30 WIL A317

Ontology for Experimental Data — •Sandor Brockhauser — Center for Materials Science Data, Humboldt-Universität zu Berlin, Germany

Ontology is the scientific field of formal knowledge representation. This field contributes to Data Science and helps Experimentalist to properly annotate their data and metadata on a FAIR way. During the last decades several different ways have been developed in the field of Ontology for describing knowledge as a set of information and their relationships. These include Information mapping, Concept maps, Topic maps, Mind maps, Knowledge graphs, BORO (Business Objects Reference Ontology), RDF (Resource Description Framework), OWL (Web Ontology Language), ORO (Object-Role Modeling), UML (Unified Modeling Language), ISO 15926 (standard for data sharing), OLOG (mathematical framework for knowledge representation), GELLISH (ontology language for data storage and communication), etc. For describing experimental facts, we suggest using an ontology in OWL which is derived from the NeXus community standard. It represents all the concepts developed for explaining experiments and experimental data, just like the relationships between them. Such representation allows connecting the concepts defined in NeXus also to other ontologies. Additionally, any data management systems, like NOMAD which accepts experiment data provided in the NeXus standard, can immediately link the data and metadata to the ontology and make them interoperable.

15 min. break

Topical Talk   TT 56.7 Thu 17:00 WIL A317

Open Research Data for Photons and Neutrons: Applications in surface scattering and machine learning — •Linus Pithan — Universität Tübingen, Institut für Angewandte Physik - DAPHNE4NFDI

Open (F.A.I.R.) research data is becoming a key ingredient for data driven machine learning (ML) applications that requires access to existing data of preceding experiments - which goes well beyond data collected in the context of one's own experiments which one might keep in a secret drawer. We will discuss current possibilities as well as future opportunities and challenges with special emphasis on surface scattering. Embedded in the DAPHNE4NFDI (DAta from PHoton and Neutron Experiments) consortium we present efforts on how data catalogs may serve as backbone for F.A.I.R. datasets provided by synchrotron and neutron sources or through community efforts. Besides suitable metadata collection also the harmonization of data- and metadata formats are issues still to be tackled especially for systematic access to fully analyzed, experimental datasets (e.g. by adopting NeXus community conventions). After a broader overview and shining light on the SciCat meta-data catalog system,[1] we discuss as application examples efforts in the field of reflectometry (XRR, NR) [2,3] and X-Ray scattering and diffraction (WAXS, GIWAXS and XPCS).[1,4]

TT 56.8 Thu 17:30 WIL A317

NOMAD OASIS as a Tool for Electron and Atom Probe Microscopists — •Markus Kühbach — Department of Physics, Humboldt-Universität zu Berlin, Germany

Embracing the FAIR principles for sharing data and knowing how to work with different tools in research data management systems is becoming an invaluable skill in a scientist's daily life. Embracing such systems of tools, one of which is offered with NOMAD OASIS, allows you to start organizing your research data locally. Learning such tools will train you to understand what schemes and electronic lab notebooks are and how the data and metadata are processed by these tools. Example implementations of specific workflows can give you ideas where to start from and how to customize these tools for the needs of your own research and colleagues. Thereby, you can provide feedback which supports the evolution and improvement of the research data management system.

NOMAD OASIS offers you many examples which show now also how data and metadata of specific experiments can be parsed into a standardized representation. These examples teach users through detailing how data can be entered, viewed, and organized with customizable schemes in NOMAD. Furthermore,

the examples suggest strategies for how the information in NOMAD can be accessed for generic or domain-specific data analytics tools.

In my talk, I will go through one or two of these examples specific to electron microscopy (orientation imaging microscopy or spectroscopy).

TT 56.9 Thu 17:45 WIL A317

FAIR Data Infrastructure for Computation: Introducing the parsers for Quantum Monte Carlo and ALF — •Jonas Schwab[1], José M. Pizarro[2], Jefferson Stafusa E. Portela[1], Luca M. Ghiringhelli[2], and Fakher F. Assaad[1] — [1]Institut für Theoretische Physik und Astrophysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany — [2]Institut für Physik und IRIS-Adlershof, Humboldt-Universität zu Berlin

DFT calculations lead to low-energy effective models. A modern example would be Kitaev types spin Hamiltonains for $RuCl_3$. Once the model is specified, many different many-body calculations can be carried out. Here, we will concentrate on the ALF [1] implementation of the auxiliary field quantum Monte Carlo algorithm that can deal with general models that includes the ones produced by DFT calculations. Being a Monte Carlo method, the ALF library produces stochastic time series. We will discuss how to implement this workflow in the NOMAD Repository & Archive (https://nomad-lab.eu) and concentrate on a FAIR metadata scheme. The first challenges are to define the models in a searchable way as well as standards for the Monte Carlo time series. In this talk we will discuss the present state of this project for the special case of the ALF-library and how users can exploit the benefits of the NOMAD repository to find, compare and reuse our QMC data.

TT 56.10 Thu 18:00 WIL A317

CAMELS - A Configurable Instrument Control Software for FAIR Data — •Alexander Fuchs[1,3], Johannes Lehmeyer[1,3], Michael Krieger[1,3], Heiko B. Weber[1,3], Patrick Oppermann[2,3], and Heinz Junkes[2,3] — [1]Lehrstuhl für Angewandte Physik, Friedrich-Alexander-Universität Erlangen-Nürnberg, — [2]Fritz-Haber-Institut der Max-Planck-Gesellschaft (FHI), Berlin — [3]FAIRmat, Humboldt-Universität zu Berlin, Berlin, Germany

We are developing a configurable measurement software (CAMELS), targeted towards the requirements of experimental solid-state physics. Here many experiments utilize a multitude of measurement devices used in dynamically changing setups. CAMELS [1] will allow to define instrument control and measurement protocols using a graphical user interface (GUI). This provides a low entry threshold enabling the creation of new measurement protocols without programming knowledge or a deeper understanding of device communication. The GUI generates python code that interfaces with instruments and allows users to modify the code for specific applications and implementations of arbitrary devices if necessary. Even large-scale, distributed systems can be implemented. CAMELS is well suited to generate FAIR-compliant output data. Nexus standards, immediate NOMAD integration and hence a FAIRmat compliant data pipeline can be readily implemented. [1] https://github.com/FAU-LAP/CAMELS

TT 56.11 Thu 18:15 WIL A317

OpenSemanticLab: Usecase Device Repository — •Matthias A. Popp and Simon Stier — Fraunhofer ISC, Neunerplatz 2, 97082 Würzburg, Germany

Fully automated experiments provide benefits regarding precision, repeatability, as well as data quality and therefore gain more and more popularity. However, setting them up can be time consuming, especially when computer interface information has to be manually transferred from device manuals to software.

In order to implement FAIR principles precise descriptions of measurement setups and instrumentation are necessary. Currently, this results in extra workload for experimental scientists.

With our framework OpenSemanticLab, we address this shortcoming by providing a central metadata repository for scientific instruments. The ontology-based repository meets both human (GUI) and machine requirements (APIs). A device ontology helps finding and classifying devices. In an associated Python package, abstract device drivers and concrete device metadata can be combined into executable workflows. Overall, this approach not only strengthens the transparency of research according to FAIR principles, but also significantly reduces the implementation effort for complex setups.

TT 57: Poster: Superconductivity I

Time: Thursday 15:00–18:00   Location: P2/OG2

TT 57.1   Thu 15:00   P2/OG2

Influence of reduced dimensionality on the superconducting properties of ultrathin aluminum films — Werner M.J. van Weerdenburg[1], •Anand Kamlapure[1], Eirik Holm Fyhn[2], Xiaochun Huang[1], Niels P.E. van Mullekom[1], Manuel Steinbrecher[1], Peter Krogstrup[3], Jacob Linder[2], and Alexander A. Khajetoorians[1] — [1]Institute for Molecules and Materials, Radboud University, 6525 AJ Nijmegen, the Netherlands — [2]Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, NO-7491 Trondheim, Norway — [3]NNF Quantum Computing Programme, Niels Bohr Institute, University of Copenhagen, 2100 Copenhagen, Denmark

Study of superconductivity (SC) in lower dimensional systems is vital to devices involving multilayers and heterostructures for future quantum information applications. In this work, using scanning tunneling microscopy/spectroscopy, we study SC in ultrathin epitaxial Al films on Si(111) as we approach the 2D limit. With reducing thickness, we observe enhancement of SC where critical temperature and gap size shows threefold enhancement. In addition, we characterize the vortex structure in presence of strong Zeeman fields and find evidence for extended vortices showing paramagnetic Meissner effect originating from triplet pairing contributions. These results illustrate two striking influences of reduced dimensionality and present a new platform to study SC in presence of large magnetic fields. Reference: arXiv:2210.10645(2022).

TT 57.2   Thu 15:00   P2/OG2

Demonstration of 300 mm CMOS-compatible superconducting HfN and ZrN thin films — •Roman Potjan[1,3], Raik Hoffmann[1], Marcus Wislicenus[1], Benjamin Lilienthal-Uhlig[1], and J. Wosnitza[2,3] — [1]Fraunhofer Institute for Photonic Microsystems (IPMS), Center Nanoelectronic Technologies (CNT), Dresden, Germany — [2]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — [3]Institut für Festkörper- und Materialphysik, TU Dresden, Germany

The increasing interest in quantum computing is pushing the development of new superconducting materials for semiconductor fab process technology. However, these are often facing CMOS process incompatibility. In contrast to common CMOS materials such as TiN and TaN, reports on the superconductivity of other suitable transition-metal nitrides are scarce, despite potential superiority. Hence, we demonstrate fully CMOS-compatible fabrication of HfN and ZrN thin films on state-of-the-art 300 mm semiconductor process technology, employing reactive DC magnetron sputtering on silicon wafers. Mechanical stress, thickness, and roughness measurements of the thin films imply process compatibility. Material phase and stoichiometry in bulk and interfaces are investigated by structural analysis. HfN and ZrN exhibit transitions into the superconducting state with critical temperature up to 5.1 and 6.1 K, respectively. A decrease in critical temperature with decreasing film thickness indicates geometric limitations and proximity effects of the interfaces. The results prepare a scalable application of HfN and ZrN in quantum computing and related applications.

TT 57.3   Thu 15:00   P2/OG2

Unraveling Charge Transfer to Understand Superconductivity in MgB$_2$ — •Simon Marotzke[1,2], Jan Oliver Schunck[1,3], Amina Alic[4], Octave Duros[4], Moritz Hoesch[1], Alessandro Nicolaou[5], Gheorghe Sorin Chiuzbaian[4], and Martin Beye[1] — [1]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]Christian-Albrechts-Universität zu Kiel, Kiel, Germany — [3]Universität Hamburg, Hamburg, Germany — [4]Sorbonne Université, Paris, France — [5]Synchrotron SOLEIL, Saint-Aubin, France

Magnesium diboride (MgB$_2$) holds the world-record for the highest transition temperature (T_C = 39 K) in a conventional Bardeen-Cooper-Schrieffer (BCS)-type, i.e., phonon-mediated, superconductor. The undoped electron configuration of MgB$_2$ is still disputed as contradicting results on the appearance of charge transfer upon crossing T_C have been reported. To settle this question, we conducted high-resolution resonant X-ray emission spectroscopy (XES) as well as X-ray absorption spectroscopy (XAS) measurements around the boron K-edge at the SEXTANTS beamline at the synchrotron SOLEIL. In order to investigate the charge transfer between in-plane and out-of-plane states, we varied the polarization of the incoming photons as well as the incidence and emission angle. We report on differences in the spectral intensity for both the absorption and emission spectra upon crossing T_C to be first indications of changes in the density of the boron 2p states. Complementary density of states calculations showing good agreement with the experimental data were performed.

TT 57.4   Thu 15:00   P2/OG2

Strain device for *in-situ* uniaxial strain measurements of strongly correlated electron materials in scanning tunneling microscopy — •Carolina A. Marques[1], Danyang Liu[1], Alexander Steppke[1,2], and Fabian D. Natterer[1] — [1]University of Zurich, Winterthurerstrasse 190, CH-8057 Zurich,

Switzerland — [2]Paul Scherrer Institut Forschungsstrasse 111 5232 Villigen PSI Switzerland

Uniaxial strain is an effective way to tune the properties of strongly correlated electron systems without introducing disorder. One seminal example is the doubling of the critical temperature of Sr$_2$RuO$_4$.

Strain devices for the *in-situ* application of strain have been used in several different measurement techniques: transport, specific heat, angle-resolved photoemission spectroscopy, muon spin relaxation, and neutron scattering measurements. Here, we describe the design and construction of a strain device compatible with a scanning tunneling microscope. Our piezo-element based strain-cell is temperature compensated and enables the continuous tuning of strain, allowing to monitor local strain response. It opens up the possibility to locally track changes to the low-energy electronic states as a function of strain, giving insight into the underlying physical mechanisms.

TT 57.5   Thu 15:00   P2/OG2

Magnon dispersion of SrRuO$_3$ studied by inelastic neutron scattering experiments — Kevin Jenni[1], •Akshay Tewari[1], Stefan Kunkemöller[1], Agustinus Agung Nugroho[2], Russell Ewings[3], Yvan Sidis[4], Astrid Schneidewind[5], Paul Steffens[6], and Markus Braden[1] — [1]II. Phys. Institut, Universität zu Köln — [2]Institut Teknologi Bandung, Bandung 40132, Indonesia — [3]ISIS Pulsed Neutron and Muon Source, United Kingdom — [4]Laboratoire Léon Brillouin, Gif-sur-Yvette CEDEX, France — [5]Jülich Centre for Neutron Science (JCNS), Garching, Germany — [6]Institut Laue Langevin, Grenoble, France

Weyl points in the ferromagnetic state in SrRuO$_3$ not only determine anomalous magnetotransport properties but also modify the spin dynamics leading to a peculiar temperature dependence of both the spin gap and of the stiffness in the ferromagnetic state [1]. In contrast the magnon chirality in SrRuO$_3$ remains normal, i.e. right handed [2]. To extend the analysis of the magnon dispersion we performed inelastic neutron scattering experiments with the time-of-flight technique as well as with polarization analysis. The magnon dispersion can be followed to about 30 meV and there is no indication for a crossover into a Stoner continuum. There is evidence for additional coupling beyond just the nearest neighbors. In addition magnon excitations exhibit pronounced broadening that further increases upon heating possibly related to the strong coupling between ferromagnetism and conductivity in SrRuO$_3$.

[1] K. Jenni et al. Phys. Rev. Lett. **123**, 17202 (2019). [2] K. Jenni et al. Phys. Rev. B. **105**, L180408 (2022).

TT 57.6   Thu 15:00   P2/OG2

Screening in a two-band model for infinite-layer nickelate — •Tharathep Plienbumrung[1,2], Maria Daghofer[1,2], Michael Schmid[3], and Andrzej M. Oles[4,5] — [1]Institute for Functional Matter and Quantum Technologies, University of Stuttgart, Stuttgart, Germany — [2]Center for Integrated Quantum Science and Technology, University of Stuttgart, Stuttgart, Germany — [3]Waseda Research Institute for Science and Engineering, Waseda University, Tokyo, Japan — [4]Max Planck Institute for Solid State Research, Stuttgart, Germany — [5]Institute of Theoretical Physics, Jagiellonian University, Kraków, Poland

Considering two-band model for infinite-layered nickelates, containing d- and s-like orbitals, on two-dimensional lattice. The extended nature of the s-like orbital leads to less electronic correlation. We thus parameterize the electronic correlations of the s-like orbital by introducing *screening parameter*. With exact diagonalization, we calculate the pairing symmetries and other electronic properties of the two-band model on two-dimensional lattice. We find that the screening strength of the s-like band plays an important role in the electronic properties of the two-band model. Interestingly, depending on the screening strength of s-like band, we find both d- and s-wave pairing symmetries within the two-band model. In strong screening, the d-wave pairing is found while the s-wave pairing is formed in the weak screening regime. The phase diagram of the two-band model for different ratio of J/U is also presented.

TT 57.7   Thu 15:00   P2/OG2

Magnetic and thermoelectric properties of Bi-substituted La$_{0.95-x}$Bi$_x$Sr$_{0.05}$CoO$_3$ — •Divya Prakash Dubey and Ratnamala Chatterjee — IIT Delhi Hauz Khas New Delhi 110016 India

We present the results of a comprehensive investigation of electric and thermal transport properties of polycrystalline Bi substituted La$_{0.95-x}$Bi$_x$Sr$_{0.05}$CoO$_3$ for x=0,0.1 and 0.2 (LBSCO-0, 1 & 2). The electrical resistivity reflects the semiconducting nature with interesting n-type to p-type transition 52K for LBSCO-1 and LBSCO-2 samples. The substitution of higher atomic weight elements Bi at La site drastically affects overall thermal conductivity by reducing the lattice contribution (κ 0.12W/m-K at T= 50K) and also enhance the Seebeck coefficient (S 354 μV/K). The increase in the resistivity and Seebeck coefficient for Bi-substituted system is related to the decrease in the available charge carrier concentration (5.12 10^{20} cm^3). The phonon mediated charge transport via phonon

drag effect below 50K and a large increment in ZT 0.17 at RT for LBSCO-2 composition has been observed that is 1-order larger to pristine undoped LBSCO-0 and even higher to the other existing cobaltite*s-based thermoelectric choice.

TT 57.8　Thu 15:00　P2/OG2

High pressure T-P phase diagram of $2H$-$TaSe_2$ — •Yuliia Tymoshenko[1], Xingchen Shen[1], Amir-Abbas Haghighirad[1], Tom Lacmann[1], Gaston Garbarino[2], and Frank Weber[1] — [1]Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76021 Karlsruhe, Germany — [2]European Synchrotron Radiation Facility, 71 avenue des Martyrs, CS 40220, Grenoble 38043, France

Many layered materials featuring charge-density waves (CDW), a modulation of the electronic density of states, acquire a superconducting ground state often associated with a quantum critical point (QCP) of the CDW order. Although $2H$ polymorph of tantalum diselenide ($2H$-$TaSe_2$) with a layered hexagonal crystal structure is one of the most studied CDW systems, to the best of our knowlege, previous studies of the phase diagram have not been carried out at pressures sufficient to suppress the CDW order at low temperatures. We investigated the CDW phase diagram in its most crucial but still unexplored area and determined the CDW quantum critical point in $2H$-$TaSe_2$ under pressure via high-resolution synchrotron x-ray diffraction (XRD). Its position together with previously published resistivity measurements and our recent ambient-pressure study of the soft phonon mode at the CDW transition enable us to argue that this compound likely has a CDW quantum critical point closely connected to the emergent superconducting phase. This can serve as a textbook example where both phases are mediated by the same mechanism, electron-phonon coupling of the CDW soft phonon mode.

TT 57.9　Thu 15:00　P2/OG2

Clarifying the origin of CDW and finding the routes to superconductivity in 1T-$TiSe_2$ — •Andrii Kuibarov[1], Alexander Fedorov[1,2], Rui Lou[1,2], Yuliia Shemerliuk[1], Oleksandr Suvorov[1], Saicharan Aswartham[1], Bastian Rubrecht[1], Dmitry Efremov[1], Helmuth Berger[3], Bernd Büchner[1], and Sergey Borisenko[1] — [1]Leibniz-Institut für Festkörper- und Werkstoffforschung Dresden — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, BESSY II — [3]Institute of Condensed Matter Physics, Ecole Polytechnique Fédérale de Lausanne

The relationship between charge density waves (CDW) and superconductivity was always one of the important questions of solid-state physics. Even though they are often observed on the phase diagram next to each other, it is still unknown whether CDW competes or cooperates with superconductivity. Utilizing the photon energy-dependent ARPES we investigate the 3D electronic structure of well-known CDW-bearing material $TiSe_2$, superconductor Cu_xTiSe_2, and TiSeS. Our results suggest that neither Mott nor the excitonic insulator model is applicable to the electronic structure of $TiSe_2$. In contrast to the generally accepted model, we find a crucial agreement with the conventional band structure calculations, which predict the absence of the energy gap in this material.

Additionally, we perform temperature-dependent ARPES studies and show that the CDW phase remains in doped superconducting samples Cu_xTiSe_2. On the basis of the obtained results, we propose a mechanism for both CDW and superconductivity $TiSe_2$ family.

TT 57.10　Thu 15:00　P2/OG2

Nematic susceptibility in heavily hole-doped iron based superconductors — •Franz Eckelt[1], Xiaochen Hong[1], Vilmos Kocsis[2], Vadim Grinenko[2], Chul-Ho Lee[3], Bernd Büchner[2], and Christian Hess[1] — [1]Bergische Universität Wuppertal, 42097 Wuppertal, Germany — [2]Leibniz-Institute for Solide State and Materials Research (IFW-Dresden), 01069 Dresden, Germany — [3]National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Ibaraki 305-8568, Japan

We investigate the elastoresistivity of the heavily hole doped iron-based superconductor $Ba_{1-x}K_xFe_2As_2$ in the range x= 0.68 - 0.98 using a piezoelectric measurement technique. We observe a divergent increase in elastoresistance along the [100] direction during cooling for all samples studied so far. We discuss our findings in terms of nematic fluctuations and Fermi surface effects in the vicinity of a Lifshitz transition.

TT 57.11　Thu 15:00　P2/OG2

Towards topological superconductivity on the surface of LiFeAs — •Luise Merkwitz[1], Andrii Kuibarov[1], Rui Lou[1], Alexander Fedorov[1,2], Sabine Wurmehl[1], Saicharan Aswartham[1], Igor Morozov[1], Bernd Büchner[1], and Sergey Borisenko[1] — [1]Leibniz-Institute for Solid State Research, IFW-Dresden, D-01171 Dresden, Germany — [2]Helmholtz-Zentrum Berlin, BESSY, D-12489 Berlin, Germany

Realisation of topological superconductivity is theoretically possible in iron-based superconductors, where the s-wave pairing in the bulk can induce superconductivity of the topological surface states. The detection of the latter by angle-resolved photoemission spectroscopy (ARPES) in LiFeAs and FeSeTe systems is questionable since the bulk-originated dispersions can mimic the Dirac crossing and inverted gap is expected to be very small (of the order of 5 meV). The only

feasible possibility to detect topological surface states in such a small gap is to bring it to the Fermi level where the scattering is minimal. We have synthesized differently doped $LiFe_{1-x}Y_xAs$ (Y=Co, V) crystals and performed synchrotron-based ARPES studies to map k_z-dispersion in detail. Our results demonstrate the principal possibility of tuning the binding energy of the inverted gap in these systems and point to the optimal composition where this binding energy is close to zero. In addition, our results reveal considerable renormalization anisotropy of the Fe d-states never detected earlier.

The superconducting symmetries of $CeRh_2As_2$ — •Fabian Jakubczyk[1,2], Julia M. Link[1,2], and Carsten Timm[1,2] — [1]Institute of Theoretical Physics, Technische Universität Dresden, 01062 Dresden, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01062 Dresden, Germany

Multiphase unconventional superconductivity is a rare phenomenon, which has recently been discovered in the tetragonal but locally noncentrosymmetric heavy-fermion compound $CeRh_2As_2$. Here, the transition between two distinct superconducting phases occurs as a function of magnetic field applied along the c axis and the formation of superconductivity takes place around $T_{SCI} = 0.26$ K. At $\mu_0H^* \approx 4$ T the superconductor changes from a low-field to a high-field state with a large critical field of $\mu_0H_{c2} = 14$ T. However, for in-plane fields only the low-field phase appears, with $\mu_0H_{c2} = 2$ T. Recent As-NQR experiments further increased the variety of intriguing phenomena in this material, for they detected the onset of antiferromagnetism within the superconducting low-field phase, i.e. at $T_N < T_{SCI}$. In order to study the coexistence and interplay of the potential superconducting and magnetic phases, as well as the effect of an external magnetic field, we conduct a symmetry analysis followed by the construction of a Landau-type energy functional. Thereby we can give a statement about the probable symmetries of the superconducting states.

TT 57.13　Thu 15:00　P2/OG2

Flat bands of surface states in chiral symmetric superconductors — •Clara Johanna Lapp[1,2], Julia M. Link[1,2], and Carsten Timm[1,2] — [1]Institute of Theoretical Physics, Technische Universität Dresden, 01069 Dresden, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01062 Dresden, Germany

Nodal noncentrosymmetric superconductors can support flat bands of zero-energy surface states in part of their surface Brillouin zone if they obey time-reversal symmetry. These bands are protected by a winding number that relies on chiral symmetry, which in these systems is realized as the product of time-reversal and particle-hole symmetry. We examine which symmetry conditions a model must obey such that a winding number is well defined and can be nonzero. In particular, time-reversal symmetric Bogoliubov-de Gennes Hamiltonians which conserve one spin component can be interpreted as chiral symmetric in each of the spin-blocks and exhibit a nonzero winding number that protects zero energy surface modes. Moreover, we classify which types of sublattice symmetry lead to nonzero winding numbers.

Eliashberg theory calculations for magnetically mediated superconductivity — •Ran Tao and Malte Grosche — Department of Physics, Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, United Kingdom

Computational modelling for realistic material parameters can speed up the search for new unconventional superconductors.

We have implemented calculations of the superconducting transition temperature in Eliashberg theory for spin fluctuation mediated superconductivity and validated them by reproducing previously published results in simple systems (e.g. [1]). Next, our code has been extended to a minimal model for iron-based superconductors, namely a 2D compensated metal with varying Fermi surface volume and interaction strength. Developing this approach further in the spirit of the UppSC code (e.g. [2]), numerical calculations are used to investigate the effects of applied field and to assist the discovery of new unconventional superconductors by surveying large numbers of candidate materials.

Yu-Shiba-Rusinov states in unconventional superconductors — •Michael Hein[1], Wolfgang Belzig[1], and Juan Carlos Cuevas[2] — [1]Universität Konstanz, Konstanz, Germany — [2]Universidad Autónoma de Madrid, Madrid, Spain

Recently there has been a huge effort to investigate individual magnetic impurities on superconducting surfaces in the context of scanning tunneling microscopy (STM) [1]. These STM-based experiments have enabled to elucidate the properties of the in-gap superconducting bound states known as Yu-Shiba-Rusinov states. These bound states are a key signature of the interplay between magnetism and superconductivity at the atomic scale and, in turn, they lead to a strong local modification of the superconducting state. In this regard, we present here our theoretical efforts to understand the physics of YSR states in the con-

text of unconventional superconductivity, with special attention to the so-called Ising superconductors. We show that the study of YSR states can provide a very valuable way to reveal the underlying properties of unconventional superconductors.

RKKY interaction in non-centrosymmetric superconductors — •Finja Tiet-jen and Jacob Linder — Department of Physics, Center for Quantum Spintronics, Norwegian University of Science and Technology, 7491, Trondheim, Norway

Recent advances in experimental studies have raised interest in how spin interactions are manifested in unconventional superconductors, which can potentially be used for spintronic devices. In particular, superconducting triplet states featuring spin-polarized Cooper pairs are expected to qualitatively alter spin interaction compared to non-superconducting materials.

We consider the RKKY-interaction between two impurity spins in a non-centrosymmetric superconductor. Such superconductors feature antisymmetric spin-orbit coupling and, generally, coexisting singlet and triplet Cooper pairs. The RKKY-interaction is treated perturbatively with a Schrieffer-Wolff transformation within the Bogoliubov-de Gennes framework. Exact numerical studies complement the analytical approach and show local decreases in the total superconducting gap as well as a change in local density of states at impurity sites. The RKKY interaction is affected by the superconductor and the corresponding change in the ground-state spin configuration is also clearly visible. We expect that the spin configuration can thus be externally controlled by entering or leaving the superconducting state.

Ongoing studies on the exact dependencies as well as advances in the analytical approach promise further insights closer to the conference date.

TT 57.17   Thu 15:00   P2/OG2

Analytical parquet renormalization group for multipocket systems — •Nora Taufertshöfer, Matteo Dürrnagel, and Ronny Thomale — Theoretische Physik I, Universität Würzburg

Materials with multi-pocket fermiology may exhibit unconventional superconductivity which arises from inter-pocket scattering. Studying this problem in the weak coupling regime by renormalization group (RG) methods requires a perturbative expansion in each flow step.

As electronically driven instabilities are predominantly governed by states close to the Fermi surface, the RG analysis can be restricted to a few distinct momentum channels between the Fermi pockets. The parquet RG [1] embeds the truncation of the flow equations into a rigorous analytical scheme to investigate superconductivity and its interplay with various competing phases. Within this framework we discuss the relevance of nematic fluctuations in a 2D model for GaAs/AlAs heterostructures, which may host the possibility for gate-tunable unconventional superconductivity [2].

Higgs mode in superconductors with Rashba spin-orbit coupling — •Tobias Kuhn and Björn Sothmann — Fakultät für Physi, Universität Duisburg-Essen, Lotharstraße 1, 47057 Duisburg, Germany

When a superconductor is periodically driven by electromagnetic radiation, the superconducting order parameter shows radial oscillation with twice the driving frequency. This so called Higgs mode can be excited resonantly when the driving frequency equals the absolute value of the order parameter. Here, we study Higgs modes for superconductors with Rashba spin-orbit coupling using two methods. We discuss the resonance condition by analyzing the dynamics of Anderson pseudospins. In addition, we use Floquet Green's functions to generalize the pseudospin approach and discuss the impact of spin-orbit coupling on the order parameter dynamics.

TT 57.19   Thu 15:00   P2/OG2

Order-parameter evolution in the FFLO phase — •H. Kühne[1], S. Molatta[1], T. Kotte[1], D. Opherden[1], G. Koutroulakis[2], J.A. Schlueter[3,4], G. Zwicknagl[5], S.E. Brown[6], and J. Wosnitza[1,7] — [1]Hochfeld-Magnetlabor Dresden, HZDR — [2]UC Santa Barbara, USA — [3]ANL, Argonne, USA — [4]NSF, Alexandria, USA — [5]IMP, TU Braunschweig — [6]UC Los Angeles, USA — [7]IFMP, TU Dresden

The Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state represents a general concept of pairing in multi-component Fermi liquids with strong population imbalance. In the superconducting FFLO state, the spin polarization varies as the modulus of the spatially modulated superconducting gap amplitude, and, thus, its modulation amplitude represents the order parameter. Indeed, NMR experiments of the organic superconductors β''-$(ET)_2SF_5CH_2CF_2SO_3$ and κ-$(ET)_2Cu(NCS)_2$ showed the emergence of inhomogeneous line broadening, stemming from the spatially modulated spin polarization. We report on our studies of the temperature-dependent order parameter of the superconducting FFLO state. For that, we utilize ^{13}C NMR spectroscopy of β''-

$(ET)_2SF_5CH_2CF_2SO_3$. From a comparison of the NMR spectra to a comprehensive modeling, we determine the evolution of the local spin-polarization modulation amplitude upon condensation of the FFLO state. Further, the modeling allows to quantify the decrease of the average spin polarization, stemming from the spin-singlet coupling of the superconducting electron pairs.

TT 57.20   Thu 15:00   P2/OG2

Comparison of window-type and cross-type Nb/Al-AlO$_x$/Nb Josephson tunnel junctions — •Fabienne Bauer[1], Martin Neidig[1], Christian Enss[2], and Sebastian Kempf[1] — [1]Institute of Micro- and Nanoelectronic Systems, Karlsruhe Institute of Technology — [2]Kirchhoff Institute of Physics, Heidelberg University

Josephson tunnel junctions (JJs) are the heart of numerous superconducting electronic devices such as SQUIDs, qubits or parametric amplifiers. Out of the multitude of junction variants, Nb/Al-AlO$_x$/Nb junctions have somehow become the state of the art as they are resilient to thermal cycling and additionally show a very high junction quality and reproducibility of characteristic junction properties. Against this background, we present two anodization-free fabrication processes for Nb/Al-AlO$_x$/Nb Josephson junctions. One is a variant of the selective niobium etching process (SNEP) for fabricating window-type junctions. The second is a process for producing self-aligning, low-capacitance cross-type Josephson junctions. For comparing both processes, we comprehensively characterized fabricated junctions by studying resonance phenomena in unshunted dc-SQUIDs to determine the intrinsic junction capacitance and determined characteristic junction figures of merit. We show that both of our processes yield very high quality JJs. However, our cross-type Josephson junctions turn out not only to greatly simplify the fabrication process and to provide much lower junction capacitance, but also to show a greatly improved homogeneity of critical current density distribution as determined by analysing the magnetic field dependence of the critical current.

TT 57.21   Thu 15:00   P2/OG2

Process optimisation for the fabrication of cross-type Nb/Al-AlO$_x$/Nb Josephson junctions — •A. Stoll, F. Bauer, L. Münch, D. Hengstler, A. Ferring-Siebert, F. Krämer, N. Kahne, D. Mazibrada, A. Fleischmann, and C. Enss — Kirchhoff-Institute for Physics, Heidelberg University, Germany.

Josephson tunnel junctions (JJs) are the basic element of many superconducting electronic devices such as qubits or superconducting quantum interference devices (SQUIDs). Since many applications demand a large number of Josephson junctions, a reliable wafer-scale fabrication process yielding JJs with a reproducible and uniform high quality is required. Very often window-type JJs are used, in which the JJ area is defined by openings in an insulating layer. The size of the JJ is thus limited by the alignment accuracy, therfore causing the need for low critical current densities j_c and in turn long oxidation times. The transition to cross-type JJs is motivated by reducing the junction area as well as parasitic capacities, and in turn suppressing or completely removing parasitic effects, e.g. LC-resonances, with the additional benefit of simplistic and time efficient fabrication steps. We present how we optimised and retained the quality of our cross-type Nb/Al-AlO$_x$/Nb junctions, for which quality checks of our in-house sputter-deposited niobium films and oxidized aluminium layers were carried out, including the measurement of the critical temperature T_c, stress of the niobium film and junction specific quality features. The parameters for the magnetron sputtering, like the Ar-pressure and power of the sputtering source, were optimised accordingly.

TT 57.22   Thu 15:00   P2/OG2

Realization of He-FIB induced Josephson junction THz detectors in YBCO thin films — •Kenny Fohmann, Christoph Schmid, Eric Dorsch, Edward Goldobin, Dieter Koelle, and Reinhold Kleiner — Physikalisches Institut, Center for Quantum Science (CQ) and LISA$^+$, Universität Tübingen, Germany

We designed and fabricated ultrawideband thin-film antennas from the high-temperature superconductor YBa$_2$Cu$_3$O$_{7-\delta}$ (YBCO) partially covered with Au. By using a focused He ion beam (He-FIB) we "draw" a Josephson Junction (JJ) [1] into the microbridge footpoint of the spiral antenna. Under microwave irradiation the JJ exhibits Shapiro steps in the $I-V$ characteristic.

We report on design optimization. This includes improved matching of the impedances of the antenna and the JJ in an ultrawide frequency band by using a logarithmic periodic antenna. Moreover, we performed simulations using CST Studio-Suite to improve the coupling of a plane-wave signal to the antenna.

To characterize the antennas, we compare the excitation of the JJ embedded in a simple linear YBCO bridge (~ 1 mm) with the one embedded in the footpoint of the antenna, for frequencies up to 40 GHz. The ultimate goal of such an antenna with a YBCO JJ is to detect the radiation from a BSCCO-mesa (placed on another chip nearby) in the frequency range $\gtrsim$ 0.5 THz. The latest measurements will be presented.

TT 57.23   Thu 15:00   P2/OG2

Investigation and optimization of YBa$_2$Cu$_3$O$_{7-\delta}$ Josephson junctions written with a focused He ion beam — •Christoph Schmid[1], Max Karrer[1], Katja Wurster[1], Moritz Meichsner[1], Isabelle Vandermoeten[1], Noor Hasan[1], Ramón Manzorro[2,3], Javier Pablo-Navarro[2,3], Cesar Magen[2,3], Dieter Koelle[1], Reinhold Kleiner[1], and Edward Goldobin[1] — [1]Physikalisches Institut, Center for Quantum Science and LISA$^+$, Universität Tübingen, Germany — [2]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Spain — [3]Laboratorio de Microscopías Avanzadas (LMA), Universidad de Zaragoza, Spain

We use a focused He Ion Beam (He-FIB) to "write" Josephson barriers across YBa$_2$Cu$_3$O$_{7-\delta}$ (YBCO) thin-film bridges. Such Josephson junctions (JJs) exhibit RCSJ-like I–V characteristics, and the dependence of critical current vs. magnetic field resembles a Fraunhofer pattern [1]. Scanning transmission electron microscopy (STEM) shows that He-FIB irradiation modifies locally ($\sim$ 10 nm) the YBCO crystal structure that can partially heal with time. Electric transport measurements provide the evolution of the JJ parameters with time or thermal annealing. Those reveal barrier recovery processes and show how to stabilize the JJ parameters on short time scales. Furthermore, we investigated the interaction of two and more JJs placed close to each other and biased in series. Using a multi-terminal arrangement we found some unexpected behavior that will be discussed. Several approaches to synchronize arrays of He-FIB written JJs are investigated.

TT 57.24   Thu 15:00   P2/OG2

On-chip driving of a phase-slip junction for dual Shapiro steps — •David Scheer and Fabian Hassler — JARA Institute for Quantum Information, RWTH Aachen University, 52056 Aachen, Germany

A single Josephson junction in the phase-slip regime exhibits Bloch oscillations that relate current to frequency if supplied with a DC voltage-bias. If additionally an AC-drive is applied to the junction, the Bloch oscillations can synchronize with the driving frequency. This leads to the emergence of dual Shapiro steps with constant current in the IV-curve of the junction with the current determined by the driving frequency. An AC-drive in the required frequency regime of > 10GHz is challenging to implement experimentally without detrimental effects due to stray capacitances. We investigate the use of a Josephson junction with a DC-bias as an on-chip AC-voltage source. We discuss the relevant coupling parameters between the oscillations caused by the DC-Josephson effect and the Bloch oscillations as well as the back action of the Bloch oscillations on the Josephson oscillations. We identify the regime in which the back action is minimized in order to obtain a steady voltage source to create dual Shapiro steps.

TT 57.25   Thu 15:00   P2/OG2

MOCCA: A 4k-pixel molecule camera for the position and energy resolved detection of neutral molecule fragments — •Daniel Kreuzberger[1], Christian Enss[1], Andreas Fleischmann[1], Lisa Gamer[1], Loredana Gastaldo[1], Christopher Jakob[2], Ansgar Lowack[1], Oldřich Novotny[2], Andreas Reifenberger[1], Dennis Schulz[1], and Andreas Wolf[2] — [1]Heidelberg University — [2]Max Planck Institute for Nuclear Physics, Heidelberg

The MOCCA detector is a 4k-pixel high-resolution molecule camera based on metallic magnetic calorimeters and read out with SQUIDs that is able to detect neutral molecule fragments with keV kinetic energies. It will be deployed at the Cryogenic Storage Ring CSR at the Max Planck Institute for Nuclear Physics in Heidelberg, a storage ring built to prepare and store molecular ions in their rotational and vibrational ground states, enabling studies on electron-ion interactions. To reconstruct the reaction kinematics, MOCCA measures the energy and position of incident particles on the detector, even with multiple particles hitting the detector simultaneously.

We present a new read-out scheme which uses only 32 SQUID channels for the 4096 pixels of the detector as well as some new fabrication details including copper-filled through-wafer vias to heat-sink the detector to the wafer backside. In addition we present the results of first characterization measurements.

TT 57.26   Thu 15:00   P2/OG2

Towards large-area 256-pixel MMC arrays for high resolution X-ray spectroscopy — •Andreas Abeln, Steffen Allgeier, Axel Brunold, Lars Eisenmann, Daniel Hengstler, Lukas Münch, Alexander Orlow, Andreas Fleischmann, and Christian Enss — Kirchhoff-Institute for Physics, Heidelberg University

Metallic Magnetic Calorimeters (MMCs) are energy-dispersive cryogenic particle detectors. Operated temperatures below 50 mK, they provide very good energy resolution, high quantum efficiency as well as linearity over a large energy range. In many precision experiments on X-ray spectroscopy the photon flux is small, thus a large active detection area is desirable. Therefore, we develop arrays with increasing number of pixels. For a cost-effective read-out of a growing number of detector channels we investigate different multiplexing techniques.

In this contribution we present the design of a novel 16 × 16 pixel MMC array. The pixels provide a total active area of 4 mm × 4 mm and are equipped with 5 μm thick absorbers made of gold. This ensures a stopping power of at least 50 % for photon energies up to 20 keV. The expected energy resolution is ΔE = 1.4 eV (FWHM) at an operating temperature of 20 mK. We give an overview about the microfabrication process and focus on the challenging task of producing through wafer vias to heat sink the MMC pixels to the wafer backside. These vias are realized by holes etched through the silicon substrate and subsequently lined with gold to achieve high thermal coupling between detector pixels and the cryostat.

TT 57.27   Thu 15:00   P2/OG2

A dedicated 2-dimensional array of metallic magnetic microcalorimeters to resolve the 29.18 keV doublet of ^{229}Th — •A. Brunold, A. Abeln, S. Allgeier, J. Geist, D. Hengstler, A. Orlow, L. Gastaldo, A. Fleischmann, and C. Enss — Heidelberg University

The isotope ^{229}Th has the nuclear isomer state with the lowest presently known excitation energy, which possibly allows to connect the fields of nuclear and atomic physics with the potential application as a nuclear clock. In order to excite this very narrow transition with a laser a precise knowledge of the transition energy is needed. Recently the isomer energy (8.338 ± 0.024) eV [Kraemer et al., arXiv:2209.10276, 2022] could be precisely determined. To get additional valuable insights, we will improve our recent high-resolution measurement [Sikorsky et al., PRL 125, 2020] of the γ-spectrum following the α-decay of ^{233}U. This decay results in excited ^{229}Th with a nuclear state at 29.18 keV. Resolving the doublet, that results from subsequent de-excitation to the ground and isomer state, respectively, would allow an independent measurement of the isomer energy and the branching ratio of these transitions. To resolve this doublet, we develop a 2D detector array consisting of 8×8 metallic magnetic calorimeters (MMCs). MMCs are operated at millikelvin temperatures and convert the energy of a single incident γ-ray photon into a temperature pulse which is measured by a paramagnetic temperature sensor. The detector array features an active detection area of 4 mm^2, a stopping power of 63.2% for 30 keV photons and an energy resolution below 3 eV (FWHM).

TT 57.28   Thu 15:00   P2/OG2

X-ray spectroscopy of U^{90+} ions with a 64-pixel metallic magnetic calorimeter array — •A. Orlow[1], S. Allgeier[1], A. Abeln[1], A. Brunold[1], M. Friedrich[1], A. Gumberidze[2], D. Hengstler[1], F. M. Kröger[2,3,4], P. Kuntz[1], A. Fleischmann[1], M. Lestinsky[2], E. B. Menz[2,3,4], Ph. Pfäfflein[2,3,4], U. Spillmann[2], B. Zhu[4], G. Weber[2,3,4], Th. Stöhlker[2,3,4], and C. Enss[1] — [1]KIP, Heidelberg University — [2]GSI/FAIR, Darmstadt — [3]IOQ, Jena University — [4]HI Jena

Metallic magnetic calorimeters (MMCs) are energy-dispersive X-ray detectors which provide an excellent energy resolution over a large dynamic range combined with a very good linearity. MMCs convert the energy of each incident photon into a temperature pulse which is measured by a paramagnetic temperature sensor. The resulting change of magnetisation is read out by a SQUID magnetometer.

To investigate electron transitions in U^{90+} at CRYRING@FAIR within the framework of the SPARC collaboration, we developed the 2-dimensional maXs-100 detector array. It features 8x8 pixels with a detection area of 1 cm^2 and a stopping power of 40 % at 100 keV. Four on-chip thermometers allow to correct for temperature drifts and to achieve an energy resolution of 40 eV at 60 keV. We show preliminary X-ray spectra of the recent U^{90+} beamtime. Due to the small rate of emitted X-rays, a good supression of background radiation is mandatory, which was ensured by a coincidence measurement with a particle detector. To increase the stopping power to above 60 % at 100 keV we develop a new maXs-100 detector with 100 μm thick absorbers.

Low temperature MMC-based muon veto for IAXO — •Daniel Unger, Christian Enss, Andreas Fleischmann, Daniel Hengstler, Ashish Jadhav, and Loredana Gastaldo — Kirchhoff Institute for Physics, Heidelberg University, Im Neuenheimer Feld 227, 69120 Heidelberg, Germany.

An array of Metallic Magnetic Calorimeter (MMC) operated at a few mK in a dilution refrigerator is considered as a possible focal plane detector for the IAXO helioscope. For such an experiment, the background rate must be smaller than $10^{-6}\,\mathrm{keV^{-1}cm^{-2}s^{-1}}$. However, we expect the rate of events related to cosmic muons to be two orders of magnitude larger. A traditional muon veto composed by scintillating panels would have to cover the full cryostat, a volume of about $3\,\mathrm{m}^3$. A cryogenic muon veto surrounding the $150\,\mathrm{cm}^3$ volume of the detector module could veto muon related events more efficiently. We present the development of a large-area MMC-based muon veto. Muons will be detected through their energy deposition while traversing a silicon wafer with thickness of 0.4 mm and an area of $30\,\mathrm{cm}^2$. We discuss the design and the fabrication challenges of the muon veto in addition to the prototype setup for testing purposes. We aim to characterize the performance of the large silicon detector and at the same time study the spectrum of muon related events detected by the MMC array as well as of the residual background due to natural radioactivity. Finally, we evaluate the suitability of MMC arrays for low background measurements.

TT 58.2　Thu 15:00　P2/OG3

Dc-SQUID readout with high dynamic range and intrinsic frequency-domain multiplexing capability — •L. Münch, A. Abeln, N. Kahne, F. Krämer, D. Hengstler, L. Hoibl, D. Mazibrada, D. Richter, A. Stoll, A. Fleischmann, and C. Enss — Kirchhoff-Institute for Physics, Heidelberg University, Im Neuenheimer Feld 227, 69120 Heidelberg, Germany.

Dc superconducting quantum interference devices (dc-SQUIDs) are periodic flux-to-voltage converters whose linear flux range is rather small. For this reason, a flux locked loop (FLL) circuit is typically used to linearize the output signal and increase the dynamic range. However, the measurement of large signals while maintaining the excellent noise performance of SQUIDs sets high demands on the digitizer sampling the SQUID signal in terms of voltage resolution. Furthermore, FLL operation often sets a practical limit for the realization of massive multi-channel SQUID systems since feedback wires have to be routed to every SQUID.

In this contribution, we discuss a SQUID readout approach which relaxes the hardware requirements of a SQUID system while maintaining a linearized output signal and a large dynamic range. At the same time, it allows for reducing the number of wires within multi-channel SQUID systems due to its intrinsic frequency-domain multiplexing (FDM) capability. We introduce the basic concept of our readout approach and demonstrate its intrinsic FDM-capability using a custom-made four channel multiplexer device. We also present a new chip design optimized for the read-out of a novel 16 x 16 pixel MMC array.

TT 58.3　Thu 15:00　P2/OG3

Integrated two-stage SQUID-chip with 6 nH input impedance — •David Mazibrada, Fabian Krämer, Alexander Stoll, Nicolas Kahne, Lukas Münch, Daniel Hengstler, Andreas Fleischmann, and Christian Enss — Kirchhoff-Institute for Physics, Im Neuenheimer Feld 227, 69120 Heidelberg, Germany.

SQUIDs are sensitive superconducting magnetic flux to voltage converters, whose operation is based on the Josephson effects. To increase the signal-to-noise ratio of a SQUID-based readout system one can amplify the signal with an N-SQUID series array. We present our first integrated two-stage chip design which combines a single current sensing dc-SQUID as front-end and a 18-dcSQUID series array as amplifier stage, in one compact, well thermalized chip. This not only eliminates the need for two separate chips, but also achieves low signal propagation delay and larger bandwidth. Compared to our most recent single-stage current sensing SQUIDs, the first stage SQUID features a 2-turn input coil with increased inductance of 6 nH increasing the input current sensitivity by a factor of about 2. To counteract the resistive heating of the two-stage setup, large thermalization pads made of gold are implemented to thermalize the resistive elements and in addition the chip can be thermally anchored to the sample holder by means of gold bonds. In future designs lossy striplines will be used in order to provide delocalized broad-band damping and suppress effects of parasitic resonances without introducing new noticeable sources of noise.

TT 58.4　Thu 15:00　P2/OG3

Identification of noise sources in superconducting microstructures — •R. Yang, A. Fleischmann, D. Hengstler, M. Herbst, D. Mazibrada, L. Münch, A. Reifenberger, C. Ständer, and C. Enss — Kirchhoff-Institute for Physics, Heidelberg University, Im Neuenheimer Feld 227, 69120 Heidelberg, Germany.

Improving the performance of a superconducting device often means identifying and eliminating noise. Many potential noise sources are independent of the specific experimental set-up and transferable across many device categories such as qubits, SQUIDs, and superconducting detectors. We have constructed a stand-alone device able to representably probe specific noise sources. The set-up consists of a Wheatstone-like bridge of microfabricated superconducting inductors and a pair of two-stage dc-SQUID read-out chains. Cross-correlation removes noise contributions from the read-out electronics giving us the sum total of all noise in the superconducting circuit. If, in comparison, the Wheatstone bridge is AC-driven, we can measure a sample material's magnetic noise via the material's complex AC susceptibility using the fluctuation-dissipation theorem. The experiment is performed at temperatures between $T = 10\,\mathrm{mK}$ and $1000\,\mathrm{mK}$ in the frequency range from $f = 100\,\mathrm{mHz}$ to $100\,\mathrm{kHz}$ on an experimental holder with excellent thermal coupling and shielding. We present first results of measurements on SiO_2 and Ag:Er thin films and compare these results with previous measurements on Au:Er. In addition, we demonstrate our device's ability to probe the dynamics of magnetic moments in a sample material.

TT 58.5　Thu 15:00　P2/OG3

Recent insights into low frequency excess flux noise in superconducting quantum devices — •Anna Ferring-Siebert, Fabian Kaap, David Mazibrada, Lukas Münch, Matthew Herbst, Andreas Fleischmann, Christian Enss, and Sebastian Kempf — Kirchhoff-Institute for Physics, Im Neuenheimer Feld 227, 69120 Heidelberg, Germany.

In many applications low frequency excess flux noise (EFN), with a frequency dependence of $1/f^{\alpha}$, limits the performance of superconducting quantum devices such as SQUIDs and Qubits. Although it was long believed that its magnitude expressed in units of magnetic flux $S_{\Phi}(1\,\mathrm{Hz})$ and exponent α are fairly independent of the device material and inductance, there meanwhile exist hints for the contrary. It is also known that EFN can depend on the equipment used for device fabrication, the reason for that however remained unknown up to now.

In this contribution, we discuss origins of fabrication induced EFN as well as means to minimize it. In particular, we show that material layers deposited with commercial deposition equipment can contain magnetic impurities causing EFN. In this context, we present how we have modified commercial sputtering sources to reduce EFN and provide evidence for a relationship between EFN amplitude and the DC magnetization of the deposited material layers. Finally, recent measurements investigating the dependence of EFN on device inductance are discussed, suggesting that energy sensitivity $\varepsilon(1\,\mathrm{Hz}) = S_{\Phi}(1\,\mathrm{Hz})/(2L)$, rather than magnetic flux noise, is the more appropriate metric to describe EFN.

TT 58.6　Thu 15:00　P2/OG3

Impedance engineering of flux-pumped Josephson traveling wave parametric amplifier — •Daniil E. Bazulin[1,2], Kedar E. Honasoge[1,2], Leon Koch[1,2], Niklas Bruckmoser[1,2], Yuki Nojiri[1,2], Thomas Luschmann[1,2], Achim Marx[1], Stefan Filipp[1,2,3], and Kirill G. Fedorov[1,2] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany

Scalable quantum computing with superconducting qubits relies on efficient and fast readout of multiple qubits. This goal can be achieved by exploiting broadband Josephson Traveling Wave Parametric Amplifiers (JTWPAs). Here, we investigate fabrication and characterization of a specific type of the JTWPA based on aluminium Superconducting Nonlinear Asymmetric Inductive eLements (SNAILs) exploiting the 3-wave mixing down-conversion process. This approach allows for separating signal and pump paths, which is expected to enhance the overall JTWPA performance by mitigating back action amplification processes and avoiding the pump depletion. Additionally, we implement a single-layer 50 Ω impedance matching approach by exploiting fish-bone capacitors fabricated simultaneously with the Josephson junctions. This technique avoids using extra dielectric layers, which are typical sources of losses and noise in JTWPAs.

TT 58.7　Thu 15:00　P2/OG3

Large-scale fabrication of Josephson parametric devices — •Maria-Teresa Handschuh[1,2], Kedar E. Honasoge[1,2], Yuki Nojiri[1,2], Niklas Bruckmoser[1,2], Leon Koch[1,2], Daniil Bazulin[1,2], Florian Fesquet[1,2], Fabian Kronowetter[1,2,4], Michael Renger[1,2], Wun K. Yam[1,2], Achim Marx[1], Rudolf Gross[1,2,3], and Kirill G. Fedorov[1,2] — [1]Walther-Meißner-Institut, 85748 Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology, 80799 Munich, Germany — [4]Rohde & Schwarz GmbH & Co. KG, 81671 Munich, Germany

The rapid progress in the field of quantum information processing with superconducting circuits requires the development of large-scale fabrication to in-

crease fabrication efficiency, reproducibility as well as to reduce costs. Moreover, many advanced quantum applications and experiments rely on using multiple nominally identical chips, such as flux-driven Josephson parametric amplifiers (JPAs) [1]. To this end, the goal is to establish good control over various fabrication parameters, such as critical current density and microwave losses, in JPAs with Nb/Al-AlOx/Nb Josephson junctions on 4-inch high-resistivity silicon wafers. We provide a detailed analysis of the related parameter distribution across the wafer and make proposals for future improvements.

TT 58.8   Thu 15:00   P2/OG3

Microwave quantum memory based on rare earth doped crystal — •Jianpeng Chen[3,1,2], Ana Strinic[3,1,2], Achim Marx[1,3], Kirill G. Fedorov[1,3], Hans Huebl[1,2,3], Rudolf Gross[1,2,3], and Nadezhda Kukharchyk[3,1,2] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology, 80799 Munich, Germany — [3]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany

Quantum memory is an essential element in the development of future quantum technologies, such as quantum computing circuits and quantum communication links. Specifically, crystals doped with rare earth ions are promising competitive candidates due to their long coherence times [1] and potential multiplexing capability [2]. Here, we aim to couple coherent microwave signals to rare earth ion dopants in yttrium orthosilicate crystals (Y2SiO5) at 10 mK. We will discuss the impact of the transmission line design on the efficiency of quantum information storage and its multimodality potential.

TT 58.9   Thu 15:00   P2/OG3

Non-Markovian effects in Er:YSO — •Owen Thomas Huisman[1,2,4], Ana Strinic[1,2,3], Rudolf Gross[1,2,3], and Nadezhda Kukharchyk[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]Physik-Department, Technische Universität München, Garching, Germany — [3]Munich Center for Quantum Science and Technologies, München, Germany — [4]Delft University of Technology, Delft, Netherlands

Erbium doped Y_2SiO_5 (Er:YSO) has proven to be a suitable platform to realise quantum memory protocols based on microwave ESR techniques [1]. The successful storage and retrieval of a microwave quantum state depends on the coherence and relaxation of spectral holes burned in inhomogeneously broadened spin transitions. Recent work has shown that relaxation and decoherence processes in Er:YSO at sub-Kelvin temperature may be affected by the phonon bottleneck process [2]. Several attempts have been made to develop a microscopic theory of the phonon bottleneck [3,4]. In this work, we attempt to connect the phonon bottleneck to more recent investigations of non-Markovian open quantum systems [5]. We propose an experiment to confirm the presence of non-Markovian effects in Er:YSO and justify the connection with a phonon bottleneck.

TT 58.10   Thu 15:00   P2/OG3

Microwave single-shot quantum key distribution — •Florian Fesquet[1,2], Fabian Kronowetter[1,2,4], Michael Renger[1,2], Nadezhda Kukharchyk[1,2], Hans Huebl[1,2,3], Achim Marx[1], Rudolf Gross[1,2,3], and Kirill. G. Fedorov[1,2] — [1]Walther- Meißner-Institut, 85748 Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany — [4]Rohde & Schwarz GmbH, 81671 Munich, Germany

Security of modern classical data encryption often relies on computationally hard-to-solve problems. A potential remedy for this challenge is quantum communication (QC) which takes advantage of the laws of quantum physics to provide secure exchange of information. Here, quantum key distribution (QKD) represents a powerful tool, allowing unconditionally secure QC between remote parties. A demand for QC at microwave frequencies has emerged due to the tremendous progress in quantum information processing with superconducting circuits. To this end, we present a realization of a continuous-variable QKD protocol based on displaced squeezed microwave states. We use a Josephson parametric amplifier (JPA) to generate squeezed microwave states at cryogenic temperatures. By implementing a single-shot quadrature readout with a second JPA in the phase-sensitive regime with quantum efficiency of 38 %, we demonstrate the unconditional security of this microwave QKD protocol. We analyze these results in terms of losses and noise in order to map them on possible real-world scenarios.

TT 58.11   Thu 15:00   P2/OG3

3D-Integration of superconducting qubits using flip-chip bump bonding technology — •Franziska Wilfinger[1,2], Ivan Tsitsilin[1,3], and Stefan Filipp[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]Physik Department, Technische Universität München, Garching, Germany — [3]Munich Center for Quantum Science and Technologies (MCQST), Munich, Germany

Superconducting quantum circuits are typically realized in a planar architecture. This approach is, however limited to dozens of qubits due to the complexity of routing signal lines when scaling beyond. 3D-integration can overcome these limitations by separating circuit components on different layers and on different chips. One promising 3D-integration strategy is to assemble two chips, patterned on one side, through flip-chip bonding using indium bumps. Quantum components such as qubits and couplers containing Josephson junctions can then be separated from the control- and readout-lines on different faces. Here, we discuss design concepts and test-structures in a flip-chip architecture and their simulated performances with respect to quality factors, decay rates and gate times. Finite-element simulation is applied to extract design parameters such as the qubit coupling to readout- and control lines and to other qubits. These parameters are optimized in order to achieve a performance comparable with planar structures. Moreover, the influence of inaccuracies in fabrication is investigated by simulating varying distance parameters and analyzing their impact on relevant quantities.

TT 58.12   Thu 15:00   P2/OG3

Probing the density of states of defects in superconducting flux qubits — •Benedikt Berlitz, Alexander Konstantin Händel, Alexey V. Ustinov, and Jürgen Lisenfeld — Physikalisches Institut, Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany

Material defects forming two-level systems (TLS) present a source of decoherence and unwanted degrees of freedom in superconducting quantum circuits. Current theoretical models make different assumptions about the frequency dependence of the TLS' density of states (DOS). To measure the TLS' DOS in a wide frequency range, spanning from about 0.1 to 20 GHz, we fabricated flux qubits as TLS detectors. Measuring the DOS will enhance our understanding of the underlying physics of TLS in amorphous materials.

TT 58.13   Thu 15:00   P2/OG3

Fast quantum state tomography with superconducting qubits — •Andras Di Giovanni[1], Adrian Aasen[3], Moritz Reh[3], Martin Gärttner[3], Markus Griedel[2], Hannes Rotzinger[1,2], and Alexey Ustinov[1,2] — [1]Physikalisches Institut, Karlsruher Institut für Technologie, Karlsruhe — [2]Institut für Quantenmaterialien und Technologien, Karlsruher Institut für Technologie, Karlsruhe — [3]Kirchhoff-Institut für Physik, Heidelberg

Quantum simulators promise insights into quantum many-body problems in regimes where classical simulation methods hit a complexity wall. One challenge towards this goal is to develop well characterized building blocks that allow to scale system sizes up while conserving reliability in terms of errors. A promising platform for building such quantum simulators are superconducting quantum circuits. We characterize small-scale quantum processors in the time domain with single-shot accuracy and minimal hardware and post-processing overhead. For this purpose we use reactive basis rotations based on greedy algorithms and adaptive Bayesian tomography. We present experimental results measured on a transmon qubit and compare the data with theoretical predictions.

TT 58.14   Thu 15:00   P2/OG3

Infrared filters for superconducting qubit applications — •Markus Griedel[1,2], Sebastian Koch[2], Alex Stehli[2], Hannes Rotzinger[1,2], and Alexey V. Ustinov[1,2] — [1]Institut for Quantum Materials and Technologies (IQMT), Karlsruhe Institut for Technology (KIT) — [2]Physikalisches Institut (PHI), Karlsruhe Institut for Technology (KIT)

Superconducting qubits are manipulated and read out using microwave signals which are generated at room temperature and guided through coaxial cables to the milikelvin temperature stage. One common problem of coax cables is their high transparency to infrared radiation originating from a rather high photon flux sources at elevated temperatures of cryostat stages. Filtering out the infrared radiation requires a low-pass filter with a sharp cutoff in the micro- or low mm-wave frequency range. We present simulations as well as experimental data on a new generation of powder based filters. The samples are investigated over the full band of infrared radiation using conventional detectors as well as superconducting qubits directly.

TT 58.15   Thu 15:00   P2/OG3

Superconducting flux qubits with stacked Josephson junctions — •Alex Kreuzer[1], Hossam Tohamy[1], Thilo Krumrey[1], Markus Griedel[1,2], Hannes Rotzinger[1,2], and Alexey V. Ustinov[1,2] — [1]Physikalisches Institut (PHI), Karlsruher Institut für Technologie (KIT) — [2]Institut für Quantenmaterialien und -technologien (IQMT), Karlsruher Institut für Technologie (KIT)

Josephson junctions are often employed as nonlinear inductive elements in superconducting qubits as they allow to tailor specific circuit properties. The

promising flux qubit types as fluxonium or quarton qubits require compact inductances which are often implemented as arrays of Josephson junctions. Here, the stray capacitance originating, for instance, from the capacitive coupling of an array island to ground, introduces the major limitation of this approach, since it introduces parasitic resonances at GHz frequencies which may degrade the overall qubit performance. We explore the possibility of implementing the qubit inductances by stacking Josephson junctions vertically and thus reducing the capacitance to ground. We present transport as well as microwave measurement data of stacked Josephson junctions and flux qubits made from them. Furthermore, we present a comparison of our experimental data with a detailed numerical simulation.

TT 58.16   Thu 15:00   P2/OG3

Flux escape mitigation in gradiometric fluxonium qubits — •Denis Bénâtre[1], Mathieu Féchant[1], Martin Spiecker[1,2], and Ioan Pop[1,2] — [1]IQMT, Karlsruhe Institute of Technology, 76344 Eggenstein-Leopoldshafen, Germany — [2]PHI, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany
Superconducting fluxonium qubits have grown in the past decade as an interesting alternative to the now standard transmons. In 2022, Gusenkova et al. proposed a new design, the gradiometric fluxonium qubit, whose two loops have shown to suppress sensitivity to homogeneous magnetic field and open the door for its use in hybrid quantum systems. However, these devices undergo flux escape triggered by radioactive and cosmic impacts, and thus require shielding from ionizing radiation, e.g. in deep-underground facilities [Gusenkova et al., 2022]. We present new designs of gradiometric fluxoniums aimed at intrinsically mitigating the rate of trapped flux escape.

TT 58.17   Thu 15:00   P2/OG3

Towards millimeter-wave superconducting qubits — •Philipp Lenhard, Jürgen Lisenfeld, and Alexey V. Ustinov — Physikalisches Institut, Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany
Superconducting circuits are a promising platform to realize a solid-state quantum computer. However, scaling up to larger multi-qubit circuits is severely hindered by decoherence of various origins. While contemporary qubits are typically operated between 3 and 6 GHz resonance frequencies, here we investigate qubit designs for millimeter-wave operation frequencies between 80 and 110 GHz. We present first spectroscopic measurements of resonant energy level transitions in a current-biased Josephson junction in the millimeter-wave regime. In addition, we show simulations of designs for integrating qubits and readout resonators in 3D-waveguides.

TT 58.18   Thu 15:00   P2/OG3

Towards dissipatively coupled photon-pressure circuits — •Janis Peter, Mohamad Adnan el Kazouini, Emily Guo, Kevin Uhl, and Daniel Bothner — Physikalisches Institut, Center for Quantum Science (CQ) and LISA$^+$, Universität Tübingen, Germany
Photon-pressure circuits are a superconducting all-circuit equivalent of cavity optomechanics. They recently gained a lot of attention since they are providing a new toolbox for sensing and controlling radiofrequency (rf) photons by high-frequency (hf) circuits. In contrast to optomechanical systems, this platform only consists of LC circuits without any mechanical resonators. As a result they offer a larger flexibility regarding device parameters and a simplified fabrication process. Until now, photon-pressure circuits have been realized using the so-called dispersive interaction: the rf-resonator modulates the resonance frequency ω_0 of the hf-circuit. To reach the quantum regime by ground state cooling, dispersively coupled devices need to be in the so-called sideband-resolved regime, that is, the resonance frequency Ω_0 of the rf-resonator is much larger than the decay rate of the hf-circuit κ (typically several 100 kHz). Extending the quantum regime to even lower frequency photons ($\lesssim 1$ MHz) requires a different interaction: dissipative photon-pressure coupling, where κ is modulated instead of ω_0. We present our progress on implementing a dissipative photonpressure interaction between two superconducting circuits and discuss in this context simulation, fabrication, device design and intermediate experimental milestones.

TT 58.19   Thu 15:00   P2/OG3

Towards non-classical state preparation in photon-pressure circuits — •Mohamad Adnan El Kazouini, Janis Peter, Emily Guo, Kevin Uhl, and Daniel Bothner — Physikalisches Institut, Center for Quantum Sciences (CQ) and LISA$^+$, Universität Tübingen, Germany
Photon-Pressure is a non-linear interaction between two electromagnetic modes in LC circuits, which gained considerable attention in the past years due to its unique possibilities to sense and control radio-frequency photons. To date, several milestone experiments have been performed such as interferometric radiofrequency thermometry, the observation of parametric strong-coupling, and the realization of resolved-sideband cooling of a low-frequency LC circuit (~ 100 MHz) into its quantum ground state. Although photon-pressure is in principle providing the possibilities, non-classical states like quantum squeezed and entangled states of MHz photonic modes have not been realized yet in these systems. Those states, however, have the potential to enhance quantum-limited sensing of

bosonic modes in the radio-frequency regime, an application of photon-pressure systems that have been discussed for instance in the context of the search for dark-matter axions. In our poster, we will present our progress in developing photon-pressure devices that are being engineered toward the preparation of non-classical radio-frequency photon states and we will discuss the next steps and our future plans.

TT 58.20   Thu 15:00   P2/OG3

Towards room temperature microwave quantum teleportation — •Wun Kwan Yam[1,2], Michael Renger[1,2], Simon Gandorfer[1,2], Florian Fesquet[1,2], Kedar Honasoge[1,2], Fabian Kronowetter[1,2,3], Yuki Nojiri[1,2], Achim Marx[1], Rudolf Gross[1,2,4], and Kirill G. Fedorov[1,2] — [1]Walther-Meißner-Institut, BAdW, 85748 Garching, Germany — [2]Physik-Department, TUM, 85748 Garching, Germany — [3]Rohde & Schwarz GmbH & Co. KG, 81671 Munich, Germany — [4]Munich Center for Quantum Science and Technology, 80799 Munich, Germany
Microwave quantum communication enables efficient and unconditionally secure exchange of quantum states. This paves the way towards distributed quantum computing and open-air quantum key distribution. One of the relevant quantum communication protocols is quantum teleportation. In the microwave regime, quantum teleportation has been successfully demonstrated by using superconducting Josephson circuits in a cryogenic setup. To investigate the limits of microwave quantum teleportation under more realistic application scenarios, we study the influence of thermal noise and losses in microwave communication channels. We show that the teleportation protocol is robust against noise in the feedforward channel and analyze experimental limits of distributing entanglement via thermal channels. Furthermore, we describe the experimental implementation of microwave quantum teleportation with the room temperature feedforward and consider microwave quantum teleportation in the open air.

TT 58.21   Thu 15:00   P2/OG3

Experimental investigations and flow simulation of regenerator configurations of a single stage GM-type pulse tube cooler — •Elias Eisenschmidt[1,3], Jack-Andre Schmidt[2,3], Bernd Schmidt[2,3], Jens Falter[3], and Andre Schirmeisen[2,3] — [1]Technische Hochschule Mittelhessen, Friedberg, Germany — [2]Justus-Liebig-university, Giessen, Germany — [3]TransMIT-Center for Adaptive Cryotechnology and Sensors, Giessen, Germany
Pulse tube coolers are increasingly used in industry and research due to their low vibrations and long service intervalls. The regenerator and especially the filling of the regenerator has a great influence on the cooling capacity as well as the achievable, minimum temperatures. The temperature-dependent heat storage capacity of the materials used in the regenerator is usually the main focus of attention when selecting regenerator fillings. [1, 2]

This poster deals with the pressure drop of two regenerator fillings of stainless steel spheres and sieves. Steady-state and transient measurements of the two regenerator fillings will be discussed. In comparison of the two fillings used, the meshes show lower pressure drops, resulting in a higher cooling efficiency as regenerator filling, while spheres are more cost efficient in time and acquisition.

[2] P. P. Steijaert, Thermodynamical aspects of pulse-tube refrigerators, Technische Universiteit Eindhoven (1999)

TT 58.22   Thu 15:00   P2/OG3

Characterization of the cooling power on a two stage 4 K pulse tube cooler operated with solenoid valves — •Xaver Herrmann[1], Jack-André Schmidt[1,2], Bernd Schmidt[1,2], Jens Falter[2], and André Schirmeisen[1,2] — [1]Institute of Applied Physics, Justus-Liebig-University Giessen, Germany — [2]TransMIT-Center for Adaptive Cryotechnology and Sensors, Giessen, Germany
Closed-cycle cryocoolers have become an important tool for low temperature scientific research[1]. Here we focus on Gifford-McMahon (GM) type pulse tube coolers (PTC), which offer low maintenance and long measurement periods. In order to create a temperature difference between the cold and hot end of the cooler, Helium is periodically compressed an expanded within the cooler. In order to do so a valve - commonly a rotary valve - allows high pressure Helium to enter the cooler or to relieve the pressure within. The high and low pressure levels are supplied by a Helium compressor[2]. In order to reduce complexity and improve flexibility of the system[3], this poster will look into the operation of a two stage 4 K PTC with solenoid valves. This removes the rotary valve from the system and therefore allows for easy access and change of parameters like high- and low-pressure duration, quiet times after high- and low-pressure pulse or frequency.

TT 58.23   Thu 15:00   P2/OG3

Development of a miniaturized, modular, nuclear demagnetization stage — •Leo Maximov[1], Nico Huber[1], Andreas Bauer[1], Keiya Shirahama[2], and Christian Pfleiderer[1] — [1]Physik-Department, Technical University of Munich, D-85748 Garching, Germany — [2]Keiyo University, Hiyoshi 3-14-1, Kohoku-ku, Yokohama, Japan

Experimental studies of condensed matter systems at sub-milli Kelvin temperatures are effectively only possible by virtue of nuclear adiabatic demagnetization refrigeration (NADR). While copper is the most commonly used refrigerant for NADR, both the development and operation of copper based NADR-stages are technically demanding and limited due to the very low starting temperatures needed for demagnetization. To overcome these limitations, hyperfine-enhanced refrigerants may be used. Here, we present the design and implementation of a compact, miniaturized, modular nuclear demagnetization stage for optional use with a conventional dilution refrigerator. Comprising a superconducting aluminum heat switch, a demagnetization stage using $PrNi_5$ with a bespoke superconducting coil, and a CMN thermometer, the setup is conceived for exploratory studies in the milli-Kelvin regime and below.

TT 58.24   Thu 15:00   P2/OG3

Study of the magnetocalotic effect in $[Ni(C_4H_3O_4)_2(H_2O)_4]$ - A Potential Realization of a Spin-1 Spatially Anisotropic Square Lattice with Ferromagnetic Interactions — •Petro Danylchenko, Róbert Tarasenko, Erik Čižmár, Vladimír Tkáč, Alžbeta Orendáčová, and Martin Orendáč — Institute of Physics, Faculty of Science, Pavol Jozef Šafárik University, Park Angelinum 9, 04154 Košice, Slovakia

The magnetocaloric effect in $[Ni(C_4H_3O_4)_2(H_2O)_4]$ was investigated using specific heat and magnetization measurements in the temperature range from 0.4 K to 50 K in magnetic fields up to 7 T. A magnetic entropy change -11.2 $JK^{-1}kg^{-1}$ at a temperature of about 3.5 K is achieved for magnetic field of 7 T. The temperature dependence of the magnetic specific heat in a zero magnetic field was compared with an $S = 1$ model with single-ion anisotropy parameters D and E (axial and rhombic). The best agreement was found for the parameters $D/k_B = 7.82$ K and $E/k_B = 2.15$ K. The divergence which appears between experimental and theoretical data at non-zero magnetic fields indicates the presence of additional factors in the system such as exchange interaction between magnetic ions. Broken-symmetry DFT calculations provided the values of ferromagnetic exchange interactions, $J_1/k_B = 1.50$ K and $J_2/k_B = 1.44$ K. The presence of such ferromagnetic correlations may explain the enhanced magnetocaloric effect. *Supported by project No. APVV-18-0197.*

TT 58.25   Thu 15:00   P2/OG3

Noise thermometers for mK- **and** μK-**temperatures in high magnetic fields** — •Pascal Willer, Christian Ständer, Nathalie Probst, Andreas Reiser, Andreas Fleischmann, and Christian Enss — Kirchhoff-Institute for Physics, Heidelberg University, Im Neuenheimer Feld 227, 69120 Heidelberg, Germany.

To measure the temperature in the presence of high magnetic fields is one of the big challenges in solid state physics labs. We developed a prototype of a cross-correlated, current sensing noise thermometer for mK-temperatures for application in high magnetic fields. The basic concept relies on the thermal motion of charge carriers in a bulk metal resistor. Two DC-SQUIDs detect the corresponding noise signal which is then recorded via two identical but independent amplifier chains. The method of cross correlation is used to eliminate uncorrelated noise contributions from the amplifier chains. As resistor materials we use the alloys $Ag_{60}Cu_{40}$ as well as $Pt_{92}W_8$, the latter being characterized by an extremely small temperature dependence of the electrical resistivity as well as the smallest magneto-resistance known to date. We show that this approach towards a relative primary thermometer for high magnetic fields is able to cover the complete temperature range below 4 K. We discuss the design and the necessary considerations of both thermometers and present first experimental results at mK temperatures.

TT 58.26   Thu 15:00   P2/OG3

Variable temperature probe stick with 2D coil system — •Claudia Köhn[1], Sylke Bechstein[2], and Doreen Wernicke[3] — [1]Entropy GmbH, Abbestr. 2-12, 10587 Berlin — [2]PTB, Abbestr. 2-12, 10587 Berlin — [3]Entropy GmbH, Gmunder Str. 37a, 81379 München

Within a technology transfer cooperation with PTB, Entropy made a probe stick for characterization of superconducting devices commercially available. It is an easy to use dip stick that can be cooled down directly in the liquid helium transport vessel while providing the possibility to vary temperature and apply magnetic fields.

The stick has two temperature stages. A 4.2 K stage and one with variable temperature (vT) stage, that can be heated up to 10 K with a temperature stability of 1 mK.

The device under test at the vT stage is placed inside a 2D coil system providing up to 500 mT parallel and 100 mT perpendicular to the chip. Homogeneity is 5% within a 1.5 mm radius around the center in the chip plane. At the moment

we are optimizing the fabrication process of the coil bodies to provide better homogeneity of the magnetic field perpendicular to the chip.

TT 58.27   Thu 15:00   P2/OG3

Cryogenic scanning tunneling microscope — •Julia Besproswanny[1], Sebastian Schimmel[1], Ronny Schlegel[1], Danny Baumann[2], Bernd Büchner[2], Ralf Voigtländer[2], Dirk Lindackers[2], and Christian Hess[1] — [1]University of Wuppertal, 42119 Wuppertal, Germany — [2]IFW Dresden, 01069 Dresden, Germany

We report the construction of a compact cryogenic scanning tunneling microscope. The design will allow to study local electronic structures at temperatures down to 2.5 K and magnetic fields of up to 15 T with atomic resolution in real space and a high energy resolution of 2 meV at 6 K. The microscope has a scanning range of 1μm x 1μm and a built-in cleaving mechanism that renders it possible to cleave the samples at a cryogenic temperature. Samples can be exchanged within a day while the measurement time can reach up to 6 weeks. These qualities combined with its compact and portable design make this STM a comfortable tool to study low temperature phenomena, e.g. superconductivity.

TT 58.28   Thu 15:00   P2/OG3

Cyclotron resonance on germanium probed by coplanar microwave resonators — •Anastasia Bauernfeind, Frederik Bolle, Martin Dressel, and Marc Scheffler — 1. Physikalisches Institut, University of Stuttgart, Stuttgart, Germany

Cyclotron resonance is a powerful way to investigate the Fermi surface of various materials. In our research we performed cyclotron resonance experiments on the semiconductor germanium by using metallic coplanar waveguides (CPW). In comparison to conventional three-dimensional cavity resonators, CPW resonators have the advantage of multiple well-accessible resonances. Furthermore, CPWs open the possibility of implementation in a dilution refrigerator, which makes the performance down to the mK regime possible, which is also interesting for Kondo insulators. By using a superconducting magnet (up to 8T) and the access to a broad frequency range in the microwave regime (up to 25 GHz), we were able to investigate the cyclotron resonance in germanium in detail. Here we analysed the frequency-, temperature- (2-40K) and power dependence of the cyclotron resonance signal. Beside the investigation of the electronic bands, we present interesting phenomena like the generation of charge carriers by the power of the microwave electric field and the process of impact ionization in p-doped germanium.

TT 58.29   Thu 15:00   P2/OG3

Sample environment communication protocol (SECoP) — •Klaus Kiefer[1], Georg Brandl[2], Niklas Ekström[3], Enrico Faulhaber[4], Thomas Herrmannsdörfer[5], Bastian Klemke[1], Thorsten Kracht[6], Anders Pettersson[3], Lutz Rossa[1], and Markus Zolliker[7] — [1]HZB, Berlin — [2]FZJ, Garching — [3]ESS, Lund — [4]TUM, Garching — [5]HZDR, Dresden — [6]DESY, Hamburg — [7]PSI, Villigen

We would like to present the Sample Environment Communication Protocol (SECoP), a software and initiative that addresses the standardization of communication between instrument-control software, sample-environment equipment (SE), and acquisition of metadata. The International Society for Sample Environment (ISSE) has developed SECoP in order to support a wide research community by tackling the challenges of data acquisition in daily laboratory routine, ([1] and references therein). Using SECoP as a common standard for controlling SE equipment will save resources and intrinsically give the opportunity to supply standardized and FAIR-data compliant SE metadata. It will also supply a well-defined interface for user-provided SE equipment, e.g. shared by different research facilities and of industry. In this poster presentation we will give an overview of the present status of SECoP and the developments within the SECoP@HMC project supported by the Helmholtz Metadata Collaboration. We would also like to advertize the SECoP booth at the exhibition of this conference, a possibility to get a first practical experience with SECoP.

Lab::Measurement – measurement control with Perl 5 — Mia Schambeck, Erik Fabrizzi, Simon Reinhardt, and •Andreas K. Hüttel — Institute for Experimental and Applied Physics, Universität Regensburg, Regensburg, Germany

`Lab::Measurement` is a collection of object-oriented Perl 5 modules for control of test and measurement devices. It allows for quickly setting up complex tasks with diverse hardware. Instruments can be connected via GPIB (IEEE 488.2), USB, or VXI-11 / raw network sockets on Ethernet. Internally, third-party backends as, e.g., Linux-GPIB, the NI-VISA library, or Zurich Instruments' LabOne API are used, in addition to lightweight drivers for USB and TCP/IP-based protocols. This enables cross-platform portability of measurement scripts between Linux and Windows machines. Based on roles within `Moose` that provide communication standards such as SCPI, dedicated instrument driver classes take care of internal details. A high-level sweep layer allows for fast and flexible creation

of nested measurement loops, where, e.g., several input variables are varied and data is logged into a customizable folder structure. Sweeps can also be retrieved directly from an instrument as, e.g., a spectrum or network analyzer. Further features include live plotting and obtaining attested timestamps for measurement data. Recent enhancements focus on support for the Nanonis Tramea quantum measurement system and for fast measurements using arbitrary waveform generators as voltage sources. `Lab::Measurement` is free software and available at `https://www.labmeasurement.de/`

Modeling a vibrating carbon nanotube Josephson junction — •Andreas K. Hüttel[1,2], Keijo Korhonen[2], and Pertti Hakonen[2] — [1]Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Low Temperature Laboratory, Department of Applied Physics, Aalto University, P.O. Box 15100, 00076 Aalto, Finland

A carbon nanotube suspended between superconducting electrodes acts simultaneously as nanomechanical resonator and as a Josephson junction. Its energy-dependent density of states and with that position-dependent critical current further adds to the complexity of the system, as does both mechanical and electronic nonlinearity.

Using parallelized Julia code[1], we numerically solve the coupled differential equation system of the driven (via an ac gate voltage and/or ac current or voltage bias) system for realistic device parameters and characterize the evolving steady state. Specific attention is given to the impact of the Josephson junction behaviour on the mechanical resonance frequency and the vibration amplitude, and on the impact of the carbon nanotube motion on the phase evolution of the junction. Density-dependence of surface transport in tellurium-enriched nanograined bulk Bi_2Te_3 — •Sepideh Izadi[1], Ahana Bhattacharya[2], Sarah Salloum[3], Stephan Schulz[3], Martin Mittendorff[2], and Gabi Schierning[1] — [1]Bielefeld University, Department of Physics, 33615 Bielefeld, Germany — [2]University of Duisburg-Essen, Department of Physics, 47057 Duisburg, Germany — [3]University of Duisburg-Essen, Department of Chemistry, 45141 Essen, Germany

Three-dimensional topological insulators (3D TI) demonstrate conventional parabolic bulk bands together with protected Dirac surface states. Bi_2Te_3 material is considered as a well-known 3D TI model, however, due to its complicated defect chemistry, high number of charge carriers in the bulk dominate transport signal, even as nanograined structures. Herein we introduce Te-enriched Bi_2Te_3 nanoparticles synthesis as a method to control the bulk charge carrier density. Therewith, defects-free and stoichiometric Bi_2Te_3 nanoparticles with sizes between 4 and 40 nm are synthesized using ionic-liquid based approach. Grain boundaries along Bi_2Te_3 facets are investigated using high resolution transmission electron microscopy (HRTEM). The resulting nanoparticles were compacted into nanograined pellets of varying porosity, thereby emphasizing the surface transport contribution. The nanograined pellets were characterized by a combination of electrical transport together with THz time-domain reflectivity measurements. Using the Hikami-Larkin-Nagaoka (HLN) model, a characteristic coherence length of　200 nm that is considerably larger than nanograins diameter is reported.

Topological phases in $TaRhTe_4$: from monolayer to bulk — •Xiao Zhang — Leibniz Institute for Solid State and Material Research, Dresden, Germany

Topological phases are studied in different dimensional $TaRhTe_4$ using the method of density functional theory (DFT). We find that bulk $TaRhTe_4$ is a Weyl semimetal, whereas both monolayer and bilayer $TaRhTe_4$ display features of quantum spin Hall (QSH) insulator. A complete phase diagram linking monolayer, bilayer, and bulk $TaRhTe_4$ is obtained by varying intra- and interbilayer distance of the three-dimensional structure. It contains phases of Weyl semimetal, weak topological insulator, and normal insulator.

TT 59.3　Thu 15:00　P2/OG4

Quantum transport through resonant Dirac states in topological insulator nanowire constrictions — •Michael Barth[1], Maximilian Fürst[1], Cosimo Gorini[2], and Klaus Richter[1] — [1]Institute of Theoretical Physics, University of Regensburg, D-93040 Regensburg, Germany — [2]Université Paris-Saclay, CEA, CNRS, SPEC, 91191, Gif-sur-Yvette, France

Quantum transport in topological insulator (TI) nanowires is expected to be mediated by surface states which wrap phase coherently around the circumference [1]. The spectrum corresponds to a quantized and gapped Dirac cone, where the gap is present because of a Berry phase of π which arises due to spin-momentum locking. In this work, we numerically study transport in TI constrictions which are subjected to an axial magnetic field. More specifically, we consider a realistic junction of a narrow TI wire which is smoothly connected at its two ends to broad TI leads and calculate the transmission through the setup with respect to the Fermi energy and the magnetic field. The latter is tuned to close the Berry gap [2]. It turns out, that perpendicular field components in the constriction lead to the formation of magnetic barriers which result in resonant Dirac states. The proposed system can be used to spectroscopically study the Dirac spectrum with respect to its gate and flux dependence. Moreover, different transport regimes are identified, which depend on the length of the central wire segment.

Topological insulator as barrier in Josephson junction — •Anton Montag, Alexander Ziesen, and Fabian Hassler — RWTH Aachen University, Aachen, Germany

We numerically study the behavior of a long Josephson junction in a superconductor-topological insulator-superconductor setup. An *s*-wave superconductor is deposited on the disordered surface of a three-dimensional topological insulator proximitizing the surface states on both sides of the junction. The normal region is probed by a local tunnelling contact. We simulate the tunnel spectrum at energies below the bulk gap of the topological insulator as a function of the phase difference of the superconducting order parameter across the junction. The low-energy spectrum can be divided into trivial Andreev bound states usually appearing at higher energies and chiral edge modes which become gapless at a phase difference of π. Since the latter are topologically protected, they are essentially not affected by symmetry preserving onsite potential disorder on the topological insulator surface. We show the simulated tunnel spectra for various disorder configurations and compare it to analytical calculations.

TT 59.5　Thu 15:00　P2/OG4

Towards the quantum anomalous Hall effect in magnetic topological insulator structures — •Justus Teller[1,2], Erik Zimmermann[1,2], Micheal Schleenvoigt[1,2], Gerrit Behner[1,2], Kristof Moors[1,2], Peter Schüffelgen[1,2], Gregor Mussler[1,2], Detlev Grützmacher[1,2], and Thomas Schäpers[1,2] — [1]Peter Grünberg Institut (PGI-9), Forschungszentrum Jülich, D-52425 Jülich, Germany — [2]JARA-Fundamentals of Future Information Technology, Jülich-Aachen Research Alliance, Forschungszentrum Jülich and RWTH Aachen University, Germany

Three-dimensional topological insulators (TIs) are a material class which may enable robust topological quantum computing by using so-called Majorana zero modes. Published theoretical work predicts the Majorana state to exist in hybrid structures of superconductors and magnetic topological insulators which exhibit the quantum anomalous Hall effect (QAHE). We present magnetotransport measurements of Cr-doped magnetic $(Bi_{0.27}Sb_{0.73})_2Te_3$ layers. At 1.2 K, the uniformly Cr-doped samples exhibit a magnetic signature whose behaviour is probed under gate influence. Based on these measurements, an existing QAHE is ruled out. The results are compared to a magnetic TI heterostructure which is comprised of a plain TI layer embedded into two layers of magnetic TI. This structure reveals the QAHE. The temperature dependence of the effect is measured. In addition, the magnetic energy gap is probed by a gate dependent measurement. The QAHE is improved by current adjustment.

TT 59.6　Thu 15:00　P2/OG4

Axial topological insulator based DC SQUID in external SQUID layout — •Jan Karthein[1,3], Erik Zimmermann[1,3], Max Vassen Carl[1,3], Gerrit Behner[1,3], Abdur Rehman Jalil[1,3], Gregor Mussler[1,3], Peter Schüffelgen[1,3], Hans Lüth[1,3], Detlev Grützmacher[1,2,3], and Thomas Schäpers[1,3] — [1]Peter Grünberg Institut (PGI-9), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Peter Grünberg Institut (PGI-10), Forschungszentrum Jülich, 52425 Jülich, Germany — [3]JARA-Fundamentals of Future Information Technology, Jülich-Aachen Research Alliance, Forschungszentrum Jülich and RWTH Aachen University, 52425 Jülich, Germany

A three-dimensional topological insulator (TI) nanowire proximitized with a superconductor is predicted to be host to Majorana bound states that provide a platform for fault-tolerant quantum computation. Recently, axial TI-nanowire based DC SQUIDs showed coherent oscillations originating from the interference of topological surface states. We fabricate an axial TI-nanowire based DC SQUID with a neighboring Josephson junction completely in-situ, using selective-area growth and shadow mask fabrication techniques. An out-of-plane magnetic field is able to tune the flux inside the so formed external SQUID loop, while being decoupled from the in-plane magnetic field that tunes the flux inside the TI-nanowire. Coherent SQUID oscillations are visible when sweeping both the out-of-plane and in-plane magnetic field, proving that the axial TI-nanowire based DC SQUID and the external DC SQUID are experiencing phase-coherent transport.

TT 59.7   Thu 15:00   P2/OG4

Controlling the real-time dynamics of a spin coupled to the helical edge states of the Kane-Mele model — •Robin Quade[1] and Michael Potthoff[1,2] — [1]I. Institute of Theoretical Physics, Department of Physics, University of Hamburg, Notkestraße 9-11, 22607 Hamburg, Germany — [2]The Hamburg Centre for Ultrafast Imaging, Luruper Chaussee 149, 22761 Hamburg, Germany

The time-dependent state of a classical spin locally exchange coupled to an edge site of a Kane-Mele model in the topologically non-trivial phase is studied numerically by solving the full set of coupled microscopic equations of motion for the spin and the electron system. Dynamics in the long-time limit is accessible thanks to dissipative boundary conditions, applied to all but the zigzag edge of interest. We study means to control the state of the spin via transport of a spin-polarization cloud through the helical edge states. The cloud is formed at a distant edge site using a local magnetic field to inject an electron spin density and released by suddenly switching off the injection field. This basic process, consisting of spin injection, propagation of the spin-polarization cloud, and scattering of the cloud from the classical spin, can be used to steer the spin state in a controlled way. We find that the effect of a single basic process can be reverted to a high degree with a subsequent process. Furthermore, we show that by concatenating several basic injection-propagation-scattering processes, the spin state can be switched completely and that a full reversal can be achieved.

TT 59.8   Thu 15:00   P2/OG4

Fermi-surface investigation of CaCdGe and CaCdSn — •B.V. Schwarze[1,2], F. Husstedt[1,2], M. Uhlarz[1], D. Kaczorowski[3], and J. Wosnitza[1,2] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL) and Würzburg-Dresden Cluster of Excellence-ct.qmat, HZDR, Germany — [2]Institut für Festkörper- und Materialphysik, TU Dresden, Germany — [3]Institute of Low Temperature and Structure Research, Polish Academy of Sciences, Poland

CaCdSn and CaCdGe are nodal-line semimetal candidate materials. These materials have one-dimensional lines or loops of topologically protected band-touching nodes. They sparked interest, due to their unique response to high magnetic or electric fields, including giant linear magnetoresistance and high charge-carrier mobility. These properties make them candidates for future technological applications. Band-structure calculations [1, 2] show for both systems non-topological and topological valence bands with the nodal band crossings above the Fermi level. Previous measurements of the magnetoresistance provide some support for the topological nature of the materials. Here, we present our investigation of the Fermi surfaces of CaCdSn and CaCdGe by use of de Haas-van Alphen measurements and band-structure calculations. Our measurements reveal many quantum-oscillation frequencies, which are not predicted by calculations. This discrepancy calls the calculated band structures [1, 2] and, thus, the precise nature of the topology of these systems into question.

TT 59.9   Thu 15:00   P2/OG4

Ultrasound propagation in candidate material for electron hydrodynamics, Weyl semimetal WTe_2 — •Rafal Wawrzynczak[1], Stanislav Galeski[1,2], and Johannes Gooth[1,2] — [1]Max Planck Institute for Chemical Physics of Solids, Nöthnitzer Straße 40, 01187 Dresden, Germany — [2]Physikalisches Institut, Universität Bonn, Nussallee 12, D-53115 Bonn, Germany

Interactions between electrons might lead to the appearance of a regime where the dominating time-scale is defined by momentum-conserving processes. This is manifested by electron liquid exhibiting features characteristic for classical liquids, like Poiseuille flow, resulting in non-Ohmic, sample-width-dependent resistivity. This was recently observed in a two-dimensional metal $PdCoO_2$ and two Weyl semimetals. Neither of the observations was accounted for with complete microscopic description. For WTe_2 there was proposed a mechanism based on the electron-electron scattering process involving a virtual phonon.

Here we report results of ultrasound propagation study performed on WTe_2 Weyl semimetal. We have analyzed temperature and field dependence of propagation of longitudinal and two transverse modes of different polarization propagating along the a crystallographic directions. The data shows anomalous decrease in speed of the longitudinal mode below 10 K and non-monotonous T-

dependence of its attenuation. Moreover, quantum oscillations observed in all six measured quantities reveal the details of coupling between measured phonon modes and different parts of systems Fermi surface.

TT 59.10   Thu 15:00   P2/OG4

Photo-thermal imaging of $ZrTe_5$ in the quasi-quantized Hall regime — •Erica Warth Pérez Arias[1], Rafal Wawrzyńczak[1], Stanislaw Galeski[1], Johannes Gooth[2], Claudia Felser[1], and Fabian Menges[1] — [1]Max Planck Institute for Chemical Physics of Solids, Germany — [2]University of Bonn, Germany

$ZrTe_5$ has recently gained attention due to various intriguing experimental observations including the chiral magnetic effect [1] and the quasi-quantized 3D quantum Hall effect [2]. However, it remains challenging to probe the characteristic features of gapless surface and edge states experimentally. Addressing this challenge, we devised an optoelectronic detection scheme based on cryogenic magneto-optical laser scanning microscopy. The technique relies on a global electrical read-out of locally-induced currents, and contrasts previous all-optical studies of photogalvanic effects. We characterized $ZrTe_5$ single crystals with this approach and visualized rich spatial patterns of photo-induced transport as function of temperature and magnetic field. Remarkably, current maps obtained in the quasi-quantized Hall regime display long-range photoresponse over mm-distances and oscillations in magnetic field, hinting towards charge movement of ambient carriers in the system [3] driven by the photo-thermal effect [4] and the external magnetic field.

Anomalous transverse transport and phase transitions in Weyl semimetals RAlSi (R = La, Ce) — •erjian cheng — Leibniz Institute for Solid State and Materials Research (IFW-Dresden), 01069 Dresden, Germany

The noncentrosymmetric RAlPn (R = rare earth elements, Pn = Si or Ge) with the space-inversion (SI) symmetry breaking and/or the time-reversal (TR) symmetry breaking host multiple types of Weyl fermions, providing a fertile platform for the exploration of novel topological matter states. In particular, when magnetic configuration couples with the electronic wavefunctions, exotic anomalous transverse transport phenomena emerge. Here, by resorting to electrical and thermoelectrical transport, we systematically studied the ferromagnetic CeAlSi and its nonmagnetic analog LaAlSi, revealing the anomalous Hall effect (AHE) and/or anomalous Nernst effect (ANE). In addition, for LaAlSi, quantum oscillations reveal five frequencies. Moreover, a temperature-induced Lifshitz transition is unveiled in LaAlSi. For CeAlSi, magnetism enhances the anomalous transverse transport, implying that magnetism tunes the positions of Weyl nodes. Besides, high-pressure electrical transport and X-ray diffraction (XRD) measurements were also implemented, demonstrating multiple phase transitions. These results indicate that LaAlSi and CeAlSi provide unique and tunable systems to explore exotic topological physics, and a potential paradise for an array of promising applications for spintronics.

TT 59.12   Thu 15:00   P2/OG4

Electronic structure of topological superconductor candidate Li_2Pd_3B — •Gabriele Domaine[1], Jonas A. Krieger[1], Wei Yao[1], Changjiang Yi[2], Claudia Felser[2], Stuart S. P. Parkin[1], and Niels B. M. Schröter[1] — [1]Max Planck Institute for Microstructure Physics, Halle, Germany — [2]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

Chiral crystals are known to host a number of exotic quasiparticles which carry large Chern numbers and, as they are unconstrained from the celebrated spin statistics connection, can exhibit a range of unconventional (effective) spins [1]. These include, for instance, spin 3/2 Rarita-Schwinger, Kramers-Weyl, spin-1 and multifold fermions, which can be considered a generalization of conventional Weyl-fermions [2]. Here we present our preliminary results for the first Angle-Resolved Photoemission Spectroscopy (ARPES) measurements of the chiral crystal Li_2Pd_3B which is expected to host an as-yet unobserved multifold topological superconducting phase of class DIII, which is time reversal invariant), even without odd parity paring [3]. The superconducting gap is expected to arise from the intraband coupling at time-reversal invariant momentum points leading to an unconventional multiband gap function and nodal rings [4].

TT 59.13   Thu 15:00   P2/OG4

Implementing superconductor/skyrmion-host heterostructures using exfoliated Fe_3GeTe_2 on NbN — •Maximilian Daschner[1,2], Thomas Reindl[2], Marion Hagel[2], Jürgen Weis[2], and Malte Grosche[1] — [1]Cavendish Laboratory, University of Cambridge, UK — [2]Max-Planck Institute for Solid State Research, Stuttgart, Germany

Experimental coupling of chiral magnetism and superconductivity through the proximity effect is a challenging and unexplored field that can lead to novel physics. Chiral magnets host topological excitations known as skyrmions that, when coupled to the vortices in a superconductor, are predicted to form Majorana fermions at its boundaries and vortex cores. The van-der-Waals material Fe_3GeTe_2 is known to host a skyrmion state over temperature and field ranges that depend on the sample thickness. We have exfoliated flakes of Fe_3GeTe_2 from a high quality crystal grown by vapour transport, deposited them on a NbN film and patterned electrical contacts using standard e-beam lithography techniques. The resulting Hall bar shaped nanodevices provide a convenient system for investigating skyrmion/superconductor interactions: Hall measurements above the superconducting transition temperature T_c3 in combination with magnetic force measurements survey the skyrmion state as a function of applied field, and measurements of the critical current density below T_c3 probe skyrmion-assisted vortex nucleation and pinning.

TT 59.14   Thu 15:00   P2/OG4

Pressure-dependent structural instabilities and transport phenomena in candidate topological semimetal $LaSb_2$ — •Theodore Weinberger, Christian de Podesta, Jiasheng Chen, Stephen Hodgson, and Malte Grosche — Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, United Kingdom

At low temperatures, and in the presence of large magnetic fields, $LaSb_2$ exhibits large, linear, non-saturating magnetoresistance, defying Fermi liquid behaviour. This phenomenon is thought to be caused by the onset of charge density wave order (CDW) below a sharp, hysteretic anomaly seen in resistivity data at ~ 355 K. This anomaly is rapidly pushed to lower temperatures under applied hydrostatic pressure, where above 6 kbar, it is fully suppressed. Surprisingly, the anomalous magnetoresistance persists to pressures beyond 20 kbar even after the suppression of the resistive anomaly. Hence, we suggest that the magnetoresistance is not driven by the onset of CDW order. Instead, we propose that the high temperature anomaly corresponds to a structural transition, similar to that seen in $CeSb_2$, which is supported by *ab initio* density functional theory calculations. Further, these calculations indicate that the Fermi surface of LaSb2 contains small pockets in both its high and low pressure structures. Small Fermi surface pockets suggest that $LaSb_2$'s band structure might feature topological, Dirac-like, cones which may explain the observed large, linear magnetoresistance.

TT 59.15   Thu 15:00   P2/OG4

2π domain walls for tunable Majorana devices — •Daniel Hauck[1], Stefan Rex[2,3], and Markus Garst[1] — [1]Karlsruhe Institute of Technology, Institute for Theoretical Solid State Physics, Wolfgang-Gaede-Str. 1, 76131 Karlsruhe — [2]Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76021 Karlsruhe, Germany — [3]Institute for Theoretical Condensed Matter Physics, Karlsruhe Institute of Technology, 76131 Karlsruhe

Superconductor-magnet hybrid structures provide a platform for investigating topological phases with localized Majorana states. Such states have previously been predicted for elongated Skyrmions in the magnetic layer. Here we consider 2π domain walls that can be easily controlled experimentally. Depending on the boundary conditions, we demonstrate that localized Majorana states can be found at both ends of such walls. This establishes 2π domain walls as tunable elements for the realization of Majorana devices.

TT 59.16   Thu 15:00   P2/OG4

DMRG simulations of the one-dimensional anyon Hubbard model — •Yannick Werner, Maximilian Kiefer-Emmanouilidis, Pascal Jung, and Sebastian Eggert — Department of Physics, Technical University of Kaiserslautern, 67663 Kaiserslautern, Germany

The recent detection of anyons in setups of ultra-cold gases has further encouraged the in-depth studies of anyonic systems. Although the existence of conventional anyons is limited to two dimensions, a realization of fractional exchange statistics in a 1D system is possible which leads to a continuous interpolation between bosons and (pseudo-)fermions. In this poster we present the effects of perturbations i.e. local impurities, in a one-dimensional anyonic Hubbard model with onsite and nearest neighbor interactions on local densities, correlation functions and density transport. Here anyonic statistics are fulfilled by mapping bosonic operators via Jordan-Wigner-transformation, leading to a density dependent Peierl's phase in the hopping term. Additionally, in the case of small filling rates, we compute and analyze numerically the Luttinger parameter via Density Matrix Renormalization Group methods and compare it with analytical results.

TT 59.17   Thu 15:00   P2/OG4

Dynamical structure factor of an anyonic Luttinger liquid — •Pascal Jung, Martin Bonkhoff, Yannick Werner, and Sebastian Eggert — Department of Physics and Research Center Optimas, Technical University of Kaiserslautern, 67663 Kaiserslautern, Germany

Luttinger liquids are a powerful tool to describe the low-energy excitations of bosonic and fermionic systems in one spatial dimension. Anyonic systems, which allow a continuous transition between those two fundamental types of statistics, can be included in this framework by an additional coupling of the current and density excitations. This results into different velocities for the left and right movers, breaking the spatio-temporal symmetries.

To study the effects of this symmetry breaking on experimentally verifiable quantities, characteristic correlation functions are calculated. Using these, the dynamical structure factor for a finite system is determined. The broken symmetry leads here to a characteristic imbalance between left and right movers with typical power laws. Furthermore, the impact of local impurities is investigated using the perturbative renormalization group. These results are compared to numerical simulations obtained by the DMRG algorithm.

TT 59.18   Thu 15:00   P2/OG4

Quantum spin dynamics in the spin-chain compound Cu_2OH_3Br — •Anneke Reinold[1], Kirill Amelin[2], Zhiying Zhao[3], Changqing Zhu[1], Patrick Pilch[1], Hans Engelkamp[4], Toomas Rõõm[2], Urmas Nagel[2], and Zhe Wang[1] — [1]TU Dortmund University, Germany — [2]National Institute of Chemical Physics and Biophysics, Tallinn, Estonia — [3]Fujian Institute of Research on the Structure of Matter, Chinese Academy of Sciences, Fuzhou, China — [4]Radboud University, Nijmegen, The Netherlands

In low-dimensional quantum magnets, exotic spin phenomena can emerge due to strong spin fluctuations. Here we investigate spin dynamics of the quantum spin-chain compound Cu_2OH_3Br by high-resolution terahertz spectroscopy as a function of temperature and in high magnetic fields. Below the Néel temperature $T_N=9.3$ K, this compound exhibits a unique magnetic structure consisting of alternating ferromagnetic and antiferromagnetic spin-1/2-chains of Cu^{2+}-ions [1,2]. In this ordered phase we observed magnetic excitations, which are characteristic for this unique spin structure and consistent with results of inelastic neutron scattering [2]. Moreover, we are able to track these spin excitations in applied magnetic fields crossing field-induced phase transitions [1].

Spin-texture topology in curved circuits driven by spin-orbit interactions — Alberto Hijano[1,2], Eusebio J. Rodríguez[3], •Dario Bercioux[4,5], and Diego Frustaglia[3] — [1]Centro de Física de Materiales (CFM-MPC) Centro Mixto CSIC-UPV/EHU, E-20018 Donostia-San Sebastián, Spain — [2]Department of Condensed Matter Physics, University of the Basque Country UPV/EHU, 48080 Bilbao, Spain — [3]Departamento de Física Aplicada II, Universidad de Sevilla, E-41012 Sevilla, Spain — [4]Donostia International Physics Center (DIPC), 20018 Donostia–San Sebastián, Spain — [5]IKERBASQUE, Basque Foundation for Science, Plaza Euskadi 548009 Bilbao, Spain

We study the response of spin carriers to the effective field textures developed in curved one-dimensional circuits subject to the joint action of Rashba and Dresselhaus spin-orbit interactions. By using a quantum network technique, we establish that the interplay between these two non-Abelian fields and the circuit's geometry modify the geometrical characteristics of the spinors, particularly on square circuits, leading to the localisation of the electronic wave function and the suppression of the quantum conductance. We propose a topological interpretation by classifying the corresponding spin textures in terms of winding numbers.

Stochastic resonance of electron tunneling in a quantum dot in spite of a periodically blind eye — •Eric Kleinherbers, Hendrik Mannel, Johann Zöllner, Marcel Zöllner, Martin Geller, Axel Lorke, and Jürgen König — Faculty of Physics and CENIDE, University Duisburg-Essen, 47057 Duisburg, Germany

The key idea of stochastic resonance is to amplify a signal by adding noise. For electron tunneling in a quantum dot, this can be used to facilitate a periodic elec-

tron transfer, where during each period a single electron enters and leaves the quantum dot. In stochastic resonance, the noise (tunneling) rate must be well adjusted to the frequency of the periodic drive that is applied to the quantum dot. The Fano factor is a possible indicator of this effect [1]. Here, we study the full counting statistics and, in particular, factorial cumulants as higher-order indicators of stochastic resonance. We discuss experimental data of electron tunneling into and out of a self-assembled InAs quantum dot, where the full counting statistics is measured using a resonance fluorescence readout scheme. We find that even if the detector is blind during half of each period, a stochastic resonance is visible in the full counting statistics.

Modifications of the local dissipation profile imposed by quantum point contacts — •Nico Leumer — Université de Strasbourg, CNRS, IPCMS, UMR 7504, F-67000 Strasbourg, France

Recent experimental progress provides access to local temperature changes on the nanoscale, three orders of magnitude lower than the sample temperature itself [1]. Since electric current is accompanied by an energy loss of the charge carriers, this advance implies that the dissipated power became in fact a local observable. The key role is adopted by electron-phonon interactions transferring the electronic energy loss to the bulk material and thus; stimulating the sample temperature profile.

Quantum point contacts (QPC) have been reported to modify the dissipation and, especially, the energy loss of charge carriers may be distributed asymmetrically around the QPC. Inspired by this feature, we develop a theory to determine why, where and how much dissipation occurs in experimental relevant geometries.

Resonant tunneling energy harvesters: Improving performance via quantum interference. — •José Balduque[1] and Rafael Sánchez[1,2] — [1]Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, Madrid, Spain. — [2]Condensed Matter Physics Center (IFIMAC), and Instituto Nicolás Cabrera, Universidad Autónoma de Madrid, Madrid, Spain.

The spectral filtering of quantum dots can be used for heat to power conversion in electronic conductors. A proposal based on resonant-tunneling three-terminal devices [1] has been recently verified experimentally [2]. Two quantum dots connect the two terminals of a conductor to a hot electronic cavity where carriers exchange heat via thermalization. We propose the heat source to be separated from the conductor via a beam-splitter (e.g., the tip of a scanning microscope) that mediates the system-bath coupling. The resulting ballistic electron propagation gives rise to interferences [3] able to improve the engine performance, both in the extracted power and efficiency [4].

Vibrational instabilities arising from non-conservative current-induced forces in nanosystems: A comparison of quantum and semi-classical approaches — •Samuel Rudge, Christoph Kaspar, and Michael Thoss — Institute of Physics, University of Freiburg, Germany

Understanding the vibrational dynamics of molecular junctions is of paramount importance to creating junctions that are mechanically stable. In systems with more than one vibrational degree of freedom, instabilities can arise due to non-conservative current-induced forces, an effect that can occur at lower voltages than the well-understood mechanism of current-induced heating [1].

In recent years, such non-conservative forces have been largely explored with semi-classical Langevin-type equations for the vibrational degrees of freedom, where the electronic friction tensor and average electronic force can be analyzed directly [1]. In this work, however, we employ both a semi-classical Langevin equation as well as a quantum master equation approach to explore instabilities in a model system with two electronic levels and two vibrational modes. Both approaches derive from the numerically exact hierarchical equations of motion (HEOM) method [2], and the resulting analysis is able to show in which regimes such semi-classical treatments can be used.

Asymmetric couplings of quantum dot systems to environments — •Lukas Litzba, Nikodem Szpak, Eric Kleinherbers, and Jürgen König — Fakultät für Physik, Universität Duisburg-Essen, Lotharstraße 1, 47057 Duisburg, Germany

We study systems with a few quantum dots, represented by the Fermi-Hubbard model, coupled to several Markovian baths with different coupling strengths. On the one hand, we compare different approximations (such as Redfield equation, coherent Lindblad approximation [1]) for a Master equation in first order of the quantum dot–bath coupling for strongly interacting electrons. On the other hand, we find exact solutions for non-interacting electrons. We compare the results for different coupling strength regimes and discuss the qualitative changes in the system behavior. Thereby we observe significant effects of the coupling asymmetry on energy coherences, which is linked to local versus global coupling. We look closer at systems from two to ten dots and study the non-equilibrium dynamics based on dressed excitation energies of the system as well as the associated damping rates. In this context we find transitions from global to local coupling behavior with increasing coupling strength asymmetry.

TT 60.7   Thu 18:45   HSZ 03

Relaxation dynamics in Fermi-Hubbard systems coupled to environment — •Nikodem Szpak[1], Gernot Schaller[2], Ralf Schützhold[2,3], and Jürgen König[1] — [1]Theoretische Physik und CENIDE, Universität Duisburg-Essen, Lotharstr. 21, 47048 Duisburg — [2]Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, 01328 Dresden — [3]Institut für Theoretis- che Physik, Technische Universität Dresden, 01062 Dresden

We study a chain of quantum dots coupled to enviroment and describe it with the Fermi-Hubbard model coupled to fermionic baths. For different coupling regimes (interdot vs bath-dot) we derive separate Lindblad master equations and compare their properties. It is shown that for strong repulsive onsite (Coulomb) interactions and low bath temperatures the system quickly reaches a low-energy sector described effectively by the Heisenberg model. Within this sector the further dynamics depends strongly on the relative coupling strengths. For weak bath-dot coupling, the system relaxes globally to the unique anti-ferromagnetic ground state with zero total spin. For strong bath-dot coupling, the system increases its total spin to the maximal possible value and ends up in (degenerate) states exhibiting ferromagnetic order. We provide rigorous derivations as well as numerical examples.

TT 61: Focus Session: Correlations in Moiré Quantum Matter II

Time: Thursday 17:45–19:00   Location: HSZ 201

TT 61.1   Thu 17:45   HSZ 201

Magnetism and metallicity in Moiré transition metal dichalcogenides — •Patrick Tscheppe[1], Jiawei Zang[2], Marcel Klett[1], Seher Karakuzu[3], Thomas Maier[4], Michel Ferrero[5,6], Andrew Millis[2,3], and Thomas Schäfer[1] — [1]Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany — [2]Department of Physics, Columbia University, 538 West 120th Street, New York, New York 10027, USA — [3]Center for Computational Quantum Physics, Flatiron Institute, 162 5th Avenue, New York, New York 10010, USA — [4]Computational Sciences and Engineering Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831-6164, USA — [5]CPHT, CNRS, Ecole Polytechnique, Institut Polytechnique de Paris, Route de Saclay, 91128 Palaiseau, France — [6]Collège de France, 11 place Marcelin Berthelot, 75005 Paris, France

The Moiré transition metal dichalcogenide homobilayer WSe_2 has recently been observed both to undergo continuous Mott transitions and to display quantum critical behavior, while also allowing for high tunability of its electronic parameters. At the same time, the effective low-energy physics of WSe_2 is believed to be adequately described by a simple one-band Hubbard model. We study the rich interplay between perfect nesting and dynamical as well as non-local correlations in this model using the cellular dynamical mean-field theory (CDMFT) in conjunction with the dynamical cluster approximation (DCA). In this way we elucidate the nature of both interaction and magnetic field-driven metal-insulator crossovers, previously observed in experiments.

TT 61.2   Thu 18:00   HSZ 201

Switching between Mott-Hubbard and Hund physics in Moiré quantum simulators — •Siheon Ryee and Tim Wehling — I. Institute of Theoretical Physics, University of Hamburg, Hamburg, Germany

Mott-Hubbard and Hund electron correlations have been realized thus far in separate classes of materials. In this talk, we show that a single Moiré homobi-

layer encompasses both kinds of physics in a controllable manner. We develop a microscopic multiband model which we solve by dynamical mean-field theory to nonperturbatively address the local many-body correlations. We demonstrate how tuning with twist angle, dielectric screening, and hole density allows to switch between Mott-Hubbard and Hund correlated states in twisted WSe_2 bilayer. The underlying mechanism bases on controlling Coulomb-interaction-driven orbital polarization and energetics of concomitant local singlet and triplet spin configurations. From comparison to recent experimental transport data, we find signatures of a filling-controlled transition from a triplet charge-transfer insulator to a Hund-Mott metal. Our finding establishes twisted transition metal dichalcogenides as a tunable platform for exotic phases of quantum matter emerging from large local spin moments.

TT 61.3　Thu 18:15　HSZ 201

Tunable topological order of pseudo spins in semiconductor heterostructures — Clemens Kuhlenkamp[1,2,3], •Wilhelm Kadow[1,2], Atac Imamoglu[3], and Michael Knap[1,2] — [1]Department of Physics, Technical University of Munich, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, D-80799 München, Germany — [3]Institute for Quantum Electronics, ETH Zürich, CH-8093 Zürich, Switzerland

We propose a novel platform to realize highly-tunable, frustrated Hubbard physics with topological order in multi-layer Moiré structures. Identifying a layer degree of freedom as a pseudo spin, allows us to retain SU(2) symmetry, while controlling ring exchange processes and concurrently quenching the kinetic energy by large external magnetic fields. This way, a broad class of interacting Hofstadter states and their transitions can be studied. Remarkably, in the limit of strong interactions the system becomes Mott insulating and we find exceptionally stable spin liquid phases which are induced by the magnetic field. As the magnetic flux can be easily tuned in Moiré systems, our approach provides a promising route towards the experimental realization and control of topologically ordered phases of matter. We also discuss how layer pseudo-spin can be probed in near-term experiments.

TT 61.4　Thu 18:30　HSZ 201

Nontrivial quantum geometry of multiband systems and implications for flat bands — •Johannes Mitscherling — Department of Physics, University of California, Berkeley, California 94720, USA

Studying the geometry of wave function manifolds helps us to identify and un-

derstand phenomena whose descriptions are not captured by the sole knowledge of the energy dispersion. A prominent example of recent interest is the distance between wave functions captured by the quantum metric. Flat-band systems are promising candidates for novel fascinating quantum metric effects since well-known contributions to observables that depend on the slope or curvature of the dispersion vanish. For instance, the dominant contribution to the superfluid stiffness and the dc electrical conductivity is proportional to the integrated quantum metric for flat bands. In this talk, I will address the role of band degeneracy in these quantum metric effects. I will use the developed framework for dc electrical conductivity [PRB 105, 085154 (2022), PRB 106, 165133 (2022)] to contrast nondegenerate and degenerate band manifolds. We will explore the common mathematical description in terms of Grassmannian manifolds and its concrete implications, such as lower bounds and the nonadditivity of the quantum metric. I close by illustrating how these concepts can be directly extended to other observables.

TT 61.5　Thu 18:45　HSZ 201

Magnetism in twisted bilayer graphene with heterostrain — Ahmed Missaoui[1], Florie Mesple[2], Javad Vahedi[3], Andreas Honecker[1], Vincent Renard[2], and •Guy Trambly de Laissardière[1] — [1]Laboratoire de Physique Théorique et Modélisation, CY Cergy Paris Université / CNRS, Cergy-Pontoise, France — [2]Université Grenoble Alpes, CEA, Grenoble INP, IRIG, PHELIQS, Grenoble, France — [3]Jacobs University, School of Engineering and Science, Bremen, Germany

The discovery of correlated insulators and superconductivity due to flat bands in twisted bilayer graphene (TBG) at so-called "magic angles" has stimulated the study of their magnetic properties [1]. Furthermore, it is now well established that heterostrain, which is generally present in the samples, is a key parameter in understanding the actual shape of the flat bands [2]. Here, we present a theoretical study of magnetism in magic-angle TBG combining a Hubbard model and the mean-filed approach including non-collinear magnetic terms. We show how heterostrain strongly modifies the magnetization and the local order of magnetic state for realistic Coulomb interaction values.

TT 62: Ultrafast Dynamics of Light-Driven Systems

Time: Friday 9:30–11:45　　　　　　　　　　　　　　　　　　　　　　　　　　　　Location: HSZ 03

TT 62.1　Fri 9:30　HSZ 03

Ultrafast dynamics of spin-density wave order in $BaFe_2As_2$ under high pressures — Ivan Fotev[1,2], Stephan Winnerl[1], Saicharan Aswartham[3], Sabine Wurmehl[3,4], Bernd Büchner[3,4], Harald Schneider[1], Manfred Helm[1,2], and •Alexej Pashkin[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Germany — [2]Technische Universität Dresden, Germany — [3]IFW Dresden, Germany — [4]Würzburg-Dresden Cluster of Excellence ct.qmat, Germany

We utilize pump-probe spectroscopy to measure the quasiparticle relaxation dynamics of $BaFe_2As_2$ in a diamond anvil cell at pressures up to 4.4 GPa and temperatures down to 8 K. Tracing the amplitude of the relaxation process results in an electronic phase diagram that illustrates the variation of the spin-density wave (SDW) order across the whole range of the applied pressures and temperatures. We observe a slowing down of the SDW relaxation dynamics in the vicinity of the phase transition boundary. However, its character depends on the trajectory in the phase diagram: the slowing down occurs gradually for the pressure-induced transition at low temperatures and abruptly for the thermally-driven transition. Our results suggest that the pressure-induced quantum phase transition in $BaFe_2As_2$ is related to the gradual worsening of the Fermi-surface nesting conditions.

TT 62.2　Fri 9:45　HSZ 03

Probing the superconducting transition in a cuprate superconductor by multi-dimensional terahertz spectroscopy — •Albert Liu[1], Danica Pavicevic[1], Michael Fechner[1], Pedro Lozano[2], Genda Gu[2], and Andrea Cavalleri[1,3] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [2]Brookhaven National Laboratory, New York, USA — [3]Oxford University, Oxford, UK

We develop two-dimensional terahertz spectroscopy in both a non-collinear and reflection geometry. We demonstrate the technique by distilling the terahertz optical response of a superconducting plasma into its constituent nonlinearities, up to fifth-order. Subsequent measurements at temperatures approaching and crossing the phase transition reveal a phase-disordering transition in lieu of a BCS transition. An outlook for probing light-induced superconducting states will be provided.

TT 62.3　Fri 10:00　HSZ 03

Tracing the dynamics of the superconducting order via transient THG — •Minjae Kim[1,2,3], Gennady Logvenov[2], Bernhard Keimer[2], Dirk Manske[2], Lara Benfatto[4], and Stefan Kaiser[1,2,3] — [1]Institute of Solid State and Materials Physics, Technical University Dresden, 01062 Dresden, Germany — [2]Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany — [3]4th Physics Institute and Research Center SCoPE, University of Stuttgart, 70569 Stuttgart, Germany — [4]Department of Physics and ISC-CNR, Sapienza University of Rome, 00185 Rome, Italy

Nonlinear THz third harmonic generation (THG) was shown to directly probe internal degrees of freedoms of the superconducting condensate and its exposure to external collective modes in the framework of driven Higgs modes [1-3]. Here we extend this idea to light-driven nonequilibrium states in superconducting La2-xSrxCuO4 establishing a transient Higgs spectroscopy. We perform an optical pump-THz-THG drive experiment and using 2D-spectroscopy we disentangle the driven TH response into the excited quasiparticles and condensates response. As such the light induced changes of the THG signals probe the ultrafast pair breaking dynamics and transient pairing amplitude of the condensate.

Influence of impurities on the Higgs mode in non-centrosymmetric superconductors — •Simon Klein and Dirk Manske — Max-Planck Institut für Festkörperforschung, Stuttgart, Deutschland

Recent interest for collective amplitude (Higgs) excitations focused on third harmonic generation (THG) experiments in single- and multi-band superconductors, both for singlet *s*- and *d*-wave gap structure. A resonance in the THG intensity appears, when matching the driving frequency to the energy of the corresponding investigated mode, leading to a phase jump at the resonance frequency. We extend these studies to superconductors without an inversion symmetry, which can be effectively described by a two-band model with an order parameter, consisting of spin singlet (even parity) and spin triplet (odd parity)

components. We calculate the THG response, showing that it contains contributions from three distinguishable sources, namely the Higgs mode, the Leggett mode and quasiparticles. In the clean limit the quasiparticle contributions dominate the collective modes for all singlet-triplet ratios of the gap structure. By including already a small amount of impurities in the system, we find a significant enhancement of the Higgs mode contributions to the THG signal. Furthermore, we notice a significant change in the phase jump, which helps to differentiate between clean and dirty superconductors.

TT 62.5　Fri 10:45　HSZ 03
Non-equilibrium phenomena in a two-band superconductor MgB$_2$ driven by narrow-band THz pulses — •Sergei Sobolev[1], Amon Lanz[1], Tao Dong[2], Alexej Pashkin[3], Amrit Pokharel[1], Zi Zhao Gan[2], Li Yu Shi[2], Nan Lin Wang[2], Stephan Winnerl[3], Manfred Helm[3], and Jure Demsar[1] — [1]Uni-Mainz, Mainz — [2]Peking Uni., Beijing — [3]HZDR, Dresden

Excitation of a superconductor (SC) with a low energy electromagnetic pulse leads to a non-equilibrium state, which may profoundly differ from a quasi-thermal one, driven by optical excitation. Such a non-equilibrium may be especially pronounced in a multi-band SC. Here, we report on systematic time-resolved studies of the dynamics of the SC order following resonant excitation with intense narrow-band THz pulses in thin films of MgB$_2$, the prototype two-band SC with two distinct superconducting gaps. We demonstrate that the temperature and excitation density dependent dynamics qualitatively follows the behavior predicted by the phenomenological Rothwarf-Taylor model for dynamics in a single gap BCS superconductor implying strong coupling between the two condensates on the ps timescale. Tracking the dependence of the amplitude of the THz driven gap suppression, however, displays a pronounced minimum near $0.6T_c$, that cannot be accounted by the phenomenological model. Comparison of the results to those obtained by excitation with NIR pulses suggests that resonant THz excitation results in long-lived (100 ps timescale) non-thermal quasiparticle distribution, which gives rise to Eliashberg-type enhancement of superconductivity, competing with pair-breaking.

TT 62.6　Fri 11:00　HSZ 03
Semi-classical analysis of high harmonic spectra in Dirac materials — •Wolfgang Hogger[1], Vanessa Junk[1], Alexander Riedel[1], Cosimo Gorini[2], Juan-Diego Urbina[1], and Klaus Richter[1] — [1]Institute for theoretical physics, University of Regensburg, Germany — [2]Université Paris-Saclay, CEA, CNRS, SPEC, 91191, Gif-sur-Yvette, France

The study of high-order harmonic generation (HHG) in solids by virtue of intense laser pulses provides a fascinating platform to study ultrafast electron dynamics as well as material properties. We theoretically investigate HHG on the basis of massive Dirac Fermions, serving as a prototypical model for topologically non-trivial matter. The high harmonic spectra resulting from a numerical solution of the equations of motion for the density-matrix are supplemented and compared to a semiclassical saddle-point analysis known as the Lewenstein or simple- man model[1,2]. We demonstrate that HHG can be interpreted as a result of interfering classical trajectories generated at different half-cycles of the laser pulse. A transparent and compact analytical formula for the high harmonic spectrum in the limit of long pulses is provided and discussed regarding

the range of its validity as well as corrections arising from short waveforms.

Driven lattice fluctuations in quantum paraelectric SrTiO$_3$ — •Michael Fechner[1], Michael Först[1], Ankit Disa[1], Michele Buzzi[1], Alex von Hoegen[1], Gal Orenstein[2], Viktor Krapivin[2], Quỳnh Le Nguyen[2], Roman Mankowsky[3], Mathias Sander[3], Henrik Lemke[3], Yunpei Deng[3], Mariano Trigo[2], and Andrea Cavalleri[1] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [2]Stanford Linear Accelerator Center, Menlo Park, United States of America — [3]Paul Scherrer Institute, Villigen, Switzerland

Enhanced fluctuations are the precursors of quantum phase transition. In the case of ferro- and antiferrodistortive structural transitions, these fluctuations arise at specific points in reciprocal space. Here we use time-resolved x-ray diffuse scattering to show how a resonantly driven zone center optical phonon in cubic SrTiO$_3$ selectively modulates lattice fluctuations at the Brillouin zone boundary. On short time scales, enhanced and oscillating lattice fluctuations are found at the R-point, which reduce to below the equilibrium value on the picosecond time scale. We attribute the fast dynamics to a finite-momentum fourth-order phonon-phonon interaction between the driven infrared-active Ti-O stretch mode and the antiferrodistortive zone-boundary soft mode. The long-term reduction indicates nonlinear coupling of the antiferrodistortive distortions to strain. We discuss the implications of these findings for the recently observed light-induced ferroelectric state of SrTiO$_3$[1].

TT 62.8　Fri 11:30　HSZ 03
Decay of photoinduced orbital excitations in the spin-Peierls system TiOCl: a study from first principle — •Paul Fadler[1], Philipp Hansmann[1], Kai Phillip Schmidt[1], Angela Montanaro[2], Daniele Fausti[1,2], and Martin Eckstein[3] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg — [2]University of Trieste — [3]Universität Hamburg

In spin-Peierls materials, the magnetic interactions caused by the electronic correlations drive a phase transition in which the unit cell is distorted. TiOCl is a quasi one-dimensional transition metal oxide with well-defined orbital (d-d) excitations that transitions to a spin-Peierls state below 67K, by doubling the unit cell along the 1-D chain. Recently, optical transmissivity measurements after a double pump excitation into the orbital excitations revealed a dependence of the decay time on the excitation sequence, which may indicate different lifetimes of various orbital excitations. To unveil the microscopic origins of this observation, we study a material-realistic multi-orbital Hubbard Hamiltonian derived from ab initio density-functional theory. The localized strong-coupling native of TiOCl then allows for perturbative elimination of charge-excitations, leading to a spin-orbital model of Kugel-Khomskii type. We compute its spin dispersion in the absence of orbital excitations. Based on this, and the computed intra and inter-orbital matrix elements, we then estimate the decay time of orbital excitations via (multi) spinon emission, and compare to the experimental findings.

Sharp Kohn-like phonon anomalies due to charge order can strongly enhance the superconducting T$_c$ — •Alessio Zaccone — Department of Physics, University of Milan, 20133 Milano, Italy

Phonon softening is a ubiquitous phenomenon in condensed matter systems which is usually associated with charge density wave (CDW) instabilities and anharmonicity. The interplay between phonon softening, CDW and superconductivity is a topic of intense debate. In this work, the effects of anomalous soft phonon instabilities on superconductivity are studied based on a recently developed theoretical framework that accounts for phonon damping and softening within the Migdal-Eliashberg theory [1]. Model calculations [2] show that the phonon softening in the form of a dip in the phonon dispersion relation, either acoustic or optical (including the case of Kohn-type anomalies typically associated with CDW), can cause a manifold increase of the electron-phonon coupling constant λ. This, under certain conditions, which are consistent with the concept of optimal frequency introduced by Bergmann and Rainer, can produce a large increase of the superconducting transition temperature T$_c$. These results suggest the possibility of reaching high-temperature superconductivity by exploiting soft phonon anomalies restricted in momentum space.

TT 63.2　Fri 9:45　HSZ 103
Universal suppression of superfluid weight by non-magnetic disorder in s-wave superconductors independent of quantum geometry and band dispersion — •Alexander Lau[1], Sebastiano Peotta[2], Dmitry I. Pikulin[3], Enrico Rossi[4], and Timo Hyart[1,2] — [1]MagTop, IF PAN, Warsaw, Poland — [2]Aalto University, Finland — [3]Microsoft Quantum, Redmond, USA — [4]William & Mary, Williamsburg, USA

Motivated by the experimental progress in controlling the properties of the energy bands in superconductors, significant theoretical efforts have been devoted to study the effect of the quantum geometry and the flatness of the dispersion on the superfluid weight. In conventional superconductors, where the energy bands are wide and the Fermi energy is large, the contribution due to the quantum geometry is negligible, but in the opposite limit of flat-band superconductors the superfluid weight originates purely from the quantum geometry of Bloch wave functions. Here, we study how the energy band dispersion and the quantum geometry affect the disorder-induced suppression of the superfluid weight [1]. In particular, we consider non-magnetic disorder and s-wave superconductivity. Surprisingly, we find that the disorder-dependence of the superfluid weight is universal across a variety of models, and independent of the quantum geometry and the flatness of the dispersion. Our results suggest that a flat-band superconductor is as resilient to disorder as a conventional superconductor.

TT 63.3   Fri 10:00   HSZ 103

Correction to Morel-Anderson-Tolmachev pseudopotential from nonlocal Coulomb interaction in 2D superconductors — •Manuel Simonato, Malte Rösner, and Mikhail I. Katsnelson — Radboud University, Nijmegen, NL

The repulsive Coulomb interaction between electrons is detrimental to conventional superconductivity. The widely accepted model to account for this is to describe this repulsion with a purely local interaction of strength μ_C. Morel, Anderson, and Tolmachev then showed that the superconducting quantities are effectively described by a renormalized parameter μ_C^*, as a direct consequence of the energy scale separation between phonons and electrons. In 2D the screening properties are less efficient and modeling the Coulomb repulsion with a strictly local interaction can result in inaccurate description. We therefore study how superconducting properties are affected by nonlocal Coulomb repulsions. We find that the superconducting state can still be accurately described when a revised Coulomb pseudopotential $\tilde{\mu}_C^*$ is used. We show that the revised parameter, which accounts for nonlocal interactions, is always larger that the convetional μ_C^*. The non-local Coulomb interaction thus suppresses superconductivity and the critical temperature even further. Analyzing the Bethe-Salpeter equation describing the screening of Coulomb interaction in 2D, we obtain an analytical expression for $\tilde{\mu}_C^*$, and show that the structure of the nonlocal Coulomb interaction weakens the screening effects from high-energy pair fluctuations and therefore yields larger values of the pseudopotential.

TT 63.4   Fri 10:15   HSZ 103

Coherence and pairing fluctuations in strongly correlated superconductors — •Niklas Witt[1,2], Sergey Brener[1], Yusuke Nomura[3], Ryotaro Arita[4,5], Alexander Lichtenstein[1,2], and Tim Wehling[1,2] — [1]University of Hamburg, Germany — [2]The Hamburg Centre for Ultrafast Imaging, Germany — [3]Keio University Japan — [4]University of Tokyo, Japan — [5]RIKEN CEMS, Japan

The fundamental properties of superfluids and superconductors are determined by the spatial coherence of the macroscopic condensate. Central to this characterization is the knowledge of the coherence length ξ, as it specifies the relevant length scales for fluctuations pertinent to, e.g., the formation of vortex latices or magneto-thermal transport. While the description of ξ is well established in weak-coupling BCS theory and Eliashberg-theory, it is a generally unknown quantity in strongly correlated superconductors, where spatiotemporal fluctuations influence the critical temperature [1] and might underlie light-induced enhancement of superconductivity [2].

In this work, we establish a link to directly calculate the coherence length for superconductors with strong electron correlations from microscopic theories and first principles. We illustrate with the example of Alkali-doped fullerides (A_3C_{60}) how proximity of superconducting and Mott-localized states impact superconducting coherence, pairing fluctuations, and critical temperature. Our analysis shows Eliashberg-type behavior of strongly correlated superconductors.

Superconductivity from repulsive interactions due to strong-coupling to a Mott-insulating layer — •Clara S. Weber[1,2], Dante M. Kennes[1], and Martin Claassen[2] — [1]RWTH Aachen, Aachen, Germany — [2]University of Pennsylvania, Philadelphia, USA

While superconductors in their conventional form are established by effective attractive interactions, mechanisms for emergent electronic pairing from strong repulsive electron-electron interactions remain under considerable debate. Here, we establish a strong-coupling mechanism that realizes intertwined superconductivity and magnetic order in a Kondo-like bilayer system with purely repulsive interactions, composed of a two-dimensional Mott insulator with strong Hubbard interactions coupled to a layer of weakly-interacting itinerant electrons. Remarkably, this model allows for a rigorous strong-coupling analysis, where we find that itinerant electrons in the nearly-metallic layer are subject to an effective attractive electron-electron interaction as a function of magnetic ordering in the Mott-insulating layer. We carefully study this behavior numerically using large scale DMRG calculations and find that the superconducting behavior persists in a wide parameter range beyond the strong-coupling regime. Additionally, we classify the rich magnetic phase diagram and find a 2-site antiferromagnetic and a 4-site antiferromagnetic phase, along with a phase separation regime. Finally, we discuss possible applications and realizations of the proposed mechanism.

Simulating superconducting properties of overdoped cuprates: The role of inhomogeneity — Mainak Pal[2], •Andreas Kreisel[1], William A. Atkinson[3], and Peter J. Hirschfeld[2] — [1]Niels Bohr Institute, University of Copenhagen, Denmark — [2]Department of Physics, University of Florida, USA — [3]Department of Physics and Astronomy, Trent University, Canada

Theoretical studies of disordered d-wave superconductors have focused, with a few exceptions, on optimally doped models with strong scatterers. Addressing recent controversies about the nature of the overdoped cuprates, however,

requires studies of the weaker scattering associated with dopant atoms. Here we study simple models of such systems in the self-consistent Bogoliubov-de Gennes (BdG) framework, and compare to disorder-averaged results using the self-consistent-T-matrix-approximation (SCTMA). Despite surprisingly linear in energy behavior of the low-energy density of states even for quite disordered systems, the superfluid density in such cases retains a quadratic low-temperature variation of the penetration depth, unlike other BdG results reported recently. We trace the discrepancy to smaller effective system size employed in that work. Overall, the SCTMA performs remarkably well, with the exception of highly disordered systems with strongly suppressed superfluid density. We explore this interesting region where gap inhomogeneity dominates measured superconducting properties, and compare with overdoped cuprates.

TT 63.7   Fri 11:00   HSZ 103

Finite energy Cooper pairing in multiband superconductors — •Masoud Bahari[1], Song-Bo Zhang[2], Chang-An Li[1], Sang-Jun Choi[1], Carsten Timm[3], and Björn Trauzettel[1] — [1]University of Würzburg, Würzburg, Germany — [2]University of Zürich, Zürich, Switzerland — [3]Technische Universität Dresden, Dresden, Germany

Extensive efforts have been carried out to understand the superconducting pairing symmetry since the birth of Bardeen-Cooper-Schrieffer theory. In weakly interacting systems, the essential ingredient is a weak effective electron-electron interaction at the Fermi energy resulting in particular bulk properties including superconducting gaps possibly with nodes.

We demonstrate and discuss the bulk and surface spectral properties of a novel pairing mechanism that occurs at finite excitation energies in multiband superconductors. In the bulk, it is manifested by the appearance of superconducting coherence peaks in the density of states at finite energies. Interestingly, on the surface, we predict the emergence of a pair of helical topological Dirac surface cones when the finite energy pairing is odd-parity.

Finally, we propose aluminum in proximity with (111) surface of gold to realize the bulk properties of finite energy pairing. We discuss the pairing symmetry of the system by employing the density-functional theory, and an analytical model based on the Bogoliubov-de Gennes formalism. The signature of such a pairing gives important information about the correct pairing symmetry of a superconductor.

Fragmented Cooper pair condensation in striped superconductors — •Alexander Wietek — Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Strasse 38, Dresden 01187, Germany

Condensation of bosons in Bose-Einstein condensates or Cooper pairs in superconductors refers to a macroscopic occupation of a few single- or two-particle states. A condensate is called *fragmented* if not a single, but multiple states are macroscopically occupied. While fragmentation is known to occur in particular Bose-Einstein condensates, we propose that fragmentation naturally takes place in striped superconductors. To this end, we investigate the nature of the superconducting ground state realized in the two-dimensional t*t**J model. In the presence of charge density modulations, the condensate is shown to be fragmented and composed of partial condensates located on the stripes. The fragments of the condensates hybridize to form an extended macroscopic wave function across the system. The results are obtained from evaluating the singlet-pairing two-particle density matrix of the ground state on finite cylinders computed via the density matrix renormalization group method. Our results shed light on the intricate relation between stripe order and superconductivity in systems of strongly correlated electrons.

Superconductivity on the honeycomb lattice: A truncated unity perspective — •Matthew Bunney[1,2], Jacob Beyer[1,2], Carsten Honerkamp[2], and Stephan Rachel[1] — [1]School of Physics, University of Melbourne, Melbourne, Australia — [2]Theoretical Solid State Physics, RWTH Aachen University, Aachen, Germany

The honeycomb lattice provides one of the simplest scenarios with sublattice degrees of freedom. For Cooper pairing of electrons on this lattice, this opens extensive and intricate opportunities of interplay between the momentum space wavefunction, the electron spins and the orbital (sublattice) dependencies. Recent advances and improvements in truncated unity versions of the functional renormalization group allows us to fully capture these phenomena. We thus revisit the honeycomb Hubbard model and its electron pairing and density wave instabilities. A particular emphasis is placed on the formation of sublattice singlets and the resulting exotic pairing states.

TT 63.10   Fri 12:00   HSZ 103

A low-dimensional ML Surrogate Model for Critical Temperature Prediction of Superconductors — •Angel Diaz Carral[1], Martin Roitegui Alonso[1], and Maria Fyta[2] — [1]Institute for Computational Physics, Universität Stuttgart, Allmandring 3, 70569, Stuttgart, Germany — [2]Computational Biotechnology, RWTH-Aachen University, Worringerweg 3, 52074, Aachen, Germany

A general theory of superconductivity has been the focus of research over the last decades. Machine learning (ML) approaches based on chemical and structural features have been developed in order to predict both the critical temperature (Tc) and potential novel superconducting structures. Nevertheless, the applied ML models lack interpretability; either the feature matrix is reduced via SVD/PCA transformations or augmented with statistical feature generation. Here, we introduce a ML model based only on electronic descriptors derived from the composition formula and the individual elements. We reach a very high accuracy (R2 over 91%) using a considerably reduced descriptor dimensionality, while retaining the physical meaning of the feature space. Our active learning model is efficiently tested in predicting critical temperatures and links to the discovery of new superconducting structures.

Ab initio study of magnetic doping in an Ising superconductor — •Mohammad Hemmati[1], Philipp Rüssmann[1,2], and Stefan Blügel[1] — [1]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, Jülich, Germany — [2]University of Würzburg, Germany

The transition-metal dichalcogenide $NbSe_2$ is a layered superconducting material that exhibits unconventional Ising superconductivity that is particularly robust to certain directions of external magnetic fields [1]. Here we combined the Bogoliubov-de-Gennes formalism in the Korringa-Kohn-Rostoker Green function method with the Coherent Potential Approximation [2,3], to study superconducting $NbSe_2$ in the presence of dilute concentrations of magnetic transition-metal impurities. The ab initio results show a suppression of superconductivity at higher magnetic impurity concentration, which is in agreement with the Abrikosov-Gorkov theory.

Chiral surface superconductivity in half-Heusler semimetals — •Tilman Schwemmer[1], Domenico Di Sante[2,3], Jörg Schmalian[4], and Ronny Thomale[1] — [1]Institute for Theoretical Physics, University of Wuerzburg — [2]Department of Physics and Astronomy, University of Bologna, Italy — [3]CCQ, Flatiron Institute, New York, USA — [4]Institute for Theory of Condensed Matter and Institute for Quantum Materials and Technologies, KIT Karlsruhe

We propose the metallic and weakly dispersive surface states of half-Heusler semimetals as a possible domain for the onset of unconventional surface super-

conductivity ahead of the bulk transition. Using density functional theory (DFT) calculations and the random phase approximation (RPA), we analyse the surface band structure of LuPtBi and its propensity towards Cooper pair formation induced by screened electron-electron interactions in the presence of strong spin-orbit coupling. Over a wide range of model parameters we find a chiral superconducting condensate featuring Majorana edge modes to be favoured energetically, while low-dimensional order parameter fluctuations trigger time-reversal symmetry breaking preceding the superconducting transition.

TT 63.13   Fri 12:45   HSZ 103

Transport in superconducting heterostructures: Quasiclassical theory and finite element method — •Kevin Marc Seja and Tomas Löfwander — Department of Microtechnology and Nanoscience - MC2, Chalmers University of Technology, Gothenburg, Sweden

We present results on steady-state transport in mesoscopic conventional and unconventional superconductors coupled to either normal-metal or superconducting reservoirs. Our self-consistent simulations are using nonequilibrium quasiclassical theory in the Eilenberger formulation which allows different order parameter symmetries at arbitrary mean free path. Previously we investigated the thermoelectric effect[1] and spectral rearrangements due to a voltage bias[2] in d-wave superconductors. These studies on nonequilibrium effects assumed translational invariance normal to the transport direction.

This talk will address the question of how to go beyond such quasi one-dimensional models and study superconducting hybrid structures in realistic device geometries. To this end we present a finite element method[3] for the self-consistent solution of the underlying quasiclassical transport equations in dimensions larger than one, and give examples of its application.

Nonlinear response of diffusive superconductors to ac electromagnetic Fields — •Pascal Derendorf, Anatoly Volkov, and Ilya Eremin — Institut für Theoretische Physik III, Ruhr-Universität Bochum, Bochum, Germany

Using the generalized Usadel equation, we theoretically study the nonlinear response of a diffusive BCS superconductor to the action of electromagnetic fields. The response is found in the second order of the perturbation in the amplitude of the field E for the superconducting order parameter Δ and in the third order for the current j. We represent the matrix Keldysh function $\hat{g}^K$ as the sum of a regular function $\hat{g}^{reg}$ and an anomalous function $\hat{g}^{an}$. On the basis of this approach, general formulas for deviations of the retarded (advanced) Green's functions, as well as the Keldysh function for an arbitrary number of harmonics of the incident field are explicitly obtained. The frequency and temperature dependencies of zero harmonic $\delta\Delta_0$ (Eliashberg effect) and the second harmonic $\delta\Delta_{2\Omega}$ under action of a monochromatic irradiation are analyzed. We also study the third harmonic $j_{3\Omega}$ and the possibility of parametric amplification of a signal with a frequency Ω_x in the presence of a pumping with a frequency Ω which excites the Higgs (amplitude) mode.

Fermi arc reconstruction in synthetic photonic lattice — •Duy Hoang Minh Nguyen[1], Chiara Devescovi[1], Dung Xuan Nguyen[2], Hai Son Nguyen[3,4], and Dario Bercioux[1,5] — [1]Donostia International Physics Center, Donostia-San Sebastian, Spain — [2]Center for Theoretical Physics of Complex Systems, Institute for Basic Science (IBS), Daejeon, Republic of Korea — [3]Univ Lyon, Ecole Centrale de Lyon, CNRS, INSA Lyon, Universite Claude Bernard Lyon 1, CPE Lyon, CNRS, INL, UMR5270, Ecully, France — [4]Institut Universitaire de France (IUF), Paris, France — [5]IKERBASQUE, Basque Foundation for Science, Euskadi Plaza, 5, Bilbao, Spain

The chiral surface states of Weyl semimetals are known for having an open Fermi surface called Fermi arc. At the interface between two Weyl semimetals, these Fermi arcs are predicted to potentially deform into unique interface states. In this work, we numerically study a one-dimensional (1D) dielectric trilayer grating where the relative displacements between adjacent layers play the role of two synthetic momenta. The lattice is described by an effective Hamiltonian whose spectral properties coincide closely with rigorous electromagnetic simulations. Our trilayer system is a simple but versatile platform that emulates 3D crystals without time-reversal symmetry, including Weyl semimetal, nodal line semimetal, and 3D Chern insulator. It allows us to not only observe phenomena such as the phase transition between Weyl semimetal and Chern insulator but also confirm the Fermi arc reconstruction between two Weyl semimetals.

Electronic correlations and pseudo Fermi arcs due to geometry of the Fermi surface in semimetals — •Elena Derunova — IFW, Helmholz str.20, Dresden

Moving forward from topological theory I present a geometrical approach to analyze the bandstructures and Fermi surfaces. Particularly, the effect of hyperbolic geometry of the Fermi surface on the Fermi liquid breakdown and correlated transport effects will be presented. As a mechanism for realizing these correlations, I introduce pseudo Fermi arcs connecting separate pockets of hyperbolic Fermi surface. A breakdown of time-reversal symmetry via tunneling through those pseudo arcs is referred as Fermi Surface Geometry Effect (FS-GE). The predictable power of FS-GE is tested on the spin and anomalous Hall effects, traditionally associated with intrinsic time-reversal symmetry breaking. An index, H_F, quantifying FS-GE in a particular direction, shows a universal correlation ($R^2 = 0.97$) with the experimentally measured intrinsic anomalous Hall conductivity in that direction, of 16 different compounds spanning a wide variety of crystal, chemical, and electronic structure families, where the topological methods give just $R^2 = 0.52$. This raises a question about the principal limits of topological physics, dominating now the predictions of non-trivial electron transport, and its transformation into a wider study of bandstructures' and Fermi surfaces' geometries, opening a horizon for the prediction of phenomena beyond topological understanding.

Markers in Landau levels for topological transitions in Bernal bilayer graphene — •Nils Jacobsen[1], Anna Seiler[1], Zhiyu Dong[2], Thomas Weitz[1], and Leonid Levitov[2] — [1]1st Physical Institute, Faculty of Physics, University of Göttingen, Göttingen, Germany — [2]Department of Physics, Massachusetts Institute of Technology, Cambridge, USA

This talk will discuss Landau levels in an electron band that exhibits the topological Lifshitz transition. We focus on Bernal-stacked bilayer graphene, a system that has drawn a lot of attention recently. A dual gated experimental setup allows to tune the out-of-plane displacement field and the charge carrier density independently, giving insights in exotic correlation effects [1]. Depending on the charge carrier density its Fermi surface changes its topology, that is, four disconnected pockets merge together to form one connected Fermi sea [2].

This topological transition results in a complex series of Landau levels which are not valley-symmetric and, as a result, change their order and degeneracy when the magnetic field is varied. These effects are added to the degeneracies that are already present due to valley and spin degrees of freedom. By virtue of numerical diagonalization methods based on a realistic tight binding model, we extract this Landau level sequence and directly relate it to transport measurements. Our model allows us to access the range of parameters of interest where the topological Lifshitz transition can occur.

Topological classification of single-particle Green functions and effective Hamiltonians for interacting systems — Maximilian Kotz[1] and •Carsten Timm[1,2] — [1]Institute of Theoretical Physics, TU Dresden, 01062 Dresden, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, 01062 Dresden, Germany

The single-particle Green function for any interacting-electron system can be written as the resolvent of a generally frequency-dependent and non-Hermitian effective Hamiltonian. Both these properties together allow for 54 instead of ten global-symmetry classes. The absence of Hermiticity also requires to reconsider the concept of a spectral gap. If the limits of the effective Hamiltonian for frequency $\omega \to \pm \infty$ coincide one can compactify the frequency axis and consider winding in $(d + 1)$-dimensional momentum-frequency space. We derive a complete list of the homotopy groups for the 54 classes and spatial dimensions d, for the cases without and with frequency dependence.

TT 64.5　Fri 10:30　HSZ 201

Solitons and topology: Observation of cnoidal wave localization in nonlinear topolectric circuits — •Hendrik Hohmann[1], Tobias Hofmann[1], Tobias Helbig[1], Hauke Brand[2], Lavi K. Upreti[1], Alexander Stegmaier[1], Alexander Fritzsche[1], Tobias Müller[1], Ching Hua Lee[3], Martin Greiter[1], Laurens W. Molenkamp[2], Tobias Kiessling[2], and Ronny Thomale[1] — [1]Institute for Theoretical Physics and Astrophysics, University of Würzburg, D-97074 Würzburg, Germany — [2]Physikalisches Institut, Universität Würzburg, 97074 Würzburg, Germany — [3]Department of Physics, National University of Singapore, Singapore, 117542

Topological phases have been realized in a variety of classical metamaterials. They provide easily accessible platforms to study topology in regimes beyond experimental limitations of real materials.

While most implementations are limited to the linear regime, investigating non-linear effects promises to reveal a plethora of new phenomena, such as solitons and chaos.

To study the intertwining of topology and non-linearity we engineered a topolectric circuit reminiscent of the Su-Schrieffer-Heeger (SSH) model with added tunable onsite non-linearity. We observe the localized cnoidal (LCn) state which maintains the spatial exponential localization of the SSH edge mode while distorting a sinusoidal input into eccentric waves in time domain.

In this talk, we complement the non-linear differential equations with the theory of topological localization and develop an analytic description of the LCn state.

TT 64.6　Fri 10:45　HSZ 201

Non-Hermitian diamond chain — •Carolina Martinez Strasser[1], Miguel Ángel Jimenez Herrera[1], and Dario Bercioux[2] — [1]Donostia International Physics Center (DIPC), 20018 Donostia-San Sebastián, Spain — [2]Ikerbasque, Basque Foundation for Science, Plaza Euskadi 5 48009 Bilbao, Spain

We investigate the spectral properties of a non-Hermitian quasi-one-dimensional lattice in several possible dimerization configurations. Specifically, we focus on a non-Hermitian diamond chain that presents a zero-energy flat band. In the Hermitian case, this flat band originates from wave interference and results in a wave function localized only on a subset of sites on the unit cell [1]. We transform the system into a non-Hermitian one by considering asymmetric hopping terms between some of the lattice sites of the chain. This leads to the accumulation of eigenstates, known as the skin effect. Despite this accumulation of eigenstates, we can characterize the presence of non-trivial edge states at zero energy by a real-space topological invariant known as biorthogonal polarization. We show that this invariant, evaluated using the destructive interference method, can also characterize the non-trivial phase of the non-Hermitian diamond chain [2].

TT 65: Correlated Electrons: Other Theoretical Topics

Time: Friday 9:30–12:15　　　　　　　　　　　　　　　　　　　　　　　　　　　　Location: HSZ 204

TT 65.1　Fri 9:30　HSZ 204

Quantum oscillations beyond the Onsager relation in a doped Mott insulator — •Valentin Leeb[1,2] and Johannes Knolle[1,2,3] — [1]Technical University of Munich, Germany; TUM School of Natural Sciences, Department of Physics, TQM — [2]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany — [3]Blackett Laboratory, Imperial College London, London SW7 2AZ, United Kingdom

The kinetic energy of electrons in a magnetic field is quenched resulting in a discrete set of highly degenerate Landau levels (LL). This gives rise to fascinating phenomena like quantum oscillations or the integer and fractional quantum Hall effect. The latter is a result of interactions partially lifting the degeneracy within a given LL while inter-LL interactions are usually assumed to be unimportant. Here, we study the LL spectrum of the Hatsugai–Kohmoto model, a Hubbard-like model which is exactly soluble on account of infinite range interactions. For the doped Mott insulator phase in a magnetic field we find that the degeneracy of LLs is preserved but inter-LL interactions are important leading to a non-monotonous reconstruction of the spectrum. As a result, strong interactions lead to aperiodic quantum oscillations of the metallic phase in contrast to Onsager's famous relation connecting oscillation frequencies with the Fermi surface areas at zero field. In addition, we find unconventional temperature dependencies of quantum oscillations and effective mass renormalizations. We discuss the general importance of inter-LL interactions for understanding doped Mott insulators in magnetic fields.

TT 65.2　Fri 9:45　HSZ 204

Non-Fermi-liquid behavior from critical electromagnetic vacuum fluctuations — •Peng Rao and Francesco Piazza — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

We study two-dimensional materials where electrons are coupled to the vacuum electromagnetic field of a cavity. We show that, at the onset of the superradiant phase transition towards a macroscopic photon occupation of the cavity, the critical electromagnetic fluctuations, consisting of photons strongly overdamped by their interaction with electrons, can in turn lead to the absence of electronic quasiparticles. Since transverse photons couple to the electronic current, the appearance of non-Fermi-Liquid behavior strongly depends on the lattice. In particular, we find that in a square lattice the phase space for electron-photon scattering is reduced in such a way to preserve the quasiparticles, while in a honeycomb lattice the latter are removed due to a non-analytical frequency dependence of the damping $\propto |\omega|^{2/3}$. Standard cavity probes could allow to measure the characteristic frequency spectrum of the overdamped critical electromagnetic modes responsible for the non-Fermi-liquid behavior.

TT 65.3　Fri 10:00　HSZ 204

Collapse of fermionic quasiparticles upon coupling to local bosons — Adam Kłosiński, Piotr Wrzosek, Krzysztof Wohlfeld, and •Cliò Efthimia Agrapidis — Insitute of Theoretical Physics, Faculty of Physics, University of Warsaw, Poland

We study the stability of the fermionic quasiparticle in a fermion-boson model on a Bethe lattice, with fermions interacting with local bosons thorough a Peierls coupling. We solve the model by mapping it onto a non-interacting chain with a site-dependent potential. We show that the model does not support a quasiparticle solution – provided that a finite number of local bosonic excitations cost zero energy. The quasiparticle disappearance becomes easier with an increase in: (i) the total number of bosons with zero energy, and (ii) the relative strength of the coupling between bosons and fermions. The postulated model can be applied to study systems in which fermions are coupled to condensed bosons or magnons in spin stripes embedded in hole-doped 2D antiferromagnets or Ising-like magnetic interfaces (ferromagnetic-antiferromagnetic). Finally, we show how this model leads to an in-depth understanding of the onset of quasiparticles in the 1D and 2D t-J^z model.

TT 65.4　Fri 10:15　HSZ 204

Breakdown of the many-electron perturbation expansion beyond particle-hole symmetry — •Herbert Essl, Matthias Reitner, and Alessandro Toschi — Institute of Solid State Physics, TU Wien

The breakdown of the self-consistent perturbation theory for many-electron systems has several physical and formal manifestations. Among the latter, one of the most studied is the divergence of two-particle irreducible vertex functions. Hitherto most investigations of the divergences appearing in the irreducible vertex functions of many-electron systems have been restricted to the particle hole symmetric cases and the calculations were performed at finite temperatures. This work is a first step beyond such restrictions. To this aim we investigate the two particle properties of the Hubbard Atom, both for positive (repulsive) and negative (attractive) on-site interaction. As a main result a *universal phase-diagram* of vertex divergences, valid for arbitrary (finite) temperatures, has been determined. Using this result as a "compass", the T=0 limit has been investigated, in order to unveil possible connections between the vertex divergences and the validity or the violation of the Luttinger Theorem. We also study the convergence of the self-consistent perturbation series beyond the particle-hole symmetry condition, determining specific constraints for the convergence of the series to the physical solution at arbitrary electronic densities.

TT 65.5　Fri 10:30　HSZ 204

Cooling and heating in the Bose-Hubbard model by parameter tuning — •Sebastian Eggert, Sven Stawinski, and Axel Pelster — University of Kaiserslautern

We investigate short-range interacting Bosons in an optical lattice at finite temperature. It is well known that the system shows a Mott-Superfluid transition when changing the repulsion U, the hopping t and/or the filling. However, it is much less clear how the temperature is affected by those changes, assuming the parameters U and/or t are tuned adiabatically. We now present higher order calculations for the full Free energy and derive the temperature and entropy in a large parameter space. We discuss where significant heating or cooling effects can be expected in the superfluid phase, in the Mott region and near the phase transition lines.

TT 65.6　Fri 11:00　HSZ 204

Fixed-point annihilation and duality in the SU(2)-symmetric spin-boson model — •Manuel Weber[1,2] and Matthias Vojta[2] — [1]Max-Planck-Institut für Physik komplexer Systeme, Dresden, Germany — [2]Institut für Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, Germany

The annihilation of two intermediate-coupling renormalization-group (RG) fixed points is of interest in diverse fields from statistical mechanics to high-energy physics, but has so far only been studied using perturbative techniques. Using the recently developed wormhole quantum Monte Carlo method, we present high-accuracy results for the SU(2)-symmetric $S = 1/2$ spin-boson (or Bose-Kondo) model. We study the model with a power-law bath spectrum $\propto \omega^s$ where, in addition to a critical phase predicted by perturbative RG, a stable strong-coupling phase is present. Using a detailed scaling analysis, we provide direct numerical evidence for the collision and annihilation of two RG fixed points at $s^* = 0.6540(2)$, causing the critical phase to disappear for $s < s^*$. In particular, we uncover a surprising duality between the two fixed points, corresponding to a reflection symmetry of the RG beta function, which we utilize to make analytical predictions at strong coupling which are in excellent agreement with numerics. Our work makes phenomena of fixed-point annihilation accessible to large-scale simulations, and we comment on the consequences for impurity moments in critical magnets.

TT 65.7　Fri 11:15　HSZ 204

Thermodynamics properties of interacting Dirac fermion with SO(3) symmetry — •Zihong Liu[1], Matthias Vojta[2], Fakher F. Assaad[1], and Lukas Janssen[2] — [1]Institut für Theoretische Physik und Astrophysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany — [2]Institut für Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01062 Dresden, Germany

In the previous work[Physical Review Letters, 128(8):087201, 2022], we figure out the zero temperature phasediagram of a interacting Dirac fermion model processed explicit SO(3) symmetry with unbias quantum Monte Carlo(QMC) method. By threading size dependent magnetic flux ($B \sim 1/L^2$) across two dimensional honeycomb lattice, we reduce the finite size effect in the QMC simulation and suppress the superconductivity in the strong coupling region. In this scenario, the ground state phase diagram of the model is splitted by two phase transitions. In this talk, we implement the QMC simulation by turning off the magnetic flux. Without the external magnetic field, the model recover to a higher symmetry and the superconductivity emergence in the strong coupling region on the ground state. In addition, we investigate the thermodynamics properties near the second transition point, where the finite temperature phase boundary are determined by the Ising type particle-hole order parameter and the Kosterlitz-Thouless transition govered by the U(1) symmetry breaking.

Long-term memory magnetic morrelations driven by local electronic repulsion — •Emin Moghadas[1], Matthias Reitner[1], Clemens Watzenböck[1], Giorgio Sangiovanni[2], and Alessandro Toschi[1] — [1]TU Wien — [2]University of Würzburg

We investigate the onset of non-decaying temporal magnetic correlations in simple electronic models with on-site (Hubbard) electrostatic repulsion U. This effect[1] corresponds to the existence of a finite difference between the static/isothermal and the zero-frequency limit of the dynamical Kubo (magnetic) susceptibility. The long-term behavior is studied, on the one hand, analytically for the non-interacting Bethe lattice case in infinite dimensions and, on the other hand, for finite-size Hubbard ring-molecules by means of exact diagonalization. This way, we can directly observe and investigate the link between the emergence of infinitely long-lived temporal correlations and the degeneracies of the exact many-body eigenspectrum, possibly inferring underlying relations with the entropic properties of the system. Our findings also pave the way to study the enhancement of the static/isothermal density response in the proximity of metal-insulator transitions [2] and, in particular, of its possible impact on the renormalization of electron-phonon coupling.

Simulation of anyonic tight-binding Hamiltonians — •Nico Kirchner[1], Adam Smith[2,3], Babatunde Ayeni[5], Frank Pollmann[1,4], and Joost Slingerland[5,6] — [1]Department of Physics, TFK, Technische Universität München, James-Franck-Straße 1, D-85748 Garching, Germany — [2]School of Physics and Astronomy, University of Nottingham, Nottingham, NG7 2RD, UK — [3]Centre for the Mathematics and Theoretical Physics of Quantum Non-Equilibrium Systems, University of Nottingham, Nottingham, NG7 2RD, UK — [4]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany — [5]Department of Mathematical Physics, National University of Ireland, Maynooth, Ireland — [6]Dublin Institute for Advanced Studies, School of Theoretical Physics, 10 Burlington Rd, Dublin, Ireland

Anyons are quasiparticles with exotic exchange statistics that can be supported in two-dimensional systems such as quantum spin liquids and fractional quantum Hall systems. In general, even effective models for such systems are not exactly solvable, which leads to numerical approaches to study the properties of anyons. In this talk, I will discuss how to numerically simulate anyonic tight-binding Hamiltonians for general abelian and non-abelian anyon models using the formalism of fusion diagrams. The presented results for such tight-binding Hamiltonians include energy level spacing statistics, which reveal level repulsion for all considered anyons. Further, it is observed that the density distribution following a quench becomes homogeneous at large times for these systems, which indicates thermalization.

TT 65.10　Fri 12:00　HSZ 204
Absence of fractal quantum criticality in the quantum Newman-Moore model
— •Raymond Wiedmann[1,2], Lea Lenke[1], Matthias Mühlhauser[1], and Kai Phillip Schmidt[1] — [1]Friedrich-Alexander-Universität, Erlangen-Nürnberg, Germany — [2]MPI-FKF, Stuttgart, Germany
The quantum phase transition between the high-field polarized phase and the low-field fracton phase with type-II fracton excitations is investigated in the two-dimensional self-dual quantum Newman-Moore model. We apply perturbative and numerical linked cluster expansions to calculate the ground-state energy per site in the thermodynamic limit revealing a level crossing at the self-dual point. In addition, high-order series expansions of the relevant low-energy gaps are determined using perturbative continuous unitary transformations indicating no gap-closing. Our results therefore predict a first-order phase transition between the low-field fracton and the high-field polarized phase at the self-dual point.

TT 66: Cryogenic Detectors

Towards ultrasensitive calorimetric detection in superconducting quantum circuits — •Bayan Karimi[1,2], Kuan-Hsun Chiang[2], Yu-Cheng Chang[2], Danilo Nikolic[3], Joonas T. Peltonen[2], Wolfgang Belzig[3], and Jukka P. Pekola[2] — [1]QTF Centre of Excellence, Department of Physics, Faculty of Science, University of Helsinki, Finland — [2]Pico group, QTF Centre of Excellence, Department of Applied Physics, Aalto University, Finland — [3]Fachbereich Physik, Universität Konstanz, D-78467, Germany
We demonstrate experimentally an ultra-sensitive thermal detector formed of an electronic absorber coupled to a phonon bath, which reaches the ultimate noise level dictated by the fundamental thermal fluctuations [1]. A scheme of coupling a superconducting qubit to this calorimeter is presented and we conclude positively about sufficient signal-to-noise ratio (SNR) in detecting a microwave photon emitted by it [2,3,4]. Recently this scheme was applied to the thermal detection of quantum phase slips in a Josephson junction [5], and currently we are performing experiments on the proposed qubit calorimetry.

TT 66.2　Fri 10:00　HSZ 304
Novel concept for a superconducting microcalorimeter with tunable gain — •Constantin Schuster, Gabriel Jülg, and Sebastian Kempf — Institute of Micro- and Nanoelectronic Systems, Karlsruhe Institute of Technology, Karlsruhe, Germany
Cryogenic microcalorimeters such as metallic magnetic calorimeters (MMC) or transition edge sensors (TES) are becoming a mature technology and are hence presently used in various applications requiring an excellent energy resolution. They rely on transducing the temperature rise upon the absorption of an energetic particle into a change of magnetic flux (MMC) or electrical current (TES) which is measured using a SQUID. Despite the overall great success, it turns out that the resolving power still lacks behind the fundamental limit set by fluctuations of thermal energy among different degrees of freedom of the detector. Against this background, we present a novel detector concept which may help to improve the energy resolution. It is based on the strong temperature dependence of the magnetic penetration depth of a superconductor close to its critical temperature. By embedding a properly chosen superconductor directly into the SQUID loop and using a special input circuit configuration, a change in temperature is transduced into a change in magnetic flux threading the SQUID loop. Moreover, it turns out that the temperature to flux transfer coefficient can be tuned in-situ. We present our detector concept and gauge the possible performance and energy resolution of this novel detector concept by discussing simulating results and and first experimental data.

TT 66.3　Fri 10:15　HSZ 304
Advances in microwave SQUID multiplexing of magnetic microcalorimeters — •Martin Neidig, Alexander Maatz, Felix Schuderer, Marvin Völlinger, Mathias Wegner, Stefan Wünsch, and Sebastian Kempf — Institute of Micro- and Nanoelectronic Systems, Karlsruhe Institute of Technology, Karlsruhe, Germany
The excellent energy resolution, very fast signal rise time and almost ideal linear detector response over a wide energy range makes magnetic microcalorimeters (MMCs) an exceedingly attractive detector technology for applications in various fields of science. The increasing necessity to operate large-scale detector arrays consisting of thousands to millions of individual detectors inherently poses the challenge of developing a suitable multiplexing technique. The presently most promising one is microwave SQUID multiplexing. Here, each individual detector is inductively coupled to a non-hysteretic, unshunted rf-SQUID that, in turn, is inductively coupled to a superconducting microwave resonator having a unique resonance frequency. In this configuration, an actual detector event results in a change of the effective SQUID inductance and hence in the resonance frequency of the related resonator. Moreover, capacitively coupling many of such readout channels to a single transmission line ultimately allows to read out hundreds to thousands of detectors simultaneously. In this contribution, we summarize our latest developments regarding the implementation of a microwave SQUID multiplexer for MMC readout. This includes aspects regarding to microfabrication as well as device characterization using software defined radio based readout electronics.

TT 66.4　Fri 10:30　HSZ 304
Design, fabrication and characterization of magnetic microcalorimeters for radionuclide metrology within the EMPIR project PrimA-LTD — •Michael Müller, Fabienne Bauer, Ria-Helen Zühlke, Trung Duc Tran, Alex Mocanu, and Sebastian Kempf — Institute of Micro- and Nanoelectronic Systems, Karlsruhe Institute of Technology, Karlsruhe.
The EMPIR project "PrimA-LTD" aims to provide ultra-precise measurements of the decay spectra of several radionuclides to enable activity standardization for medicine and industry. As the measurements require an outstanding energy resolution and great linearity over a wide energy range, magnetic microcalorimeters (MMCs) are used as detector technology. The latter are cryogenic particle detectors that make use of a paramagnetic temperature sensor linked to a particle absorber in which the radionuclide is embedded. The sensor is biased by a magnetic field to create a temperature dependent sensor magnetization which is altered by the temperature rise upon a radioactive decay within the absorber and measured using a SQUID. To provide a flexible detector platform, we designed three optimized MMC layouts allowing for different methods of source preparation. For in-house microfabrication of the detectors, we established deposition processes for the various materials needed. This particularly includes an electroplating process for thick, highly conductive absorbers made of gold that are free-standing on stems having a diameter of only 5 μm. We summarize the detector layouts as well as the fabrication status of the detectors and discuss characterization measurements of detector prototypes.

TT 66.5　Fri 10:45　HSZ 304
Fluxon counters and velocimeters at superconducting strips — •Oleksandr Dobrovolskiy — University of Vienna, Faculty of Physics, Nanomagnetism and Magnonics, SuperSpin Laboratory
Thin strips with large critical current Ic are required for superconducting microstrip single-photon detectors (SMSPDs) [1] and Cherenkov generators/detectors of spin waves by ultra-fast moving fluxons [2]. In this regard, high Ic implies blocking of the penetration of vortices via the strip edges and their control via material and edge-barrier engineering [3]. Thus, at sufficiently large transport currents Itr, a slit at the edge of a superconducting strip acts as a gate for the vortices entering into it. These vortices form a jet, which is narrow near the slit and expands due to the repulsion of vortices as they move to the opposite edge of the strip, giving rise to a transverse voltage Vp. In my talk, I will present our experimental results on voltage kinks in the I-V curves which occur each time the number of fluxons crossing the strip is increased by one [4]. I will also dwell on the appearance of the non-monotonic Vp in MoSi strips with slits milled by FIB at various distances from the transverse voltage leads [5]. Our findings are relevant for the performance of SMSPDs and superconducting devices operated in the single-fluxon regime.

Superconducting 3D-cavity architecture for microwave single-photon detection — •Yuki Nojiri[1,2], Kedar E. Honasoge[1,2], Daniil Bazulin[1,2], Florian Fesquet[1,2], Maria-Teresa Handschuh[1,2], Fabian Kronowetter[1,4], Michael Renger[1,2], Achim Marx[1], Kirill G. Fedorov[1,2], and Rudolf Gross[1,2,3] — [1]Walther-Meißner-Institut, Bavarian Academy of Sciences and Humanities, Germany — [2]Technical University of Munich, TUM School of Nat-

ural Sciences, Physics Department, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 Munich, Germany — [4]Rohde & Schwarz GmbH & Co. KG, Mühldorfstraße 15, 81671 München

Microwave single-photon detectors (SPDs) are essential quantum devices required in a large variety of quantum communication and quantum computation protocols. First microwave SPDs have been realized with the help of superconducting qubits and resonators. Here, we experimentally study an SPD design compatible with the superconducting 3D cavity architecture. We exploit the multimode nature of horseshoe aluminum cavities in combination with transmon qubits to experimentally realize efficient detection of single microwave photons. We analyze the performance of such devices and discuss possible ways to improve it.

TT 66.7   Fri 11:15   HSZ 304

Novel susceptibility thermometer for mK-temperatures based on Au:Er micro-fabricated on a copper substrate — •Nathalie Probst, Andreas Fleischmann, Andreas Reifenberger, Andreas Reiser, and Christian Enss — Kirchhoff-Institute for Physics, Heidelberg University

There are not too many options for fast, highly sensitive and reliable thermometers for use at low and ultra-low temperatures. Here, we present a novel concept of a susceptibility thermometer based on the paramagnetic alloy Au:Er that has the potential to meet these requirements. To ensure very good thermal contact, the superconducting readout coils and the paramagnetic materials are micro fabricated on a polished copper wafer. In this concept, four planar meander-shaped niobium coils each with a width of 5μm and a total length of 20m, are arranged as a Wheatstone bridge. Two opposite coils are covered with sensor material. The inductances of the covered and uncovered coils were chosen so that the bridge is balanced at a certain temperature, as indicated by the zero detector. This temperature can be conveniently set by the erbium concentration and the design of the coils. For certain applications, this can serve as an individual fixed point for precise temperature stabilization. The imbalance due to the paramagnetic contribution of the Au:Er at different temperatures is used to establish a temperature scale by calibration with another thermometer. We will discuss the design, fabrication, function and readout of this novel susceptibility thermometer.

TT 67: Dynamics and Chaos in Many-Body Systems II (joint session DY/TT)

Time: Friday 9:30–12:30   Location: MOL 213

TT 67.1   Fri 9:30   MOL 213

Towards a more fundamental understanding of eigenstate thermalization — •Tobias Hofmann, Tobias Helbig, Ronny Thomale, and Martin Greiter — Institut für Theoretische Physik und Astrophysik, Universität Würzburg, 97074 Würzburg, Germany

We explore several venues how eigenstate thermalization may be understood on a more fundamental level. In particular, we report on extensive numerical work in spin systems with random interactions, where a small subsystem is subject to thermalization. We discuss possible directions towards an understanding of our numerical results.

TT 67.2   Fri 9:45   MOL 213

Spectral Response of Disorder-Free Localized Lattice Gauge Theories — •Nilotpal Chakraborty[1], Markus Heyl[1,2], Petr Karpov[1], and Roderich Moessner[1] — [1]Max Planck Institute for Physics of Complex Systems, Dresden — [2]University of Augsburg

We show that certain lattice gauge theories exhibiting disorder-free localization have a characteristic response in spatially averaged spectral functions: a few sharp peaks combined with vanishing response in the zero frequency limit. This reflects the discrete spectra of small clusters of kinetically active regions formed in such gauge theories when they fragment into spatially finite clusters in the localized phase due to the presence of static charges. We obtain the transverse component of the dynamic structure factor, which is probed by neutron scattering experiments, deep in this phase from a combination of analytical estimates and a numerical cluster expansion. We also show that local spectral functions of large finite clusters host discrete peaks whose positions agree with our analytical estimates. Further, information spreading, diagnosed by an unequal time commutator, halts due to real space fragmentation. Our results can be used to distinguish the disorder-free localized phase from conventional paramagnetic counterparts in those frustrated magnets which might realize such an emergent gauge theory.

TT 67.3   Fri 10:00   MOL 213

Chaos in the three-site Bose-Hubbard model - classical vs quantum — •Goran Nakerst[1] and Masudul Haque[1,2] — [1]Institut für Theoretische Physik, Technische Universität Dresden, D-01062 Dresden, Germany — [2]Max-Planck-Institut für Physik komplexer Systeme, D-01187 Dresden, Germany

We consider a quantum many-body system - the Bose-Hubbard system on three sites - which has a classical limit, and which is neither strongly chaotic nor integrable but rather shows a mixture of the two types of behavior. We compare quantum measures of chaos (eigenvalue statistics and eigenvector structure) in the quantum system, with classical measures of chaos (Lyapunov exponents) in the corresponding classical system. As a function of energy and interaction strength, we demonstrate a strong overall correspondence between the two cases. In contrast to both strongly chaotic and integrable systems, the largest Lyapunov exponent is shown to be a multi-valued function of energy.

TT 67.4   Fri 10:15   MOL 213

Many-Body Dwell-time and Density of States — •Georg Maier, Carolyn Echter, Juan-Diego Urbina, and Klaus Richter — Universität Regensburg, Regensburg, Germany

Many body systems with a large number of degrees of freedom are usually described by statistical physics on the theoretical side while experiments usually relay on scattering (e.g. particle physics). Is it possible to relate scattering and statistical physics, or to measure scattering-related observables which directly relate to quantities of statistical physics? At least for single particle systems a close relation exists between the well known Wigner-Smith delay time in scattering theory and the density of states of the scattering system.

I will present a novel ansatz relating a many-body version of dwell-/Wigner-Smith delay time and many body density of states based on the famous Birman-Krein-Friedel-Loyd formula connecting scattering theory and statistical observales in the many-body context. This formalism could provide answers to a wide variety of interesting questions, e.g. can we observe the effect of interactions (or even the emergence of chaos) through the lens of the dwell-time? Another interesting point is the roll of particle statistics on dwell-time meaning e.g. does it take longer for a particle to leave a fermionic or bosonic system?. I will present our analytical and numerical results on these questions.

TT 67.5   Fri 10:30   MOL 213

Dynamical correlations and domain wall relocalisation in transverse field Ising chains — •Philippe Suchsland[1], Benoît Douçot[2], Vedika Khemani[3], and Roderich Moessner[1] — [1]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Str. 38, 01187 Dresden, Germany — [2]LPTHE, UMR 7589, CNRS and Sorbonne Université, 75252 Paris Cedex 05, France — [3]Department of Physics, Stanford University, Stanford, California 94305, USA

We study order parameters and out-of-time-ordered correlators (OTOCs) for a wide variety of transverse field Ising chains: classical and quantum, clean and disordered, integrable and generic. The setting we consider is that of a quantum quench. We find a remarkably rich phenomenology, ranging from stable periodic to signals decaying with varying rates. This variety is due to a complex interplay of dynamical constraints (imposed by integrability and symmetry) which thermalisation is subject to. In particular, a process we term dynamical domain wall relocalisation provides a long-lived signal in the clean, integrable case, which can be degraded by the addition of disorder even without interactions. Our results shed light on a proposal to use an OTOC specifically as a local dynamical diagnostic of a quantum phase transition even when evaluated in a state with an energy density corresponding to the paramagnetic phase.

15 min. break

TT 67.6   Fri 11:00   MOL 213

Time evolution at the quantum-critical point of the sawtooth chain — •Jannis Eckseler, Florian Johannesmann, and Jürgen Schnack — Fakultät für Physik, Universität Bielefeld, Postfach 100131, D-33501 Bielefeld, Germany

It is known for the antiferromagnetic sawtooth chain with Heisenberg interactions to develop a flat band at the quantum-critical point of $J_1 = 2J_2$, where J_1 is the exchange interaction between nearest neighbors and J_2 the interaction at the base of the triangles [1]. We investigate the time evolution of several observables of the sawtooth chain, especially near that point and in particular in view of their equilibration properties. [1] J. Schulenburg, A. Honecker, J. Schnack, J. Richter, H.-J. Schmidt, Phys. Rev. Lett. 88 (2002) 167207

TT 67.7   Fri 11:15   MOL 213

Quantum Noise as a Symmetry-Breaking Field — •Paul McClarty[1], Beatriz Dias[2], Domagoj Perkovic[3], Masudul Haque[4], and Pedro Ribeiro[5] — [1]MPI PKS, Dresden, Germany — [2]TU Munich, Garching, Germany — [3]Cavendish Lab, University of Cambridge, UK — [4]TU Dresden, Germany — [5]IST, Lisbon, Portugal

We investigate the effect of quantum noise on the measurement-induced quantum phase transition in monitored random quantum circuits. Using the efficient simulability of random Clifford circuits, we find that the transition is broadened into a crossover and that the phase diagram as a function of projective measurements and noise exhibits several distinct regimes. We show that a mapping to a classical statistical mechanics problem accounts for the main features of the random circuit phase diagram. The bulk noise maps to an explicit permutation symmetry breaking coupling; this symmetry is spontaneously broken when the noise is switched off. These results have implications for the realization of entanglement transitions in noisy quantum circuits.

TT 67.8   Fri 11:30   MOL 213

Finite-size prethermal behavior at the chaos-to-integrable transition — •Johannes Dieplinger[1] and Soumya Bera[2] — [1]Institute of Theoretical Physics, University of Regensburg, D-93040 Germany — [2]Department of Physics, Indian Institute of Technology Bombay, Mumbai 400076, India

We investigate the dynamics of the complex Sachdev-Ye-Kitaev model complemented with a single particle hopping term, leading to a chaos-to-integrable transition of the eigenstates. We determine the dynamics close to the transition via the density-density correlator, where we observe a prethermal plateau in the ergodic phase. This indicates a finite time localised behavior up to an interaction-dependent thermalization time scale. This time scale is quantified as $t_{th} \propto 2^{\alpha/\sqrt{\lambda}}$ as a function of the relative interaction strength λ. The results are validated by investigating the time-dependent structure of the time-evolved wave functions in the Fock space.

TT 67.9   Fri 11:45   MOL 213

Quasiparticle Description of Entanglement Growth — •Molly Gibbins, Bruno Bertini, and Adam Smith — University of Nottingham

The quasiparticle picture of entanglement is a novel way to describe a feature unique to quantum many-body systems. Recent research has found excellent agreement of this description with numeric results: a description that had been shown to hold for the general family of Rényi entanglement entropies, for different classes of quench and different geometries of the boundary across which entanglement develops.

The aim of this project is to develop a quasiparticle description of the entanglement growth in free-fermionic systems with translational invariance in both 1D and 2D. The propagation of quasiparticles across this cut will respect this translational invariance and it is expected that the entanglement generated between these particles will be in very good agreement with the exact solution for these systems.

TT 67.10   Fri 12:00   MOL 213

Excitation Transport in Molecular Aggregates with Thermal Motion — •Ritesh Pant and Sebastian Wüster — Indian institute of science education and research, Bhopal, India

Molecular aggregates can under certain conditions transport electronic excitation energy over large distances due to the long range dipole-dipole interactions. These interactions are also the characteristics of Rydberg aggregates which have been proved as the quantum simulators for molecular aggregates. An idea that naturally arises in Rydberg aggregates, is adiabatic excitation transport through atomic motion, where slow motion of the atoms combined with excitation transport can result in efficient and guided transport of the excitation from one end of an atomic chain to the other. Based on the analogy between Rydberg and Molecular aggregates, in ref. [1] we explore whether the adiabatic excitation transport can play a functional role in molecular aggregates in the absence of intra-molecular vibrations. But because the transport is partially adiabatic and because it involves transitions between non-eigenstates, it is challenging to estimate the adiabaticity of transport in molecular aggregates. Hence, in ref [2] we established a measure to quantify the adiabatic character of quantum transitions in general. Next, the effect of intramolecular vibrations is included by extending our calculation for excitation transport to an open-quantum- system technique [3].

Tailoring the Phonon Environment of Embedded Rydberg Aggregates — •Sidharth Rammohan[1], Sebastian Wüster[1], and Alexander Eisfeld[2] — [1]IISER Bhopal, Madhya Pradesh, India — [2]MPIPKS, Dresden, Germany

State-of-the-art experiments can controllably create Rydberg atoms inside a Bose-Einstein condensate (BEC) such that the Rydberg electron orbital volume contains many neutral atoms, which can be tuned, resulting in electron-atom scattering events [1]. In my talk, I will discuss the physics of the interaction and corresponding dynamics of a single or multiple Rydberg atoms in two internal electronic states embedded inside a BEC, to assess their utility for controlled studies of decoherence and quantum simulations of excitation transport similar to photosynthetic light-harvesting. We initially developed a theoretical framework to calculate the open quantum system input parameters for a single Rydberg atom, possibly in two internal states, in BEC and then for a chain of Rydberg atoms, forming an aggregate [2]. The electron-atom interactions lead to Rydberg-BEC coupling, creating phonons in the BEC. Using the spin-boson model with the calculated parameters, we then examine the decoherence and the Non-Markovian features of a Rydberg atom in a superposition, resulting from the interaction with the environment [3]. The scenario with a single Rydberg atom is then extended to the aggregate case, allowing us to set up dynamics similar to those found in light-harvesting complexes. Ref:1. J. B. Balewski, et.al; Nature 502 664 (2013).2. S. Rammohan, et.al; PRA 103, 063307 (2021).3. S. Rammohan, et.al; PRA 104, L060202 (2021).

Multi-Dimensional Photoemission Spectroscopy: a concept for FAIR photoemission data — •Florian Dobener[1], Tommaso Pincelli[2,3], Abeer Arora[2,4], Steinn Ymir Augustsson[5], Dmytro Kutnyakhov[6], Michael Hartelt[7], Laurenz Rettig[1], Martin Aeschlimann[2], Ralph Ernstorfer[7], and Sandor Brockhauser[2,3] — [1]Department of Physics, HU Berlin, Germany —

[2]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — [3]Institut für Optik und Atomare Physik, TU Berlin, Germany — [4]FU Berlin, Fachbereich Physik, Berlin, Germany — [5]Institut für Physik, Johannes Gutenberg-Universität Mainz, Germany — [6]DESY, Hamburg, Germany — [7]Department of Physics and OPTIMAS, University of Kaiserslautern, Germany

The complexity and size of photoemission data is rapidly increasing as new technological breakthroughs have enabled multidimensional parallel acquisition. However, most of the community is currently using heterogeneous data formats and workflows. We propose a new data format based on NeXus, a hierarchically organized hdf5 structure. This multidimensional photoemission spectroscopy format is designed to allow high-performance automated access, enabling experimental databases for high-throughput material search. Our approach involves reaching out to the community using a website with extensive documentation of our proposed standard. As a demonstrator of the potential of our approach we present a workflow and data pipeline integrated into the NOMAD research data management solution, which provides powerful analysis and search functionalities.

TT 68.4   Fri 10:30   WIL A317

Towards an Infrastructure for FAIR Synthesis Data — •Sebastian Brückner[1,2], Andrea Albino[1], Jose Marquez[1], Florian Dobener[1], Hampus Nässtrōm[1], Markus Scheidgen[1], Claudia Draxl[1], and Martin Albrecht[2] — [1]HU Berlin, Zum Großen Windkanal 2, 12489 Berlin — [2]IKZ Berlin, Max-Born-Straße 2, 12489 Berlin

A data infrastructure based on the FAIR (findable, accessible, interoperable and reusable) principles promises a new way of sharing and exploring data by using highly efficient data analysis and artificial intelligence tools. This also applies to data related to sample synthesis. At present, most synthesis data are not structured comprehensively or not even stored digitally but in handwritten lab books. There hardly exists any data standards in synthesis, which is in contrast to data from characterization techniques. The FAIRmat project (https://FAIRmat-NFDI.eu) is building a FAIR data infrastructure for condensed-matter physics and the chemical physics of solids. In FAIRmat's Area A, we focus on synthesis data to make sample synthesis reproducible, accelerate the development of novel materials, and make characterization data of synthesized materials assessable. Here we summarize our ongoing work and progress including: providing a general data model for synthesis which is harmonized with data from measurements and theory (ontologies); implementation of our data model in use cases and electronic laboratory notebooks; developing tools for data acquisition and analysis; data governance guidelines to enable a sustainable change of research data management at the institute/university level.

TT 68.5   Fri 10:45   WIL A317

FAIRifying Material Synthesis with the NOMAD Electronic Laboratory Notebook (ELN) — •Andrea Albino[1], Hampus Nässtrōm[1], Florian Dobener[1], Jose Marquez Prieto[1], Lauri Himanen[1], David Sikter[1], Mohammad Nakhaee[1], Amir Golparvar[1], Sebastian Brückner[1], Martin Albrecht[2], Markus Scheidgen[1], and Claudia Draxl[1,3] — [1]Physics Department and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany. — [2]Leibniz-Institut für Kristallzüchtung, Berlin, Germany. — [3]The NOMAD Laboratory at the Fritz Haber Institute of the Max Planck Society, Berlin, Germany.

Approaching the era of big data-driven materials science, one crucial step to collecting, describing, and sharing experimental data is the adoption of ELNs. The project FAIRmat (fairmat-nfdi.eu) is offering such tools by developing and operating the open-source software NOMAD. The NOMAD ELN aims at offering a secure environment to protect the integrity of both data and metadata, whilst also affording the flexibility to adopt new synthetic processes or changes to existing ones without recourse to further software development.

We find that to promote an early adoption, it is important to adapt to a single user's needs and workflows. An inductive approach, going from a particular set of experiments to a general description of the similarities recurring in each of them, led us to adopt a common data structure as a standard. The state-of-the-art ELN features for a synthetic process will be shown in the talk, highlighting the development of both data modeling and specific implementation solutions.

TT 68.6   Fri 11:00   WIL A317

FAIR Data Infrastructure for Computation: Classical Simulations and Multiscale Modeling — •Joseph F. Rudzinski[1,2], José M. Pizarro[1], Nathan Daelman[1], Luca M. Ghiringhelli[1], Karsten Reuter[3], Kurt Kremer[2], Silvana Botti[4], and Claudia Draxl[1] — [1]Institut für Physik, Humboldt-Universität zu Berlin — [2]Max-Planck-Institut für Polymer Forschung, Mainz — [3]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin — [4]Institut für Festkörpertheorie und Optik, Friedrich-Schiller-Universität Jena

The emergence of the (big-)data-centric techniques as a fundamental paradigm of science calls for the development of infrastructure for ensuring FAIR—findable, accessible, interoperable, reusable—data management. The FAIRmat consortium aims to build extensive infrastructure for a wide variety of materials-science data, including soft matter simulations [1], by expanding upon the success of the NOMAD Laboratory—a repository for atomistic calculations in ma-

terials science [2]. Both the large volume and heterogeneous nature of classical molecular-dynamics simulation data presents a number of distinct challenges. In this talk, we present FAIRmat's progress in developing infrastructure for molecular-dynamics simulations, including metadata for molecular topologies and tools for workflow management. We will also discuss the need for standardization of metadata schemas and ontologies within the community, and planned collaborations with other open science initiatives and software developers.

Topical Talk   TT 68.7   Fri 11:15   WIL A317

Electronic Lab Notebooks in Teaching and Implications on Science — •Michael Krieger — Lehrstuhl für Angewandte Physik, Department Physik, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU)

In our department, we have recently introduced Electronic Lab Notebooks (ELN) in the obligatory electronic lab course in the 4th semester of the physics curriculum. Immediate advantages for the students are obvious: all data, raw data and metadata including experiment description and experimental observations, are digitally stored at the same place. Moreover, student teams share and actively work in their group ELN with access at the university as well as at home, and script-based evaluations can be performed directly in the ELN.

The introduction of ELNs in teaching has also implications on science. Students carry their ELN experience and data competences into all research groups. There, however, modern research data management is much more complex. According to the FAIR principles, it requires structured, machine-readable data using open formats and vocabularies that meet community standards. The development of such standards is in many cases still to be done and is the core of the Nationale Forschungsdateninfrastruktur (NFDI). Here, ELNs in teaching provide a sandbox with short learning and innovation cycles for testing structured schemas. The experience helps to develop and establish sustainable and FAIR documentation of research workflows in science.

TT 68.8   Fri 11:45   WIL A317

A step towards predicting synthesis conditions of metal-organic frameworks — •Dinga Wonanke[1], Thomas Heine[2], and Christof Wöll[1] — [1]Institut für Funktionelle Grenzflächen (IFG), Karlsruher , Germany — [2]Faculty of Chemistry and Food Chemistry,Dresden, Germany

The process of synthesising metal-organic frameworks (MOFs) falls under a branch of chemistry known as reticular chemistry. Here, well defined crystalline compounds are synthesised from a well thought out design principle by linking predefined building blocks under specific conditions. Although, this approach appears to be intuitive, the synthesis of any novel MOF still follows the conventional approach that begins with a thorough literature survey to explore reagents, calculations of aliquots and finally a series of time consuming and stressful trial-and-error syntheses. Consequently, although millions of stable hypothetical MOFs with interesting properties have been predicted, only approximately 100 thousand crystal structures of MOFs currently exist in the Cambridge Structural Database (CSD). Indicating a significant bottleneck in the intelligent design of novel stable MOFs with targeted properties.

In this talk, we will present an overview of our journey to design a new machine learning algorithm for predicting the synthesis condition of existing and hypothetical MOFs. We will discuss our experiences and challenges in mining and curating the MOF subset in the CSD. Finally, we will present our new MOF database that maps every MOF to its experimental synthetic conditions.

TT 68.9   Fri 12:00   WIL A317

Deep learning surface scattering data analysis for processing large synchrotron datasets — •Vladimir Starostin, Valentin Munteanu, Linus Pithan, Alexander Gerlach, Alexander Hinderhofer, and Frank Schreiber — Institute of Applied Physics, University of Tübingen, Germany

In situ real-time surface scattering experiments such as grazing-incidence wide-angle X-ray scattering (GIWAXS) produce large amounts of data, frequently exceeding the capabilities of traditional data processing methods. Here we demonstrate an automated pipeline for the analysis of GIWAXS images, based on a machine learning architecture for object detection, designed to conform to the specifics of the scattering data [1]. Our pipeline enables real-time GIWAXS analysis and is designed to be employed at synchrotron facilities. We also present FAIR data strategies and traceable data resources from the raw data to the corresponding scientific publication and vice versa [2] including intermediate processing steps.

We demonstrate our method on real-time tracking of lead halide perovskite structure crystallization processes, which are relevant for hybrid solar cell applications. However, our approach is equally suitable for other crystalline thin-film materials by design. In general, the solution substantially accelerates the analysis process of GIWAXS images, potentially boosting the speed of scientific discoveries in material science.

TT 68.10   Fri 12:15   WIL A317

FAIR Data Infrastructure for Computation: Mapping out the Space of Density Functionals — •Nathan Daelman[1], Joseph F. Rudzinski[1,2], José M. Pizarro[1], Luca M. Ghiringhelli[1], Miguel A. L. Marques[3], Silvana Botti[4], and Claudia Draxl[1] — [1]Institut für Physik und IRIS-Adlershof, Humboldt-Universität zu Berlin, Berlin — [2]Max-Planck-Institut für Polymer Forschung, Mainz — [3]Institut für Physik, Martin-Luther-University Halle-Wittenberg, Halle — [4]Friedrich Schiller Universität Jena, Jena

The NOMAD Laboratory [1] holds over 135 million computational results, the vast majority of which stem from density-functional theory (DFT). The platform provides adequate querying and data analytics tools (e.g., machine-learning modelling) for processing such Big Data. However, the exchange-correlation (xc) functional with which the data was generated, limits the analysis scope of most thermodynamic and kinetic properties. Here, we present a strategy rooted in semantics for extending method interoperability. We will showcase our map of the entire xc-functional space that, in the context of the FAIRmat consortium [2], is built to be widely accessible and facilitate findability. Lastly, we will discuss the integration of this xc-functionals map into the NOMAD data platform, as well as its publication in ontology format as an effort towards a community-wide vocabulary standard.

OpenSemanticLab: Towards Open Semantic Research — •Simon Stier and Matthias A. Popp — Fraunhofer ISC, Neunerplatz 2, 97082 Würzburg, Germany

In materials science, complex relationships exist between the properties of materials and their composition and processing. Therefore, digital transformation and acceleration in this domain represents a particularly important challenge. Although it is generally agreed that data must be linked by means of semantics and ontologies to form holistic data spaces, there is still a lack of suitable tools for integrating the necessary structures into the everyday work of scientists.

Fraunhofer ISC addresses this challenge with a broad-based strategy that closely links activities at all relevant levels. The goal hereby is the development towards Lab 4.0, the machine-readable documentation of scientific processes and the harmonization of data structures in accordance with international standards.

Core of the resulting OpenSource solution architecture is the central web data platform OpenSemanticLab [1] that links people (knowledge), machines (data) and algorithms (AI) equally. As an open system, this platform is easily adaptable even without programming knowledge and without losing the uniform structure. In this way, OpenSemanticLab enables us as scientists to contribute individually and yet in a standardized fashion to future digital materials research.

VA 1: Vacuum Technology: New Developments and Applications

Time: Monday 9:30–12:00 Location: HSZ 301

VA 1.1 Mon 9:30 HSZ 301

Ultra-high-quality-factor membrane oscillators for gas pressure sensing — •Hossein Masalehdan[1], Christoph Reinhardt[2], Axel Lindner[2], and Roman Schnabel[1] — [1]Institut für Laserphysik und Zentrum für Optische Quantentechnologien der Universität Hamburg, 22761 Hamburg, Germany — [2]Deutsches Elektronen Synchrotron (DESY), 22607 Hamburg, Germany

Recent years have seen a rapid development of nanomechanical resonators with ultra-high mechanical quality factors Q. As a result, these devices become increasingly sensitive to smallest changes in certain environmental parameters, such as the pressure of the surrounding gas. In this work, we demonstrate the practical use of a mm-scale nanomechanical trampoline resonator with intrinsically-limited $Q \sim 10^7$ for gas pressure sensing. To this end, we place the trampoline inside an ultra-high-vacuum chamber and investigate the pressure-dependency of its resonance frequency and Q from high-vacuum to ambient pressure. We present a combined model, including molecular and viscous loss, which matches measured values within ±15%, for air and helium gas. Finally, we discuss potential applications and possible next steps towards improved sensing capabilities.

*This work was supported and partly financed (HM) by the DFG under Germany's Excellence Strategy EXC 2121 'Quantum Universe'-390833306 and via a PIER Seed Project.

VA 1.2 Mon 10:00 HSZ 301

Transient modeling of neutral gas flow in particle exhaust system of fusion reactors — •Christos Tantos, Stylianos Varoutis, and Christian Day — Karlsruhe Institute of Technology, Karlsruhe, Germany

In the present work the transient response of the neutral gas flows inside the geometrical complex particle exhaust systems of fusion reactors is studied. In this study the particle exhaust system of DEMO fusion reactor is investigated in a wide range of the operating conditions. The transient flow behavior is analyzed by solving the Boltzmann equation by applying kinetic models supplemented with the Discrete Velocity Method (DVM). The time of the neutral gas flow establishment is studied as a function of the initial divertor conditions as well as the pumping capability of the vacuum pumps. In addition, the effect of the intermolecular interaction law on the transient distributions of the neutrals gas flow quantities is also investigated. The analysis shows that the applied deterministic methodology allows a computationally efficient transient study of the neutral gas dynamics in the particle exhaust of the future fusion reactors.

VA 1.3 Mon 10:30 HSZ 301

Advanced simulation methodologies for optimizing aerosol injectors used for single-particle diffractive imaging — •Surya Kiran Peravali[1,4], Lena Worbs[1,2], Amit K Samanta[1,3], Muhamed Amin[1], Jochen Küpper[1,2,3], Philipp Neumann[4], and Michael Breuer[4] — [1]Center for Free-Electron Laser Science, Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]Department of Physics, Universität Hamburg, Germany — [3]Center for Ultrafast Imaging, Universität Hamburg, Germany — [4]Fakultät für Maschinenbau, Helmut-Schmidt-Universität,Germany

Single particle diffractive imaging (SPI) is a technique used for imaging atomic-scale structures and dynamics of nano-particles or bio-molecules. These experiments require the collection of thousands of diffraction patterns from identical particles. The particles are transferred into the gas phase and the collimated particle stream is then extracted in vacuum. The sample injection methods used for SPI must be optimized to produce high-quality particle beams, i.e., a high particle density and sample purity. We present a novel simulation framework which provides a quick and efficient way to search the experimental parameter space for optimizing the process. The framework requires simulating the gas flow inside the particle injectors and the expansion into the experimental vacuum chamber. Since the flow is at least partially in the rarefied regime i.e., high Knudsen number, a multi-scale approach combining simulation tools for continuum and free-molecular flow is applied. Subsequently, particle trajectories are computed using the forces obtained from interpolated force fields.

VA 1.4 Mon 11:00 HSZ 301

Novel Ionization Vacuum Gauge Suitable as Reference Standard — •Matthias Bernien[1], Frédéric Boineau[2], Nenad Bundaleski[3], Claus Illgen[1], Berthold Jenninger[4], Janez Šetina[5], Ricardo A.S. Silva[3], Anke Stöltzel[4], Orlando M.N.D. Teodoro[3], Martin Wüest[6], and Karl Jousten[1] — [1]PTB, Abbestr. 2-12, 10587 Berlin, Germany — [2]LNE, 1 rue Gaston Boissier, 75724 Paris Cedex 15, France — [3]CEFITEC, Nova University of Lisbon 2829-515 Caparica, Portugal — [4]CERN, 1211 Geneva 23 Switzerland — [5]IMT, Lepi pot 11, 1000 Ljubljana, Slovenia — [6]INFICON AG, Alte Landstrasse 6, LI-9496 Balzers, Liechtenstein

Within the EURAMET project 16NRM05 (www.ptb.de/empir/16nrm05-home.html) a new type of ionization vacuum gauge was developed for the pressure range from 10^{-6} Pa to 10^{-2} Pa. Unlike conventional Bayard-Alpert and extractor gauges, the new gauge features well-defined electron trajectories and mechanically robust electrodes. It exhibits excellent stability and linearity resulting in a measurement uncertainty of 1%, a reduction by one order of magnitude compared to the conventional gauges. The gauge revealed excellent metrological properties and is suitable as accurate reference and transfer standard.

At the moment the ISO standard 6737 is written standardizing the essential parameters of the gauge geometry and electrode voltages. By adhering to the standard manufactures can produce gauges with predictable gauge sensitivity and relative gas sensitivity factors without the need of characterizing them metrologically.

VA 1.5 Mon 11:30 HSZ 301

Inelastic electron scattering at a single-beam structured light wave — •Sven Ebel[1] and Nahid Talebi[1,2] — [1]Institute of Experimental and Applied Physics, Kiel University, 24098 Kiel, Germany — [2]Kiel Nano, Surface and Interface Science KiNSIS, Kiel University, 24118 Kiel, Germany

In this work we demonstrate the inelastic scattering of slow-electron wave packets at a propagating Hermite-Gaussian light beam. The pulsed Hermite-Gaussian beam thereby forms a pondermotive potential for the electron with large enough momentum components, leading to the inelastic scattering of electrons and their bunching along the longitudinal direction. We show that the resulting energy-gain spectra after the interaction is strongly influenced by the self-interference of the electron in this pondermotive potential. It is shown that this effect is observable for various optical wavelengths and intensities and further discuss how the variation of the electron velocity and the light intensity allow to control the energy modulation of the electron wave packet. This effect opens up a new platform for manipulating the electron wave packet by utilizing the vast landscape of structured electromagnetic fields.

VA 2: Vacuum Technology: New Developments and Applications – Poster

Time: Monday 14:00–16:00   Location: P2/OG2

VA 2.1   Mon 14:00   P2/OG2

A Novel Multilayer Barrier Coatings For Improved Cold-Field Electron Emitters — •Daniel Burda — Institute of Scientific Instruments of the CAS, v. v. i., Královopolská 147, 612 64 Brno, Czech Republic

By fabricating ultrathin, hard multilayer barrier coatings on top of the cold-field tungsten emitter, the parameters of the electron emission can be tuned. A multilayer structure of semiconducting and dielectric layers, i.e. Al_2O_3, HfO_2, on top of the electropolished tungsten tip is fabricated using Atomic Layer Deposition. The introduction of multilayered barriers enables modification of macroscopically observable electron emission parameters. The optimized material properties of the multilayer structure such as number of layers, thickness of single layers, and crystallinity lead to improvements in the emitted electron beam parameters, mainly in lowering the threshold emission voltage, increasing the spatial and temporal electron beam stability.

VA 2.2   Mon 14:00   P2/OG2

Reparing the seal faces of an MBE main flange — •Timo A. Kurschat[1,2], Sascha R. Valentin[2], Finn Krage[1], and Andreas D. Wieck[1] — [1] Angewandte Festkörperphysik, Ruhr-Universität Bochum, Universitätsstraße 150, D-44780 Bochum — [2] Gesellschaft für Gerätebau mbH, Klönnestraße 99, D-44143 Dortmund

During the refurbishment of an MBE the surface of the main flange was attacked by an etching solution used for cleaning. This also affected the seal faces of the 500 mm main flange, a 250 mm CF flange and five 40 mm CF flanges. The surface was very rough and therefore not UHV compatible any more.

In the absence of a sufficiently large lathe and because the 40 mm flanges are not arranged concentrically, we designed manual tools with specialized geometry to sand and polish the flanges. The grid size of the sandpaper used was between 1000 and 3000. The seal faces were polished until the surfaces were smooth and specular again. After cleaning and assembly, we performed a leak test and did not find any leaks after the procedure.

The details of the individual work steps, the geometry of the tools, and also the tools themselves will be shown.

Als Physiker*in Krankenhäuser digitalisieren? Klar doch! — •CHARLES LUDWIG MAJER — Siemens Healthcare GmbH, Weissacher Str. 11, 70499 Stuttgart
Als Physiker*in ist man bestens vorbereitet neue, komplexe und vielfältige Themenfelder zu erfassen und sich diese zu Eigen zu machen. In diesem Sinne sind auch der Gesundheitssektor und im Besonderen Krankenhäuser ein spannendes Entwicklungsfeld für Physiker*innen – und das nicht nur als Medizinphysiker*in. Als Digital Portfolio Expert bin ich vertrieblich verantwortlich für das gesamte digitale Portfolio von Siemens Healthineers. Zu meinen Aufgaben gehört es, dieses bei Kund*innen vorzustellen und vor allem zu erklären.

Da digitale Systeme hochspezialisiert sind und individuell an jeden Einzelfall und die bereits vorhandene IT-Infrastruktur angepasst werden müssen, ist ein konzeptionelles Arbeiten ein Muss. Aber nicht nur die IT-technischen Voraussetzungen müssen Berücksichtigung finden, sondern auch die individuellen Bedürfnisse der Anwender*innen und gegebenenfalls der Patient*innen. Bereits aus diesen beiden Anforderungen können sehr komplexe Projekte entstehen.

Zudem ergibt sich durch sich immer schneller entwickelnde Trends und Änderungen im Gesundheitswesen, der Geschäftsmodelle unserer Kund*innen und der gesetzlichen Rahmenbedingungen ein hoch spannendes klinisches Ökosystem. Sich in diesem komplexen System tagtäglich zu bewegen ist eine meiner vielen spannenden Aufgaben als Physiker bei Siemens Healthineers.

How start-ups and alumni networks enrich young scientist's career options — •JOACHIM RÄDLER — Ludwig-Maximilians-Universität, Geschwister-Scholl-Platz 1, München
The Center for NanoScience (CeNS) at LMU Munich has fostered relations with alumni and start-ups that emerged from the center. In my talk I will share our experience how institutionalized relations between industry and university enrich the academic landscape, improve career options of young scientists and leverage excellence in research.

Invited Talk   AIW 2.2   Wed 16:00   KRO 1.11

Karrieremöglichkeiten für Physikerinnen und Physiker auf dem Gebiet des Gewerblichen Rechtschutzes — •UDO WEIGELT — Partner Grünecker Patent- und Rechtsanwälte, Leopoldstr. 4, 80802 München
In dem Vortrag werden das Gebiet des gewerblichen Rechtsschutzes und die Karrierechancen, die Physikerinnen und Physikern auf diesem Gebiet offenstehen, vorgestellt. Dem Studium der Physik und/oder der Promotion in Physik schließt sich ein Training on the Job an, in dem die erforderlichen juristischen Kenntnisse erlernt werden. Neben und gleichzeitig zu diesem Training on the Job können weitere Zusatzqualifikationen in Form einer Ausbildung zum Europäischen Patentanwalt und/oder zum deutschen Patentanwalt und/oder in Form eines Studiums zum Master of Laws und/oder eines Jurastudiums als Doppelstudium erworben werden. In Abhängigkeit von den erworbenen Zusatzqualifikationen lassen sich verschiedenste Karrieren auf dem Gebiet des gewerblichen Rechtschutzes einschlagen, im öffentlichen Dienst als einfacher Prüfer in Patentämtern bis zur leitenden Stellung in denselben oder als einfacher Richter in Patentgerichten und Zivilgerichten bis zur leitenden Stellung in denselben, oder in der Privatwirtschaft als einfacher Mitarbeiter in einer Patentabteilung in kleinen und großen Unternehmen bis zur Leitung einer Patentabteilung, als angestellter Patentanwalt, als freiberuflicher Patentanwalt in eigener Kanzlei oder als Gesellschafter einer Anwaltskanzlei.

AIW 3: Podiumsdiskussion

The tragic destiny of Mileva Marić Einstein — •Pauline Gagnon — CERN, Geneva

What were Albert Einstein's first wife*s contributions to his extraordinary productivity in the first years of his career? A first biography of Mileva Marić Einstein was published in Serbian in 1969 but remained largely unknown despite being translated first in German, then in French in the 1990*s. The publication of Mileva and Albert*s love letters in 1987 revealed how they lived together while two recent publications shed more light on Mileva Marić*s life and work. I will review this evidence in its social and historical context to give a better idea of her contributions. In this presentation, I avoid all type of speculation and do not attack Albert Einstein personally, but rather strictly stick to facts. The audience will be able to appreciate why such a talented physicist has been so unkindly treated by history.

Invited Talk   AKC 1.2   Tue 11:30   ZEU 250
Physik-Projekt-Tage – Ein Workshop für Schülerinnen der Oberstufe — Anna Albrecht[2], •Anna Benecke[1], Dietmar Block[3], Franko Greiner[3], Andreas Hinzmann[2] und Roman Kogler[4] — [1]Université catholique de Louvain, CP3 — [2]Universität Hamburg, Inst. f. Exp. Physik — [3]CAU Kiel, Sektion Ohysik, IEAP — [4]DESY, CMS, Hamburg

Gleichstellungsarbeit ist gerade auch in der Physik ein wichtiges Thema. Dies zeigen nicht zuletzt die Einschreibezahlen von Studentinnen in den Physikstudiengängen. In Kiel z.B. liegt der Prozentsatz von der Frauen hier bei etwa 15%. Die Gleichstellungsarbeit erst an der Universität zu beginnen genügt daher nicht. Statt dessen müssen bereits die Schulen einbezogen werden. Mit den Physik-Projekt-Tagen (PPT) wurde ein viertägiger Workshop nur für Schülerinnen ins Leben gerufen. Die Teilnehmerinnen haben die Möglichkeit, zu Schuljahresbeginn vier Tage lang in einem Projekt ihrer Wahl zu experimentieren, ihr Interesse an Physik zu steigern und Netzwerke über Schulgrenzen hinweg aufzubauen. *Die Projekte umspannen verschiedene Forschungsfelder der Physik und reichen von Teilchenphysik, über Laserphysik und Plasmaphysik bis hin zu Nanowissenschaften. Zur Qualitätssicherung und Weiterentwicklung dieser Veranstaltung werden die PPT von einer kritischen Evaluation begleitet. Das Konzept der PPT, Inhalte und ausgesuchte Ergebnisse der Evaluation werden vorgestellt. Seit 2015 ist das Projekt im Instrumentenkasten für Gleichstellungsarbeit der DFG.

Invited Talk   AKC 1.3   Tue 12:00   ZEU 250
Belonging – a key to success in STEM?! — Lennart Brademann, Denise Dörfel, •Barbara M. Gordalla, and Anika Ihmels — TU Dresden, Faculty of Psychology, WOP

Women continue to be underrepresented in science, technology, engineering or mathematics (STEM) fields as students and also in professional roles. What factors influence women's choice, persistence, and success? In the US, studies evidenced that women do not feel like they belong in STEM community: they experience an impeding study climate (also called *chilly climate*) or suffer from stereotypical views on possible careers. This results in a decreased desire to choose a STEM carrier (for an overview see Shapiro & Sax, 2011). The probability to drop out of the program (Höhne & Zander, 2019b; Peters et al., 2015) is increased in the case of high *belonging uncertainty*, or when there is a conflict between an occupational stereotype and one's self-description.

The talk presents results from an online survey conducted among students, focusing on the field of physics. 122 physics students (40% female) completed it regarding success in studying physics (GPA, number of last attempts for an exam), turnover intention, chilly climate (e.g. exclusion, hostility), expectation of success (e.g. perceived potential, sense of belonging (e.g. belonging uncertainty), identification with physics, enjoyment, interest, a list of adjectives to describe oneself and to describe a *successful physicist*, and sociodemographic variables.

Results revealed lower social belonging and higher belonging uncertainty as well as a worse stereotype fit for women as compared to non-female students. Es; pecially, social belonging turned out to be the most important predictor for GPA, identification, turnover intention, interest, enjoyment, perceived potential and self-efficacy. Social belonging hence was identified as an important influencing factor to enhance women's interest, persistence, and success in STEM. Therefore, this factor demands for more attention in the future, both in research and in actual working environments - for a continued success of Germany in STEM fields.

AKC 2: Women in Physics Lunch

Time: Tuesday 12:30–13:30   Location: ZEU 250 Foyer

Female physicists of all career stages are cordially invited to join our meet-and-greet networking lunch. Diverse and all kinds of interested colleagues are also welcome!

Index of Exhibitors Dresden (SKM) 2023

Exhibition venue:

Technische Universität Dresden, Campus Südvorstadt, Bergstraße 64, 01069 Dresden

- Lecture Hall Centre (HSZ)
- Tent A (A)

Opening hours exhibition:

- Tuesday, 28 March   09:00 – 18:00
- Wednesday, 29 March   09:00 – 18:00
- Thursday, 30 March   09:00 – 16:00

Company	Location	Stand-No.
ADDITIVE Soft- und Hardware für Technik und Wissenschaft GmbH Max-Planck-Straße 22 b, 61381 Friedrichsdorf *ADDITIVE steht für Berechnen, Visualisieren, Automatisieren für Statistik und Wissensmanagement im Qualitäts-/Ingenieurwesen mit den Produkten Minitab, Origin, Mathematica und ADDITIVE-Cloud-Services.*	Tent A	A 69
