Content

Greeting

Dear Participants,

Welcome to the DPG-Frühjahrstagung (DPG Spring Meeting) of the Condensed Matter Section (SKM) with the participating divisions and working groups involved on the campus of the Technische Universität Dresden (TUD).

I am very pleased that with our DPG-Frühjahrstagungen (DPG Spring Meetings), even more so in presence, we can once again set a widely visible and public sign for the outstanding importance of basic research for scientific and societal progress. Basic research is indispensable for tackling the major societal challenges. Above all a sustainable energy supply with regard to climate change with its dramatic consequences for all life on our planet. On the other hand, the spring conferences are probably the most important instrument of the DPG to enable as many scientists as possible, especially young scientists, to participate in a cross-border, international and peaceful scientific exchange.

The last year has shown us with full force how important and by no means self-evident such a necessary and international exchange is, how vulnerable our world order is and how quickly a change can take place that even threatens the existence of countries. Therefore, it is the special responsibility of the DPG – guided by the values in our DPG Statutes, our compass – to stand up for freedom, tolerance, truthfulness and dignity in science and to act in awareness that we are particularly responsible for shaping the whole of human life: Especially and particularly in troubled times!

The DPG conference at the TUD plays an outstanding role for peaceful international scientific exchange and discourse as well as for the perception and appreciation of the work of the DPG. I would therefore like to thank all those involved for their great commitment to the success of this conference.

My special thanks go to the Technische Universität Dresden (TUD) for its hospitality and support. I would like to sincerely thank the Wilhelm and Else Heraeus Foundation for once again generously supporting all DPG Spring Meetings. My great appreciation goes to the participating divisions and working groups for a great programme.

I would especially like to thank the Local Organising Committee, Prof. Jochen Geck, Technische Universität Dresden (TUD), Institute of solid state and material physics (IFMP), and his entire team.

For the support of all DPG-Frühjahrstagungen (DPG Spring Meetings), my special thanks go to the DPG Head Office.

Prof. Dr. Joachim Ullrich
President
Deutsche Physikalische Gesellschaft e.V.

Chairs of the Participating Divisions of the DPG:

(BP)	Biological Physics	–	Prof. Dr. Joachim Rädler (raedler@lmu.de)
(CPP)	Chemical and Polymer Physics	–	Prof. Dr. Hans-Jürgen Butt (butt@mpip-mainz.mpg.de)
(DS)	Thin Films	–	Prof. Dr. Stefan Krischok (stefan.krischok@tu-ilmenau.de)
(DY)	Dynamics and Statistical Physics	–	Prof. Dr. Markus Bär (markus.baer@ptb.de)
(HL)	Semiconductor Physics	–	Prof. Dr. Axel Lorke (axel.lorke@uni-due.de)
(KFM)	Crystalline Solids and their Microstructure	–	J. Prof. Dr. Anna Grünebohm (anna.gruenebohm@rub.de)
(MA)	Magnetism	–	Prof. Dr. Heiko Wende (heiko.wende@uni-due.de)
(MM)	Metal and Material Physics	–	Prof. Dr. Christian Elsässer (christian.elsaesser@iwm.fraunhofer.de)
(O)	Surface Science	–	Prof. Dr. Ulrich Höfer (ulrich.hoefer@physik.uni-marburg.de)
(SOE)	Physics of Socio-economic Systems	–	Dr. Philipp Hövel (phoevel@physik.tu-berlin.de)
(TT)	Low Temperature Physics	–	Prof. Dr. Elke Scheer (elke.scheer@uni-konstanz.de)
(VA)	Vacuum Science and Technology	–	Dr.-Ing. Stylianos Varoutis (stylianos.varoutis@kit.edu)

Chairs of the Participating Working Groups

(AGYouLeap)	Young Leaders in Physics	–	Dr. Tobias Heindel (tobias.heindel@tu-berlin.de) Dr. Doris Reiter (doris.reiter@tu-dortmund)
(AKC)	Equal Opportunities	–	OStR Agnes Sandner (akc@dpg-physik.de)
(AIW)	Industry and Business	–	Dr. Udo Weigelt (weigelt@grunecker.de)
(AKjDPG)	Young DPG	–	Vivienne Leidel (leidel@jdpg.de)

Symposia

SYFP	–	Physics of Fluctuating Paths
SYGM	–	Green Magnets for Efficient Energy Conversion
SYHS	–	Physics of van der Waals 2D Heterostructures
SYOF	–	Dynamics of Opinion Formation – From Quorum Sensing to Polarization
SYQC	–	Topology in Quantum and Classical Physics – From Topological Insulators to Active Matter

SYQD – Real-Time Measurements of Quantum Dynamics
SYSD – SKM Dissertation Prize 2023
SYTS – Topological Superconductor-Magnet Heterostructures
SYUE – Ultrafast Excitation Pathways of Quantum Materials

Organisation of the Exhibition of Scientific Instruments and Literature

Programme

The scientific programme consists of **4.134** contributions:

11	Plenary Talks
1	Evening Talk
5	Prize Talks
1	Ceremonial Talk
5	Lunch Talks
211	Invited Talks
54	Topical Talks
2667	Contributions
7	Tutorials
1169	Posters
3	Discussions

The programme stated in this document corresponds to the status from February 10, 2023 and will not be updated!

Deutsche Physikalische Gesellschaft **ΦDPG**

Video Contest:

Physics in the Future

March 27-31, 2023

POLICE

BOX
What are the major challenges for physics in the future?
Which research areas will come into focus?
Or will time travel even be possible?
Join in and win!

What will the physics of the future look like and what will it be used for?

Share your vision with us!

The aim of this video competition is to bring together all kinds of different ideas for the future of physics.
Even without a Police Box or a converted DeLorean, the competition promises numerous exciting answers.
Tell us your vision – only time will tell if it comes true.

More information:

www.skm23.dpg-tagungen.de/veranstaltungen/wettbewerb

Information for Participants

The conference will be held March 26 – 31, 2023.

1. Conference Information

1.1 Conference Venue
Technische Universität Dresden
Campus Südvorstadt
Bergstraße 64
01069 Dresden

The central activities like registration etc. will take place in the Lecture Hall Center (HSZ) of the TU Dresden (Bergstraße 64). For a detailed map of the campus and the buildings please see end of this document. The position of the lecture rooms on the campus can be found at the campus navigator of TU Dresden *https://navigator.tu-dresden.de/* or the DPG-App (see 1.3.1).

1.2 Conference Office / Information Desk
The conference office and the information desk are located in the Lecture Hall Center, HSZ E01.

		Registration	Information Desk
Sunday	March 26	15:00 – 19:00	15:00 – 20:00
Monday	March 27	08:00 – 18:00	08:00 – 20:00
Tuesday	March 28	08:00 – 16:00	08:00 – 18:00
Wednesday	March 29	08:00 – 16:00	08:00 – 18:00
Thursday	March 30	08:00 – 16:00	08:00 – 18:00
Friday	March 31	08:00 – 12:00	08:00 – 15:00

You will receive your name tag, a receipt for your conference fee, the Login-Password for using WLAN (WiFi) as well as food and drink vouchers for the Welcome Evening (Sunday 18:30-21:30). The name tag must be worn visibly during the entire conference.
Please note: This year, no conference ticket for public transportation is included in the conference pass. We kindly ask you to buy a ticket yourself if you need it (the DVB one-week ticket price level A1 Dresden tariff zone at the normal price for 22,90 EUR is transferable, i.e. it is not personal).

The organisers, staff of the conference desk and student assistants will be identifiable by colored name tags and T-shirts. Please contact them if you have any questions. Do not hesitate to come to the information desk and inquire about all necessary information concerning the conference, orientation in Dresden, accommodation, restaurants, going out and cultural events.

1.3 Lecture Rooms
The lecture rooms will be signposted by abbreviations for the respective buildings and the room number. The campus map and location of the buildings are printed at the end of this document.

Abbr. **Building** *(see also: https://navigator.tu-dresden.de/)*

BAR	Barkhausen-Bau		REC	Recknagel-Bau
CHE	Chemiegebäude (Chemistry Building)		SCH	Georg-Schumann-Bau
GER	von-Gerber-Bau		Tents	Tents behind the Lecture Hall Center / Exhibition
GÖR	Görges-Bau		TOE	Toepler-Bau
HSZ	Hörsaalzentrum (Lecture Hall Center)		TRE	Trefftz-Bau
MER	Merkel-Bau		WIL	Willers-Bau
MOL	Mollier-Bau		ZEU	Zeuner-Bau
POT	Gerhard-Potthoff-Bau			

1.3.1 With the DPG-App through the Spring Meetings!
With the app you can find out not only about the conference programme but also about the venue and exhibitors at the industry and book exhibition. With the help of new functions such as "What's going on now?" or the building plan overview it is now even easier to find your way around on site. Download the free "DPG Spring Meetings" app for Android or iOS now!

1.4 Presentation

Scientific presentations will be held either orally or by poster. Presentations with a German abstract will be given in German.

1.4.1 Oral Presentation

Lecturers are requested to provide their presentations electronically. All lecture rooms are equipped with a projector ("beamer") mainly with HDMI input. Overhead Presenters are not available.

Laptops must be provided by the speakers as well as all associated adapters (e.g. HDMI to VGA, Apple-adapter). Furthermore, the presentation should be recorded onto an USB stick as back-up in PDF or Power Point format.

All laptops must be set up and connected with the data projector before the start of the respective session. All rooms will be opened at latest 30 minutes prior to the lecture. Speakers are requested to be in the lecture room at least 20 minutes prior to the start of the session*, to report to the chairperson as well as the technical staff, to ensure that the laptops handshake with the beamer, and to receive a brief introduction to the equipment in the lecture room.

In HSZ 01, HSZ 02, HSZ 03 and HSZ 04 it is recommended to transfer the presentation on the day before the lecture or on Monday morning.

1.4.2 Poster Presentation

Sites for poster sessions are named and located as follows:

P1A   Tent A behind the Lecture Hall Center (Exhibition Tent)
P2/EG   Lecture Hall Center (HSZ): foyer
P2/1OG   HSZ: 1st floor (hallway)
P2/2OG   HSZ: 2nd floor (hallway)
P2/3OG   HSZ: 3rd floor (hallway)
P2/4OG   HSZ: 4th floor (hallway)
P3   Chemiegebäude (Chemistry Building (CHE)) in the foyer

Posters must fit within a rectangle 90 cm wide and 120 cm high (DIN A0), portrait format!

The poster boards will be marked with the number according to the scientific programme. Authors are asked to mount their poster when the poster board is prepared with the corresponding poster number. Usually this will be arranged in the morning, or one hour before the session when there are several poster sessions per day. Each poster should display the number according to the scientific programme.

For the mounting of the poster please use the prepared "power strips" at the poster frame or contact the available student staff. Please make sure to use only power strips for mounting the poster (residue-free removing). The presenting authors should be at hand for discussion at their poster during at least half of the poster session and should note this time at the poster.

The posters have to be removed after the poster session. Any posters remaining on display walls after the poster session will be removed and disposed of without requesting your permission. The conference management accepts no liability for the posters.

1.5 Notice Board

All changes to the conference programme (i.e. cancellation of presentations, change of rooms, etc.) will be continuously updated on the notice board of the conference website. All upcoming changes are also taken into account in the regular updates of the electronic version of the conference programme which is available in different formats (sorted by publication date, filterable by conference parts and as an rss-feed). Please use the form *https://skm23.dpg-tagungen.de/ programm/notice-board-form* to notify changes or cancellations.

2. General Information

2.1 Internet

EDUROAM

The TU Dresden is member of the eduroam-network. Users from eduroam institutions, who have registered for eduroam, can use WLAN at the TU Dresden without local registration in Dresden. Eduroam in Dresden is possible with WLAN SSID eduroam.

For internet access at TU Dresden, please use your individual login-password on your registration document. Please search for and connect to the network named „VPN/WEB". If this network isn't shown in the list of available networks, the access isn't possible. After you have been connected, please visit any website with your browser to get redirected to the login page of the network. Enter your username and password and click on „Login". Afterwards you should be able to access the internet. This connection is not encrypted.

2.2 Message Board
Important general information about TU Dresden and the city of Dresden is displayed on a message board in the foyer of the Lecture Hall Center (HSZ). Alterations of the scientific programme however will be announced via the conference website "Notice Board".

2.3 Public Working Area
Public working rooms where you can work on your laptop are located in CHE 184 and GER 007.

2.4 Cloakroom
A guarded cloakroom is located in the basement of the Lecture Hall Centre (HSZ). The opening hours are as follows:

Sunday	March 26	15:00 — 21:30
Monday	March 27	08:00 — 21:30
Tuesday	March 28	08:00 — 20:30
Wednesday	March 29	08:00 — 20:30
Thursday	March 30	08:00 — 22:00
Friday	March 31	08:00 — 14:00

2.5 Lost and Found Property
You can bring found items to the Lecture Hall Center, room E03 (next to the information desk). There you can also get your lost property back.

3. Catering

3.1 Coffee Breaks
Coffee and tea are offered for free during the breaks in nearly all conference locations (see also in the legend of the campus map). You want to actively contribute to protect our climate and environment? Then please bring your own cup or use your paper cup several times. Thank you!

3.2 Snacks
You can get coffee, tea, refreshments and snacks as indicated in the campus map at the:

• Tent B behind the Lecture Hall center	Monday to Thursday, 08:00 – 19:00; Friday 08:00 – 14:00
• „Grill-Cube" next to the exhibition Tent B	Monday to Friday, 09:00 – 15:00
• Restaurant of the Leibniz-Institute IFW Dresden	Monday to Friday, 08:00 – 15:00
• „insgrüne coffeebar" in the Georg-Schumann-Bau (SCH)	Monday to Friday, 10:00 – 15:00
• Cafeteria & Mensa "Alte Mensa", Mommsenstraße 13	Monday to Thursday, 08:00 – 16:00; Friday 08:00 – 15:00
• Cafeteria & Mensa Zeltschlösschen, Nürnberger Str. 55	Monday to Friday, 08:00 – 15:30
• Cafeteria & Mensa Siedepunkt, Zellescher Weg 17	Monday to Friday, 11:00 – 15:00

as well as at Bergstr. 68 „FIRAT-Kebap-Haus" and Münchner Str. „DERSIM-Dürüm-Kebab-Haus" and bakery „Möbius".

3.3 Lunch
The Mensa Zeltschlösschen, Mensa Siedepunkt and the Mensa Mommsenstraße offer plenty of opportunities for lunch at moderate prices (self-payment). The IFW restaurant offers regular meals for a limited number of conference participants.

Please note: Only cash payment is possible in all mensas (no cards!).

4. Events

4.1 Public Evening Lecture
Sunday, March 26, 18:30 – 20:00, HSZ 01 (Audimax, in german language)
Prof. Dr. Ricarda Winkelmann, Potsdam Institute for Climate Impact Research (PIK) will speak about „*Kipp-Punkte im Klimasystem: Vorboten aus dem polaren Eis*". All conference participants and the interested public are welcome.

4.2 Welcome Evening
On Sunday, March 26, 18:30 – 21:30 the Welcome Evening will be held in the Tent A. Small food, beer and soft drinks will be served. Do not miss the opportunity to register (15:00 – 19:00) before the official beginning of the conference and to meet people in an informal atmosphere. When registering for the conference you will receive your badge and food and drink vouchers for the Welcome Evening. Please wear your badge which you have received at the registration.

4.3 Opening of the Conference
A short opening address will be given by the chair of the Condensed Matter Section (SKM) on Monday, March 27 from 8:25 until 8:30 in HSZ 01 (Audimax).

4.4 EinsteinSlam
Monday, March 27, 20:00, HSZ 01 (Audimax)
EinsteinSlam is the competitive art of making complex science accessible to a broad audience. There are just 10 minutes for every attendee to present his/her self-made performance. The event will finish with a public poll in order to evaluate if a particular contribution was either instructive and amusing or rather should have never been performed. All presentations will be given in German. For more information please refer to *www.einstein-slam.de.*

4.5 Ceremonial Session with Award Ceremony
On Tuesday, March 28, at 15:30 the Ceremonial Session with Award Ceremony will take place in HSZ 01 (Audimax). The programme is as follows:

Music
„Viviendo Trio"

Welcome
Prof. Dr. Jochen Geck, TU Dresden
Local Organiser

Prof. Dr. Ronald Tetzlaff, Prorector for Research at the Technical University of Dresden
Chief Officer Technologietransfer und Internationalisierung

Speech
Dr. Lutz Schröter
Vice-President of the Deutsche Physikalische Gesellschaft

Music

Award Ceremony

Walter-Schottky-Prize 2023
to Dr. Kai-Qiang Lin, Universität Regensburg

Gaede-Prize 2023
to Dr. Benjamin Stadtmüller, TU Kaiserslautern und Johannes Gutenberg-Universität Mainz

Dissertation Prize of the Condensed Matter Section 2023
(The Laureate will be announced after the SKM-Dissertations-Prize Symposium)

Ceremonial Lecture

Prof. Dr. Metin Tolan, Universität Göttingen
„Die Star Trek Physik – Warum die Enterprise nur 158 kg wiegt und andere galaktische Erkenntnisse"

4.6 Job Market
During the conference, various companies and organisations will present their working fields and career opportunities to all interested participants. The presentations will last for about 30 minutes plus discussion and will take place in Room HSZ 405 (Tuesday-Thursday). For additional information and contacts refer to the information board close to the conference office.

Programme:
Tuesday, March 28

11:30 – 12:30   **neocx GmbH & Trace Tronic GmbH**
Tracetronic / neocx: Automate Everything – speeding up software testing in the automotive industry

12:45 – 13:45   **Ritzenhoefer GmbH**
Transformation Consulting – #impact23

14:00 – 15:00   **Wiley VCH-Verlag GmbH**
Physiker:innen im Wissenschaftsverlag

Wednesday, March 29

11:30 – 12:30   **Bundesamt für Sicherheit in der Informationstechnik**
Aus der Physik in die IT-Sicherheit – Karriere beim BSI

12:45 – 13:45   **Trumpf Lasersystems for Semiconductor Manufacturing GmbH**
TRUMPF Lasersystems for EUV Lithography – Enabler für das digitale Zeitalter gesucht

14:00 – 15:00   **Basycon Unternehmensberatung GmbH**
Aus der Wissenschaft in die Beratung

15:15 – 16:15   **ZEISS**
Am Herzschlag der Digitalisierung: Forschung & Entwicklung in der Halbleiterfertigungstechnik

Thursday, March 30

11:30 – 12:30   **Horn & Company Financial Services GmbH**
Horn & Company – Gewinne Einblicke in unsere Projekte zu Data Analytics, Big Data und Künstlicher Intelligenz und lerne unseren Beratungsansatz kennen!

14:00 – 15:00   **d-fine GmbH**
Einblicke in die Beratungspraxis bei d-fine – Projekte im Bankensektor

4.7 Exhibition of Scientific Instruments and Literature
From Tuesday to Thursday there will be an exhibition of Scientific Instruments and Literature. The exhibition will take place in the Lecture Hall Center (Foyer) and the nearby exhibition tent A. More than 130 companies (see list of exhibitors at the end of this document) will present their products. Opening hours are from 09:30 to 18:00 (Thursday until 16:00). All conference participants are welcome to attend the exhibition. The entrance is free.

4.8 Scientific Bar Hopping
On Tuesday, March 28, a scientific Bar Hopping will take place in cooperation with the jDPG, the student council Dresden and the Studiclubs of Dresden.
At a Scientific Bar Hopping scientists have the opportunity to communicate their research to an interested public. General comprehensibility is a must. The intimate atmosphere of the venues helps the public to overcome fears of contact with the researchers. After all, follow-up questions are explicitly encouraged. Spread over several Studiclubs in Dresden, several talks happen in parallel. Further details will be announced on the event website https://scientific-barhopping. stura.tu-dresden.de/.

4.9 jDPG Pub Crawl
On Wednesday evening, the young DPG invites to a pub crawl through Dresden. Next to the opportunity to be on a move outside and network with others, the members of the local regional group will tell about the Dresden physics, the life in the city and other facts worth knowing. Further details will be announced on the website of the conference.

4.10 Video competition: Physics in the Future
The public and also the physics community have various imaginations of how physics will look like in the future and what physics will be needed for in the future. The aim of this video competition is to bring together these different views

and ideas for the "future of physics". Even without a modified DeLorean and flux capacitor, the competition will bring to light many exciting answers. Time will show which ones will come true.

A Video box will be available from Monday to Friday in Tent A (exhibition tent) to help you easily participate in the video competition. Take part and tell us what you think about "physics in the future".

5. Wilhelm and Else Heraeus Communication Programme

Important notes for participants who apply for a grant of the Wilhelm and Else Heraeus Foundation:

At the beginning of the conference you will receive an identification form at the conference office. The participation in the conference must be certified by the conference desk. You have the possibility to leave this certificate by the staff members of the DPG (recommended!) in the conference office or submit it to the DPG head office (DPG-Geschäftsstelle, Hauptstr. 5, 53604 Bad Honnef, Germany) by April 14, 2023 at the latest.

For more detailed information refer to *https://skm23.dpg-tagungen.de/registrierung/weh*.

The Deutsche Physikalische Gesellschaft thanks the Wilhelm and Else Heraeus Foundation for the generous financial support of young academic talents. We hope that young physicists will continue to seize the offered opportunity for active scientific communication at scientific conferences. A total of about 37,800 young academics were supported by this programme so far.

6. Members' Assemblies of the Divisions and Working Groups

During the DPG Spring Meeting, Members' Assemblies of the divisions and working groups take place. Please refer to the scientific programme for the time and place of the meetings.

7. CO_2 compensation for the DPG conferences

By decision of the Executive Board, the DPG will compensate for fossil CO_2 emissions resulting from mobility for DPG conferences and committee meetings.

8. Acknowledgement

The organisers want to thank

- the Wilhelm and Else Heraeus Foundation, Hanau
- the TU Dresden
- the official sponsors of the DPG-Frühjahrstagung (refer to page 15)

for supporting the conference and all staff, who make the conference possible.

9. SAY CHEESE!

The DPG Spring Meetings are basically public to the press. Please note: On behalf of DPG, photos and videos will be recorded during the Spring Meetings. In the context of public relations, these recordings (as the case may be) will be published on our website, in social media or within prints of the DPG for example.

10. Disclaimer of liability

Participants are asked to look carefully after their wardrobe, valuables, laptops, and other belongings. The organisers are not liable.

Industrietag 2023

„Karrieren für Physikerinnen und Physiker in Industrie und Wirtschaft"

im Rahmen der DPG-Frühjahrstagung an der Universität Dresden

„Physikerinnen und Physiker sind in unzähligen Branchen und Berufsgruppen gefragt. Sie werden gerne in Führungs- und Managementpositionen aufgrund hoher Problemlösekompetenz häufig eingesetzt.

Wie vielseitig die Möglichkeiten für Physikerinnen und Physiker sind, soll exemplarisch an fünf Karrieren gezeigt werden, die unterschiedlicher nicht sein können und alle eines gemeinsam haben: alle Vortragenden sind Physikerinnen oder Physiker."

Mit Vorträgen von:

Prof. Dr. Joachim Rädler
CeNs (Centre For Nanoscience), LMU München

Dr. Diana Nanova
Customer Engineering Manager, Google Cloud

Dr. Udo Weigelt
LL.M., Patentanwalt und Partner in der Kanzlei
Grünecker Patent- und Rechtsanwälte, München

Dr. Oliver de Haas
CEO und Gründer von evico, Dresden

Dr. Charles Majer

Synopsis of the Daily Programme

Sunday, March 26, 2023

Tutorials

16:00	HSZ 01	TUT 1	**Physics Meets Machine Learning**
16:00	HSZ 01	TUT 1.1	Machine Learning for Quantum Technologies •Florian Marquardt
16:45	HSZ 01	TUT 1.2	The Unreasonable Effectiveness of Gaussians in the Theory of Deep Neural Networks •Zohar Ringel
17:30	HSZ 01	TUT 1.3	Computing learning curves for large machine learning models using the replica approach •Manfred Opper

16:00	HSZ 02	TUT 2	**Stochastic Processes of Opinion Formation**
16:00	HSZ 02	TUT 2.1	Bounded Confidence Revisited: What We Overlooked, Underestimated, and Got Wrong •Rainer Hegselmann
16:45	HSZ 02	TUT 2.2	When intuition fails: the complex effects of assimilative and repulsive influence on opinion polarization •Michael Maes
17:30	HSZ 02	TUT 2.3	How growing connectivity and self-organization changes opinion dynamics •Philipp Lorenz-Spreen

16:00	HSZ 03	TUT 3	**Hands-on tutorial on workflows for materials science simulation**
16:00	HSZ 03	TUT 3.1	Hands-on tutorial on workflows for materials science simulations •Jörg Neugebauer

16:00	HSZ 04	TUT 4	**Strategic elements and sustainability**
16:00	HSZ 04	TUT 4.1	Making better batteries? – From Li-ion to Na-ion batteries •Philipp Adelhelm
16:30	HSZ 04	TUT 4.2	Sustainable Thermoelectric Materials Predicted by Data Mining and Machine Learning •Kornelius Nielsch
17:00	HSZ 04	TUT 4.3	Design strategies for electrocatalysts – an electrochemist's perspective •Kristina Tschulik
17:30	HSZ 04	TUT 4.4	Green magnetic materials for efficient energy, transport and cooling applications •Oliver Gutfleisch

Public Evening Talk (free entrance)

18:30	HSZ 01	PSV I	Kipp-Punkte im Klimasystem: Vorboten aus dem polaren Eis •Ricarda Winkelmann

18:30	Tent A		**Welcome Evening** (for registered participants)

Monday, March 27, 2023

08:25	HSZ 01		**Opening**

Plenary Talks

08:30	HSZ 01	PLV I	Spin-Photon Interfaces and Their Applications •Mete Atatuere
14:00	HSZ 01	PLV II	New directions in electromagnetic field mapping in materials in the transmission electron microscope •Rafal E. Dunin-Borkowski
14:00	HSZ 02	PLV III	Microgels at Interfaces •Regine von Klitzing

Lunch Talk, Discussion

13:15	HSZ 02	PSV II	Patentanwalt, Verfahren zu dessen Herstellung und Verwendung eines Patentanwalts •Carina Ehrig
13:15	HSZ 03	PSV III	Talking about different career paths into Academia •Alexander Osterkorn, Christoph Kastl, Anna Grünebohm, and Amelie Heuer-Jungemann

SYOF

Symposium

09:30	HSZ 01	SYOF 1	Dynamics of Opinion Formation – from Quorum Sensing to Polarization

Invited Talks

09:30	HSZ 01	SYOF 1.1	Towards understanding of the social hysteresis – insights from statistical physics •Katarzyna Sznajd-Weron
10:00	HSZ 01	SYOF 1.2	Polarization in attitude distributions from surveys and models of continuous opinion dynamics •Jan Lorenz
10:30	HSZ 01	SYOF 1.3	Collective patterns and stable misunderstandings in networks striving for consensus without a common value system •Johannes Falk
11:15	HSZ 01	SYOF 1.4	A yet undetected cognitive bias, revealed by opinion dynamics simulations •Guillaume Deffuant
11:45	HSZ 01	SYOF 1.5	Extreme switches in kinetic exchange models of opinion. •Parongama Sen

SYSD

Symposium

09:30	HSZ 04	SYSD 1	SKM Dissertation Prize

Invited Talks

09:30	HSZ 04	SYSD 1.1	Diffusion of antibodies in solution: from individual proteins to phase separation domains •Anita Girelli
10:00	HSZ 04	SYSD 1.2	Intermediate Filament Mechanics Across Scales •Anna V. Schepers
10:30	HSZ 04	SYSD 1.3	Ultrafast Probing and Coherent Vibrational Control of a Surface Structural Phase Transition •Jan Gerrit Horstmann
11:00	HSZ 04	SYSD 1.4	Electro-active metasurfaces employing metal-to-insulator phase transitions •Julian Karst
11:30	HSZ 04	SYSD 1.5	The role of unconventional symmetries in the dynamics of many-body systems •Pablo Sala

Monday, March 27, 2023

Symposium

15:00	HSZ 01	SYGM 1	Green Magnets for Efficient Energy Conversion

Invited Talks

15:00	HSZ 01	SYGM 1.1	Data mining protocols for functional magnetic materials •Olle Eriksson
15:30	HSZ 01	SYGM 1.2	High performance permanent magnets; elements criticality, new demands, and extrinsic magnetic properties •Hossein Sepehri-Amin
16:00	HSZ 01	SYGM 1.3	Magnetic shape memory Heuslers: microstructure-related effects on the martensitic transformation •Franca Albertini
16:45	HSZ 01	SYGM 1.4	Thin film combinatorial studies of hard magnetic materials •Nora Dempsey
17:15	HSZ 01	SYGM 1.5	Magnetocaloric materials for energy-efficient thermal control systems •Victorino Franco

Invited Talks

11:15	BAR Schö	BP 1.7	Cell-free expression of membrane proteins and control of their spatial organization in synthetic lipid membranes •Jan Steinkühler
09:30	TOE 317	BP 2.1	Emergent properties in motile active matter •Roland G. Winkler
10:30	BAR 0106	BP 3.5	Resolving gating and allosteric modulation in ion channels through simulations and small-angle neutron scattering •Erik Lindahl
15:00	TOE 317	BP 5.1	Repurposing nucleic acids as high-resolution force sensors: From fundamental mechanotransduction to translational biophysics •Khalid Salaita
16:15	BAR 0106	BP 6.5	Mechanical and electrical properties of bacterial biofilms modulate antibiotic tolerance •Berenike Maier

Sessions

09:30	BAR Schö	BP 1	Membranes, Vesicles, Synthetic Cells
09:30	TOE 317	BP 2	Active Matter I
09:30	BAR 0106	BP 3	Computational Biophysics I
15:00	BAR Schö	BP 4	Tissue Mechanics I
15:00	TOE 317	BP 5	Focus Session NanoAgents
15:00	BAR 0106	BP 6	Bacterial Mechanics
15:00	ZEU 160	BP 7	Active Matter II

Invited Talks

09:30	GÖR 226	CPP 1.1	Strategies for advancing the performance of organic photovoltaics •Thomas Anthopoulos
11:30	GÖR 226	CPP 1.7	Lost in translation? Transport resistance in organic solar cells •Carsten Deibel
09:30	MER 02	CPP 2.1	Molecular Theories meet Explainable Machine Learning – Novel Concepts for Advanced Drug Formulations •Jens Smiatek
15:00	GÖR 226	CPP 11.1	Quantifying the potential of organic solar cells using luminescence measurements and modelling •Jenny Nelson
15:00	MER 02	CPP 12.1	Adaptive Resolution Simulations: Past, Present and Open (Boundaries) Future •Robinson Cortes-Huerto

<div align="right">**CPP**</div>

15:00	ZEU 255	CPP 13.1	Nanocomposites and polymer thin films: from gas phase synthesis to functional applications •Franz Faupel

Sessions

09:30	GÖR 226	CPP 1	Focus: Organic Solar Cells Based on Non-fullerene Acceptors: Loss Mechanism and Options for Above 20 % Efficiencies I
09:30	MER 02	CPP 2	Modeling and Simulation of Soft Matter I
09:30	ZEU 255	CPP 3	Hydrogels and Microgels
09:30	TOE 317	CPP 4	Active Matter I
09:30	POT 81	CPP 5	2D Materials I
09:30	POT 251	CPP 6	Perovskite and photovoltaics I
09:30	POT 361	CPP 7	Organic Semiconductors
10:45	ZEU 255	CPP 8	Responsive and Adaptive Systems
11:30	SCH A 315	CPP 9	Organic Thin Films, Organic-Inorganic Interfaces
14:30	POT 106	CPP 10	Instrumentation and Methods for Micro- and Nanoanalysis
15:00	GÖR 226	CPP 11	Focus: Organic Solar Cells Based on Non-fullerene Acceptors: Loss Mechanism and Options for Above 20 % Efficiencies II
15:00	MER 02	CPP 12	Modeling and Simulation of Soft Matter II
15:00	ZEU 255	CPP 13	Composites and Functional Polymer Hybrids
15:00	ZEU 160	CPP 14	Active Matter II
15:00	POT 81	CPP 15	2D Materials II
15:00	GER 39	CPP 16	Nanostructures at Surfaces
18:00	P3	CPP 17	Poster Session I

<div align="right">**DS**</div>

Sessions

09:30	SCH A 316	DS 1	2D Materials and their Heterostructures I: Graphene
11:30	SCH A 316	DS 2	2D Materials and their Heterostructures II: h-BN and WSe_2
11:30	SCH A 315	DS 3	Organic Thin Films, Organic-Inorganic Interfaces
15:30	SCH A 316	DS 4	Thin Film Properties I

<div align="right">**DY**</div>

Invited Talks

09:30	MOL 213	DY 5.1	Extreme events, entropies and instantons for turbulence and water waves •Joachim Peinke
12:30	ZEU 250	DY 8.1	Novel phenomena and analysis methods in oscillator networks: higher-order interactions, higher-order averaging, and inference •Hiroshi Kori
16:30	ZEU 160	DY 10.6	Long-range communications enable the hierarchical self-organization of active matter •Igor Aronson
15:00	ZEU 250	DY 11.1	The challenge of structured disorder in statistical physics •Marc Mezard
15:30	ZEU 250	DY 11.2	The emergence of concepts in shallow neural-networks •Elena Agliari
16:00	ZEU 250	DY 11.3	Adaptive Kernel Approaches to Feature Learning in Deep Neural Networks •Zohar Ringel
17:00	ZEU 250	DY 11.5	Analysing the dynamics of message passing algorithms •Manfred Opper
17:30	ZEU 250	DY 11.6	Deep Learning Theory Beyond the Kernel Limit •Cengiz Pehlevan

Sessions

09:30	HSZ 03	DY 2	Focus Session: Physics Meets ML I – Machine Learning for Complex Quantum Systems
09:30	TOE 317	DY 3	Active Matter I

<div align="right">

DY

</div>

09:30	ZEU 250	DY 4	Pattern Formation, Delay and Nonlinear Stochastic Systems
09:30	MOL 213	DY 5	Fluid Physics: Turbulence and Convection
10:00	ZEU 160	DY 6	Statistical Physics: General I
10:00	ZEU 147	DY 7	Granular Matter and Contact Dynamics
12:30	ZEU 250	DY 8	Invited Talk: Dynamics of Networks
14:00	MOL 213	DY 9	Quantum Dynamics, Decoherence and Quantum Information
15:00	ZEU 160	DY 10	Active Matter II
15:00	ZEU 250	DY 11	Focus Session: Physics Meets ML II – Understanding Machine Learning as Complex Interacting Systems

<div align="right">

HL

</div>

Invited Talks

09:30	POT 151	HL 3.1	Schrödinger cat states of a 16-microgram mechanical oscillator •Yiwen Chu
10:00	POT 151	HL 3.2	High-fidelity quantum information processing with spins and phonons •Peter Rabl
11:30	POT 151	HL 3.5	Control of spin centers in silicon carbide using acoustic fields •Alberto Hernández-Mínguez
17:30	POT 81	HL 8.9	Time-resolved optical spectroscopy of 3R-stacked MoS_2 •Swarup Deb
15:00	POT 361	HL 9.1	Spin and valley lifetime in graphene quantum dots •Guido Burkard
15:30	POT 361	HL 9.2	Microscopic modelling of electrostatically induced bilayer graphene quantum dots •Angelika Knothe
16:45	POT 361	HL 9.4	Single-shot spin and valley Pauli blockade read-out in bilayer graphene quantum dots •Chuyao Tong
17:15	POT 361	HL 9.5	Particle-hole symmetry protects spin-valley blockade in graphene quantum dots •Christian Volk
15:00	POT 151	HL 10.1	Surface Acoustic Wave Cavity Optomechanics with 2D Materials •Galan Moody
15:30	POT 151	HL 10.2	Phononic Microresonators Coupled by Surface Acoustic Waves •Sarah Benchabane

Sessions

09:30	POT 81	HL 1	2D Materials I
09:30	POT 361	HL 2	Organic Semiconductors
09:30	POT 151	HL 3	Focus Session: Progress in Hybrid Phononic Quantum Technologies I
09:30	POT 251	HL 4	Perovskite and photovoltaics I
10:00	POT 112	HL 5	Heterostructures, interfaces and surfaces
10:30	TRE Ma	HL 6	Focus Session: Frontiers of Electronic-Structure Theory III
13:00	P2/EG	HL 7	Poster I
15:00	POT 81	HL 8	2D Materials II
15:00	POT 361	HL 9	Focus Session: Graphene quantum dots
15:00	POT 151	HL 10	Focus Session: Progress in Hybrid Phononic Quantum Technologies II
15:00	POT 251	HL 11	Quantum transport and quantum Hall effects I
15:00	POT 112	HL 12	Semiconductor lasers I
15:00	TRE Ma	HL 13	Focus Session: Frontiers of Electronic-Structure Theory II

<div align="right">

KFM

</div>

Invited Talks

09:00	POT 51	KFM 1.1	Investigations of multiferroic behavior within domains and domain walls of a multiferroic Aurivillius phase system •Lynette Keeney
10:45	POT 51	KFM 1.5	Domains or no Domains in Wurtzite-Type Ferroelectrics •Simon Fichtner

Monday, March 27, 2023

KFM

| 14:30 | POT 51 | KFM 2.1 | Formation of conducting channels along of dislocations in $SrTiO_3$ •Christian Rodenbücher |
| 15:55 | POT 51 | KFM 2.4 | Plastic properties of MgO: Insights from numerical modeling •Philippe Carrez |

Sessions
09:00	POT 51	KFM 1	Focus: Domains and Domainwalls in (Multi)Ferroics I
14:30	POT 51	KFM 2	Focus: Dislocations in Ceramics: Mechanics, Structures and Functionality
14:30	POT 106	KFM 3	Instrumentation and Methods for Micro- and Nanoanalysis

MA

Invited Talks
| 09:30 | HSZ 02 | MA 2.1 | Two-dimensional Skyrmions in the real three-dimensional world •Nikolai Kiselev |
| 15:00 | HSZ 04 | MA 8.1 | Optical control of antiferromagnetism •Christian Tzschaschel |

Sessions
09:30	HSZ 02	MA 2	Skyrmions I
09:30	HSZ 401	MA 3	Magnetic Materials for Efficient Energy Conversion
09:30	HSZ 403	MA 4	Spin Transport and Orbitronics, Spin-Hall Effects
09:30	POT 6	MA 5	Thin Films: Magnetic Coupling Phenomena / Exchange Bias
14:30	POT 51	MA 6	Focus: Dislocations in Ceramics: Mechanics, Structures and Functionality
15:00	HSZ 02	MA 7	Computational Magnetism
15:00	HSZ 04	MA 8	Ultrafast Magnetization Effects I
15:00	HSZ 401	MA 9	Cooperative Phenomena: Spin Structures and Magnetic Phase Transitions
15:00	HSZ 403	MA 10	Topological Insulators
15:00	POT 6	MA 11	Non-Skyrmionic Magnetic Textures I

MM

Invited Talks, Topical Talks
09:30	SCH A 251	MM 2.1	Function follows form: on tailoring functional materials via microstructural design •Erica Lilleodden
10:15	SCH A 216	MM 4.1	Crack and dislocations interactions: coupling DDD and XFEM •Marc Fivel
10:45	SCH A 216	MM 4.2	multiscale studies on the fracture behaviors of body centered cubic metal •Yinan Cui
11:45	SCH A 216	MM 4.4	Capturing Micromechanical Crack Tip Stress States and Toughening Plasticity in 2D and 3D •Thomas E. J. Edwards
15:00	SCH A 251	MM 7.1	Molecular dynamics simulations of shock waves in alloys: Interplay of defects and phase transition •Nina Merkert
15:45	SCH A 216	MM 9.1	Modeling of grain boundary embrittlement phenomena in metallic materials •Lorenz Romaner

Sessions
09:30	SCH A 251	MM 2	Invited Talk: Lilleodden
10:15	SCH A 251	MM 3	Development of Computational Methods: Evaporation, Growth and Oxidation – Density Functional, Tight Binding
10:15	SCH A 216	MM 4	Topical Session: Fundamentals of Fracture – Micromechanical Fracture Experiments
10:15	SCH A 215	MM 5	Materials in Energy Conversion: Mechanical Properties and Solid State Batteries
10:15	SCH A 118	MM 6	Transport in Materials: Ion, Charge and Heat Transport
15:00	SCH A 251	MM 7	Invited Talk: Merkert
15:45	SCH A 251	MM 8	Development of Computational Methods: Diverse Topics and Machine Learning
15:45	SCH A 216	MM 9	Topical Session: Fundamentals of Fracture – Interface Fracture

15:45	SCH A 215	MM 10	Materials for Storage and Conversion of Energy: New Storage Materials
17:00	SCH A 215	MM 11	Functional Materials: Performance, Reliability and Degradation
18:15	P2/OG1+2	MM 12	Poster I

Invited Talk, Topical Talks

09:30	TRE Phy	O 1.1	From surface structure to exciton evolution: a many-body theoretical perspective •Sivan Refaely-Abramson
10:30	GER 38	O 5.1	Highly charged, slow and swift ions interacting with surfaces and 2D materials •Marika Schleberger
11:30	GER 38	O 5.4	A contactless single-step process for simultaneous nanoscale patterning and cleaning of large-area graphene •Tuan Tran
10:30	REC C 213	O 7.1	Superconductivity in atom-by-atom crafted quantum corrals •Lucas Schneider
11:00	TRE Ma	O 9.3	Large-scale machine-learning assisted discovery and characterization of materials •Miguel Alexandre Lopes Marques
15:00	CHE 89	O 10.1	Photoemission Orbital Tomography: Imaging Molecular Wave Functions in Reciprocal and Real Space •F. S. Tautz
15:00	GER 38	O 13.1	Space weathering of planetary surfaces •Peter Wurz
15:45	TRE Phy	O 16.4	Microscopic insight into non-equilibrium dynamics through time-resolved x-ray absorption spectroscopy •Andrea Eschenlohr
15:00	TRE Ma	O 17.1	Coupled-cluster theory for complex solids made ready •Andreas Grüneis

Sessions

09:30	TRE Phy	O 1	Overview Talk Sivan Refaely-Abramson
10:30	CHE 89	O 2	Organic Molecules on Inorganic Substrates I: Electronic, Optical and Other Properties I
10:30	CHE 91	O 3	Metal Substrates: Adsorption and Reaction of Small Molecules I
10:30	GER 37	O 4	Tribology: Surfaces and Nanostructures
10:30	GER 38	O 5	Focus Session: Ion Beam Interaction with Surfaces and 2D Materials I
10:30	GER 39	O 6	New Methods: Experiments and Theory
10:30	REC C 213	O 7	Spins on Surfaces at the Atomic Scale I
10:30	TRE Phy	O 8	Ultrafast Electron Dynamics at Surface and Interfaces I
10:30	TRE Ma	O 9	Focus Session: Frontiers of Electronic-Structure Theory I
15:00	CHE 89	O 10	Organic Molecules on Inorganic Substrates II: Electronic, Optical and Other Properties II
15:00	CHE 91	O 11	Surface Reactions
15:00	GER 37	O 12	Scanning Probe Techniques: Method Development I
15:00	GER 38	O 13	Focus Session: Ion Beam Interaction with Surfaces and 2D Materials II
15:00	GER 39	O 14	Nanostructures at Surfaces
15:00	REC C 213	O 15	Spins on Surfaces at the Atomic Scale II
15:00	TRE Phy	O 16	Ultrafast Electron Dynamics at Surface and Interfaces II
15:00	TRE Ma	O 17	Focus Session: Frontiers of Electronic-Structure Theory II
18:00	P2/EG	O 18	Poster: 2D Materials I
18:00	P2/EG	O 19	Poster: Ultrafast Electron Dynamics at Surface and Interfaces I
18:00	P2/EG	O 20	Poster: Spins and Magnetism at Surfaces
18:00	P2/EG	O 21	Poster: Scanning Probe Techniques
18:00	P2/EG	O 22	Poster Session: Organic Molecules on Inorganic Substrates I
18:00	P2/EG	O 23	Poster: Surface Reactions
18:00	P2/EG	O 24	Poster: Ion Beam Interaction with Surfaces and Interfaces
18:00	P2/EG	O 25	Poster: Metal Substrates
18:00	P2/EG	O 26	Poster: New Methods

Monday, March 27, 2023

<div align="right">SOE</div>

Invited Talks

| 15:10 | HSZ 03 | SOE 3.1 | Initial Progress on the Science of Science
•Dashun Wang (Laureate of the SOE-Young Scientist Award 2023) |
| 16:00 | HSZ 03 | SOE 3.2 | Complexity science can address marginalization in society and algorithms
•Fariba Karimi (Laureate of the SOE-Young Scientist Award 2023) |

Sessions

12:30	ZEU 250	SOE 2	Invited Talk: Dynamics of Networks
15:00	HSZ 03	SOE 3	Award Session: Young Scientist Award for Socio- and Econophysics (YSA)
17:00	P2/OG2	SOE 4	Poster

<div align="right">TT</div>

Invited Talks

09:30	HSZ 03	TT 2.1	Enhanced variational Monte Carlo for Rydberg atom arrays •Stefanie Czischek
10:00	HSZ 03	TT 2.2	Data mining the output of quantum simulators – from critical behavior to algorithmic complexity •Marcello Dalmonte
10:30	HSZ 03	TT 2.3	Reinforcement learning for quantum technologies •Florian Marquardt
11:00	HSZ 03	TT 2.4	Machine learning of phase transition •Christof Weitenberg
15:00	HSZ 103	TT 8.1	Molecules on a superconductor: Inducing magnetism and resonance-enhanced vibrational spectroscopy •Richard Berndt
17:15	HSZ 304	TT 17.3	Noise signatures of anyon statistics and Andreev scattering in the $v = 1/3$ fractional quantum Hall regime •Anne Anthore

Sessions

09:30	HSZ 03	TT 2	Focus Session: Physics Meets ML I – Machine Learning for Complex Quantum Systems
09:30	HSZ 103	TT 3	Superconductivity: Properties and Electronic Structure
09:30	HSZ 201	TT 4	f-Electron Systems and Heavy Fermions I
09:30	HSZ 204	TT 5	Correlated Electrons: Method Development
09:30	HSZ 304	TT 6	Topological Semimetals
09:30	HSZ 403	TT 7	Spin Transport and Orbitronics, Spin-Hall Effects
15:00	HSZ 103	TT 8	Yu-Shiba-Rusinov Systems
15:00	HSZ 201	TT 9	f-Electron Systems and Heavy Fermions II
15:00	HSZ 204	TT 10	Correlated Electrons: Other Materials
15:00	HSZ 304	TT 11	Spintronics, Spincalorics and Magnetotransport
15:00	HSZ 403	TT 12	Topological Insulators
15:00	ZEU 250	TT 13	Focus Session: Physics Meets ML II – Understanding Machine Learning as Complex Interacting Systems

17:15	HSZ 201	TT 18	Nano- and Optomechanics

<div align="right">VA</div>

Sessions

| 09:30 | HSZ 301 | VA 1 | Vacuum Technology: New Developments and Applications |
| 14:00 | P2/OG2 | VA 2 | Vacuum Technology: New Developments and Applications – Poster |

| 20:00 | HSZ 01 | | **EinsteinSlam** |

Ceremonial Session with Award Ceremony

Deutsche Physikalische Gesellschaft

Award Ceremony

Walter-Schottky-Prize 2023
to Dr. Kai-Qiang Lin
Universität Regensburg

Gaede-Prize 2023
to Dr. Benjamin Stadtmüller, TU Kaiserslautern and
Johannes Gutenberg-Universität Mainz

Dissertation Prize of the Condensed Matter Section (SKM)
(The award winner will be selected after the
Dissertation Award Symposium SYSD)

Ceremonial Lecture

Prof. Dr. Metin Tolan, Universität Göttingen

*„Die Star Trek Physik – Warum die Enterprise nur 158 kg wiegt
und andere galaktische Erkenntnisse"*

Tuesday, March 28, 2023, 15:30

HSZ 01 (Audimax)

Deutsche Physikalische Gesellschaft ⦰ DPG

Tuesday, March 28, 2023

08:30	HSZ 01	PLV IV	**Plenary Talk** Stochastic thermodynamics: From concepts to model-free inference •Udo Seifert
13:15	HSZ 01	PRV I	**Prize Talk** Seeing is believing: Nonlinear optics on ferroic materials •Manfred Fiebig (Laureate of the Stern-Gerlach-Medal 2023)
			Ceremonial Talk, Lunch Talks
13:15	HSZ 02	PSV IV	Berufswege für Physiker in Elektrotechnik, Unternehmensberatung und IT •Philipp Dedié
13:15	HSZ 03	PSV V	Research Funding by the DFG – Insights into the Decision Process •Michael Mößle
15:30	HSZ 01		**Ceremonial Session with Award Ceremony and Ceremonial Lecture**
		PSV VI	Die Star Trek Physik – Warum die Enterprise nur 158 kg wiegt und andere galaktische Erkenntnisse •Metin Tolan

SYFP

09:30	HSZ 01	SYFP 1	**Symposium** Physics of Fluctuating Paths
			Invited Talks
09:30	HSZ 01	SYFP 1.1	Time at which a stochastic process achieves its maximum •Satya Majumdar
10:00	HSZ 01	SYFP 1.2	Fluctuations and molecule-spanning dynamics of single Hsp90 proteins on timescales from nanoseconds to days •Thorsten Hugel
10:30	HSZ 01	SYFP 1.3	Path reweighting for Langevin dynamics •Bettina Keller
11:15	HSZ 01	SYFP 1.4	Out-of-equilibrium dynamics of trapped Brownian particles •Raul A. Rica
11:45	HSZ 01	SYFP 1.5	Thermodynamics of Clocks •Patrick Pietzonka

BP

			Invited Talks
10:45	BAR Schö	BP 8.5	Microtubule Lattice Dynamics •Laura Schaedel
09:30	BAR 0106	BP 10.1	Protein evolution in sequence landscapes: from data to models and back •Martin Weigt
			Sessions
09:30	BAR Schö	BP 8	Cell Mechanics I
09:30	TOE 317	BP 9	Active Matter III
09:30	BAR 0106	BP 10	Evolution and Origin of Life
12:30	P1	BP 11	Poster Session I

CPP

			Invited Talks
09:30	MER 02	CPP 19.1	Multiscale Model of Flow-Induced Crystallization in Polymers •Gregory Rutledge
09:30	ZEU 255	CPP 20.1	Granular Matter Rheology – fluid-/solid-like behavior and state-transitions •Stefan Luding

Tuesday, March 28, 2023

<div align="right">**CPP**</div>

Sessions

09:30	GÖR 226	CPP 18	Organic Electronics and Photovoltaics I
09:30	MER 02	CPP 19	Crystallization, Nucleation and Self-Assembly
09:30	ZEU 255	CPP 20	Polymer and Molecular Dynamics, Friction and Rheology
09:30	TOE 317	CPP 21	Active Matter III
09:30	POT 81	CPP 22	2D Materials III
09:30	POT 112	CPP 23	Optical Properties
10:00	MOL 213	CPP 24	Complex Fluids and Soft Matter I
12:00	HSZ 201	CPP 25	Molecular Electronics and Photonics
14:00	MER 02	CPP 26	Electrical, Dielectrical and Optical Properties of Thin Films
14:00	ZEU 147	CPP 27	Glasses and Glass Transition I

<div align="right">**DS**</div>

Invited Talk

09:30	SCH A 316	DS 5.1	Operando infrared studies of confined water and protons in MXene •Mailis Lounasvuori

Sessions

09:30	SCH A 316	DS 5	2D Materials and their Heterostructures III
10:00	SCH A 315	DS 6	Thin Film Properties II
11:15	SCH A 316	DS 7	2D Materials and their Heterostructures IV
11:30	SCH A 315	DS 8	Thin Film Properties III

<div align="right">**DY**</div>

Invited Talk

09:30	MOL 213	DY 14.1	Unraveling structural and dynamical features in glassy fluids using machine learning •Laura Filion

Sessions

09:30	HSZ 204	DY 12	Nonequilibrium Quantum Many-Body Systems I
09:30	TOE 317	DY 13	Active Matter III
09:30	MOL 213	DY 14	Invited Talk: Machine Learning and Complex Fluids
09:30	ZEU 260	DY 15	Physics of Contagion Processes I
10:00	MOL 213	DY 16	Complex Fluids and Soft Matter
10:00	ZEU 160	DY 17	Machine Learning in Dynamics and Statistical Physics I
10:00	ZEU 147	DY 18	Nonlinear Dynamics, Synchronization and Chaos
10:00	ZEU 260	DY 19	Physics of Contagion Processes II
11:00	ZEU 260	DY 20	Networks: From Topology to Dynamics I
14:00	MOL 213	DY 21	Quantum Chaos and Coherent Dynamics
14:00	ZEU 160	DY 22	Machine Learning in Dynamics and Statistical Physics II
14:00	ZEU 250	DY 23	Statistical Physics: General II
14:00	ZEU 147	DY 24	Glasses and Glass Transition

<div align="right">**HL**</div>

Sessions

09:30	POT 81	HL 14	2D Materials III
09:30	POT 361	HL 15	Spin phenomena in semiconductors
09:30	POT 151	HL 16	Quantum dots: Transport
09:30	POT 251	HL 17	THz and MIR physics in semiconductors
09:30	POT 112	HL 18	Optical Properties
09:30	GÖR 226	HL 19	Organic Electronics and Photovoltaics I
10:30	TRE Ma	HL 20	Focus Session: Frontiers of Electronic-Structure Theory I
11:00	POT 361	HL 21	Thermal properties

Tuesday, March 28, 2023

KFM

Invited Talk

09:00	POT 51	KFM 4.1	Towards spatially resolved measurements of thermal transport and electrocaloric effects at the nanoscale in ferroelectric materials •Raymond McQuaid

Sessions

09:00	POT 51	KFM 4	Focus: Domains and Domainwalls in (Multi)Ferroic II
10:00	SCH A 315	KFM 5	Thin Film Properties
17:00	P3	KFM 6	Poster

MA

Invited Talk

09:30	HSZ 04	MA 14.1	Antiferromagnetism-driven two-dimensional topological nodal-point superconductivity •Roberto Lo Conte

Sessions

09:30	HSZ 02	MA 12	Skyrmions II
09:30	HSZ 03	MA 13	Focus Session: New Perspectives for Adiabatic Demagnetization Refrigeration in the Kelvin and sub-Kelvin Range
09:30	HSZ 04	MA 14	Surface Magnetism
09:30	HSZ 401	MA 15	INNOMAG e.V. Prizes 2023 (Diplom-/Master and Ph.D. Thesis)
09:30	HSZ 403	MA 16	Magnonics
09:30	POT 6	MA 17	Thin Films: Magnetic Anisotropy
15:00	HSZ 02	MA 18	Functional Antiferromagnetism I
15:00	HSZ 04	MA 19	Molecular Magnetism I
15:00	HSZ 401	MA 20	Spintronics (other effects)
15:00	HSZ 403	MA 21	Spin-Dependent Phenomena in 2D
15:00	POT 6	MA 22	Terahertz Spintronics
17:00	P1	MA 23	Poster Magnetism I

MM

Invited Talks

09:30	SCH A 251	MM 13.1	Exploring the Slow Dynamics of Interfaces and Glasses via Markov State Models •Chad Sinclair
10:15	SCH A 216	MM 15.1	Multiscale Quantum-Atomistic and Atomistic-Continuum Modelling of Crack Propagation •James Kermode

Sessions

09:30	SCH A 251	MM 13	Invited Talk: Sinclair
10:15	SCH A 251	MM 14	Development of Computational Methods: Thermodynamics and Local Chemistry, Electronic Structure
10:15	SCH A 216	MM 15	Topical Session: Fundamentals of Fracture – Atomistic Studies of Fracture
10:15	SCH A 215	MM 16	Energy Conversion
10:15	SCH A 118	MM 17	Phase Transformations: Microstructural Transformations
11:30	SCH A 118	MM 18	Transport in Materials: Metals, Alloys and Oxides
14:15	SCH A 251	MM 19	Development of Computational Methods: Simulation Methods – Theory
14:15	SCH A 216	MM 20	Topical Session: Fundamentals of Fracture – Microstructure Impact on Fracture (Experiments)
14:15	SCH A 215	MM 21	Materials for Storage and Conversion of Energy: Energy Conversion
14:15	SCH A 118	MM 22	Mechanical Properties and Alloy Design: Porous and Nanostructured Materials
18:15	P2/OG1+2	MM 23	Poster II

<div style="text-align: right">

O

</div>

Invited Talk, Topical Talks

09:30	TRE Phy	O 27.1	Dive right in! Molecular insights into electrochemical surface science •Katrin F. Domke
10:30	GER 38	O 31.1	Ultra-low energy ion implantation of two-dimensional materials •Hans Hofsäss
10:30	REC C 213	O 33.1	Fermi liquids, Luttinger integrals, topological invariants ... and magnetic molecules •Rok Zitko
11:45	TRE Phy	O 34.6	Photoemission orbital tomography for excitons •Peter Puschnig
11:15	TRE Ma	O 35.4	Towards low-scaling GW calculations for 2D materials •Jan Wilhelm

Sessions

09:30	TRE Phy	O 27	Overview Talk Katrin Domke
10:30	CHE 89	O 28	Organic Molecules on Inorganic Substrates III: Adsorption and Growth I
10:30	CHE 91	O 29	Supported Nanoclusters: Structure, Reactions and Catalysis
10:30	GER 37	O 30	2D Materials I: Electronic Structure
10:30	GER 38	O 31	Focus Session: Ion Beam Interaction with Surfaces and 2D Materials III
10:30	GER 39	O 32	Semiconductor Substrates
10:30	REC C 213	O 33	Spins on Surfaces at the Atomic Scale III
10:30	TRE Phy	O 34	Ultrafast Electron Dynamics at Surface and Interfaces III
10:30	TRE Ma	O 35	Focus Session: Frontiers of Electronic-Structure Theory III
18:00	P2/EG	O 36	Poster: 2D Materials II
18:00	P2/EG	O 37	Poster: Ultrafast Electron Dynamics at Surface and Interfaces II
18:00	P2/EG	O 38	Poster: Organic Molecules on Inorganic Substrates II
18:00	P2/EG	O 39	Poster Session: Heterogeneous Catalysis and Surface Dynamics
18:00	P2/EG	O 40	Poster: Semiconductor Substrates
18:00	P2/EG	O 41	Poster: Supported Nanoclusters
18:00	P2/EG	O 42	Poster: Nanostructures at Surfaces
18:00	P2/EG	O 43	Poster: Plasmonics and Nanooptics I

<div style="text-align: right">

SOE

</div>

Invited Talk

09:30	ZEU 260	SOE 5.1	Digital Pandemiology – Is that physics? •Dirk Brockmann

Sessions

09:30	ZEU 260	SOE 5	Physics of Contagion Processes I
10:00	ZEU 260	SOE 6	Physics of Contagion Processes II
11:00	ZEU 260	SOE 7	Networks: From Topology to Dynamics I
14:00	ZEU 260	SOE 8	Semantic Networks, Language and Culture

<div style="text-align: right">

TT

</div>

Invited Talks

09:30	HSZ 03	TT 19.1	Self-cooling molecular spin quantum processors •Marco Evangelisti
10:00	HSZ 03	TT 19.2	Triangular rare-earth borates for milli-Kelvin adiabatic demagnetization refrigeration •Philipp Gegenwart
10:30	HSZ 03	TT 19.3	A millikelvin scanning tunnelling microscope in ultra-high vacuum with adiabatic demagnetisation refrigeration •Ruslan Temirov
11:15	HSZ 03	TT 19.4	ADR cryostats in low temperature physics and their applications •Doreen Wernicke
11:45	HSZ 03	TT 19.5	Frustrated dipolar materials for low-temperature magnetic refrigeration •Mike Zhitomirsky

Tuesday, March 28, 2023

11:00	HSZ 204	TT 22.6	Higgs spectroscopy of superconductors in nonequilibrium •Dirk Manske

Sessions

09:30	HSZ 03	TT 19	Focus Session: New Perspectives for Adiabatic Demagnetization Refrigeration in the Kelvin and sub-Kelvin Range
09:30	HSZ 103	TT 20	Superconductivity: Tunnelling and Josephson Junctions
09:30	HSZ 201	TT 21	Correlated Electrons: Electronic Structure Calculations
09:30	HSZ 204	TT 22	Nonequilibrium Quantum Many-Body Systems I
09:30	HSZ 304	TT 23	Kagome Systems
09:30	POT 151	TT 24	Quantum Dots: Transport
12:00	HSZ 201	TT 25	Molecular Electronics and Photonics
14:00	HSZ 304	TT 26	Members' Assembly

Invited Talks

10:30	ZEU 250	AKC 1.1	The tragic destiny of Mileva Marić Einstein •Pauline Gagnon
11:30	ZEU 250	AKC 1.2	Physik-Projekt-Tage – Ein Workshop für Schülerinnen der Oberstufe •Anna Benecke
12:00	ZEU 250	AKC 1.3	Belonging – a key to success in STEM?! •Barbara M. Gordalla

Sessions

10:30	ZEU 250	AKC 1	AKC
12:30	ZEU 250	AKC 2	Women in Physics Lunch

09:30	Foyer HSZ / Tent A	**Exhibition of Scientific Instruments and Literature**

Job Market

11:30	HSZ 405	neocx GmbH & Trace Tronic GmbH *"Tracetronic / neocx: Automate Everything — speeding up software testing in the automotive industry"*
12:45	HSZ 405	Ritzenhoefer GmbH *"Transformation Consulting – #impact23"*
14:00	HSZ 405	Wiley-VCH Verlag GmbH *"Physiker:innen im Wissenschaftsverlag"*

Wednesday, March 29, 2023

Plenary Talks

08:30	HSZ 01	PLV V	Advances in Ultrafast Electron Microscopy •Claus Ropers
14:00	HSZ 01	PLV VI	Topological defects in active and living matter •M Cristina Marchetti
14:00	HSZ 02	PLV VII	Ferroelectric and multiferroic domain walls for nanotechnology •Dennis Meier

Prize Talk

| 13:15 | HSZ 01 | PRV II | Towards chemical and optical band structure engineering in molecular-based heterostructures
•Benjamin Stadtmueller (Laureate of the Gaede-Prize 2023) |

Lunch Talk, Discussion

| 13:15 | HSZ 02 | PSV VII | Vom Physiker zum (erfolgreichen) Unternehmer der Plasway-Technologies GmbH
•Stephan Wege |
| 13:15 | HSZ 03 | PSV VIII | Vielfalt der Wissenschaftskommunikation
•Ulrich Bleyer, Nicolas Wöhrl und Peter Kohl |

SYUE

Symposium

| 09:30 | HSZ 01 | SYUE 1 | Ultrafast Excitation Pathways of Quantum Materials |

Invited Talks

09:30	HSZ 01	SYUE 1.1	Dynamics and control in quantum materials using multi-terahertz spectroscopy •Richard Averitt
10:00	HSZ 01	SYUE 1.2	Accessing the nonthermal phonon populations in 2D materials with femtosecond electron diffuse scattering •Hélène Seiler
10:30	HSZ 01	SYUE 1.3	Exciting potentials – Exploring the realms of ultrafast phase transitions •Laurenz Rettig
11:15	HSZ 01	SYUE 1.4	Sub-cycle multidimensional spectroscopy of strongly correlated materials •Olga Smirnova
11:45	HSZ 01	SYUE 1.5	Witnessing many-body entanglement in light-driven quantum materials •Matteo Mitrano
12:15	HSZ 01	SYUE 1.6	Optical responses of photoexcited materials: from parametric amplification to photoinduced superconductivity •Eugene Demler

SYQC

Symposium

| 15:00 | HSZ 01 | SYQC 1 | Topology in Quantum and Classical Physics – From Topological Insulators to Active Matter |

Invited Talks

15:00	HSZ 01	SYQC 1.1	Topological magnetic whirls for computing •Karin Everschor-Sitte
15:30	HSZ 01	SYQC 1.2	Topological waves from solids to geo/astrophysical flows •Pierre Delplace
16:00	HSZ 01	SYQC 1.3	Topological Phase Transitions in Population Dynamics •Erwin Frey
16:45	HSZ 01	SYQC 1.4	Topological invariants protect robust chiral currents in active matter •Evelyn Tang
17:15	HSZ 01	SYQC 1.5	Topological defects in biological active matter •Amin Doostmohammadi

BP

Invited Talks

10:15	TOE 317	BP 12.4	Materials properties of bacterial biofilms. •Cécile M. Bidan
09:30	BAR 0106	BP 13.1	Biological signal processes across scales •Steffen Rulands
11:15	BAR 0106	BP 16.1	Systems biophysics of bacterial response to cell wall-targeting antibiotics •Rosalind Allen

Sessions

09:30	TOE 317	BP 12	Biopolymers and Biomaterials
09:30	BAR 0106	BP 13	Signaling, Biological Networks
09:30	ZEU 160	BP 14	Focus Session: From Inter-individual Variability to Heterogeneous Group Dynamics and Disorder in Active Matter
10:30	BAR Schö	BP 15	Tissue Mechanics II
11:15	BAR 0106	BP 16	Systems Biophysics
15:00	BAR 0106	BP 17	Protein Structure and Dynamics
15:00	ZEU 250	BP 18	Biologically Inspired Statistical Physics
16:30	MER 02	BP 19	Biopolymers, Biomaterials and Bioinspired Functional Materials
18:00	BAR Schö	BP 20	Members' Assembly

CPP

Invited Talk

09:30	MER 02	CPP 29.1	Imaging mineral-water interfaces with atomic force microscopy •Angelika Kühnle

Sessions

09:30	GÖR 226	CPP 28	Molecular Electronics and Excited State Properties
09:30	MER 02	CPP 29	Interfaces and Thin Films
09:30	TOE 317	CPP 30	Biopolymers and Biomaterials I
09:30	ZEU 160	CPP 31	Focus Session: From Inter-individual Variability to Heterogeneous Group Dynamics and Disorder in Active Matter
09:30	POT 81	CPP 32	2D Materials IV
09:30	POT 251	CPP 33	Perovskite and photovoltaics II
10:00	ZEU 147	CPP 34	Wetting, Droplets and Microfluidics I
11:00	P1	CPP 35	Poster Session II
15:00	GÖR 226	CPP 36	Organic Electronics and Photovoltaics II
15:00	MER 02	CPP 37	Nanostructures, Nanostructuring and Nanosized Soft Matter
15:00	MOL 213	CPP 38	Microswimmers and Fluid Physics of Life
15:00	ZEU 160	CPP 39	Focus Session: Physics of Fluctuating Paths
15:00	GER 37	CPP 40	2D Materials V: Growth, Structure and Substrate Interaction
16:30	MER 02	CPP 41	Biopolymers, Biomaterials and Bioinspired Functional Materials II

DS

Invited Talk

09:30	SCH A 316	DS 9.1	Flüssigphasen-Elektrochemie im Ultrahochvakuum unter XPS-Kontrolle •Frank Endres

Sessions

09:30	SCH A 316	DS 9	Layer Properties I
11:00	SCH A 316	DS 10	Layer Properties II
11:00	SCH A 315	DS 11	Thin Film Application
17:00	P3	DS 12	Poster

DY

Invited Talks

09:30	MOL 213	DY 25.1	Many-body localization from Hilbert- and real-space points of view •Ivan Khaymovich

Wednesday, March 29, 2023

<div align="right">**DY**</div>

09:30	ZEU 160	DY 26.1	More is different: High-throughput 3D tracking reveals bacterial navigation strategies •Katja Taute
10:00	ZEU 160	DY 26.2	Variability and heterogeneity in natural swarms •Gil Ariel
11:15	ZEU 160	DY 26.5	Superstatistical Analysis and Modelling of Complex Dynamical Systems •Claus Metzner
09:30	ZEU 250	DY 27.1	Evolution in changing environments and driven disordered systems •Joachim Krug

Sessions

09:30	MOL 213	DY 25	Many-Body Quantum Dynamics
09:30	ZEU 160	DY 26	Focus Session: From Inter-individual Variability to Heterogeneous Group Dynamics and Disorder in Active Matter
09:30	ZEU 250	DY 27	Statistical Physics: Far From Equilibrium I
09:30	ZEU 260	DY 28	Focus Session: Critical Transitions in Society, Economy, and Nature
10:00	ZEU 147	DY 29	Wetting, Droplets and Microfluidics
15:00	HSZ 204	DY 30	Nonequilibrium Quantum Many-Body Systems II
15:00	MOL 213	DY 31	Microswimmers and Fluid Physics of Life
15:00	ZEU 160	DY 32	Focus Session: Physics of Fluctuating Paths
15:00	ZEU 250	DY 33	Biologically Inspired Statistical Physics
16:45	ZEU 250	DY 34	Statistical Physics: Far From Equilibrium II

<div align="right">**HL**</div>

Invited Talks

09:30	POT 361	HL 23.1	Vertical-cavity surface-emitting lasers – this is the way •Å. Haglund
10:00	POT 361	HL 23.2	Towards GaN-based diode lasers with narrow linewidth and high reliability •Sven Einfeldt
10:30	POT 361	HL 23.3	Use of wafer patterning for new functionalities of InGaN light emitters •Anna Kafar
09:30	POT 251	HL 25.1	Interfaces in perovskite optoelectronics: role of energy level alignment and interface chemistry •Selina Olthof
15:00	POT 81	HL 27.1	experimentamus! Forschendes Lernen von Physik und Chemie in der Grundschule •Sebastian Schlücker
16:00	POT 81	HL 27.4	Under the Microscope – spotlighting materials and nano science •Svenja Lohmann
17:00	POT 81	HL 27.5	Phyphox – A pocketful of physics •Christoph Stampfer
18:00	POT 81	HL 27.8	Physics for school and the public at the LMU •Dr. Cecilia Scorza-Lesch
15:00	POT 361	HL 28.1	Fabrication of AlGaN-based UV-B laser diodes on lattice-relaxed high-quality AlGaN •Motoaki Iwaya
15:30	POT 361	HL 28.2	Breakthrough technologies to realize room-temperature continuous-wave deep-ultraviolet laser diodes •Maki Kushimoto

Sessions

09:30	POT 81	HL 22	2D Materials IV
09:30	POT 361	HL 23	Focus Session: Breakthroughs in wide-bandgap semiconductor laser diodes I
09:30	POT 151	HL 24	Quantum dots: Optics
09:30	POT 251	HL 25	Perovskite and photovoltaics II
10:30	TRE Ma	HL 26	Focus Session: Frontiers of Electronic-Structure Theory IV
15:00	POT 81	HL 27	Focus Session: Wissenschaftskommunikation / Outreach
15:00	POT 361	HL 28	Focus Session: Breakthroughs in wide-bandgap semiconductor laser diodes II
15:00	POT 151	HL 29	Materials and devices for quantum technology I
15:00	POT 251	HL 30	Quantum transport and quantum Hall effects II

Wednesday, March 29, 2023

HL

15:00	TRE Ma	HL 31	Focus Session: Frontiers of Electronic-Structure Theory V
15:00	GÖR 226	HL 32	Organic Electronics and Photovoltaics II
17:00	P1	HL 33	Poster II

KFM

Invited Talks

09:00	POT 51	KFM 7.1	Novel device integration – combining bottom-up and topdown approaches •Artur Erbe
11:05	POT 51	KFM 7.6	4D meso-scale electronics for next generation medical tools and electronic skins •Daniil Karnauschenko

Sessions

09:00	POT 51	KFM 7	Focus: High-resolution Lithography and 3D Patterning
14:00	POT 51	KFM 8	Diamond and related dielectric materials
09:00	POT 106	KFM 9	Microscopy and Tomography with X-ray Photons, Electrons, Ions and Positron

MA

Invited Talks

09:30	HSZ 04	MA 25.1	MAGNOTHERM – One way to start a deep tech spin-off from research •Max Fries
10:00	HSZ 04	MA 25.2	Spin-Ion Technologies: taking the research from a lab to a start-up company •Dafiné Ravelosona
10:30	HSZ 04	MA 25.3	MagREEsource: the green Rare Earth Magnet company •Sophie Rivoirard
11:00	HSZ 04	MA 25.4	THATec Innovation – we automate your lab •Thomas Sebastian
11:30	HSZ 04	MA 25.5	Kiutra: Magnetic refrigeration for science and technology •Alexander Regnat
09:30	HSZ 401	MA 26.1	The self-induced spin glass: the perplexing magnetism of elemental neodymium •Alexander Khajetoorians
15:00	HSZ 02	MA 30.1	Femto- phono- magnetism •Sangeeta Sharma
15:30	HSZ 02	MA 30.2	Spin-switchable molecules in interaction with their environment. •Cyrille Barreteau
16:15	HSZ 02	MA 30.3	Yep, real photodoping. •Julia Stähler
16:45	HSZ 02	MA 30.4	Probing ultrafast magnetization thanks to ultrashort soft X-ray pulses •Emmanuelle Jal

Sessions

09:30	HSZ 02	MA 24	Molecular Magnetism II
09:30	HSZ 04	MA 25	Focus Session: Startups in Magnetism
09:30	HSZ 401	MA 26	Non-Skyrmionic Magnetic Textures II
09:30	HSZ 403	MA 27	Electron Theory of Magnetism and Correlations
09:30	POT 6	MA 28	Bulk Materials: Soft and Hard Permanent Magnets
11:30	HSZ 02	MA 29	Neuromorphic Magnetism / Magnetic Logic
15:00	HSZ 02	MA 30	PhD Focus Session: Non-equilibrium dynamics in theory and experiment
15:00	HSZ 04	MA 31	Functional Antiferromagnetism II
15:00	HSZ 401	MA 32	Magnetic Imaging Techniques I
15:00	HSZ 403	MA 33	Frustrated Magnets I

MM

Invited Talks, Topical Talks

09:30	SCH A 251	MM 24.1	Characterization of hydrogen effect on mechanical properties of metals at different length scales •Afrooz Barnoush

MM

15:00	SCH A 251	MM 30.1	Direct observations of grain boundary phase transformations in metallic alloys •Christian Liebscher
15:45	SCH A 216	MM 32.1	Defect phase diagrams: Concepts, computational approaches and applications •Jörg Neugebauer
18:00	SCH A 216	MM 32.8	Towards a Rigorous Theory of Grain Boundary Segregation in Polycrystals •Christopher Schuh

Sessions

09:30	SCH A 251	MM 24	Invited Talk: Barnoush
10:15	SCH A 251	MM 25	Development of Computational Methods: Crystal Structure and Properties
10:15	SCH A 216	MM 26	Interface Controlled Properties and Nanomaterials: Grain Boundaries and Stability, Spectroscopy and Interatomic Potentials
10:15	SCH A 215	MM 27	Hydrogen in Materials
10:15	SCH A 118	MM 28	Liquid and Amorphous Metals
11:45	SCH A 251	MM 29	Data Driven Materials Science: Big Data and Work Flows – Electronic Structure
15:00	SCH A 251	MM 30	Invited Talk: Liebscher
15:45	SCH A 251	MM 31	Data Driven Materials Science: Big Data and Work Flows – Machine Learning
15:45	SCH A 216	MM 32	Topical Session: Defect Phases I
15:45	SCH A 215	MM 33	Topical Session: Fundamentals of Fracture – Amorphous Metals
18:45	SCH A 251	MM 34	Members' Assembly

O

Invited Talk, Topical Talks

09:30	TRE Phy	O 44.1	Spins on Surfaces: A Gateway to the Quantum World •Christian R. Ast
10:45	CHE 89	O 45.2	Single-molecule reactions performed and characterized using atomic force microscopy •Leo Gross
10:30	GER 38	O 48.1	Surface functionalization of semiconductors: Introducing spectroscopic labels, monolayer control for ultra-shallow doping, and providing surface passivation for atomically-precise processes •Andrew Teplyakov
11:15	GER 38	O 48.3	Growth of organic monolayers on Si(111) •Martin Franz
11:15	TRE Phy	O 52.4	Modeling and Design of Single-Atom Alloy Catalysts •Mie Andersen
10:45	TRE Ma	O 53.2	TREX: an integrated HPC software platform for quantum Monte Carlo calculations •Claudia Filippi
15:00	CHE 89	O 54.1	Peering into interfacial water by qPlus-based atomic force microscopy •Ying Jiang
16:15	CHE 89	O 54.5	AFM with the qPlus sensor: An indeal tool for oxide surface science •Ulrike Diebold
16:15	CHE 91	O 55.6	Towards Understanding and Controlling On-Surface Reactions and Self-Assembly Mechanisms •Daniel Ebeling
15:00	GER 38	O 57.1	Incorporation of arsenic into silicon (001) and germanium (001) for atomic-scale device fabrication. •Steven R. Schofield
15:45	GER 38	O 57.3	Semiconductor surface chemistry towards hybrid interfaces with ab initio approaches •Ralf Tonner-Zech
15:30	WIL A317	O 58.3	Phase-locked photon-electron interaction without a laser •Nahid Talebi
15:00	REC C 213	O 59.1	Interplay of Inversion Symmetry Breaking and Spin-Orbit Coupling •Maximilian Ünzelmann
16:15	TRE Ma	O 61.5	Challenges in modelling correlated electronic matter •Roser Valenti

SOE

</div>

Topical Talks

09:30	ZEU 260	SOE 9.1	Many universality classes in an interface model restricted to non-negative heights •Peter Grassberger
10:00	ZEU 260	SOE 9.2	Nonequilibrium phase transitions and critical behavior in networks •Eckehard Schöll
10:45	ZEU 260	SOE 9.3	Critical transition to monsoon: statistical physics principles of monsoon forecasting •Elena Surovyatkina

Sessions

09:30	ZEU 260	SOE 9	Focus Session: Critical Transitions in Society, Economy, and Nature
15:00	ZEU 260	SOE 10	Traffic Dynamics, Urban and Regional Systems I
16:45	ZEU 260	SOE 11	Traffic Dynamics, Urban and Regional Systems II
18:30	ZEU 260	SOE 12	Members' Assembly

<div align="right">

TT

</div>

Invited Talks

09:30	HSZ 03	TT 27.1	Superconducting diode effect in Rashba superlattice •Teruo Ono
10:00	HSZ 03	TT 27.2	Quasiparticle-based and Cooper-pair based superconducting diodes •Maria Spies
10:30	HSZ 03	TT 27.3	Non-reciprocal superconductivity and the field free Josephson diode •Mazhar Ali
10:45	HSZ 103	TT 28.6	Studying the Fulde-Ferrell-Larkin-Ovchinnikov order parameter in quasi-2D organic superconductors •Tommy Kotte

<div align="right">

TT

</div>

15:00	HSZ 03	TT 35.1	Strongly correlated excitons in atomic double layers •Phuong Nguyen
15:30	HSZ 03	TT 35.2	The Quantum Twisting Microscope •Shahal Ilani
16:00	HSZ 03	TT 35.3	Light-driven phenomena in two-dimensional and correlated quantum materials •Angel Rubio
16:45	HSZ 03	TT 35.4	Cascade of transitions in twisted and non-twisted graphene layers within the van Hove scenario •Laura Classen
17:15	HSZ 03	TT 35.5	Topology and strong correlation: From twisted bilayer graphene to the boundary zeros of Mott insulators •Giorgio Sangiovanni
15:00	HSZ 304	TT 39.1	Sensing and control of MHz photons with microwave photon-pressure •Daniel Bothner

Sessions

09:30	HSZ 03	TT 27	Focus Session: Unconventional Transport Phenomena in Low-Dimensional Superconducting Heterostructures
09:30	HSZ 103	TT 28	Unconventional Superconductors
09:30	HSZ 201	TT 29	Frustrated Magnets: General
09:30	HSZ 204	TT 30	Complex Oxides
09:30	HSZ 304	TT 31	Topology: Majorana Physics
09:30	GÖR 226	TT 32	Molecular Electronics and Excited State Properties
09:30	MOL 213	TT 33	Many-Body Quantum Dynamics
11:30	HSZ 103	TT 34	Fe-based Superconductors
15:00	HSZ 03	TT 35	Focus Session: Correlations in Moiré Quantum Matter I
15:00	HSZ 103	TT 36	Topological Insulators
15:00	HSZ 201	TT 37	Ruthenates
15:00	HSZ 204	TT 38	Nonequilibrium Quantum Many-Body Systems II

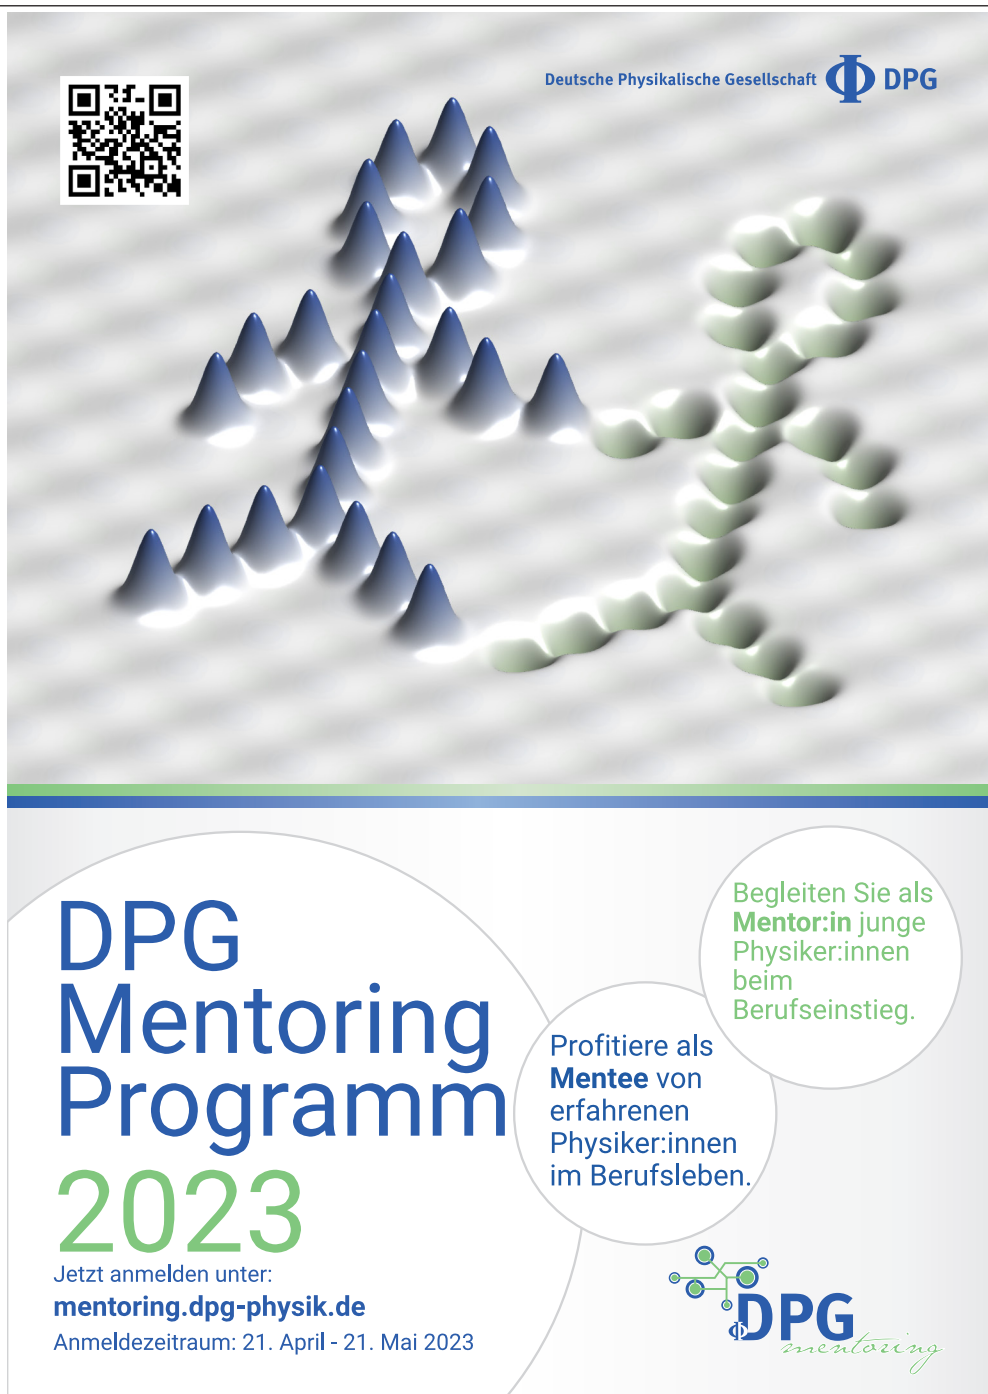
Invited Talks

13:45	KRO 1.11	AIW 1.1	Als Physiker*in Krankenhäuser digitalisieren? Klar doch! •Charles Ludwig Majer
14:15	KRO 1.11	AIW 1.2	From the Lab to Customer Engineering at Google – the Unconventional Career Path of an Experimental Physicist •Diana Nanova
14:45	KRO 1.11	AIW 1.3	Von der Promotion zur eigenen Firma •Oliver de Haas
15:30	KRO 1.11	AIW 2.1	How start-ups and alumni networks enrich young scientist's career options •Joachim Rädler
16:00	KRO 1.11	AIW 2.2	Karrieremöglichkeiten für Physikerinnen und Physiker auf dem Gebiet des Gewerblichen Rechtschutzes •Udo Weigelt


Sessions

13:45	KRO 1.11	AIW 1	AIW Industrietag I
15:30	KRO 1.11	AIW 2	AIW Industrietag II
16:45	KRO 1.11	AIW 3	Podiumsdiskussion
17:30	KRO 1.11	AIW 4	Gemütlicher Ausklang mit Networking bei Bier & Brezn

09:30	Foyer HSZ / Tent A		**Exhibition of Scientific Instruments and Literature**

Job Market

11:30	HSZ 405	Bundesamt für Sicherheit in der Informationstechnik *"Aus der Physik in die IT-Sicherheit – Karriere beim BSI"*
12:45	HSZ 405	Trumpf Lasersystems for Semiconductor Manufacturing GmbH *"TRUMPF Lasersystems for EUV Lithography – Enabler für das digitale Zeitalter gesucht"*
14:00	HSZ 405	Basycon Unternehmensberatung GmbH *"Aus der Wissenschaft in die Beratung"*
15:15	HSZ 405	ZEISS *"Am Herzschlag der Digitalisierung: Forschung & Entwicklung in der Halbleiterfertigungstechnik"*

Deutsche Physikalische Gesellschaft Φ DPG

DPG Mentoring Programm 2023

Jetzt anmelden unter:
mentoring.dpg-physik.de
Anmeldezeitraum: 21. April - 21. Mai 2023

Begleiten Sie als **Mentor:in** junge Physiker:innen beim Berufseinstieg.

Profitiere als **Mentee** von erfahrenen Physiker:innen im Berufsleben.

DPG mentoring

Thursday, March 30, 2023

Plenary Talks

08:30	HSZ 01	PLV VIII	Nanomechanics: Tunes of the nanoguitar •Eva Weig
14:00	HSZ 01	PLV IX	Metal Halide Perovskites for Photovoltaic Applications •Laura Herz
14:00	HSZ 02	PLV X	Single-electron-spin-resonance detection by microwave photon counting •Patrice Bertet

Prize Talk

13:15	HSZ 01	PRV III	High-lying excitons and excitonic quantum interference in 2D semiconductors •Kai-Qiang Lin (Laureate of the Walter-Schottky-Prize 2023)

Lunch Talk, Discussion

13:15	HSZ 02	PSV IX	Working as a Physicist in the Microelectronic Industry •Matthias U. Lehr
13:15	HSZ 03	PSV X	NFDI and FAIR research data: benefit or burden? Laurenz Rettig, Heiko B. Weber, and •Martin Aeschlimann

SYQD

Symposium

09:30	HSZ 01	SYQD 1	Real-Time Measurements of Quantum Dynamics

Invited Talks

09:30	HSZ 01	SYQD 1.1	Real-time measurement and control of spin dynamics in quantum dots •Seigo Tarucha
10:00	HSZ 01	SYQD 1.2	Quantum Dot arrays for Quantum Information Transfer •Gloria Platero
10:30	HSZ 01	SYQD 1.3	Optical Detection of Real-Time Quantum Dynamics in Quantum Dots •Martin Geller
11:30	HSZ 01	SYQD 1.4	Cooper Pair Splitting in Real-Time •Christian Flindt
12:00	HSZ 01	SYQD 1.5	Trajectory-based detection in stochastic and quantum thermodynamics •Jukka Pekola

SYTS

Symposium

15:00	HSZ 01	SYTS 1	Topological Superconductor-Magnet Heterostructures

Invited Talks

15:00	HSZ 01	SYTS 1.1	Blending of superconductivity and magnetism via topological solitons •Christos Panagopoulos
15:30	HSZ 01	SYTS 1.2	Topological landscaping in magnet-superconductor heterostructures •Sebastián A. Díaz
16:00	HSZ 01	SYTS 1.3	Experimental study of minigaps and end states in bottom-up designed multi-orbital Shiba chains •Jens Wiebe
16:45	HSZ 01	SYTS 1.4	Quantum spins and hybridization in artificially-constructed chains of magnetic adatoms on superconducting 2H-NbSe$_2$ •Katharina J. Franke
17:15	HSZ 01	SYTS 1.5	Braiding of Majorana zero modes •Stephan Rachel

BP

Invited Talks

11:15	BAR Schö	BP 21.7	Visualizing the inner life of microbes •Ulrike Endesfelder

BP

10:30	TOE 317	BP 22.5	Statistical Physics of Spatially Organized Catalytic Particles
			•Ulrich Gerland
09:30	BAR 0106	BP 23.1	Conformational dynamics of SARS-CoV-2 spike protein modulates the binding affinity to ACE2
			•Felix Rico
15:00	TOE 317	BP 26.1	Decoding Molecular Plasticity in the Dark Proteome of the Nuclear Transport Machinery
			•Edward Lemke

Sessions

09:30	BAR Schö	BP 21	Bioimaging
09:30	TOE 317	BP 22	Statistical Physics of Biological Systems I
09:30	BAR 0106	BP 23	Single Molecule Biophysics
09:30	ZEU 160	BP 24	Active Matter IV
15:00	BAR Schö	BP 25	Cell Mechanics II
15:00	TOE 317	BP 26	Focus Session mRNA Physics
15:00	BAR 0106	BP 27	Computational Biophysics II
18:00	P2/EG	BP 28	Poster Session II

CPP

Invited Talk

15:00	ZEU 255	CPP 53.1	Aqueous nanoclusters govern ionic transport in dense polymer membranes
			•Joachim Dzubiella

Sessions

09:00	POT 51	CPP 42	Battery Materials
09:30	GÖR 226	CPP 43	Organic Electronics and Photovoltaics III
09:30	MER 02	CPP 44	Wetting, Fluidics and Liquids at Interfaces and Surfaces II
09:30	ZEU 255	CPP 45	Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods
09:30	ZEU 160	CPP 46	Active Matter IV
09:30	POT 81	CPP 47	2D Materials VI
10:15	SCH A 251	CPP 48	Data Driven Materials Science: Big Data and Work Flows – Microstructure-Property-Relationships
10:30	GER 37	CPP 49	2D Materials VII: Heterostructures
12:15	ZEU 255	CPP 50	Glasses and Glas Transition II
15:00	GÖR 226	CPP 51	Hybrid and Perovskite Photovoltaics III
15:00	MER 02	CPP 52	Wetting, Fluidics and Liquids at Interfaces and Surfaces III
15:00	ZEU 255	CPP 53	Charged Soft Matter, Polyelectrolytes and Ionic Liquid
16:30	MER 02	CPP 54	2D Materials VIII
18:00	MER 02	CPP 55	Members' Assembly

DS

Invited Talks

09:30	SCH A 316	DS 13.1	Towards Catalytic Applications of Infrared Laser Polarimetry
			•Andreas Furchner
11:15	SCH A 316	DS 15.1	In-Situ Optical Investigation of Electrochemically Induced Conformational Changes at Solid Liquid Interfaces: A Source of new Electronic States
			•Christoph Cobet
16:15	SCH A 316	DS 17.1	In-situ optical spectroscopy on electrochemical interfaces: From OER electrocatalysts to "smart" electro-switchable interfaces
			•Martin Rabe
16:45	SCH A 316	DS 17.2	The physics of low symmetry semiconductors: Gallium oxide for the future of green energy as example
			•Mathias Schubert
17:15	SCH A 316	DS 17.3	Spectroscopic ellipsometry studies of optical constants in highly excited semiconductors
			•Stefan Zollner

DS

Sessions

09:30	SCH A 316	DS 13	Optical Analysis of Thin Films I
09:30	SCH A 315	DS 14	Thin Oxides and Oxide Layers
11:15	SCH A 316	DS 15	Optical Analysis of Thin Films II
11:30	SCH A 315	DS 16	Thermoelectric and Phase Change Materials; Layer Deposition
16:15	SCH A 316	DS 17	Optical Analysis of Thin Films III
18:00	SCH A 315	DS 18	Members' Assembly

DY

Invited Talks

11:00	MOL 213	DY 37.6	Power law error growth rates – a dynamical mechanism for a strictly finite prediction horizon in weather forecasts •Holger Kantz
09:30	ZEU 160	DY 38.1	Acoustically propelled nano- and microparticles: From fundamentals to applications •Raphael Wittkowski

Sessions

09:30	TOE 317	DY 35	Statistical Physics of Biological Systems I
09:30	MER 02	DY 36	Wetting, Fluidics and Liquids at Interfaces and Surfaces I
09:30	MOL 213	DY 37	Data Analytics of Complex Dynamical Systems
09:30	ZEU 160	DY 38	Active Matter IV
09:30	ZEU 260	DY 39	Networks: From Topology to Dynamics II
10:00	ZEU 250	DY 40	Stochastic Thermodynamics
10:00	ZEU 260	DY 41	Networks: From Topology to Dynamics III
13:00	P1	DY 42	Poster: Active Matter, Soft Matter, Fluids
13:00	P1	DY 43	Poster: Quantum Dynamics and Many-Body Systems
13:00	P1	DY 44	Poster: Statistical Physics
13:00	P1	DY 45	Poster: Nonlinear Dynamics, Pattern Formation and Networks
13:00	P1	DY 46	Poster: Machine Learning and Data Analytics
15:00	MER 02	DY 47	Wetting, Fluidics and Liquids at Interfaces and Surfaces II
15:00	MOL 213	DY 48	Dynamics and Chaos in Many-Body Systems I
15:00	ZEU 160	DY 49	Critical Phenomena and Phase Transitions
15:00	ZEU 260	DY 50	Evolutionary Game Theory
18:00	ZEU 160	DY 51	Members' Assembly

HL

Invited Talks

09:30	POT 361	HL 35.1	Quantum Dynamics of Polarons in Doped Semiconductor Monolayers •Xiaoqin Elaine Li
10:00	POT 361	HL 35.2	Impact of phonons on time-resolved optical signals from excitons •Doris E. Reiter
10:30	POT 361	HL 35.3	Hot-Exciton Quantum Dynamics in Zero-Dimensional Structures •Alfred Leitenstorfer
12:00	POT 361	HL 35.6	Ultrafast dynamics and wave mixing at excitonic resonances in atomically thin semiconductors •Andreas Knorr
12:30	POT 361	HL 35.7	Spontaneous parametric down-conversion in semiconductor metasurfaces •Maria Chekhova
15:00	POT 251	HL 43.1	Superradiance as a witness to multipartite entanglement •Frederik Lohof

Sessions

09:30	POT 81	HL 34	2D Materials V
09:30	POT 361	HL 35	Focus Session: Transient multi-wave mixing on excitonic resonances
09:30	POT 151	HL 36	Transport properties
09:30	POT 251	HL 37	Materials and devices for quantum technology II

HL

09:30	POT 6	HL 38	Functional semiconductors for renewable energy solutions I
09:30	GÖR 226	HL 39	Organic Electronics and Photovoltaics III
10:30	TRE Ma	HL 40	Focus Session: Frontiers of Electronic-Structure Theory VI
15:00	POT 81	HL 41	Oxide Semiconductors I: Ga_2O_3
15:00	POT 151	HL 42	Quantum dots: Growth
15:00	POT 251	HL 43	Semiconductor lasers II
15:00	POT 112	HL 44	Nitrides: Devices
15:00	POT 6	HL 45	Functional semiconductors for renewable energy solutions II
18:00	POT 6	HL 46	Members' Assembly

KFM

Sessions

09:00	POT 51	KFM 10	Battery Materials
14:00	POT 51	KFM 11	Crystal Structure Defects / Real Structure / Microstructure
18:00	POT 51	KFM 12	Members' Assembly
10:00	POT 106	KFM 13	Polar Oxide Crystals and Solid Solutions I
14:00	POT 106	KFM 14	Polar Oxide Crystals and Solid Solutions II

MA

Invited Talks

09:30	HSZ 02	MA 34.1	Polarized phonons carry angular momentum in ultrafast demagnetization •Peter Baum
10:00	HSZ 02	MA 34.2	Spin-phonon coupling in ordered magnets: origin and consequences •Akashdeep Kamra
10:30	HSZ 02	MA 34.3	Magnon-mechanics in high overtone acoustic resonators •Hans Huebl
11:15	HSZ 02	MA 34.4	Cavity Magnomechanics: Harnessing the Magnomechanical Coupling for Applications in the Microwave and Optical Regimes •Silvia Viola Kusminskiy
11:45	HSZ 02	MA 34.5	Coherent spin-wave transport in an antiferromagnet •Andrea Caviglia
15:00	HSZ 02	MA 41.1	Altermagnetism and spin symmetries •Libor Šmejkal
15:30	HSZ 02	MA 41.2	Spontaneous Hall effect in Mn5Si3 altermagnet •H. Reichlova
16:30	HSZ 02	MA 41.5	Generation of tilted spin-current by the collinear antiferromagnet RuO2 •Arnab Bose
17:00	HSZ 02	MA 41.6	First-principles studies on the anomalous transport properties of ferromagnets, antiferromagnets, and altermagnets •Wanxiang Feng
17:30	HSZ 02	MA 41.7	Insight into chemical and magnetotransport properties of epitaxial α-Fe2O3/Pt bilayers •Anna Kozioł-Rachwał

Sessions

09:30	HSZ 02	MA 34	Focus Session: Spin-Phonon Coupling
09:30	HSZ 04	MA 35	Skyrmions III
09:30	HSZ 401	MA 36	Magnetic Particles / Clusters
09:30	HSZ 403	MA 37	Magnetic Heuslers
11:30	HSZ 401	MA 38	Micro- and Nanostructured Magnetic Materials
11:30	HSZ 403	MA 39	Weyl Semimetals
14:00	P2/EG	MA 40	Poster Magnetism II
15:00	HSZ 02	MA 41	Focus Session: Altermagnetism: Transport, Optics, Excitations
15:00	HSZ 04	MA 42	Caloric Effects in Ferromagnetic Materials
15:00	HSZ 401	MA 43	Magnetic Imaging Techniques II
15:00	HSZ 403	MA 44	Frustrated Magnets II
18:00	HSZ 04	MA 45	Members' Assembly

MM

Topical Talks

09:30	SCH A 251	MM 35.1	Configuration entropy and sample size effect on glass transition temperature •Yannick Champion
10:15	SCH A 216	MM 37.1	Structural and chemical atomic complexity of lattice defects – From defect phase diagrams to properties of intermetallics •Sandra Korte-Kerzel
11:45	SCH A 216	MM 37.5	Density-based Grain Boundary Phase Diagrams •Reza Darvishi Kamachali
10:15	SCH A 215	MM 38.1	The Fundamental physics of the onset of frictional motion: How does friction start? •Jay Fineberg
15:45	SCH A 216	MM 41.1	Entropy in grain boundary segregation •Pavel Lejcek

Sessions

09:30	SCH A 251	MM 35	Invited Talk: Champion
10:15	SCH A 251	MM 36	Data Driven Materials Science: Big Data and Work Flows – Microstructure-Property-Relationships
10:15	SCH A 216	MM 37	Topical Session: Defect Phases II
10:15	SCH A 215	MM 38	Topical Session: Fundamentals of Fracture – Fracture Experiments
11:45	SCH A 215	MM 39	Phase Transformations: Simulation and Machine Learning
15:45	SCH A 251	MM 40	Mechanical Properties and Allloy Design
15:45	SCH A 216	MM 41	Topical Session: Defect Phases III
15:45	SCH A 215	MM 42	Interface Controlled Properties and Nanomaterials: Nanoporous Materials and Nanolaminates

O

Invited Talk, Topical Talks

09:30	TRE Phy	O 71.1	Surface dynamics under reaction conditions •Edvin Lundgren
10:30	GER 38	O 75.1	Ultrafast nano-imaging: probing quantum dynamics in space and time •Markus Raschke
11:45	GER 38	O 75.5	Lightwave-driven scanning tunneling microscopy and spectroscopy at the atomic scale •Vedran Jelic
11:00	TRE Ma	O 79.3	New Opportunities for First Principles Simulations of Thousands of Atoms Using Linear Scaling Density Functional Theory •Laura Ratcliff
15:30	CHE 89	O 80.3	Topological Plasmonics and Plasmonic Twistronics: Skyrmions, Merons, Quasicrystals, and Sykrmion Bags •Harald Giessen
15:00	GER 38	O 83.1	Imaging ultrafast electron dynamics in isolated nanoparticles •Daniela Rupp
16:15	GER 38	O 83.5	Ultrafast coherent manipulation of free electrons via quantum interaction with shaped optical fields •Giovanni Maria Vanacore
15:00	WIL A317	O 84.1	Introducing a FAIR research data management infrastructure for experimental condensed matter physics data •Christoph Koch
17:00	WIL A317	O 84.7	Open Research Data for Photons and Neutrons: Applications in surface scattering and machine learning •Linus Pithan
15:30	TRE Phy	O 86.3	Novel concepts to simulate electrified liquid/solid interfaces from first principles •Stefan Wippermann
15:00	TRE Ma	O 87.1	Quartz-sensor detection for single-electron tunneling spectroscopy •Jascha Repp

| 16:15 | TRE Ma | O 87.5 | Application of atomic force microscopy with quartz sensors to quantum states in graphene and related twisted heterostructures •Joseph Stroscio |

Sessions

09:30	TRE Phy	O 71	Overview Talk Edvin Lundgren
10:30	CHE 89	O 72	Gerhard Ertl Young Investigator Award Competition
10:30	CHE 91	O 73	Metal Substrates: Adsorption and Reaction of Small Molecules II
10:30	GER 37	O 74	2D Materials IV: Heterostructures
10:30	GER 38	O 75	Focus Session: Ultrafast Dynamics in Nanostructures I
10:30	WIL A317	O 76	Plasmonics and Nanooptics III: Light-Matter Interaction and Spectroscopy II
10:30	REC C 213	O 77	Scanning Probe Techniques: Method Development II
10:30	TRE Phy	O 78	Heterogeneous Catalysis and Surface Dynamics II
10:30	TRE Ma	O 79	Focus Session: Frontiers of Electronic-Structure Theory VI
15:00	CHE 89	O 80	Plasmonics and Nanooptics IV: Light-Matter Interaction and Spectroscopy III
15:00	CHE 91	O 81	Oxide and Insulator Surfaces I: Adsorption and Reaction of Small Molecules
15:00	GER 37	O 82	Graphene I: Adsorption, Intercalation and Doping
15:00	GER 38	O 83	Focus Session: Ultrafast Dynamics in Nanostructures II
15:00	WIL A317	O 84	Focus Session: Making Experimental Data F.A.I.R. – New Concepts for Research Data Management I
15:00	REC C 213	O 85	Electronic Structure of Surfaces II

62. Wochenendseminar „Physiker:innen im Beruf"

Der Übergang von der Hochschule in die **berufliche Karriere** fällt vielen nicht leicht: Die Möglichkeiten und Aufgabengebiete sind vielfältig - und wer kennt schon nach Studium oder Promotion die verschiedenen Anforderungen und Arbeitsabläufe?

Das Seminar bietet durch **Erfahrungsberichte** etablierter Physiker:innen sowie junger Berufsanfänger:innen Orientierung. Die 15 Vortragenden repräsentieren ganz verschiedene Arbeitsgebiete und zeigen damit das breite **Einsatzspektrum** von Physikerinnen und Physikern.

Neben den Vorträgen bietet der gemütliche Lichtenbergkeller des Physikzentrums Bad Honnef ein ideales Forum, mit den Vortragenden am Abend **in kleiner Runde offen** zu **diskutieren** und Erfahrungen zu sammeln.

Zielgruppe:
Physikstudierende ab Bachelor bis zur Promotion. Max. 80 Personen.

5. bis 7. Mai 2023

Physikzentrum Bad Honnef

Weitere Infos und Anmeldung: www.pib.dpg-physik.de

Sessions
– Plenary Talks –

Plenary Talk   PLV I   Mon 8:30   HSZ 01
Spin-Photon Interfaces and Their Applications — •Mete Atatuere — University of Cambridge
Optically active spins in solids are often considered prime candidates for scalable and feasible quantum-optical devices. Numerous material platforms including diamond, semiconductors, and atomically thin layered materials are investigated, where each platform brings their own advantages along with their challenges. I will highlight the common challenges and the ways forward for some of the promising systems for applications in quantum networks and quantum sensing.

Plenary Talk   PLV II   Mon 14:00   HSZ 01
New directions in electromagnetic field mapping in materials in the transmission electron microscope — •Rafal E. Dunin-Borkowski — Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons, Forschungszentrum Jülich, 52425 Jülich, Germany
Transmission electron microscopy has been revolutionized in recent years, both by the introduction of new hardware such field-emission electron guns, aberration correctors and in situ stages and by the development of new techniques that take advantage of increased computational speed and the ability to control and automate modern electron microscopes. In this talk, I will describe how electron microscopy can be used to obtain quantitative information about not only local variations in microstructure and composition in materials, but also magnetic fields and charge density distributions with close-to-atomic spatial resolution. When combined with model-based iterative reconstruction, electron tomography and in situ techniques, this information can be obtained quantitatively, in three dimensions, as a function of temperature, with high temporal resolution and in the presence of applied fields, light and reactive gases. I will present results obtained from studies of magnetization distributions in individual magnetic nanocrystals and three-dimensional magnetic solitons in geometrically-confined structures, from measurements of electric fields in nanoscale materials and from studies of electron-light-matter interactions. I will conclude with a personal perspective on directions for the future development of transmission electron microscopy, which may require radical changes to the design of electron microscopes.

Plenary Talk   PLV III   Mon 14:00   HSZ 02
Microgels at Interfaces — •Regine von Klitzing — Institute for Condensed Matter Physics, TU Darmstadt, Germany
Rupturing foams (and emulsions) on demand is a big challenge for many applications. One strategy is to use stimuli-responsive surface-active polymer particles as stabilizers. Here we use thermosensitive microgel particles which show an LCST-like volume phase transition. In order to understand their impact on foam stabilisation it is important to get deeper insight into different length scales of the foams, i.e. from adsorption of microgels at the air/water interface studied by scanning force microscopy (AFM), via forces across microscopic foam lamellas measured with a thin film pressure balance and foam bubbles to macroscopic foams stabilized by PNIPAM microgels. The foam structure is investigated by small angle neutron scattering (SANS). The deformation of the microgels plays an important role for the stabilisation mechanism and is related to their inner structure (studied by SANS), the swelling behaviour and nanomechanical and nanorheological properties that are investigated by dynamic indentation with an AFM tip. The combination of these studies on different length scales almost completes the picture about the stabilisation ability of microgels and might by transferred to other types of colloidal dispersions.

Plenary Talk   PLV IV   Tue 8:30   HSZ 01
Stochastic thermodynamics: From concepts to model-free inference — •Udo Seifert — II. Institut für Theoretische Physik, Universität Stuttgart
Stochastic thermodynamics provides a universal framework for analyzing nano- and micro-sized non-equilibrium systems. Prominent examples are single molecules, molecular machines, colloidal particles in time-dependent laser traps and biochemical networks. Thermodynamic notions like work, heat and entropy can be identified on the level of individual fluctuating trajectories. They obey universal relations like the fluctuation theorem.

Thermodynamic inference as a general strategy uses consistency constraints derived from stochastic thermodynamics to infer otherwise hidden properties of non-equilibrium systems. As a paradigm for thermodynamic inference, the thermodynamic uncertainty relation discovered in 2015 provides a lower bound on the entropy production through measurements of the dispersion of any current in the system. Likewise, it quantifies the cost of temporal precision for biomolecular processes and provides a model-free bound on the thermodynamic efficiency of molecular motors and microscopic heat engines.

Plenary Talk   PLV V   Wed 8:30   HSZ 01
Advances in Ultrafast Electron Microscopy — •Claus Ropers — Max-Planck Institute for Multidisciplinary Sciences, Göttingen — University of Göttingen
Providing the most detailed views of atomic-scale structure and composition, Transmission Electron Microscopy (TEM) serves as an indispensable tool for structural biology and materials science. The combination of electron microscopy with pulsed electrical or optical stimuli allows for the study of transient phenomena, involving magnetization dynamics, strain evolution and structural phase transformations. Ultrafast transmission electron microscopy (UTEM) is a pump-probe technique, in which non-equilibrium processes can be tracked with simultaneous femtosecond temporal and nanometer spatial resolutions.

This talk will cover recent developments and applications in UTEM based on laser-triggered field emitters, including the real-space and diffractive probing of a structural phase transition. Moreover, the mechanisms involved in free-electron beams interacting with optical fields at photonic structures will be discussed, emphasizing quantum effects. In particular, recent progress in the coupling of electron beams to integrated photonic structures will be presented. Finally, harnessing developments in event-based electron spectroscopy, we demonstrate the preparation and characterization of electron-photon and electron-electron pair states.

Plenary Talk   PLV VI   Wed 14:00   HSZ 01
Topological defects in active and living matter — •M Cristina Marchetti — University of California Santa Barbara, USA
Topological defects play a central role in the physics of many materials, including magnets, superconductors and liquid crystals. In oriented active fluids defect acquire a new life as spontaneous local currents turn them into self-propelled particles that drive chaotic flows. There is growing evidence that living systems may exploit this relation between structure and dynamics and use defects to localize stress or perform specific functions. The intimate connection between defect textures and active flow suggests that properties of active materials can be engineered by controlling defects. In this talk I will describe our work on formulating the dynamics of active topological defects as particle-like excitations, their role in driving the turbulent-like dynamics of active liquid crystals, and recent approaches to manipulate the defect dynamics in both space and time.

Plenary Talk   PLV VII   Wed 14:00   HSZ 02
Ferroelectric and multiferroic domain walls for nanotechnology — •Dennis Meier — Department of Materials Science and Engineering, NTNU Norwegian University of Science and Technology — Center for Quantum Spintronics, Department of Physics, NTNU Norwegian University of Science and Technology
Ferroelectric and multiferroic domain walls have emerged as a new type of functional interface. Because of their distinct symmetry and chemical environment, the domain walls offer a wide variety of functional electric and magnetic properties, representing excellent 2D components for the development of more agile next-generation nanotechnology. In my talk, I will discuss fundamental key properties of domain walls in ferroics and how the field of domain wall nanoelectronics evolved from classical device ideas to advanced concepts, where the walls themselves are used as ultra-small electronic components. I will conclude with a discussion of open experimental challenges and newly discovered domain-wall phenomena that may play an important role in future directions of the field.

Plenary Talk   PLV VIII   Thu 8:30   HSZ 01
Nanomechanics: Tunes of the nanoguitar — •Eva Weig — Technical University of Munich, Garching, Germany
Nanomechanical resonators - freely suspended, vibrating nanostructures - show great promise as versatile elements in hybrid nanosystems, as sensors or signal transducers both in the classical and in the quantum realm. Here I will focus on nanomechanical string resonators. These seemingly simple devices exhibit remarkably large room temperature quality factors and enable electrostatic control. Nanostrings are thus an ideal testbed to explore a variety of dynamical phenomena. I will review recent progress in controlling the coherent as well as the nonlinear dynamics of nanostring resonators. This includes the realization of a nanomechanical two-mode system mimicking the coherent dynamics of a quantum two-level system, and novel insights into squeezing and frequency comb generation.

Plenary Talk   PLV IX   Thu 14:00   HSZ 01
Metal Halide Perovskites for Photovoltaic Applications — •Laura Herz — University of Oxford, Department of Physics, Parks Road, Oxford OX1 3PU, U.K.
Organic-inorganic metal halide perovskites have emerged as attractive materials for solar cells with power-conversion efficiencies now exceeding 25%. This talk

will provide an overview of our work unravelling the fundamental processes that have enabled these materials to be such efficient light-harvesters and charge collectors, examining e.g. fundamental mechanisms underpinning charge-carrier mobility and recombination. Our analysis of intrinsic photophysical parameters opens the promise of targeted material design for solar energy harvesting, based on readily accessible parameters, such as band structure, phonon frequencies and the dielectric function.

We further discuss a range of remaining challenges and opportunities relating to material microstructure, ionic migration and toxicity. We examine how the optoelectronic properties of hybrid perovskites are governed by their nanostructure and structural phases. In the context of silicon-perovskite tandem cells, we discuss the peculiar mechanisms underlying detrimental halide segregation in mixed iodide-bromide lead perovskites with desirable electronic band gaps near 1.8eV. We further outline the challenges and rewards of lead-free metal halide perovskites and their structural derivatives.

Plenary Talk PLV X Thu 14:00 HSZ 02

Single-electron-spin-resonance detection by microwave photon counting —
•Patrice Bertet[1], Zhiren Wang[1], Leo Balembois[1], Eric Billaud[1], Milos Rancic[1], Marianne Le Dantec[1], Thierry Chaneliere[2], Alban Ferrier[3], Philippe Goldner[3], Sylvain Bertaina[4], Denis Vion[1], Daniel Esteve[1], and Emmanuel Flurin[1] — [1]Université Paris-Saclay, Gif-sur-Yvette, France — [2]Université Grenoble-Alpes, Grenoble, France — [3]Université PSL, Paris, France — [4]Université Aix-Marseille, Marseille, France

We report a new method for single-electron-spin-resonance spectroscopy at millikelvin temperatures. It consists in measuring the spin fluorescence signal at microwave frequencies using a microwave photon counter based on a superconducting transmon qubit. In our experiment, individual paramagnetic erbium ions in a scheelite crystal of CaWO4 are magnetically coupled to a small-mode-volume, high-quality factor superconducting microwave resonator to enhance their radiative decay rate. We detect the microwave photon spontaneously emitted by a spin following its excitation with a signal-to-noise ratio of 1.9 in one second integration time. Coherence times up to 3 ms are measured, limited by the spin radiative lifetime. The method applies to arbitrary paramagnetic species with long enough non-radiative relaxation time, and offers large detection volumes ($10\ \mu m^3$); as such, it may find applications in magnetic resonance and quantum computing.

Plenary Talk PLV XI Fri 8:30 HSZ 01

Physics in Nanopores: From Data storage to DNA/RNA analysis — •Ulrich Keyser — Cavendish Laboratory, University of Cambridge, JJ Thomson Ave, Cambridge, CB3 0HE, UK

DNA and RNA are the molecules of life. Their sequence encodes the blueprints from cells to viruses. Both polymers store information in their three-dimensional structure.

RNA and DNA are often analysed by translocating single molecules through small holes known as nanopores. An accurate understanding of the translocation dynamics is essential for the read out of polymer structure, including the localization of binding sites or sequences. Here we use synthetic nanopores and nanostructured DNA molecules to directly measure the velocity profile of driven polymer translocation through synthetic nanopores. We adjust nanopore geometry and translocation direction to resolve individual nanostructures only 7 nm apart and with a surface-to-surface gap distance of 2 nm. We then discuss the potential and challenges of our super-resolution nanopore sensing for future DNA data storage.

In the second part of the talk, we use our insights on polymer dynamics in nanopore confinement to analyse RNA molecules. We identify target RNA through making distinct three-dimensional structures with designed RNA:DNA interactions. Finally, we highlight multiplexed detection of RNA viruses - like SARS-CoV-2 and its variants - as one exciting application of nanopore sensing and DNA nanotechnology.

Sessions
– Prize Talks –

Prize Talk   PRV I   Tue 13:15   HSZ 01

Seeing is believing: Nonlinear optics on ferroic materials — •Manfred Fiebig — Dept. of Materials, ETH Zurich, Switzerland — Laureate of the Stern-Gerlach-Medal 2023

For millennia, ferromagnetism was the only form of ferroic order known to humankind. Now, however, a large variety of magnetic, electrical and mechanical types of ferroic phenomena is discussed. All of these all have one property in common: The ferroic ordering breaks the symmetry of the host material. Nonlinear optical processes are very sensitive to these symmetry changes. Even its simplest representative, doubling of the frequency of the light or "second harmonic generation" (SHG), therefore couples to the ferroic order parameter and accesses important features of the ferroic state that are often inaccessible to non-optical techniques. Novel ferroic states like ferrotoroidicity as a spontaneous order of magnetic whirls can thus be probed. Ultrafast processes can be resolved — how fast can a magnetic state be switched? In particular, the coexistence of different types of ferroic order in a material can be imaged by SHG. Thus, SHG became an invaluable tool for resolving the magnetoelectric coupling of domains in multiferroics as materials uniting magnetic and ferroelectric order. In my talk I will give an overview of the most important milestones in the classification of (multi-)ferroic materials by nonlinear optics. I will discuss basic questions such as the search for yet unknown types of ferroic order and correlations. I will also address highly application-relevant issues such as the use of SHG for tracking the emergence of ferroic order in thin films in-situ, during the growth process. A not-too-serious concept for "magnetoelectric teleportation" will conclude the lecture.

Prize Talk   PRV II   Wed 13:15   HSZ 01

Towards chemical and optical band structure engineering in molecular-based heterostructures — •Benjamin Stadtmueller — Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, 67663 Kaiserslautern, Germany — Institute of Physics, JGU Mainz, 55128 Mainz, Germany — Laureate of the Gaede-Prize 2023

Optical excitations with femtosecond light pulses offer the intriguing opportunity to control material properties on ever-shorter timescales down to the duration of the optical excitation itself. One of the most promising ways to reduce the timescale of the ultrafast material response is to exploit optical-induced spin and charge transfer processes that can directly act on the material's band structure and its population. In this presentation, I will introduce molecular-based heterostructures as a highly intriguing platform to chemically and optically tailor charge and spin carrier functionalities on the nanoscale. Using time-, spin- and momentum-resolved photoemission with fs-XUV radiation, I will first demonstrate that optical excitation of charge transfer states in molecular materials can instantaneously alter the local energy level alignment within the molecular film on ultrafast timescales [1,2]. This approach can be transferred to heterostructures between molecular and 2D semiconductors where it allows us to transiently uncover the otherwise hidden spin polarization of the prototypical layered semiconductor WSe2. These findings will open new avenues for optical controlling and functionalizing spin phenomena in molecular-based heterostructures on ultrafast timescales. [1] Nat. Commun. 10, 1470 (2019), [2] J. Electron. Spectros. Relat. Phenomena 252, 147110 (2021).

Prize Talk   PRV III   Thu 13:15   HSZ 01

High-lying excitons and excitonic quantum interference in 2D semiconductors — •Kai-Qiang Lin — Department of Physics, University of Regensburg, Regensburg, Germany — College of Chemistry and Chemical Engineering, Xiamen University, Xiamen, China — Laureate of the Walter-Schottky-Prize 2023

Two dimensional semiconductors such as transition-metal dichalcogenide (TMDC) monolayers show a wealth of exciton physics. We present the existence of a novel excitonic species, the high-lying exciton (HX), in TMDC monolayers with almost twice the energy of the band-edge A-exciton but with a linewidth as narrow as that of band-edge excitons. The HX is populated through momentum-selective optical excitation in the K-valleys, and is identified experimentally in upconverted photoluminescence and theoretically in ab initio GW-BSE calculations. These calculations show that the HX is comprised of electrons of negative effective mass. The coincidence of such high-lying excitonic species at around twice the energy of band-edge excitons gives rise to a well-defined excitonic three-level system, which enables quantum-interference phenomenon revealed in optical second-harmonic generation. We show that the temporal dynamics in such a three-level system can be probed through time-resolved sum-frequency generation and four-wave mixing. The HXs can also be tuned over a wide range by twisting and Stark effect in bilayer WSe2, which gives control over the excitonic quantum interference and the corresponding optical nonlinearities. Finally, we show how an electrical gate can be used to tune excitonic quantum interference in a monolayer TMDC transistor device by forming trions.

Sessions

– Ceremonial, Lunch, Evening Talks and Discussions –

Evening Talk   PSV I   Sun 18:30   HSZ 01
Kipp-Punkte im Klimasystem: Vorboten aus dem polaren Eis — •Ricarda Winkelmann — Potsdam Institute for Climate Impact Research, Member of the Leibniz Association, Germany — Institute of Physics and Astronomy, University of Potsdam, Germany

Der kälteste, der windigste, der trockenste Ort der Welt: Die Antarktis ist ein Ort der Extreme. Der Kontinent am Südpol ist von einem gigantischen Eisschild bedeckt, der Millionen von Jahre alt und in einigen Gebieten mehr als 4.000 m dick ist. Würde das gesamte Eis der Antarktis abschmelzen, hätte das einen globalen Meeresspiegelanstieg von etwa 58 m zur Folge.

Trotz dieser gewaltigen Ausmaße ist der antarktische Eisschild besonders anfällig gegenüber Klimaänderungen – über die vergangenen Jahrzehnte hat insbesondere die Westantarktis beschleunigt Eis verloren. Aufgrund von sich gegenseitig verstärkenden Wechselwirkungen zwischen Eis, Atmosphäre und Ozean steigt mit zunehmender globaler Erwärmung das Risiko, dass Kipp-Punkte in der Antarktis ausgelöst werden: Ist eine kritische Temperaturschwelle erst einmal überschritten, könnte dies zu einem selbsttragenden und möglicherweise irreversiblen Eisverlust in Teilen der West- und Ostantarktis führen.

In diesem Vortrag werden die zugrundeliegenden physikalischen Prozesse und die Risiken solcher dynamischer Instabilitäten genauer beleuchtet, sowie die daraus resultierenden Auswirkungen auf den Anstieg des Meeresspiegels und unser globales Klima – nicht nur in den kommenden Jahrzehnten, sondern für die nächsten Jahrhunderte und darüber hinaus.

Lunch Talk   PSV II   Mon 13:15   HSZ 02
Patentanwalt, Verfahren zu dessen Herstellung und Verwendung eines Patentanwalts — •Carina Ehrig — Kailuweit & Uhlemann Patentanwälte Partnerschaft mbB, Bamberger Straße 49, 01187 Dresden

Wie wird man Patentanwalt? Und wie sieht der Arbeitsalltag im Patentwesen aus? Der Vortrag gibt einen Überblick über die Ausbildung und die Arbeit im gewerblichen Rechtsschutz. Die Arbeit als Patentanwalt ist abwechslungsreich und spannend. Als Übersetzer zwischen Technik und Recht sind insbesondere Physiker gefragt und geeignet, da sie in der Lage sind, sich schnell in neue, komplexe und interdisziplinäre Sachverhalte einzuarbeiten. Der Weg zum fertigen Anwalt hingegen birgt noch so manche Herausforderung, auf die im Vortrag eingegangen wird.

Discussion   PSV III   Mon 13:15   HSZ 03
Talking about different career paths into Academia — •Alexander Osterkorn[1], Christoph Kastl[2], Anna Grünebohm[2], and Amelie Heuer-Jungemann[2] — [1]jDPG — [2]AGyouLeaP

On the way to a position in academia, nowadays several career paths are available. After the PhD, people usually go through a PostDoc phase and then take the next qualification step. For the latter, besides the more established Habilitation, one can become for example a Junior-Professor or an independent group leader funded by third-party funding like an Emmy-Noether fellowship. We want to discuss with people who followed these different career paths about their experiences and viewpoints on their career path. The panel discussion will be moderated by Alexander Osterkorn from jDPG and on the panel we are happy to welcome the AGyouLeaP members Christoph Kastl (Habilitant, TU München), Anna Grünebohm (Junior-Professor, Ruhr-Universität Bochum) and Amelie Heuer-Jungemann (Emmy-Noether Group Leader, Max-Planck Institut für Biochemie).

Lunch Talk   PSV IV   Tue 13:15   HSZ 02
Berufswege für Physiker in Elektrotechnik, Unternehmensberatung und IT — •Philipp Dedié — PhDSoft-Ingenieure GmbH, Hartriegelweg 12B, 38112 Braunschweig

Ich berichte aus meinem eigenen beruflichen Werdegang zu Berufswegen für Physiker in den Bereichen elektrische Energiespeicher und -wandler, Unternehmensberatung in der Automobilbranche und Informationstechnologie branchenübergreifend. Dazu gebe ich aktuelle Tätigkeitsbeispiele aus der IT in verschiedenen Branchen und Unternehmensgrößen von Startup über KMU bis Großunternehmen.

Lunch Talk   PSV V   Tue 13:15   HSZ 03
Research Funding by the DFG – Insights into the Decision Process — •Michael Mössle[1], Mario Bomers[1], Joanna Kowalska[1], Christian Hahn[1], and Sarah Köster[2] — [1]Deutsche Forschungsgemeinschaft, Bonn — [2]Institute for X-Ray Physics, Universität Göttingen

The German Research Foundation (DFG) is one of the largest research funding organizations in Germany. It is self-governed by the scientific community and

offers a broad range of funding opportunities from individual grants to larger coordinated programmes. The talk will give an overview of the DFG funding schemes and the bodies involved in the decision process, in particular the elected review boards. Also, we will attempt to give some first-hand insights into the review and decision process from the perspective of the DFG head office and a current review board member.

Ceremonial Talk   PSV VI   Tue 16:30   HSZ 01
Die Star Trek Physik – Warum die Enterprise nur 158 kg wiegt und andere galaktische Erkenntnisse — •Metin Tolan — Georg-August-Universität Göttingen

Die Serie Star Trek wurde 1966 im amerikanischen Fernsehen gestartet und nach Anlaufschwierigkeiten zur erfolgreichsten Serie überhaupt. Dazu beigetragen hat sicher auch die Beschreibung physikalischer Sachverhalte. In diesem Vortrag werden verschiedene Beispiele aus der klassischen und der Quantenphysik gezeigt und durchgerechnet. Ein physikalisch vorgebildetes Publikum wird dabei sicher nicht überfordert.

Lunch Talk   PSV VII   Wed 13:15   HSZ 02
Vom Physiker zum (erfolgreichen) Unternehmer der Plasway-Technologies GmbH — •Stephan Wege — Plasway-Technologies GmbH, 01728 Bannewitz, Heinrich-Heine Str. 2b

Werdegang Herr Stephan Wege: Vom Studium über die Erfahrungen in der Industrie und eine Kurzübersicht der Plasway-Technologies GmbH. Neben einer guten fachlichen Ausbildung (Diplom in Physik) sind Themen wie die Führung von Personal sowie gute Kenntnisse im Projektmanagement und Planung sehr wichtig. Die Darstellung der Arbeit auf einer höheren Managementebene bis hin zu Gesprächen mit Banken und Fördermittelgebern gehören schon fast zum täglichen Geschäft. Es werden viele öffentliche Fördermittel angeboten. Die Formulare sind eine zu große Herausforderung. Externe kostenpflichtige Berater können helfen. Ab einem gewissen Zeitpunkt können auch externe Investoren hilfreich sein. Die Erstellung eines Businessplanes ist hilfreich für die eigene Transparenz und wird von den Banken vorausgesetzt. Basiswissen im Steuer- Handels- und Finanzrecht sind ebenfalls sehr hilfreich. Ein guter Steuerberater ist unerlässlich. Die Rechtsform der zukünftigen Firma sollte man sich gut überlegen (GmbH, GbR). Welcher Standort ist günstig? Werbung für die Außendarstellung von großem Vorteil (Homepage, Visitenkarten, Filme, Flyer). Aber auch über Themen soziale Absicherung sollte man frühzeitig nachdenken. Das Wichtigste zum Schluss: Eine positive Einstellung zu einer 80 Stunden-Woche ist offensichtlich. Eine hohe Frustrationstoleranz gegenüber den Behörden und vor allem dem Finanzamt und auch der IHK sind selbstverständlich. Warum das Ganze? Es macht sehr viel Spaß.

Discussion   PSV VIII   Wed 13:15   HSZ 03
Vielfalt der Wissenschaftskommunikation — •Ulrich Bleyer[1], Nicolas Wöhrl[2] und Peter Kohl[2] — [1]Urania Berlin (a.D), 10787 Berlin — [2]Universität Duisburg-Essen, 47048 Duisburg

Gerade Physiker:innen sind durch den Anwendungsbezug ihrer Arbeit gefragt, wenn es um Wissenschaftskommunikation geht, z.B. bei transformativen Themen wie Quantenkryptographie, alten und neuen Energietechniken oder dem Klimawandel. Wir brauchen zielgruppenspezifische Kommunikation, die interaktiv und dialogorientiert ist. Dabei geht es nicht nur um die reinen Forschungsergebnisse, sondern auch darum, Prozesse und Methoden von wissenschaftlicher Arbeit transparent abzubilden - eine Aufgabe, die prinzipiell alle Forschenden übernehmen können. In dieser Veranstaltung soll zunächst die Bedeutung und die Vielfalt von Methoden der Öffentlichkeitsarbeit aus Sicht der DPG durch zwei erfahrene Akteure dargestellt werden. Zum einen die Berliner Gesellschaft Urania, die mit dem Ziel gegründet wurde wissenschaftliche Erkenntnis auch einem Laienpublikum zugänglich zu machen. Zum anderen die 'Junge DPG' die beispielsweise den 'Einsteinslam' und andere Formate –bei DPG-Veranstaltungen und darüber hinaus– veranstaltet. Anschließend werden in einer Focus-Session erfolgreiche Projekte der Wissenschaftskommunikation aus dem Bereich der Festkörperphysik vorgestellt. In ihrer Gesamtheit sollen sie das Spektrum der Wissenschaftskommunikation, auch im Hinblick auf den benötigten Aufwand, aufzeigen, Methoden für unterschiedliche Zielgruppen vorstellen und Hinweise geben, wie man bei Interesse konkret mit der Kommunikation beginnen kann.

Lunch Talk   PSV IX   Thu 13:15   HSZ 02
Working as a Physicist in the Microelectronic Industry — •Matthias U. Lehr — Globalfoundries Dresden, Germany

This talk describes the career path from a PhD work in basic research towards a technical manager position in the microelectronic industry. The variety of tasks

and different options for the personal development in a big high-tech company are discussed. It will be shown what is needed in terms of technical expertise as well as personal behavior to become successful as a physicist in a challenging, competitive and international environment.

Discussion   PSV X   Thu 13:15   HSZ 03

NFDI and FAIR research data: benefit or burden? — Laurenz Rettig[1], Heiko B. Weber[2], and •Martin Aeschlimann[3] — [1]Fritz Haber Institute of the MPG, Berlin, Germany — [2]Friedrich-Alexander-Universität Erlangen, Germany — [3]TU Kaiserslautern, Germany

Big data is becoming an ever more important resource for future research, especially for data-driven research fields and artificial intelligence. This is certainly also true for research data in solid state physics, which, however, are so far nei-

ther homogeneously structured nor openly accessible. The necessary requirements have been cast into the FAIR (findable, accessible, interoperable, reusable) principles, which provide a guideline for suitable data infrastructures. Given the growing demand from society, policymakers, and research funding agencies for open access to research data as well as metadata, researchers face a variety of questions and challenges:

How does the requirement for FAIR data influence daily laboratory routines? What reservations, what (e.g. legal) limitations do exist, and what is the meaning of FAIR, if corresponding (meta-) data standards or their documentation are (still) lacking? Are researchers willing and able to share data? These topics are at the focus of this discussion forum with invited speakers from research and funding agencies, followed by a dialogue with the audience.

Invited and Contributed Talks

TUT 1: Physics Meets Machine Learning (joint session DY/TUT/TT)

Machine learning has revolutionized many application fields such as computer vision and natural language processing. In physics there is a growing interest in using machine learning to enhance the analysis of experimental data and to devise and optimize experiments or numerical simulations. On the other hand physicists use their intuition and methods from statistical physics and complex systems theory to better understand the working principles of modern machine learning methods. This tutorial session introduces some subfields within this area and the basic methods involved.

Organized by Sabine Andergassen (Tübingen), Martin Gärttner (Heidelberg), Moritz Helias (Jülich), and Markus Schmitt (Cologne)

Time: Sunday 16:00–18:15   Location: HSZ 01

Tutorial   TUT 1.1   Sun 16:00   HSZ 01

Machine Learning for Quantum Technologies — •FLORIAN MARQUARDT — Max Planck Institute for the Science of Light and Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany

Machine learning is revolutionizing science and technology. In the past few years, it has become clear that it promises significant benefits as well for the development of quantum technologies. In this tutorial I will first give a brief introduction to neural networks. I will then discuss a number of areas and examples in which machine learning is being successfully applied in this context. These include measurement data analysis and quantum state representation, approximate quantum dynamics, parameter estimation, discovering strategies for hardware-level quantum control, the optimization of quantum circuits, and the discovery of quantum experiments, discrete quantum feedback strategies, and quantum error correction protocols.

Reference: "Artificial intelligence and machine learning for quantum technologies", M. Krenn, J. Landgraf, T. Foesel, and F. Marquardt, Phys. Rev. A 107, 010101 (2023).

Tutorial   TUT 1.2   Sun 16:45   HSZ 01

The Unreasonable Effectiveness of Gaussians in the Theory of Deep Neural Networks — •ZOHAR RINGEL — Racah Institute of Physics, Hebrew University in Jerusalem

Physical Sciences are in many ways the success story of explaining fundamental phenomena using simple math [1]. The fact that physical phenomena could be arranged in that manner is remarkable. Yet this simplicity does not necessarily carry over to life sciences or data sciences. Indeed prominent authors have argued against our desire to rely on neat mathematical structures when analyzing big data [2].

In the past half-decade several results have emerged which balance mathematical simplicity with data-induced complexity. These could be seen as a middle ground between the above juxtaposing views. The common divider here is the use of Gaussian distributions as approximants of various different quanti-
ties in deep neural networks (DNNs). Specifically these Gaussians emerge when describing outputs of DNNs with random weights, outputs of trained DNNs at random times, outputs of fixed DNNs over random input data, and fluctuations of hidden DNN pre-activations. In this tutorial I will present these quantities, provide arguments supporting their Gaussianity, and outline several theoretical implications.

[2] The Unreasonable Effectiveness of Data. Halevy, Norvig, Pereira (2009)

Tutorial   TUT 1.3   Sun 17:30   HSZ 01

Computing learning curves for large machine learning models using the replica approach — •MANFRED OPPER — Inst. für Softwaretechnik und Theor. Informatik, TU Berlin — Centre for Systems Modelling and Quantitative Biomedicine, University of Birmingham, UK

Methods of statistical physics have been used for a long time to mathematically analyse the typical performance of machine learning models in the limit where both the number of data and the number of parameters (such as network weights) is large. By defining Boltzmann-Gibbs probability distributions over parameters where the cost function of the machine learning problem plays the role of a hamiltoninan, one can derive analytical expressions for training errors and generalisation errors using the corresponding partition functions and free energies in terms of a usually small number of order parameters.

Since the models depend on a set of random data to be learnt, additional appropriate statistical (so-called quenched) averages of free energies over this 'disorder' have to be performed. The replica approach is a prominent analytical tool from the statistical physics of disordered systems to solve this nontrivial technical challenge.

In this tutorial I will give an introduction to this approach. Starting with an explicit calculation for simple single layer perceptrons, I will then argue how the method can be applied to more complex problems such as kernel machines (support vector machines and Gaussian processes) and multilayer networks.

TUT 2: Stochastic Processes of Opinion Formation (joint session SOE/TUT)

Time: Sunday 16:00–18:15   Location: HSZ 02

Tutorial   TUT 2.1   Sun 16:00   HSZ 02

Bounded Confidence Revisited: What We Overlooked, Underestimated, and Got Wrong — •RAINER HEGSELMANN — Frankfurt School of Finance & Management, 60322 Frankfurt, Adickesallee 32-34

The talk will discuss the so called bounded confidence model (BC-model, for short). The model is very simple: Period by period, all agents average over all opinions that are not further away from their actual opinion than a given distance Epsilon, their *bound of confidence*.

The simplicity of the model is deceptive. Two decades ago, Ulrich Krause and me published an analysis of the model in which we overlooked completely a decisive feature of our model: For increasing values of Epsilon, our analysis back then suggests smooth transitions in the model*s behavior. But in fact, the transitions are wild, chaotic, and non-monotonic.

In my talk I will present a new type of approach in which everything we overlooked at the time becomes directly obvious and, in a sense, unmissable. Key component of the new approach is an algorithm that identifies, exactly and exhaustively, all bounds of confidence, that make a difference. We get a list that, then, allows direct checks for wild behavior exhaustive of all possible cases. That is a good news. But it is accompanied by a bad one: The algorithm that does
the work, requires an absolutely exact fractional arithmetic with integers of arbitrary length. As a consequence, we have to pay a price in terms of computational speed.

Tutorial   TUT 2.2   Sun 16:45   HSZ 02

When intuition fails: the complex effects of assimilative and repulsive influence on opinion polarization — •MICHAEL MAES[1], ANDREAS FLACHE[2], SHUO LIU[3], and HAOXIANG XIA[3] — [1]Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]University of Groningen, Groningen, The Netherlands — [3]Dalian University of Technology, Dalian, China

There is a debate about whether personalized services of social-media platforms contribute to the rise of bipolarization of political opinions. On the one hand, it is argued that personalized services of online social networks generate filter bubbles limiting contact between users who disagree. This reduces opportunities for assimilative social influence between users from different camps and prevents opinion convergence. On the other hand, empirical research also indicated that exposing users to content from the opposite political spectrum can activate the counter-part of assimilative influence, repulsive influence. Fostering contact that leads to opinion assimilation and limiting contacts likely to induce repulsive interactions, it has been concluded, may therefore prevent bipolarization.

We demonstrate that these conclusions fail to capture the complexity that assimilative and repulsive influence generate in social networks. Sometimes, more assimilative influence can actually lead to more and not less opinion bipolarization. Likewise, increasing the exposure of users to like-minded individuals sometimes intensifies opinion polarization.

Tutorial TUT 2.3 Sun 17:30 HSZ 02

How growing connectivity and self-organization changes opinion dynamics — •Philipp Lorenz-Spreen — Center for Adaptive Rationality, Max Planck Institute for Human Development, Berlin, Germany

Information technology has made various aspects of our lives more dynamic and self-organized. Connections with others can be made across spatial and socio-demographic boundaries and undone with the click of a button. Since the famous six degrees of separation, networks seem much more connected; Facebook reports 3.5 degrees of separation on its friendship graph. Yet there have been repeated reports of segregated, homophilic network structures and related trends of increasing polarization on most online platforms. The mechanism that could resolve this apparent paradox may lie behind the question of whether we change our opinions according to our friends or whether we change our friends according to our opinions. We have recently proposed that an agent's opinion changes as a process of mutual reinforcement within clusters of shared attitudes and a coevolution of the associated network structure that dynamically adapts to changing opinions and follows a probability distribution governed by homophily. This combination helps explain the potential emergence of increasing polarization even as connectivity increases. Moreover, extending this model to multiple dimensions of topics can explain the empirical observation of increasing alignment of issues, where opinions become increasingly correlated within ideological clusters.

TUT 3: Hands-on tutorial on workflows for materials science simulation (joint session MM/TUT)

Time: Sunday 16:00–18:00 Location: HSZ 03

Tutorial TUT 3.1 Sun 16:00 HSZ 03

Hands-on tutorial on workflows for materials science simulations — •Jörg Neugebauer[1], Tilmann Hickel[1], and Ralf Drautz[2] — [1]Max-Planck-Institut für Eisenforschung, Düsseldorf — [2]ICAMS, Ruhr-Universität Bochum

Advanced computational simulations in materials science have reached a maturity that allows one to accurately describe and predict materials properties and processes. The underlying simulation tasks often involve several different models and software that requires expert knowledge to set up a project and to vary input parameters. The accompanying increasing complexity of simulation protocols means that the workflow along the simulation chain becomes an integral part of research. Effective workflow management therefore is important for efficient research and transparent and reproducible results.

In this hands-on tutorial we will provide an interactive hands-on introduction into managing workflows with pyiron (www.pyiron.org). Pyiron is an integrated development environment for materials science built on python and Jupyter notebooks that may be used for a wide variety of simulation tasks, from rapid prototyping to high performance computing. The tutorial will first give a general introduction to using pyiron, with a focus on atomistic simulation tasks. In the second part of the tutorial, the training and validation of ace-machine learning potentials from reference density functional calculations will provide a real-life application example.

TUT 4: Strategic elements and sustainability (joint session MA/TUT)

Our appetite for resources is insatiable. The path to a climate-neutral society and economy requires the increasingly intensive use of strategy metals such as lithium, cobalt, nickel, but also the group of rare earth elements. This major transformation is not possible without the sustainable use of these so-called critical elements along the entire value chain. In the Tutorial "Strategic elements and sustainability", we have four eminent speakers looking in this context at new developments in batteries, catalysis, thermoelectrics and magnetism.

Organizers: Oliver Gutfleisch (TU Darmstadt) and Heiko Wende (U. Duisburg-Essen).

Time: Sunday 16:00–18:00 Location: HSZ 04

Invited Talk TUT 4.1 Sun 16:00 HSZ 04

Making better batteries? – From Li-ion to Na-ion batteries — •Philipp Adelhelm — Humboldt-University Berlin, Berlin, Germany — Helmholtz-Zentrum Berlin, Berlin, Germany

The shift to electromobility is one of the most important transformations currently taking place in our society. This is associated with a sharp increase in battery production, which on the one hand opens up new opportunities, but on the other hand also has a massive impact on raw material supply and supply chains. In addition, new large markets are emerging, such as stationary energy supply or mobile robotics. Lithium-ion batteries are currently the most attractive technology for this. However, due to the large demand for batteries and the different application scenarios, other technologies are also being pursued. Sodium ion batteries can be produced on the same production lines as lithium ion batteries and are therefore considered a "drop-in" technology. The aim here is to replace not only costly lithium but also other expensive elements such as nickel or copper. Work is therefore being done worldwide on a cell chemistry for sodium ion batteries that works almost as well as lithium ion technology, but at the same time is cheaper and more readily available, or has other specific advantages. The tutorial gives an introduction to sodium ion technology. The motivation and state-of-the art are explained in more detail and material aspects are discussed. In particular, the question is addressed which electrode materials are promising for sodium ion batteries, what is needed to achieve further progress and what actually happens when lithium ions are replaced by sodium ions in a battery.

Invited Talk TUT 4.2 Sun 16:30 HSZ 04

Sustainable Thermoelectric Materials Predicted by Data Mining and Machine Learning — •Kornelius Nielsch — Leibniz Institute of Solid States and Materials Research, Dresden, Germany — Institute of Materials Research at TU Dresden, Germany — Institute of Applied Physcis at TU Dresden, Germany

Generating electricity from temperature differences has proven itself in space. Thanks to this technology, the Voyager probes launched in 1977 are still sending signals today. In the meantime, the car industry and ship producers have become interested in thermoelectrics. The combustion of fossil fuels produces exhaust gas that is up to 1300 °C hot. Modern thermoelectric materials are continuously expanding the fields of thermoelectric applications. The experimental search for new thermoelectric materials remains largely restricted to a limited number of successful chemical and structural families, such as chalcogenides, skutterudites and zintl phases. In principle, computational tools such as density functional theory (DFT) offer the possibility of directing experimental synthesis efforts towards very different chemical structures. In practice, however, predicting thermoelectric properties based on first principles remains a difficult endeavour, and experimental researchers do not usually use computations directly to drive their own synthesis efforts. Strategies to bridge this practical gap between experimental requirements and computational tools will be discuss und presented in this tutorial talk. Ref: Energy Environ. Sci. 14, 3559 (2021) and Advanced Theory and Simulations 5, 2200351 (2022)

Invited Talk TUT 4.3 Sun 17:00 HSZ 04

Design strategies for electrocatalysts – an electrochemist's perspective — •Kristina Tschulik — Ruhr-Universität Bochum, Faculty for Chemistry and Biochemistry, Chair for Electrochemistry and Nanoscale Materials — Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Straße 1, 40237 Düsseldorf

The aim to produce highly active, selective, and long-lived electrocatalysts by design drives major research efforts toward gaining fundamental understanding of the relationship between material properties and their catalytic performance. Surface characterization tools enable to assess atomic scale information on the complexity of electrocatalyst materials. Advancing electrochemical methodologies to adequately characterize such systems was less of a research focus point. In this tutorials, we shed light on the ability to gain fundamental insights into electrocatalysis and establish design strategies based on these. Concepts on how to improve mass transport, e.g. by exploiting magnetic fields are highlighted in this

respect. Particular attention is paid to deriving design strategies for nanoelectrocatalysts, which is often impeded, as structural and physical material properties are buried in electrochemical data of whole electrodes. Thus, a second major approach focuses on overcoming this difference in the considered level of complexity by methods of single-entity electrochemistry. The gained understanding of intrinsic catalyst performance will ultimately allow us to advance design concepts to transforming "pre-catalysts" in the forseeable future.

Invited Talk TUT 4.4 Sun 17:30 HSZ 04
Green magnetic materials for efficient energy, transport and cooling applications — •OLIVER GUTFLEISCH — TU Darmstadt, Material Science, Functional Materials

High performance hard and soft magnets are key components of energy-related technologies, such as direct drive wind turbines and e-mobility. They are also important in robotics and automatization, sensors, actuators, and information technology. The magnetocaloric effect (MCE) is the key for new and disruptive solid state-based refrigeration. Magnetic hysteresis and its inherent energy product characterise the performance of all magnetic materials. In the 60th position of the periodic table of elements is neodymium - an element that belongs to the rare earth-lanthanides and essential for the above applications. Basic material requirements, figure of merits, demand and supply, criticality of strategic elements and their recycling are explained for both permanent magnets and magnetocalorics referring to the benchmark materials NdFeB and LaFeSi. Every battery needs a magnet. 95% of electric vehicles utilize rare earth magnet-based drive motors, the quantities required global will grow from 5.000 t in 2019 to about 40.000 - 70.000 t per anno in 2030. The material history of neodymium is exciting and complex; monopolistic mining in China under ruinous conditions is just as problematic as our dependence on it. How "green" are the metals for renewable technologies? Who pays which price for it, and when?

Symposium Dynamics of Opinion Formation – From Quorum Sensing to Polarization (SYOF)

jointly organised by
the Physics of Socio-economic Systems Division (SOE),
the Dynamics and Statistical Physics Division (DY),
and the Biological Physics Division (BP)

Karoline Wiesner	Sven Banisch	Jens Christian Claussen
Department of Physics and Astronomy	Institute of Technology Futures	Institute of Technology Futures
University of Potsdam	Karlsruhe Institute of Technology	University of Birmingham
Germany	Germany	United Kingdom
karoline.wiesner@uni-potsdam.de	sven.banisch@universecity.de	j.c.claussen@bham.ac.uk

Quorum sensing is a widespread biological mechanism through which cells can exchange information and achieve a consensus state – hence a pre-social opinion formation process. In societies, opinion formation is a complex dynamical process that can, depending on the voting system and social interactions, lead to polarized societies or multi-parties systems. This symposium focuses on the dynamical processes underlying this opinion formation, the influence of the underlying topology of the opinion space (binary/Ising, Potts, continuous, higher-dimensional) and the resulting phase transitions.

Overview of Invited Talks and Sessions

(Lecture hall HSZ 01)

Invited Talks

SYOF 1.1 Mon 9:30–10:00 HSZ 01 **Towards understanding of the social hysteresis – insights from statistical physics** — •Katarzyna Sznajd-Weron

SYOF 1.2 Mon 10:00–10:30 HSZ 01 **Polarization in attitude distributions from surveys and models of continuous opinion dynamics** — •Jan Lorenz, Martin Gestefeld

SYOF 1.3 Mon 10:30–11:00 HSZ 01 **Collective patterns and stable misunderstandings in networks striving for consensus without a common value system** — •Johannes Falk, Edwin Eichler, Katja Windt, Marc-Thorsten Hütt

SYOF 1.4 Mon 11:15–11:45 HSZ 01 **A yet undetected cognitive bias, revealed by opinion dynamics simulations** — •Guillaume Deffuant

SYOF 1.5 Mon 11:45–12:15 HSZ 01 **Extreme switches in kinetic exchange models of opinion.** — •Parongama Sen, Kathakali Biswas

Sessions

SYOF 1.1–1.5 Mon 9:30–12:15 HSZ 01 **Dynamics of Opinion Formation – From Quorum Sensing to Polarization**

Sessions
– Invited Talks –

SYOF 1: Dynamics of Opinion Formation – From Quorum Sensing to Polarization

Time: Monday 9:30–12:15   Location: HSZ 01

Invited Talk   SYOF 1.1   Mon 9:30   HSZ 01
Towards understanding of the social hysteresis – insights from statistical physics — •Katarzyna Sznajd-Weron — Wrocław University of Science and Technology, Wroclaw, Poland
Hysteresis and tipping points are common features found in many complex social and psychological systems. For example, empirical studies suggest that public opinion demonstrates both of these phenomena, where it appears to be unresponsive to change (related to hysteresis) and then suddenly shifts abruptly at the tipping point. Hysteresis is used in social science to explain the inflexibility of change and is seen as a slow response of society to new issues, even when they are acknowledged by experts. From a statistical physics point of view, hysteresis is associated with first-order (discontinuous) phase transitions. This has led us to investigate what factors promote discontinuous phase transitions in models of opinion dynamics. We have been working on this subject for the last 10 years, focusing mainly on the q-voter model which is particularly attractive both from a theoretical and social point of view. In the first part of the lecture I will briefly review these results, and discuss which results are particularly relevant from the point of view of social sciences.

Someone might ask why physicists are concerned with social systems. Probably the first answer that comes to mind is that the methods and concepts of statistical physics can also be useful in the social sciences. But is feedback possible? During the lecture I will show that result obtained within the model originally proposed to describe social opinion dynamics can go beyond the state of the art in physics.

Invited Talk   SYOF 1.2   Mon 10:00   HSZ 01
Polarization in attitude distributions from surveys and models of continuous opinion dynamics — •Jan Lorenz and Martin Gestefeld — Constructor University (formerly Jacobs University), Bremen, Germany
Empirical attitude distributions from the European Social Survey often have non-trivial shapes with varying degrees of polarization. We analyze a large sample of 4,155 attitude distribution from various European countries and topics like left-right self-placement, European unification, and the cultural implications of migrations (and several others) for years between 2002 to 2018. All opinion distributions are built on questions with an 11-point quasi-continuous scale. Even in this one-dimensional setting, measuring polarization has many aspects, but not all are empirically relevant. Many distributions have up to five modes with modes: Two at both extremes, one in the center, and two off-center. We specify a measurement model for these opinion distributions and use it to decompose polarization. Finally, we discuss to what extent an opinion dynamics model with individual attitude change functions from psychological theory can replicate the empirically observed attitude distributions as stable outcomes.

Invited Talk   SYOF 1.3   Mon 10:30   HSZ 01
Collective patterns and stable misunderstandings in networks striving for consensus without a common value system — •Johannes Falk[1], Edwin Eichler[2,3], Katja Windt[3,1], and Marc-Thorsten Hütt[1] — [1]Constructor University, Bremen, Germany — [2]EICHLER Consulting AG, Weggis, Switzerland — [3]SMS Group GmbH, Düsseldorf, Germany
Collective phenomena in systems of interacting agents have helped us understand diverse social, ecological and biological observations. The corresponding explanations are challenged by incorrect information processing. In particular, the models typically assume a shared understanding of signals or a common

truth or value system, i.e., an agreement on whether the measurement or perception of information is right or wrong. It is an open question whether a collective consensus can emerge without these conditions. We introduce a model of interacting agents that strive for consensus, however, each with only a subjective perception of the world. We do not presuppose a definition of right or wrong and the actors can hence not distinguish between correct and incorrect observations. Depending on how responsive the agents are to changing their world-view we observe a transition between an unordered phase of individuals that are not able to communicate and a phase of an emerging shared signalling framework. We find that there are two types of convention-aligned clusters: one, where all social actors in the cluster have the same set of conventions, and one, where neighbouring actors have different but compatible conventions (stable misunderstandings). [1] Sci Rep 12, 3028 (2022)

15 min. break

Invited Talk   SYOF 1.4   Mon 11:15   HSZ 01
A yet undetected cognitive bias, revealed by opinion dynamics simulations — •Guillaume Deffuant — Université Clermont Auvergne, INRAE, UR LISC, Aubière, France
In the first part of the talk, I consider a recent opinion dynamics model in which the agents hold opinions about each other. The simulations of this model show surprising patterns. When agents do not gossip, the average opinion tends to increase and then to remain at a high value. When agents gossip, the average opinion tends to decrease and then to stabilise at a negative value. The mathematical analysis shows that a positive bias on the self-evaluation appears in the model and plays a crucial role in the pattern emergence. In the second part of the talk, I present an experiment that provides evidence supporting the existence of a similar positive bias in human subjects. I argue that this bias is different from the well-known positive bias from self-enhancement and was yet undetected.

Invited Talk   SYOF 1.5   Mon 11:45   HSZ 01
Extreme switches in kinetic exchange models of opinion. — •Parongama Sen[1] and Kathakali Biswas[2] — [1]Department of Physics, University of Calcutta, 92 APC Road, Kolkata 700009, India — [2]Department of Physics, Victoria Institution, 78B APC Road, Kolkata 700009, India
We consider a kinetic exchange opinion formation model, where the opinions can take three discrete values represented by $\pm 1, 0$. Such states may represent the support for two candidates/parties and a neutral opinion or three different ideologies where ± 1 correspond to radically different ones. We take a finite probability to switch from +1 to -1 and vice versa, which is usually not considered in similar models studied earlier. Except for initially completely disordered states, consensus states are reached for this model in general. Subsequently, a noise is incorporated by making the interactions both positive and negative. An order-disorder phase transition is obtained for this two parameter model. We discuss the critical properties and dynamical behaviour of the model in a mean field approach where results can be obtained analytically. Although the effect of the negative interactions is stronger, the extreme switches alone determine the nature of the disordered phase. As the extreme switches are allowed with larger probability, the system tends to a polarisation. For the maximum possible extreme switch, the system becomes identical to a two state voter model after a transient time.

Symposium SKM Dissertation Prize 2023 (SYSD)

jointly organised by
the divisions of the Condensed Matter Section (SKM)

Sarah Köster
Georg-August-Universität Göttingen
Friedrich-Hund-Platz 1
37077 Göttingen
sarah.koester@uni-goettingen.de

The divisions belonging to the Condensed Matter Section (SKM) of the DPG annually award the SKM Dissertation Prize. The prize acknowledges outstanding research during the PhD work in the research areas of SKM completed in 2021 or 2022, and its excellent oral presentation. Based on nominations, a jury consisting of the chairpersons of all SKM divisions has selected five finalists for the award to present their work in this symposium. The winner will be selected after the symposium and publicly announced Tuesday, March 28th in the afternoon during the ceremonial session.

Invited Talk SYSD 1.1 Mon 9:30 HSZ 04
Diffusion of antibodies in solution: from individual proteins to phase separation domains — •Anita Girelli — Universität Tübingen, Tübingen, Germany — Stockholm University, Stockholm, Sweden
We investigated the diffusion of a model system for liquid-liquid phase separation (LLPS), which is a biological mechanism for the formation of intracellular organelles. The solution of γ-globulin and PEG spontaneously separates and reaches a gel state due to the high concentration of the more concentrated of the two phases. The hierarchy of motions requires to probe the sample from nanometers to micrometers and time scales from picoseconds to hundreds of seconds. We achieved this by combining light, neutron, and X-ray scattering. At LLPS domains length scale, X-ray photon correlation spectroscopy (XPCS) reveals correlation functions which show typical characteristics of ballistic motion as seen for colloidal gels [1]. The experimental results are compared with simulated data based on the Cahn-Hilliard equation. Qualitative comparability is obtained by adding a strong dependence of the protein mobility on protein concentration. The validity of this assumption is confirmed by probing the diffusion on the protein length scale and below with neutron quasi-elastic scattering and XPCS [2,3]. The combination of Neutron Spin Echo and XPCS allows to access the diffusion at protein length scale over 10 orders of magnitude.

Invited Talk SYSD 1.2 Mon 10:00 HSZ 04
Intermediate Filament Mechanics Across Scales — •Anna V. Schepers — Rosalind Franklin Institute and University of Oxford, UK — Georg-August University Göttingen, DE
The mechanical properties of cells are largely determined by the cytoskeleton, an intricate and complex structure formed by protein filaments, motor proteins, and crosslinkers. The three main types of protein filaments are microtubules, actin filaments, and intermediate filaments (IFs). Whereas microtubules and actin filaments are exceptionally conserved, the family of IFs is diverse. The variety of IF proteins is potentially linked to the various mechanics of different cell types. We combined studies of IF mechanics on different time scales and in systems of increasing complexity, from single filaments to networks in cells. This multiscale approach allows us to interpret observations from simplified system while adding increasing physiological context in subsequent experiments. We focussed on the tunability of IF mechanics by environmental cues. In a series of experiments, including single filament stretching measurements and filament-filament interaction measurements with optical tweezers, microrheology, and cell stretching, we characterised how electrostatic and hydrophobic interactions provide mechanisms by which the IF cytoskeleton can be tuned. The studies revealed how small changes influence IF mechanics on multiple scales. In combination with simulations, we characterised how charge shifts alter single filament mechanics. Such insights provide a deeper understanding of the mechanisms by which cells can maintain their integrity and mechanically adapt to their environment.

Invited Talk SYSD 1.3 Mon 10:30 HSZ 04
Ultrafast Probing and Coherent Vibrational Control of a Surface Structural Phase Transition — •Jan Gerrit Horstmann — Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — Dept. of Materials, ETH Zürich, Zürich, Switzerland
The desire to exert active optical control over matter is a unifying theme across multiple scientific fields. In femtochemistry, multi-pulse optical excitation schemes exploit coherences in decisive electronic and vibrational degrees of freedom of molecules to influence the efficiencies of chemical reactions. The application of this concept to solid-state systems is, however, complicated by, e.g., the high electronic and vibrational density of states, or couplings to an external heat

bath. In this respect, low-dimensional and strongly correlated systems represent a promising intermediate between molecules and bulk solids, with phase transitions assuming the role of a 'reaction'.

In this talk, I report on the coherent vibrational control of a metal-insulator structural phase transition in a quasi-one-dimensional surface system, namely, atomic indium wires on the (111) surface of silicon. By analogy with repeatedly pushing a child on a swing, we use timed sequences of femtosecond light pulses to manipulate the amplitudes of key phonon modes connecting the insulating and metallic phases, thereby steering the system across the transition state. Our results confirm the applicability of coherent control tactics from femtochemistry to solids, creating not only strong conceptual links between the two fields, but also providing a new handle to switch the chemical and physical functionalities of materials on ultrafast time scales.

Invited Talk SYSD 1.4 Mon 11:00 HSZ 04
Electro-active metasurfaces employing metal-to-insulator phase transitions — •Julian Karst — 4th Physics Institute and Research Center SCoPE, University of Stuttgart, Germany
Functional and active plasmonic nanostructures and metasurfaces are at the heart of emerging and novel optical technologies as they allow to confine and actively manipulate light on very small length scales. Ultimately, they will contribute to the miniaturization of existing and novel optical devices necessary in a great variety of different fields. They include but are not limited to new display and projection technologies for augmented and virtual reality, dynamic 3D holography devices or miniaturized LiDAR (Light Detection and Ranging) approaches. I will introduce and give an in-depth analysis of our novel approaches for such functional and active plasmonic systems and metasurfaces, utilizing metal-to-insulator phase change materials. In particular, I will highlight nanoantennas and metasurfaces from metallic polymers which can be electrically switched in the infrared spectral range via CMOS-compatible voltages. This concept is based on an electrically driven metal-to-insulator phase transition and allows me to demonstrate, on the one hand, metasurfaces for ultra-high-contrast active beam switching. On the other hand, I realize an electro-active metaobjective comprising metalenses-on-demand. By using gel electrolytes, the presented metadevices can even be integrated into state-of-the-art on-chip electro-optic components.

Invited Talk SYSD 1.5 Mon 11:30 HSZ 04
The role of unconventional symmetries in the dynamics of many-body systems — •Pablo Sala — California Institute of Technology (Caltech), Pasadena, United States
Symmetries are essential to classify equilibrium phases of matter and to explain how thermal equilibrium is attained. In this talk, we explore the role that certain unconventional symmetries play in the dynamics of many-body systems.

To begin with, we show that the conservation of a charge and its associated dipole moment leads to a provable fragmentation of the Hilbert space into exponentially many disconnected sectors. In turn, this can translate into non-vanishing bulk correlators and the existence of localized among other unexpected phenomena. In general, we find that this conservation leads to novel universal hydrodynamic behavior, which can coexist with initial states that avoid thermalization, hence providing examples of weak ergodicity breaking.

We then show that dipole-conserving models become good approximations of strongly-tilted interacting systems. In fact, the high level of control of current experimental platforms makes these phenomena accessible to present-day experiments. We use our previous insights to analyze experimental results obtained via ultracold atoms, where the system is observed to remain localized at accessible times.

We conclude by revisiting the notion of symmetry from a broader perspective. In particular, we inquire about what spatially-modulated symmetries a system can have, providing a novel approach to realize some of them.

Symposium Green Magnets for Efficient Energy Conversion (SYGM)
jointly organised by

michael.farle@uni-due.de

Ever increasing demands for efficient, low cost energy conversion require the development of new materials, which can be used in e-mobility, power generation, robotics and refrigeration. The class of magnetic materials covers all of these technologies; in fact hard and soft magnets as well as caloric materials are often overlooked key enablers of a net-zero CO_2 emission scenario. In e-mobility, every battery needs a magnet, i.e. either the mass of the battery is reduced or the range is extended when highly efficient hard and soft magnets are employed in motor and generator. The complexity of magnetostructural phase transitions offers ample opportunities to design (magneto-)caloric and elastic properties for efficient, climate friendly future cooling technologies, smart actuators and soft magnetic robotics.

SYGM 1: Green Magnets for Efficient Energy Conversion

Time: Monday 15:00–17:45   Location: HSZ 01

Invited Talk   SYGM 1.1   Mon 15:00   HSZ 01
Data mining protocols for functional magnetic materials — •OLLE ERIKSSON — Uppsala University, Uppsala, Sweden
Theory of functional magnetic materials for use in permanent magnet applications or for magneto caloric cooling is described in this presentation. Using a high-throughput approach of calculations based on density functional theory together with a data-mining algorithm, several new rare-earth-free permanent magnets are reported. An interesting set of elements is found for materials containing 3d and p-elements, in particular Fe2C, Mn2MoB4, and Mn2WB4. For these systems doping protocols were also investigated and, in particular, (Fe0.75X0.25)2C (X = Mn, Cr, V, and Ti), Mn2XB4 (X = Mo and W) along with Mn2(X0.5Y0.5)B4 (X,Y = Mo, W, Ta, Cr) are suggested here as promising permanent magnets. Screening algorithms for magneto caloric materials are also discussed, and promising compounds will be presented.

Invited Talk   SYGM 1.2   Mon 15:30   HSZ 01
High performance permanent magnets; elements criticality, new demands, and extrinsic magnetic properties — •HOSSEIN SEPEHRI-AMIN, XIN TANG, TADAKATSU OHKUBO, and KAZUHIRO HONO — National Institute for Materials Science, Tsukuba, Japan
Permanent magnets are widely used in the green energy conversions and they play an important role toward realization of carbon neutrality. In order to maintain sustainable production of permanent magnets in a long term, efforts are required to eliminate the permanent magnets* reliance on critical elements such as Dy and to diverge rare-earth usage while maintaining sufficiently large coercivity and energy product in the magnets. we will first present our research efforts on development of high coercivity Dy-free Nd-Fe-B magnets for applications in traction motor of hybrid/electric vehicles and generator of wind turbines. We will demonstrate how grain boundary/interface engineering in the hot-deformed Nd-Fe-B magnets has led to a large coercivity of 2.5 T, remanent magnetization of 1.32 T and excellent thermal stability of coercivity. In the second part of the talk, the potential of Fe-rich SmFe12-based magnets and the current challenges to realize these materials as new permanent magnets will be discussed. we will show our recent success in realizing a sufficiently large coercivity of 1.0 T in rare-earth lean SmFe12-based anisotropic sintered magnets assisted by machine learning. Based on detailed microstructure characterizations, modeled thin films, and micromagnetic simulations, we will discuss the optimum microstructure which can lead to a larger coercivity and remanent magnetization in the SmFe12-based magnets.

Invited Talk   SYGM 1.3   Mon 16:00   HSZ 01
Magnetic shape memory Heuslers: microstructure-related effects on the martensitic transformation — •FRANCA ALBERTINI — Institute of Materials for Electronics and Magnetism (IMEM) - CNR, Parma, Italy
The vast family of magnetic shape memory Heuslers provides an extended playground of physical properties. The interplay between a martensitic transformation and magnetically ordered states gives rise to a series of functional properties that can be exploited in different technological sectors, among which solid state refrigeration, thermomagnetic generation, and robotics. Their excellent responsiveness to external fields, i.e. magnetic field, pressure and stress and their combined application, makes them promising for multifunctional exploitation. On the other hand, the hysteretic character of the martensitic transformation limits the performances of these materials in cyclic operations. In my talk I report some recent results on micro and nanoscale materials obtained by different fabrication methods, i.e. epitaxial thin films, micro/nanostructures obtained by

lithographic techniques, and mechanically-milled particles. Thin films and micro/nanostructures are of particular interest not only for the realisation of miniaturised devices, but also for providing insights into the magneto-structural coupling at the different length scales. The talk will focus on microstructure tuning and microstructure-related effects on the martensitic transformation, in view of the fully exploitation of this class of materials in caloric and smart applications.

15 min. break

Invited Talk   SYGM 1.4   Mon 16:45   HSZ 01
Thin film combinatorial studies of hard magnetic materials — •NORA DEMPSEY — Univ. Grenoble Alpes, CNRS, Grenoble INP, Institut NEEL, 38000 Grenoble, France
Combinatorial thin film studies are used for the screening and optimization of a range of functional materials. The basic idea is to produce compositionally graded films, to allow high throughput characterisation of materials properties as a function of composition, as well as other processing parameters such as deposition temperature and post-deposition annealing conditions. This approach holds much potential for the development of green magnets for efficient energy conversion. In particular, it can be used to study the effect of element substitution in Rare Earth - Transition Metal hard magnetic phases, so as to reduce dependence on critical rare earth elements.

In this talk I will present both recent [1] and on-going studies of compositionally graded hard magnetic materials produced by sputtering asymmetric targets or co-sputtering of multiple targets followed by annealing under different conditions. I will discuss the influence of composition and processing parameters on structural and magnetic properties, as probed using high throughput scanning mode characterisation tools (EDX, XRD and MOKE). I will finish up by presenting future prospects for such studies, in particular when combined with ab-initio calculations on the one hand and machine learning on the other.

Invited Talk   SYGM 1.5   Mon 17:15   HSZ 01
Magnetocaloric materials for energy-efficient thermal control systems — •VICTORINO FRANCO, AUN N. KHAN, JORGE REVUELTA-LOSADA, ÁLVARO DÍAZ-GARCÍA, LUIS M. MORENO-RAMÍREZ, and JIA YAN LAW — University of Seville, Spain
Energy efficient and environmentally friendly thermal management have a direct impact on the sustainability of our way of life, with magnetocaloric refrigeration being promising for achieving a greener cooling technology [1]. However, appliances are not yet on the consumer market due to relevant limitations of the active materials. In addition to applications point of view, the effect can be used to perform studies of phase transitions. Focusing on rare earth free materials, two new types of have a promising future: high entropy alloys and materials for additive manufacturing. We will present a novel fabrication procedure for obtaining homogeneous composite filaments for additive manufacturing and we will demonstrate that the magnetocaloric response of the fillers is not affected by the manufacturing procedure [2]. We will also highlight magnetocaloric high-entropy alloys, for which new compositions have allowed to close the gap between traditional HEA and high-performing magnetocaloric materials [3,4].

State-of-the-art experiments probe physical observables, such as heat, work or entropy production, empirical densities and currents, on the level of individual, stochastic paths. Such experiments are typically analysed by averaging along a limited number of individual realisations, which leads to substantial uncertainties in estimates. The systematic sample-to-sample fluctuations of such path-observables encode important information about the underlying, microscopic dynamical processes and are therefore a frontier of experimental, theoretical, and computational physics. Recently there has been a surge in the development and applications of path-based concepts across many fields of physics, which are surveyed in this symposium.

SYFP 1: Physics of Fluctuating Paths

Time: Tuesday 9:30–12:15   Location: HSZ 01

Invited Talk   SYFP 1.1   Tue 9:30   HSZ 01
Time at which a stochastic process achieves its maximum — •Satya Majumdar — Lptms, Universite paris-saclay, Bat 530, Rue Andre Riviere, Orsay 91405, france
For any stochastic time-series of duration T, the time t_{max} at which the process achieves its maximum is an important observable. For example, for a stock price over a trading period T, one would like to sell the stock at the time when the price is maximal. I'll discuss the statistics of t_{max} for a variety of stochastic processes. In particular, for several stationary processes, both in and out of equilibrium systems, we show that the distribution of t_{max} over $[0, T]$ exhibits a universal and interesting edge behavior (near 0 and T).

Invited Talk   SYFP 1.2   Tue 10:00   HSZ 01
Fluctuations and molecule-spanning dynamics of single Hsp90 proteins on timescales from nanoseconds to days — •Thorsten Hugel — Institute of Physical Chemistry, University of Freiburg, Germany — Signalling research centers BIOSS and CIBSS, University of Freiburg, Germany — Cluster of Excellence livMatS @ FIT, University of Freiburg, Germany
Protein dynamics have been investigated on a wide range of timescales. Nano- and picosecond dynamics have been assigned to local fluctuations, while slower dynamics have been attributed to larger conformational changes. However, it is largely unknown how local fluctuations can lead to global changes and on which timescales the proteins dynamics are ergodic and if they show ageing. These questions become even more challenging if ATP hydrolysis is involved.

Here we set out to understand the fluctuations and conformational dynamics in the molecular machine and heat shock protein Hsp90. Therefore, we measure the dynamics of single Hsp90s on timescales from nanoseconds to days with a combination of single-molecule fluorescence, Neutron scattering and Plasmon resonance supported by MD simulations.

I will show that molecule-spanning dynamics on the 100 ns timescale likely precede hierarchical allosteric processes on slower timescales. Then the very good statistic on the even slower conformational dynamics allows us to discuss directionality, ergodicity and ageing in this fascinating ATP fueled molecular machine.

Invited Talk   SYFP 1.3   Tue 10:30   HSZ 01
Path reweighting for Langevin dynamics — •Bettina Keller — Freie Universität Berlin, Berlin, Germany
Transition processes in molecular dynamics are investigated by simulating the molecular dynamics as underdamped Langevin dynamics on a high-dimensional energy surface. The accuracy of the rate estimates depends critically on the number of transitions observed in the simulated trajectories. However, the relevant molecular timescales are often beyond the reach of molecular simulations - even when the simulation is conducted on a supercomputer. Slow molecular processes include formation of molecular complexes, transitions through membranes, or phase transitions in crystalline materials. By biasing the potential energy one can sample transitions of rare events, but the rate estimates are distorted. Path reweighting techniques [1, 2] unbias the rate estimates by explicitly calculating the path probability density in the original and biased potential, and thus enable us to characterize slow molecular processes. While the path probability density for overdamped Langevin dynamics is well-documented, little information is available on the path probability densities for underdamped Langevin dynam-

ics [3]. This hampers the use of path reweighting in molecular simulations. I will focus on Langevin integrators constructed via the operator splitting technique, and derive their path probability density. An important intermediate result is the single-step transition probability which maps a point in state space to another point in state space. The image of this function determines whether the integrator can be used (efficiently) for path reweighting. I will demonstrate the results on model potentials and molecular examples.

Invited Talk   SYFP 1.4   Tue 11:15   HSZ 01
Out-of-equilibrium dynamics of trapped Brownian particles — •Raul A. Rica — Universidad de Granada, Granada (Spain)
Micro and nanoparticles can be individually manipulated by different trapping mechanisms, among which optical tweezers and Paul traps are the most extended approaches. Trapped particles are subject to Brownian motion due to collisions with the molecules of the dispersing medium. Once trapped, the particles can be driven out of equilibrium under the action of external fields, giving rise to very rich dynamics. In this talk, we will discuss some of our work with trapped nanoparticles dispersed in different media, including water, air, and vacuum. We will present recent experimental results demonstrating the occurrence of anomalous relaxation processes, time asymmetries, and bistability with trapped particles.

Invited Talk   SYFP 1.5   Tue 11:45   HSZ 01
Thermodynamics of Clocks — •Patrick Pietzonka — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany
The thermodynamic uncertainty relation (TUR) establishes a seemingly universal trade-off between cost and precision for classical non-equilibrium systems in a steady state. Applied to clocks subject to thermal noise, it states that the product of the energy used for the driving and the squared relative uncertainty of the displayed time is always greater than $2k_B T$. The TUR has been proven for models based on Markov jump dynamics or overdamped Brownian motion. It had also been conjectured to hold for underdamped Brownian dynamics, i.e., systems where inertia plays a role. This conjecture can now be disproven. I will present a counterexample that is inspired by a pendulum clock, consisting of an underdamped oscillator and a discrete counter, with thermal noise accounted for in both degrees of freedom. As it turns out analytically, this classic design principle of a clock allows one to overcome the bounds on precision set by the TUR . Beyond the minimal model, I also show numerically that the TUR can be broken in a fully continuous model with two underdamped degrees of freedom. Finally, I present a new bound valid for time-symmetric observables, which shows that for overdamped systems there is a minimal cost for producing a precise sequence of "ticks".

martin.eckstein@uni-hamburg.de

Ultrafast laser experiments provide avenues to utilizing ultrafast light-matter interaction to control macroscopic properties of quantum materials. While conventional photo-induced processes in condensed matter often rely on ultrafast laser heating, there are intriguing pathways towards emergent macroscopic properties in quantum materials that are inherently non-thermal in nature. The mechanisms behind such pathways include transient modifications of the free-energy landscape by population redistributions, the dynamical modification of coupling strengths, and coherent light-matter dressing via Floquet engineering. This symposium brings together leading researchers in the field to showcase experimental and theoretical progress and discuss new avenues.

Invited Talk   SYUE 1.1   Wed 9:30   HSZ 01
Dynamics and control in quantum materials using multi-terahertz spectroscopy — •Richard Averitt — UC San Diego, Department of Physics
Dynamics and control of quantum materials using light has emerged as a frontier research area. There are numerous possibilities to investigate including photoinduced metastability, creating non-equilibrium states with emergent properties, driving coherent many-body dynamics, or impulsively driving an order parameter to investigate the nonlinear *optical* response which can encode properties not evident with linear optical probes. In this vein, terahertz to mid-infrared spectroscopy is a particularly useful probe of low energy electrodynamics in quantum materials in both the static and dynamic limits. I will present examples from my research group. This includes: (i) Efficient coherent magnon generation in the Mott insulator Sr_2IrO_4 using sub-gap circularly polarized mid-IR pulses. (ii) Gentle photoexcitation of the putative excitonic insulator Ta_2NiSe_5 resulting in stimulated nonlinear parametric terahertz generation that serves as a reporter of the excitonic condensate and its coupling to phonons.

Invited Talk   SYUE 1.2   Wed 10:00   HSZ 01
Accessing the nonthermal phonon populations in 2D materials with femtosecond electron diffuse scattering — •Hélène Seiler[1,2], Marios Zacharias[1,3], Daniela Zahn[1], Patrick-Nigel Hildebrandt[1], Thomas Vasileiadis[1], Yoav William Windsor[1,4], Yingpeng Qi[1], Christian Carbogno[1], Claudia Draxl[5], Ralph Ernstorfer[1,4], and Fabio Caruso[6] — [1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — [2]Freie Universität Berlin, Berlin, Germany — [3]INSA de Rennes, 35708 Rennes, France — [4]Technische Universität Berlin, Berlin, Germany — [5]Humboldt-Universität zu Berlin, Berlin, Germany — [6]Christian-Albrechts-Universität zu Kiel, Kiel, Germany
Femtosecond electron diffuse scattering (FEDS) is a powerful technique to access nonthermal phonon populations in photo-excited materials. We perform FEDS experiments to study the microscopic energy flow in two prototypical 2D materials, black phosphorus and MoS2. The experiments are complemented by first-principles calculations of the coupled electron-phonon dynamics based on the time-dependent Boltzmann equations. We also introduce an efficient first-principles methodology for the calculation of the all-phonon inelastic scattering in solids, and demonstrate its broad applicability to other 2D materials. Our joint experimental-theoretical approach provides a detailed picture of nonthermal phonons in photo-excited materials.

Invited Talk   SYUE 1.3   Wed 10:30   HSZ 01
Exciting potentials – Exploring the realms of ultrafast phase transitions — •Laurenz Rettig — Fritz Haber Institute of the Max Planck Society, Berlin, Germany
Phase transitions, ubiquitous in nature, are characterized by breaking of characteristic material symmetries, which can be described by an order parameter. The phase of a material is then determined by the shape and the minima of the free energy surface. While in thermal equilibrium, a system occupies the phase space close to these minima, and phase transitions occur as function of thermodynamic state variables, ultrafast laser excitation allows modifying the energy surfaces on timescales faster than the response time of the system, thereby driving ultrafast phase transitions, and triggering coherent dynamics within the transient energy surfaces. This approach not only provides information about the microscopic couplings behind a phase transition, but also allows for coherent manipulation of material properties.

In my talk, I will discuss recent experiments employing time- and angle-resolved photoemission spectroscopy (trARPES), unearthing rich dynamics of photoinduced phase transitions in prototypical charge-density wave materials, including a transition into a hidden, metastable state.

15 min. break

Invited Talk   SYUE 1.4   Wed 11:15   HSZ 01
Sub-cycle multidimensional spectroscopy of strongly correlated materials — Viktor Valmispild[3], Evgeny Gorelov[3], Martin Eckstein[6], Alexander Lichtenstein[4,5], Hideo Aoki[7], Mikhail Katsnelson[8], Misha Ivanov[1,9], and •Olga Smirnova[1,2] — [1]Max-Born-Institut Berlin — [2]Technische Universitaet Berlin — [3]European XFEL, Germany — [4]Institute of Theoretical Physics, University of Hamburg — [5]The Hamburg Centre for Ultrafast Imaging — [6]Department of Physics, University of Erlangen-Nuremberg — [7]National Institute of Advanced Industrial Science and Technology (AIST), Japan — [8]Institute for Molecules and Materials, Radboud University, — [9]Department of Physics, Imperial College London
Strongly correlated solids are extremely complex and fascinating quantum systems, where new states continue to emerge and where interaction with light may trigger interplay between them. In this interplay, sub-laser cycle electron response is particularly attractive as a tool for ultrafast manipulation of matter at PHz scale.

We introduce a new type of non-linear multidimensional spectroscopy, which allows us to unravel the sub-cycle dynamics of strongly correlated systems interacting with few-cycle infrared pulses and the complex interplay between different correlated states evolving on the sub-femtosecond time-scale. We use laser-driven two-dimensional Hubbard model to resolve sub-cycle transitions between Mott-insulating and metallic states, and follow pathways of charge and energy flow leading to final non-equilibrium state stabilized by correlations after the end of the laser pulse.

Invited Talk   SYUE 1.5   Wed 11:45   HSZ 01
Witnessing many-body entanglement in light-driven quantum materials — •Matteo Mitrano[1], Denitsa Baykusheva[1], Mona Kalthoff[2], Damian Hofmann[2], Martin Claassen[3], Dante Kennes[2,4], and Michael Sentef[2] — [1]Department of Physics, Harvard University, Cambridge, Massachusetts 02138, USA — [2]Max Planck Institute for the Structure and Dynamics of Matter, Center for Free-Electron Laser Science (CFEL), Luruper Chaussee 149, 22761 Hamburg, Germany — [3]Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19104, USA — [4]Institut für Theorie der Statistischen Physik, RWTH Aachen University, 52056 Aachen, Germany and JARA-Fundamentals of Future Information Technology, 52056 Aachen, Germany
Many-body entanglement in condensed matter systems can be diagnosed from equilibrium response functions through the use of entanglement witnesses and operator-specific quantum bounds. Here, we investigate the applicability of this approach for detecting entangled states in quantum systems driven out of equilibrium. We use a multipartite entanglement witness, the quantum Fisher information, to study the dynamics of a paradigmatic fermion chain undergoing a time-dependent change of the Coulomb interaction. Our results show that the quantum Fisher information is able to witness distinct signatures of multipartite entanglement both near and far from equilibrium that are robust against decoherence. We discuss implications of these findings for probing entanglement in light-driven quantum materials with time-resolved optical and x-ray scattering methods.

Invited Talk   SYUE 1.6   Wed 12:15   HSZ 01
Optical responses of photoexcited materials: from parametric amplification to photoinduced superconductivity — •Eugene Demler — ETH, Zurich, Switzerland
Optical drives at terahertz and mid-infrared frequencies in quantum materials are commonly used to explore the nonlinear dynamics of interacting many-body systems. Recent experiments demonstrated several surprising optical properties of transient states induced by driving, including the appearance of photo-induced edges in the reflectivity, enhancement of reflectivity, and even light amplification. I will show that many of these unusual properties can be understood from the general perspective of reflectivity from Floquet materials, in which pump-induced oscillations of a collective mode lead to parametric generation of excitation pairs. This analysis predicts a universal phase diagram of drive induced features in reflectivity, which evidence a competition between driving and dissipation. I will argue that this mechanism explains several recent experimental observations, including photoinduced superconductivity in the pseudogap phase of high Tc cuprates.

Symposium Topology in Quantum and Classical Physics – From Topological Insulators to Active Matter (SYQC)

jointly organised by

antoine.venaille@ens-lyon.fr

The field of solid state physics, especially of material physics, has grown vigorously thanks to the discovery of topological protection and the universality of topological notions in many solid state systems. These ideas, rooted in the low temperature physics, have since expanded into other domains of physics, even into bio- and geophysics. The topological defects in bacterial colonies and tissues decide the life and death of cells; topological modes arise in active matter on curved surfaces; equatorial waves form at the boundary between two regions with opposite sign of the Coriolis force. It is fascinating that topological ideas flourish even in the chaotic environments of living matter and Earth systems. The aim of this symposium is to bring together the speakers and audience from the seemingly disparate fields of biological and low temperature physics, to explore together the mathematical connection between these two domains.

SYQC 1: Topology in Quantum and Classical Physics – From Topological Insulators to Active Matter

Time: Wednesday 15:00–17:45

Location: HSZ 01

Invited Talk SYQC 1.1 Wed 15:00 HSZ 01

Topological magnetic whirls for computing — •Karin Everschor-Sitte — Faculty of Physics and Center for Nanointegration Duisburg-Essen, University of Duisburg-Essen, 47057 Duisburg, Germany

Novel computational paradigms in combination with suitable hardware solutions are required to overcome the limitations of our state-of-the-art computer technology. In this talk, I focus on the potential of magnetic whirls – so-called skyrmions – for computing.

Skyrmions are topologically stable whirls that occur in various areas of physics and were discovered by Tony Skyrme in the 1960s in particle physics. Skyrmions occurring in magnetic systems were first observed experimentally in 2009. Within a decade, the field of magnetic skyrmions has become a very active area of research, with the aim of exploiting the topological properties of the magnetic whirl-like particles for spintronics applications. For example, the peculiar twist of the magnetization in skyrmions leads to a very efficient coupling to electric currents and allows for "banana kicks" analogous to those in soccer. More recently, magnetic skyrmions have become the focus of unconventional computing schemes such as reservoir computing.

Invited Talk SYQC 1.2 Wed 15:30 HSZ 01

Topological waves from solids to geo/astrophysical flows — •Pierre Delplace[1], Antoine Venaille[1], Nicolas Perez[1,2], Guillaume Laibe[2], Armand Leclerc[2], Manolis Perrot[1], and Brad Marston[3] — [1]CNRS, Laboratory of Physics, ENS de Lyon, France — [2]CRAL, ENS de Lyon France — [3]Brown University

Robust uni-directionnal edge modes are the hallmark of Chern insulators, a peculiar kind of topological insulators. Such topological states have been engineered in various platforms, from quantum solids to various classical analogs in photonics, acoustics and mechanics. Remarkably, such chiral modes also exist in continuous media encountered in nature. This is the case of oceanic and atmospheric equatorial waves that only propagate their energy eastward. This remarkable property, that triggers the El nino southern oscillations and impacts the climate over the globe, has a topological interpretation somehow similar to Chern insulators. Maybe more importantly, such topological tools actually also allow the prediction of previously unoticed waves in strongly stratified fluids that might be observable e.g. in stars.

Invited Talk SYQC 1.3 Wed 16:00 HSZ 01

Topological Phase Transitions in Population Dynamics — •Erwin Frey — LMU Muenchen, Theresienstrasse 37, 80333 Muenchen, Germany

In this talk, I discuss how topological phases determine the behavior of nonlinear dynamical systems that arise, for example, in population dynamics. We have shown that topological phases can be realized with the antisymmetric Lotka-Volterra equation (ALVE). It governs, for example, the evolutionary dynamics of zero-sum games, such as the rock-paper-scissors game [1]. It also describes the condensation of non-interacting bosons in driven-dissipative setups [2]. We have shown that robust polarization emerges at the chain's edge for the ALVE, defined on a one-dimensional chain of rock-paper-scissors cycles [3]. The system undergoes a transition from left to right polarization as the control parameter passes through a critical value. We found that the polarization states are topological phases and that this transition is indeed a topological phase transition. Remarkably, this phase transition falls into symmetry class D within the

"ten-fold way" classification scheme of gapped free-fermion systems. Beyond the observation of topological phases in the ALVE, it might be possible to generalize the approach of our work to other dynamical systems in biological physics whose attractors are nonlinear oscillators or limit cycles.

Invited Talk SYQC 1.4 Wed 16:45 HSZ 01

Topological invariants protect robust chiral currents in active matter — •Evelyn Tang — Rice University, Houston, USA

Living and active systems exhibit various emergent dynamics necessary for system regulation, growth, and motility. However, how robust dynamics arises from stochastic components remains unclear. Towards understanding this, I develop topological theories that support robust edge currents, effectively reducing the system dynamics to a lower-dimensional subspace. In particular, I will introduce stochastic networks in molecular configuration space that can model different systems from a circadian clock to the stochastic dynamics of cytoskeletal filaments. The edge localization results in new properties, e.g., the clock demonstrates increased precision with simultaneously decreased cost. These out-of-equilibrium systems further possess uniquely non-Hermitian features such as exceptional points and vorticity. More broadly, my work provides a blueprint for the design and control of novel and robust function in correlated and active systems.

Invited Talk SYQC 1.5 Wed 17:15 HSZ 01

Topological defects in biological active matter — •Amin Doostmohammadi — Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark

The spontaneous emergence of collective flows is a generic property of active fluids and often leads to chaotic flow patterns characterized by topological defects [1]. I will first discuss two examples of these collective features helping us understand biological processes: (i) to explain the tortoise & hare story in bacterial competition: how motility of Pseudomonas aeruginosa bacteria leads to a slower invasion of bacteria colonies, which are individually faster [2], and (ii) how self-propelled defects lead to finding an unanticipated mechanism for cell death [3,4]. I will then discuss various strategies to tame, otherwise chaotic, active flows, showing how hydrodynamic screening of active flows can act as a robust way of controlling and guiding active particles into dynamically ordered coherent structures. I will also explain how combining hydrodynamics with topological constraints can lead to further control of exotic morphologies of active shells [6].

Institut für Festkörperphysik
Appelstraße 2
30167 Hannover
haug@nano.uni-hannover.de

Time-resolved studies of quantum systems are the key to understanding quantum dynamics at its core. The real-time measurement of individual quantum jumps yields maximal physical insight. This includes electrical and optical detection schemes to monitor individual quantum jumps in nanoscopic devices. It is, furthermore, a prerequisite for coherent control of quantum states and can be used to optimise devices for metrological applications. The symposium is meant to report on recent experimental progress in performing real-time measurements of quantum dynamics, to present recently-developed theoretical methods for analyzing measured data, and to highlight recent successful examples of accessing quantum dynamics via real-time measurements.

SYQD 1: Real-Time Measurements of Quantum Dynamics

Time: Thursday 9:30–12:30   Location: HSZ 01

Invited Talk   SYQD 1.1   Thu 9:30   HSZ 01
Real-time measurement and control of spin dynamics in quantum dots —
•Seigo Tarucha — Center for Emergent Matter Science and Quantum Computing, RIKEN, Wako, Saitama 351-0198, Japan
The progress of quantum information technologies using semiconductor quantum dots has provided novel methods to control and detect quantum dynamics of single electron spins. The quantum information unit (qubit) is prepared using a concept of electron spin resonance and the qubit dynamics is dependent on dephasing or fluctuations of the resonance frequency through interactions with electromagnetic environment. In this talk I will first show experiments on real-time measurements of fluctuating frequencies of the respective spins and exchange-coupled two spins in a double quantum dot. The quantum dot is made in natural Si and also isotopically purified 28Si, which have different magnetic environments of nuclear spins. We use Ramsey interference sequence to derive the auto- and cross-power spectral density of the fluctuating resonance frequencies and address the influences from magnetic and charge noise in the respective quantum dots. We find an evident cross-correlation between two spins arising from the charge noise and devise a model of two-level fluctuators to account for the cross-correlation. Lastly I will show feedback control to suppress the influence on the spin dynamics from the environment.

Invited Talk   SYQD 1.2   Thu 10:00   HSZ 01
Quantum Dot arrays for Quantum Information Transfer — •Gloria Platero, David Fernandez-Fernandez, and Juan Zurita — Instituto de Ciencia de Materiales de Madrid (CSIC),Spain
The fabrication and control of semiconductor quantum dot arrays open the possibility to use these systems as quantum links, for transferring quantum information between distant sites, an indispensable part of large-scale quantum information processing. In this talk I will discuss different pulse-based protocols to transfer spin holes between edges of a quantum dot chain with high fidelity. I will show how the spin polarization of the transferred holes can be controlled by tuning the ratio between the SOC and the spin conserving tunneling rate [1]. Also, I will discuss how to transfer entangled hole spin qubits between edge dots. Our theoretical results suggest the feasibility of quantum dot arrays as high-fidelity quantum buses to distribute information between distant sites and perform one qubit gates in parallel.

An alternative way to transfer information between distant sites is mediated by protected topological edge states. I will discuss the long-range particle dynamics mediated by edge states in different quantum dot array configurations [2], which opens a new avenue for quantum state transfer protocols in low dimensional topological lattices.

Invited Talk   SYQD 1.3   Thu 10:30   HSZ 01
Optical Detection of Real-Time Quantum Dynamics in Quantum Dots —
•Martin Geller[1], Jens Kerski[1], Eric Kleinherbers[1], Jürgen König[1], Annika Kurzmann[2], Pia Lochner[1], Axel Lorke[1], Arne Ludwig[3], Hendrik Mannel[1], Philipp Stegmann[1], Andreas Wieck[3], and Marcel Zöllner[1] — [1]Faculty of Physics, University of Duisburg-Essen, 47057 Duisburg, Germany — [2]2nd Institute of Physics and JARA-FIT, RWTH Aachen University, 52074 Aachen, Germany — [3]Applied Solid State Physics, Ruhr-University, 44780 Bochum, Germany

Recording every single quantum event in a real-time measurement gives the maximum information of a dynamical quantum system. The obtained time traces can be used in a statistical evaluation to get a deep understanding about the underlying physical mechanisms. We use a self-assembled quantum dot coupled to a reservoir in combination with resonant optical excitation to study phenomena such as electron tunneling [1] and Auger recombination [2] with a time resolution down to single quantum events. The resulting telegraph signal is evaluated by full counting statistics to obtain deep insights into the spin and charge dynamics, where we use factorial cumulants as a very sensitive statistical tool to reduce the influence of statistical and systematic errors [3]. We show that factorial cumulants together with optical excitation push the limits in the detection and analysis of random telegraph data.

Invited Talk   SYQD 1.4   Thu 11:30   HSZ 01
Cooper Pair Splitting in Real-Time — •Christian Flindt — Department of Applied Physics, Aalto University, Finland
Cooper pair splitters are promising candidates for generating spin-entangled electrons. By splitting the Cooper pairs in a superconductor into different normal-state leads, spin-entanglement between spatially separated electrons can be achieved. In this talk, I will give an overview of our recent works on Cooper pair splitters [1-5]. I will discuss our proposal for observing and characterizing the splitting of Cooper pairs in real-time as well as its experimental realization [2,3]. I will then go on to talk about two proposals for controlling the splitting of Cooper pairs using time-dependent gate voltages [4]. Finally, if time allows, I will discuss how an entanglement witness can be formulated in terms of current cross-correlation measurements, which makes it possible to detect the entanglement of the split Cooper pairs [5].

Symposium Topological Superconductor-Magnet Heterostructures (SYTS)

jointly organised by
the Low Temperature Physics Division (TT),
the Magnetism Division (MA), and
the Metal and Material Physics Division (MM)

Ilya Eremin	Karin Everschor-Sitte	Wulf Wulfhekel
Ruhr-Universität Bochum	Universität Duisburg-Essen	KIT Karlsruhe
Theoretische Physik III	Fakultät für Physik	Physikalisches Institut
Universitätsstraße 150	Lotharstraße 1	Wolfgang-Gaede-Str. 1
44801 Bochum	47057 Duisburg	76131 Karlsruhe
Ilya.Eremin@rub.de	karin.everschor-sitte@uni-due.de	wulf.wulfhekel@kit.edu

Superconductivity and magnetism have been usually regarded, in a rather pessimistic sense, as antagonistic. Nevertheless, phenomena arising from the competition between them have captivated physicists for almost a century. Nowadays, we are at the verge of a paradigm shift where we can embrace the synergy between superconductivity and magnetism. In fact, owing to recent advances in sample fabrication together with guiding principles from topology, it is now possible to engineer novel superconductor-magnet hybrid systems. These are unique platforms for exotic topological states whose fascinating properties can be exploited, for example, for topological quantum computing. The goal of this symposium is to bring together the community of this burgeoning field to strengthen the communication line between theorists and experimentalists from various divisions, to collaboratively identify challenges and set the research agenda for the coming years.

SYTS 1: Topological Superconductor-Magnet Heterostructures

Time: Thursday 15:00–17:45 Location: HSZ 01

Invited Talk SYTS 1.1 Thu 15:00 HSZ 01
Blending of superconductivity and magnetism via topological solitons —
•CHRISTOS PANAGOPOULOS — Nanyang Technological University, Singapore
Topological solitons and quantum mechanics have been intertwined for the past
60 years. Even before the term soliton had been coined, Abrikosov theory predicted the formation of vortices in the phase field of superconductors, an exemplar exposition of macroscopic quantum coherence. Recent work shows that
solitons are in fact a timely and promising platform for quantum operations. I
will demonstrate the viability of using spin topology to influence a superconductor at selective length scales through a completely new material architecture
namely, a stack of magnets and a superconductor that shows stable vortices above
elongated chiral spin textures, as well as isolated skyrmions. This is an ideal geometry for fluxonics and chiral superconductivity, as well as quantum processes
such as non-perturbative, non-contact Majorana braiding.

Invited Talk SYTS 1.2 Thu 15:30 HSZ 01
Topological landscaping in magnet-superconductor heterostructures —
•SEBASTIÁN A. DÍAZ — University of Duisburg-Essen, Duisburg, Germany
Magnet-superconductor heterostructures, due to the rich interplay between their
adjacent order parameters, are fertile grounds for novel topological phenomena. Our theoretical studies demonstrate that topological defects in the magnetic order parameter lend themselves as versatile tools to landscape the superconducting order and its topological excitations. A chain of antiferromagnetic
skyrmions induces topological superconductivity and supports Majorana bound
states - the building blocks of topological quantum computing [1]. Ferromagnetic skyrmions coupled to superconducting vortices form a bound pair that can
be used to braid Majorana bound states [2]. These findings strongly suggest that
magnet-superconductor heterostructures are ideal arenas to further explore how
magnetism and superconductivity influence each other to engineer and manipulate their order parameters and topological excitations.

Invited Talk SYTS 1.3 Thu 16:00 HSZ 01
Experimental study of minigaps and end states in bottom-up designed multiorbital Shiba chains — •JENS WIEBE — Universität Hamburg, Department of
Physics, 20355 Hamburg, Germany
Chains of transition-metal atoms on s-wave superconductors evoke multiorbital
Shiba bands inside the gap of the substrate. If a spin-orbit coupled band overlaps
with the Fermi energy, a topologically nontrivial minigap may open up which can
potentially host Majorana bound states at the chain's ends. We study atom-by-atom fabricated chains with respect to such phenomena [1]. Most recent strategies in order to increase the width of topological minigaps [2,3] and experimental
methods to decide on the Majorana nature of close-to-zero-energy end states [4]
will be presented.

Quantum spins and hybridization in artificially-constructed chains of magnetic adatoms on superconducting 2H-NbSe$_2$ — •KATHARINA J. FRANKE —
Freie Universität Berlin, Berlin, Germany
Magnetic adatom chains on superconducting substrates are promising platforms
for topological superconductivity and Majorana zero modes. Signatures of these
have been found in densely packed chains with direct exchange interaction
among the adatoms. Theoretical predictions suggest chains, where the atoms are
sufficiently far spaced that direct hybridization of their d orbitals is negligible,
but close enough for substrate-mediated interactions, as an alternative platform.

We build such chains from individual Fe atoms on a 2H-NbSe$_2$ substrate using
the tip of a scanning tunneling microscope. In each step we track the evolution
of the Yu-Shiba-Rusinov (YSR) states. We find signatures of quantum-spin behavior and YSR band formation consistent with ferromagnetic coupling [1,2].

Invited Talk SYTS 1.5 Thu 17:15 HSZ 01
Braiding of Majorana zero modes — •STEPHAN RACHEL — School of Physics,
University of Melbourne, Australia
There has been tremendous experimental progress in recent years in establishing magnet-superconductor hybrid (MSH) systems as a promising platform for
Majorana physics.

In the first part of this talk, I will discuss MSH structures with Re or Nb as a superconducting substrate, and Fe or Mn as magnetic adatoms. In particular, I will
illustrate the theoretical challenges to simulate and understand the topological
superconductivity and their concomitant Majorana modes in such materials

In the second part of this talk, I will explain our first steps to investigate the
braiding of Majorana zero modes. In particular, I will focus on braiding errors
which can be introduced from sources such as quasiparticle poisoning and Majorana hybridization, and how these error rates behave in a full quasiparticle
background.

Symposium Physics of van der Waals 2D Heterostructures (SYHS)

jointly organised by
the Low Temperature Physics Division (TT),
the Semiconductor Physics Division (HL),
the Surface Science Division (O),
the Magnetism Division (MA), and
the Thin Films Division (DS)

Van der Waals heterostructures based on 2D layered materials provide an exciting platform to engineer and control electronic, transport, optical properties, spin, and magnetic properties. Many exciting phenomena have been reported in stacked materials coupled by weak van der Waals interactions. Perhaps most spectacular are strong correlations and superconductivity in graphene and transition-metal dichalcogenides multilayers. Also in the exciton physics, there is a trend towards investigating signatures of many-body effects. New directions of research include searches for novel topological states, investigations of spin and magnetic proximity effects, strain physics, or studying magnetic excitations. The aim of this symposium is to present an overview of some of the recent developments in this field by leading experts in this forefront area of condensed matter physics.

SYHS 1: Physics of van der Waals 2D Heterostructures

Time: Friday 9:30–12:15   Location: HSZ 01

Invited Talk   SYHS 1.1   Fri 9:30   HSZ 01
Novel moiré excitons and ultrafast optical dynamics in van der Waals 2D heterostructures — •STEVEN G. LOUIE — Physics Dept, University of California, Berkeley, and Lawrence Berkeley National Lab, Berkeley, CA, USA
Recent experiments have revealed signatures of novel exciton states and intriguing pump-probe optical responses in van der Waals 2D heterostructures. But their microscopic nature remains to be fully understood. We perform ab initio GW-Bethe Salpeter equation calculations and discover a rich diversity of excitonic states in these moiré systems. In rotationally aligned WSe_2/WS_2 heterobilayer, we find some excitons of a modulated Wannier character and others of a previously unidentified intralayer charge-transfer character. In 57.7° twisted bilayer WS_2, we discover layer-hybridized excitons with in-plane charge transfer character. Many of the theoretical predictions are confirmed by experiments. Ultrafast optical dynamics in 2D heterostructures is also of fundamental and practical interest. We discover a new many-body mechanism for ultrafast photoexcited dynamics in pump-probe measurement of the optical response of transition metal dichalcogenide heterobilayers. We show that coupling between the intralayer and interlayer excitons dominates the measured ultrafast dynamics, conceptually different from a previously believed picture of single-particle charge transfer between layers. These studies are made possible with the development of two new methods that allow for the ab initio calculations of the excitonic physics and optical response of systems with thousands of atoms in the unit cell and in the time domain.

Invited Talk   SYHS 1.2   Fri 10:00   HSZ 01
Interaction induced magnetism in 2D semiconductor moiré superlattices — •XIAODONG XU — Department of Physics, Department of Materials Science and Engineering, University of Washington, Seattle, USA
Many-body interactions between carriers lie at the heart of correlated physics. The ability to tune such interactions would open the possibility to access and control complex electronic phase diagrams on demand. Recently, moiré superlattices formed by two-dimensional materials have emerged as a promising platform for quantum engineering such phenomena. In this talk, I will present a systematic study of the emergent magnetic interactions (both antiferromagnetic and ferromagnetic) in strongly correlated transition metal dichalcogenides moiré superlattices. I will show that the combination of doping, electric field, and optical excitation provide dynamic controls of the moiré many-body Hamiltonian.

Invited Talk   SYHS 1.3   Fri 10:30   HSZ 01
Ions in tight places: intercalation and transport of ions in van der Waals heterostructures — •IRINA GRIGORIEVA — University of Manchester, UK
Understanding and control of ion transport through angstrom-scale channels and capillaries is important in diverse technological fields, from sieving and separation to Li ion batteries and energy storage. I will review our recent work on using few-layer graphene as a model system for understanding ion intercalation in layered crystals and on ion transport through designer nanochannels made by van der Waals assembly. It allowed us to answer such questions as what limits the Li ion storage capacity of bilayer graphene, whether protons can fit into the interlayer space in van der Waals crystals, and why protons can diffuse through monolayer water while no other ions can.

15 min. break

Invited Talk   SYHS 1.4   Fri 11:15   HSZ 01
Spin-orbit proximity in van der Waals heterostructures — •FELIX CASANOVA — CIC nanoGUNE, Donostia, Basque Country
Transition metal dichalcogenides (TMD) can be used to enhance the spin-orbit coupling of graphene, leading to new spin transport channels with unprecedented spin textures [1]. We have optimized bilayer graphene/WSe_2 van der Waals heterostructures to achieve magnetic-field-free spin precession. Remarkably, the sign of the precessing spin polarization can be tuned electrically by backgate voltage and drift current [2], being the first realization of a spin field-effect transistor at room temperature in a diffusive system, a long-awaited goal.

The spin-orbit proximity in graphene/TMD van der Waals heterostructures also leads to spin-to-charge conversion (SCC) of spins along z due to spin Hall effect (SHE), which was first observed by our group using MoS_2 as the TMD [3]. The combination of long-distance spin transport and SHE in the same material gives rise to an unprecedented figure of merit (product of spin Hall angle and spin diffusion length) of 40 nm in graphene proximitized with WSe_2, which is also gate tunable [4]. Finally, we demonstrate SCC of spins oriented in all three directions (x, y, and z) in graphene/$NbSe_2$ heterostructure, due to spin-orbit proximity and broken symmetry at the twisted graphene/$NbSe_2$ interface [5].

Invited Talk   SYHS 1.5   Fri 11:45   HSZ 01
Plethora of many-body ground states in magic angle twisted bilayer graphene — •DMITRI EFETOV — LMU Munich, Germany
Twist-angle engineering of 2D materials has led to the recent discoveries of novel many-body ground states in moiré systems such as correlated insulators, unconventional superconductivity, strange metals, orbital magnetism and topologically nontrivial phases. These systems are clean and tuneable, where all phases can coexist in a single device, which opens up enormous possibilities to address key questions about the nature of correlation induced superconductivity and topology, and allows to create entirely novel quantum phases with enhanced interactions. In this talk we will introduce some of the main concepts underlying these systems, concentrating on magic angle twisted bilayer graphene (MATBG) and show how symmetry-broken states emerge at all integer electron fillings [1]. We further will discuss recent experiments including screened interactions [2], Chern insulators [3], magnetic Josephson junctions [4], quantum criticality [5], re-entrant correlated insulators at high magnetic fields [6], Dirac spectroscopy of correlated states in magic angle trilayers and discuss some of the avenues for novel quantum sensing applications [8].

Overview of Invited Talks and Sessions
(Lecture halls BAR Schö, TOE 317, and BAR 0106; Poster P1 and P2/EG)

Invited Talks

BP 1.7	Mon	11:15–11:45	BAR Schö	**Cell-free expression of membrane proteins and control of their spatial organization in synthetic lipid membranes** — •Jan Steinkühler
BP 2.1	Mon	9:30–10:00	TOE 317	**Emergent properties in motile active matter** — •Roland G. Winkler
BP 3.5	Mon	10:30–11:00	BAR 0106	**Resolving gating and allosteric modulation in ion channels through simulations and small-angle neutron scattering** — •Erik Lindahl
BP 5.1	Mon	15:00–15:30	TOE 317	**Repurposing nucleic acids as high-resolution force sensors: From fundamental mechanotransduction to translational biophysics** — •Khalid Salaita
BP 6.5	Mon	16:15–16:45	BAR 0106	**Mechanical and electrical properties of bacterial biofilms modulate antibiotic tolerance** — •Berenike Maier
BP 8.5	Tue	10:45–11:15	BAR Schö	**Microtubule Lattice Dynamics** — Subham Biswas, Rahul Grover, Cordula Reuther, Mona Grünewald, Stefan Diez, •Laura Schaedel
BP 10.1	Tue	9:30–10:00	BAR 0106	**Protein evolution in sequence landscapes: from data to models and back** — •Martin Weigt
BP 12.4	Wed	10:15–10:45	TOE 317	**Materials properties of bacterial biofilms.** — •Cécile M. Bidan
BP 13.1	Wed	9:30–10:00	BAR 0106	**Biological signal processes across scales** — •Steffen Rulands
BP 16.1	Wed	11:15–11:45	BAR 0106	**Systems biophysics of bacterial response to cell wall-targeting antibiotics** — Rebecca Brouwers, Sharareh Tavaddod, Leonardo Mancini, Jacob Biboy, Elizabeth Tatham, Pietro Cicuta, Waldemar Vollmer, •Rosalind Allen
BP 21.7	Thu	11:15–11:45	BAR Schö	**Visualizing the inner life of microbes** — •Ulrike Endesfelder
BP 22.5	Thu	10:30–11:00	TOE 317	**Statistical Physics of Spatially Organized Catalytic Particles** — •Ulrich Gerland
BP 23.1	Thu	9:30–10:00	BAR 0106	**Conformational dynamics of SARS-CoV-2 spike protein modulates the binding affinity to ACE2** — Fidan Sumbul, Claire Valotteau, Prithwidip Saha, Ignacio Fernadez, Annalisa Meola, Eduard Baquero, Dorota Kostrz, James R Portman, François Stransky, Pablo Guardado Calvo, Charlie Gosse, Terence Strick, Felix Rey, •Felix Rico
BP 26.1	Thu	15:00–15:30	TOE 317	**Decoding Molecular Plasticity in the Dark Proteome of the Nuclear Transport Machinery** — •Edward Lemke
BP 30.1	Fri	9:30–10:00	TOE 317	**Experiments on Active Polymer-Like Worms** — •Antoine Deblais, Daniel Bonn, Sander Woutersen
BP 32.1	Fri	12:15–13:00	HSZ 03	**The physical regulation of brain development** — •Kristian Franze

Invited Talks of the joint Symposium Dynamics of Opinion Formation − From Quorum Sensing to Polarization (SYOF)
See SYOF for the full program of the symposium.

SYOF 1.1	Mon	9:30–10:00	HSZ 01	**Towards understanding of the social hysteresis – insights from statistical physics** — •Katarzyna Sznajd-Weron
SYOF 1.2	Mon	10:00–10:30	HSZ 01	**Polarization in attitude distributions from surveys and models of continuous opinion dynamics** — •Jan Lorenz, Martin Gestefeld

SYOF 1.3	Mon	10:30–11:00	HSZ 01	**Collective patterns and stable misunderstandings in networks striving for consensus without a common value system** — •Johannes Falk, Edwin Eichler, Katja Windt, Marc-Thorsten Hütt
SYOF 1.4	Mon	11:15–11:45	HSZ 01	**A yet undetected cognitive bias, revealed by opinion dynamics simulations** — •Guillaume Deffuant
SYOF 1.5	Mon	11:45–12:15	HSZ 01	**Extreme switches in kinetic exchange models of opinion.** — •Parongama Sen, Kathakali Biswas

Invited Talks of the joint Symposium SKM Dissertation Prize 2023 (SYSD)

See SYSD for the full program of the symposium.

SYSD 1.1	Mon	9:30–10:00	HSZ 04	**Diffusion of antibodies in solution: from individual proteins to phase separation domains** — •Anita Girelli
SYSD 1.2	Mon	10:00–10:30	HSZ 04	**Intermediate Filament Mechanics Across Scales** — •Anna V. Schepers
SYSD 1.3	Mon	10:30–11:00	HSZ 04	**Ultrafast Probing and Coherent Vibrational Control of a Surface Structural Phase Transition** — •Jan Gerrit Horstmann
SYSD 1.4	Mon	11:00–11:30	HSZ 04	**Electro-active metasurfaces employing metal-to-insulator phase transitions** — •Julian Karst
SYSD 1.5	Mon	11:30–12:00	HSZ 04	**The role of unconventional symmetries in the dynamics of many-body systems** — •Pablo Sala

Invited Talks of the joint Symposium Physics of Fluctuating Paths (SYFP)

See SYFP for the full program of the symposium.

SYFP 1.1	Tue	9:30–10:00	HSZ 01	**Time at which a stochastic process achieves its maximum** — •Satya Majumdar
SYFP 1.2	Tue	10:00–10:30	HSZ 01	**Fluctuations and molecule-spanning dynamics of single Hsp90 proteins on timescales from nanoseconds to days** — •Thorsten Hugel
SYFP 1.3	Tue	10:30–11:00	HSZ 01	**Path reweighting for Langevin dynamics** — •Bettina Keller
SYFP 1.4	Tue	11:15–11:45	HSZ 01	**Out-of-equilibrium dynamics of trapped Brownian particles** — •Raul A. Rica
SYFP 1.5	Tue	11:45–12:15	HSZ 01	**Thermodynamics of Clocks** — •Patrick Pietzonka

Invited Talks of the joint Symposium Topology in Quantum and Classical Physics – From Topological Insulators to Active Matter (SYQC)

See SYQC for the full program of the symposium.

SYQC 1.1	Wed	15:00–15:30	HSZ 01	**Topological magnetic whirls for computing** — •Karin Everschor-Sitte
SYQC 1.2	Wed	15:30–16:00	HSZ 01	**Topological waves from solids to geo/astrophysical flows** — •Pierre Delplace, Antoine Venaille, Nicolas Perez, Guillaume Laibe, Armand Leclerc, Manolis Perrot, Brad Marston
SYQC 1.3	Wed	16:00–16:30	HSZ 01	**Topological Phase Transitions in Population Dynamics** — •Erwin Frey
SYQC 1.4	Wed	16:45–17:15	HSZ 01	**Topological invariants protect robust chiral currents in active matter** — •Evelyn Tang
SYQC 1.5	Wed	17:15–17:45	HSZ 01	**Topological defects in biological active matter** — •Amin Doostmohammadi

BP 1.1   Mon 9:30   BAR Schö

Bottom-up assembly of a synthetic glycocalyx on lipid vesicles — •Kevin Jahnke and David A. Weitz — Harvard University, Cambridge, MA, USA

The glycocalyx serves as physicochemical barrier that increases cellular rigidity and as interface for chemical cues to guide cell-cell communication. However, while preliminary results highlight the importance of the glycocalyx, the biophysical functioning remained elusive and mostly untested due to the complexity within natural cells. Recent advances in the membrane functionalization of giant unilamellar vesicles (GUVs) with macromolecules like DNA and proteins (Jahnke et al., ACS Nano 2022; Jahnke et al. Nat. Commun. 2021) pave the way for a systematic investigation of glycocalyx properties within a fully-controlled environment. Here, we engineer biomimetic glycocalyces to understand their effect on the biophysical properties of GUVs. The synthetic glycocalyx consists of polysaccharides functionalized with cholesterol that self-assemble in the lipid membrane. We employ fluorescence recovery after photobleaching and micropipette aspiration to assess the changes in diffusion and membrane rigidity of glycocalyx-decorated GUVs. The control over the type of polysaccharide, its molecular weight and density on the vesicle enable us to design and study a variety of synthetic glycocalyces. Additionally, we compare them to other common vesicle functionalizations like polyethyleneglycol and explore their potential for carbohydrate-specific adhesion. This work underpins bottom-up glycocalyx engineering as important tool for cellular biophysics and biotechnological applications.

BP 1.2   Mon 9:45   BAR Schö

Surface-induced phase separation of reconstituted nascent integrin clusters — •Chiao-Peng Hsu[1], Jonas Aretz[2], Reinhard Fässler[2], and Andreas Bausch[1] — [1]Center for Functional Protein Assemblies and Lehrstuhl für Zellbiophysik (E27), Physics Department, Technische Universität München, Garching, Germany — [2]Max Planck Institute of Biochemistry, Martinsried, Germany

Integrin adhesion complexes are essential membrane-associated cellular compartments for multi-cellular life. While biomolecular condensates organize specific functions in cells, cell membranes can regulate the positions and dynamics of many biomolecular condensates. Yet, the role played by membrane surfaces in the formation of initial integrin adhesion complexes still needs to be fully understood. Here, we report that phosphoinositides containing lipid membranes induce minimal integrin adhesion condensates composed of integrin β tails, kindlin, talin, paxillin, and FAK at physiological ionic strengths and protein concentrations. We show that the presence of phosphoinositides is key to enriching kindlin and talin on the membrane, forming first nascent integrin complexes, which in turn are necessary to further nucleate condensates. These results demonstrate that the biophysical properties of lipid membranes are key for inducing specific membrane-associated condensates throughout the cell.

BP 1.3   Mon 10:00   BAR Schö

Small-Angle and Inelastic Neutron Scattering from Polydisperse Oligolamellar Vesicles Containing Glycolipids — •Lukas Bange[1], Ingo Hoffmann[2], and Emanuel Schneck[1] — [1]Institute for Condensed Matter Physics, Technical University Darmstadt, Germany — [2]nstitut Laue-Langevin, Grenoble, France

Glycolipids are known to stabilize biomembrane multilayers through preferential sugar-sugar interactions that act as weak transient membrane crosslinkers [1, 2]. We use small-angle and inelastic neutron scattering on oligolamellar phospholipid vesicles containing defined glycolipid fractions in order to elucidate the influence of glycolipids on membrane mechanics and dynamics. Small-angle neutron scattering (SANS) reveals that the oligolamellar vesicles (OLVs) obtained by extrusion are polydisperse with regard to the number of lamellae, n, which renders the interpretation of the inelastic neutron spin echo (NSE) data [3] non-trivial. To overcome this problem, we propose a method to model the NSE data in a rigorous fashion based on the obtained histograms of n and on their q-dependent intensity-weighted contribution. This procedure yields meaningful values for the bending rigidity of individual lipid membranes and insights into the mechanical coupling between adjacent membrane lamellae, including the effect of the glycolipids.

Controlling phase separations and reaction kinetics in microfluidically trapped droplets — •Sebastian W. Krauss, Paula Girones Paya, and Matthias Weiss — Experimental Physics I, University of Bayreuth, Germany

Droplet-based microfluidics is an efficient and versatile tool to study biomimetic reactions and self-organization in selected geometries and small volumes. It is also frequently used to perform high-throughput experiments, e.g. as selection platforms for directed evolution or for personalised medicine. While elaborate techniques are available for the production of picoliter-sized droplets, there is an increasing demand for subsequent manipulation and control of the droplet interior after production. Here we report on a straightforward method to rapidly and reversibly adjust the size of single to several hundred double-emulsion droplets in a microfluidic sieve by varying the osmotic pressure, leading to a change in concentration of enclosed molecules. We show that this approach allows for driving reversible demixing transitions of a biomimetic binary fluid which can be used to control the kinetics of enclosed enzymatic reactions. We also show that changing droplet sizes can be exploited for a reversible denaturing of double-stranded DNA, which may eventually allow for an osmotically driven PCR in small droplets.

BP 1.5   Mon 10:30   BAR Schö

Predicting membrane turnover during cytokinesis — •Felix Frey[1] and Timon Idema[2] — [1]Institute of Science and Technology Austria, Klosterneuburg, Austria — [2]Department of Bionanoscience, Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands

When animal cells divide, they split into two equal parts. Since the volume of the cell is typically conserved during cell division, the projected area of the cell membrane has to increase to allow for the change of shape. The membrane area is controlled by exocytosis, resulting in an increase in membrane area and its counterpart endocytosis, resulting in a decrease in membrane area. However, it is unclear how exo- and endocytosis need to adapt to enable successful division. To address this question, we developed a kinetic model in which membrane gain and loss depend on membrane curvature and tension [1]. We apply this model to a series of calculated vesicle shapes, which we take as a proxy for the shape of dividing cells. We find that the ratio of membrane gain and loss changes non-monotonically during cytokinesis due to the complex interplay between membrane area and shape. Our results suggest that controlling membrane turnover is critical for the successful division of both biological and artificial cells. [1] Felix Frey and Timon Idema, Phys. Rev. E 106, 024401 (2022).

Antimicrobial peptides: Revealing the Penetration Mechanism of Melittin in the Outer Membrane of Gram-Negative Bacteria — •Justus C. Stephani[1], Luca Gerhards[1], Ilia A. Solov'yov[1], and Izabella Brand[2] — [1]Dept. of Physics, Carl von Ossietzky Universität, Germany — [2]Dept. of Chemistry, Carl von Ossietzky Universität Oldenburg, Germany

Studying the interaction between antimicrobial peptides (AMPs) and bacterial membranes might aid to find new treatments against bacterial pathogens and even drug-resistant bacteria. The AMP melittin can target the complex structure of a cell membrane leading to membrane permeabilization via hole formation or disruption. We report on the results of electrochemical experiments, aided by modern, all-atom molecular dynamics simulations that reveal the role of lipopolysaccharides (LPS) in the outer membrane of gram-negative bacteria in melittin binding and penetration. We demonstrate that certain amino acid residues play a key role in the binding of melittin to the membrane and thereby stabilizing and preserving the confirmation of the peptide. With a combined method of polarization modulation infrared reflection-absorption spectroscopy (PM IRRAS) and the statistical analysis of C=O bond orientation in the peptide, we determine the orientation of melittin on the membrane and observed penetration of the N-Terminus of the peptide into the membrane and a formation of hydrogen bonds between the N-Terminus and carboxylate and phosphate of the LPS.

Cell-free expression of membrane proteins and control of their spatial organization in synthetic lipid membranes — •Jan Steinkühler — Northwestern University, Evanston, USA — Georg-August-Universität Göttingen, Germany

Cell-free expression (CFE) is a powerful tool for synthesizing proteins outside of living cells, including membrane proteins. In this talk, we will discuss the factors that affect the yield of synthesized membrane proteins in CFE systems, including ribosome stalling and the balance between peptide-membrane association and peptide aggregation rates. We will also present a quantitative kinetic model that can be used to rationalize the engineering of protein N-terminal domain sequences and membrane composition for improved membrane protein synthesis. In addition to covering the synthesis of natural membrane proteins, we will show how CFE of de novo membrane protein designs can be used to study the role of membrane-protein hydrophobic mismatch in protein integration and organization in synthetic lipid membranes. [DOI:10.1101/2022.06.01.494374]. Our findings provide insight into protein organization in biological membranes and a framework for building up of synthetic cell membranes with new functions.

Entry of Microparticles into Giant Lipid Vesicles Induced by Optical Force — •Fessler Florent, Sharma Vaibhav, Muller Pierre, Thalmann Fabrice, Marques Carlos, and Stocco Antonio — Institut Charles Sadron, Strasbourg, France
Interactions between micro- or nano-sized objects and lipid membranes are crucial in many processes such as entry of viruses in host cells, microplastics pollution, drug delivery or biomedical imaging. Here, we investigated the physical principles of particle crossing of lipid membranes using microparticles and giant unilamellar vesicles (GUVs) in the absence of strong irreversible binding and for low membrane tensions. In these conditions, we observed that organic as well as inorganic particles can always penetrate inside GUVs provided that an external picoNewton force is applied. In the limit of a vanishing particle-membrane affinity, we pointed out the role of membrane area reservoirs and showed that a force barrier minimum exists when the particle size is comparable to the bendo-capillary length.

BP 1.9   Mon 12:00   BAR Schö
Simulating transient pores in hemifused membranes — •Russell Spencer and Marcus Müller — Georg-August Universität Göttingen, Institute for Theoretical Physics, 37077 Göttingen, Germany
Transportation of material from one side of a hemifused membrane to another can be facilitated through the formation of transient pores, which open, allow the material to pass and then close. One important example of this occurs in the 'kiss and run' (KAR) mechanism for transporting material from inside a vesicle in a cell to outside of the cell. The vesicle first fuses with the membrane, forming a hemifusion diaphragm (HD). A pore then opens in the HD allowing the material out, then the pore closes and the vesicle detaches. This process occurs in the release of neurotransmitters from a synapse into the post-synaptic cleft. This work uses self-consistent field theory and the string method to calculate the minimum free energy path for membrane fusion and the opening and closing of the transient pore. We also study the effects of proteins, which facilitate the process by altering the thermodynamics of pore formation.

Lipid movement in monolayers at the air/water interface: hydrodynamic coupling to the subphase — Florian Gellert, Heiko Ahrens, and •Christiane A. Helm — Institute of Physics, University of Greifswald, Germany
Domain nucleation and growth in the liquid expanded/liquid condensed

(LE/LC) phase transition in erucic acid monolayers at the air/water interface is studied. Dendritic domains are observed at high compression speeds and seaweed domains at low compression speeds. The different domain types are distinguished by fractal dimension, tip width, and the spacing of the side arms. A local, normalized supersaturation describes the hydrodynamic coupling of lipids in the LE phase moving towards the domain border to subphase movement. The coupling differs for the growth regimes. Additionally, the shape and symmetry of the domains are affected by barrier movement. The downstream side of the domains grows faster than the upstream side, as shown by directionality diagrams and FFTs. We suggest that the flow direction disturbs the diffusion direction of the lipids within the LE phase but not the coupling to the subphase.

BP 1.11   Mon 12:30   BAR Schö
X-ray studies of bidirectional switching in phospholipid membranes containing photoswitchable glycolipids — •Svenja C. Hövelmann[1,2,3], Jonas E. Warias[1], Rajendra P. Giri[1], Jule Kuhn[1], Karin Hansen[1], Lukas Petersdorf[1], Nicolas Hayen[1], Philipp Jordt[1], Andrea Sartori[1], Chen Shen[3], Franziska Reise[4], Olaf M. Magnussen[1], Thisbe K. Lindhorst[4], and Bridget M. Murphy[1,3] — [1]Institute of Experimental and Applied Physics, Kiel, Germany — [2]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [3]Ruprecht Haensel Laboratory, Kiel, Germany — [4]Otto Diels Institute of Organic Chemistry, Kiel, Germany
Lipid molecules not only play an essential role in the structure and geometry in biomembranes but also in the functionality and self-assembly of membrane proteins and channels. Their dynamic is under intense investigation owing to their applications in biosensor engineering and drug delivery. To understand the interaction between lipid and functional molecules, we investigate photoswitchable glycoconjugates embedded in a 1,2-dipalmitoyl-phosphatidylcholine (DPPC) model systems in the form of Langmuir films and vesicles. The glycoconjugates change reversibly between their trans- and cis-conformation by illumination with visible and UV light inducing a reversible change in the surrounding molecular arrangement. These structural changes, their evolution and time scales are characterised with multiple measurement techniques including X-ray scattering. Studies performed on mixed monolayers and vesicles with varying glycoconjugates identify bidirectional switching in the in DPPC monolayers.

BP 1.12   Mon 12:45   BAR Schö
Structure/Friction relationship in solid supported phospholipid layers — •Swen Helstroffer, Pierre Muller, and Thierry Charitat — Institute Charles Sadron, Strasbourg, France
Stacks of phospholipid bilayers adsorbed on biological rubbing surfaces lubricate remarkably well under severe conditions. However, the energy dissipation pathway allowing ultra low friction is still unknown. To elucidate the mechanism, we propose here to study an experimental model consisting of hydrated phospholipid layers deposited at the air/solid interface. Our system presents a well-controlled geometry in which we can fine-tune the hydration level of the lipid heads. By combining neutron reflectometry and ellipsometry studies with macroscopic tribology experiments, we demonstrated a negative correlation between hydration and friction coefficient. Using the Eyring model, we obtained microscopic activation volumes characteristic of slip. Our results suggest that the hydration level is a key parameter for lubrication. We believe that the sliding plane is located in the confined water layers.

BP 2: Active Matter I (joint session BP/CPP/DY)

Time: Monday 9:30–13:00   Location: TOE 317

Invited Talk   BP 2.1   Mon 9:30   TOE 317
Emergent properties in motile active matter — •Roland G. Winkler — Theoretical Physics of Living Matter (IBI-5/IAS-2), Forschungszentrum Jülich, Jülich
Motile active matter systems, ranging from assemblies of bacteria, self-organized bio-polymers such as the cytoskeleton of living cells, to schools of fish and flocks of birds, exhibit intriguing emerging structural and dynamical out-of-equilibrium properties, even with reminiscence to classical turbulence. Their spatiotemporal dynamics is controlled by the propulsion of the active agents in combination with various direct interactions. The latter are typically anisotropic and emerge from different sources, such as elongated agent shapes, intrinsic flexibility and constraints, microswimmer flow fields etc. By analytical theory and mesoscale simulations, we study the physical aspects of motile active matter, ranging from propulsion of bacteria and linear filaments to large-scale collective properties of active agents, and unravel its generic features. Studies on individual polymers reveal fundamental differences in their dynamical and conformational properties depending on their propulsion mechanism, which is illustrated for polymers either tangentially driven or composed of active Brownian particles. In the latter case, hydrodynamic interactions additionally affect the conformational properties, in contrasts to passive polymers. Moreover, hydrodynamic

interactions determine the activity-induced phase behavior. For spherical microswimmers (squirmers), hydrodynamics suppresses motility-induced phase separation, but enhances collective turbulent-like large-scale flows.

BP 2.2   Mon 10:00   TOE 317
High-resolution mapping of odd fluctuations and oscillations in living chiral crystals — •Jinghui Liu[1,2], Lisa Lin[1], Yuchao Chen[1], Yu-Chen Chao[1], and Nikta Fakhri[1] — [1]Department of Physics, Massachusetts Institute of Technology — [2]Center for Systems Biology Dresden
It has been shown that active crystals formed by self-assembling clusters of swimming starfish embryos exhibit signatures of odd mechanics, such as self-sustained chiral waves. How are these observed chiral waves and oscillations are actuated and how their dynamics couple to the formation and dissolution of the living/chiral crystal? Here, we report the use of vibrational mode decomposition to dissect various non-equilibrium phases of the crystal dynamics. By analyzing embryo cluster trajectories over the time course of crystal formation and dissolution, we identify the spatial modes responsible for the collective actuation of an oscillatory active crystal both in spontaneous and mechanically excited conditions. We also report a direct extraction of dispersion relation from fluctuations

of confined crystals to infer odd elastic moduli. Taken together, our results unveil the complex spatiotemporal origin of mechanical waves in non-reciprocal materials and provide insight on the design principles of collective phases of active metamaterials.

BP 2.3   Mon 10:15   TOE 317

Self-organized chemotaxis of coupled cell populations — •Mehmet Can Ucar and Edouard Hannezo — Institute of Science and Technology Austria, Am Campus 1, 3400 Klosterneuburg, Austria

Many processes in development and disease such as tissue morphogenesis, cancer invasion and immune response rely on collective directional movement of cells. In a wide array of systems this collective motility is driven locally by self-generated chemokine or stiffness gradients, as opposed to pre-patterned, global guidance cues. While recent studies have explored migration mechanisms of a single species of cells, the role of self-generated gradients navigating multiple cell types remains largely untested. Here we address this issue by introducing a theoretical framework for self-organized guidance of chemotactically coupled cell populations. Combining analytical theory and simulations with experiments on immune cell populations, we discover a diverse spectrum of collective migration patterns controlled by single-cell properties. We find that differential chemotactic sensitivity leads to efficient colocalization of distinct cell types, and show that this coupling also depends on the geometry and initial configuration of the dynamical system. We finally outline conditions for robust, sustained multicellular interactions relevant for physiological settings such as during immune response.

BP 2.4   Mon 10:30   TOE 317

Geometry-induced patterns in collective cell migration — •David Brückner — Institute of Science and Technology, Am Campus 1, 3400 Klosterneuburg, Austria

The coordinated migration of cell collectives is increasingly well understood at the level of large two-dimensional confluent monolayers. However, many physiological migration processes rely on small polarized cell clusters and their responses to external confining geometries, such as 2D channels and 3D curved environments. How active motion and cell-cell interactions interplay with such external boundaries remains poorly understood. I will discuss how external geometries can induce patterns in collective cell migration, using two examples. First, we show that the migration efficiency of 2D confined cell clusters is determined by the contact geometry of cell-cell contacts that are either parallel or perpendicular to the direction of migration. Our minimal active matter model reveals how cell-cell interactions determine a geometry-dependent supracellular stress field that controls this response to external boundaries. Secondly, we show how the interplay of curvature and active flocking dynamics of 3D cell spheroids induces a collective mode of cell migration manifesting as a propagating velocity wave. Together, these approaches provide a conceptual framework to understand how cell-cell interactions interplay with 2D and 3D geometries to determine the emergent dynamics of collective cell migration.

BP 2.5   Mon 10:45   TOE 317

Shape primed AC-electrophoretic microrobots — •Florian Katzmeier and Friedrich C. Simmel — Technical University of Munich, Munich, Germany

Second-order electrokinetic flow around colloidal particles caused by concentration polarization electro-osmosis can be utilized to controllably move asymmetric particle dimers in AC electrical fields. To demonstrate this actuation mechanism, we created particle dimers from micron-sized silica spheres with sizes 1.01 μm and 2.12 μm by connecting them with DNA linker molecules. The dimers can be steered along arbitrarily chosen paths within a 2D plane by controlling the direction of the AC electric field in a fluidic chamber with the joystick of a gamepad. Further utilizing induced dipole-dipole interactions, we demonstrate that particle dimers can be used to controllably pick up monomeric particles and release them at any desired position, and also to assemble several particles into groups. Systematic experiments exploring the dependence of the movement direction and velocity on buffer composition, frequency, and field strength further elucidate the underlying physical mechanism, and provide operational parameter ranges for our micro robotic swimmers which we termed 'SPACE-bots'.

BP 2.6   Mon 11:15   TOE 317

Rodrolls: self-rolling rods powered by light and chemical gradients — •Ann Rosna George[1], Martin Wittmann[2], Antonio Stocco[1], Igor M. Kulić[1], and Juliane Simmchen[2] — [1]CNRS, Institute Charles Sadron, Strasbourg, France — [2]Physical chemistry, TU Dresden, Germany

The self-rolling motion upon spontaneous symmetry breaking is demonstrated by certain rod-shaped microorganisms like viruses. Hence it is imperative that we understand the mechanism of this symmetry breaking triggering the active rolling motion. This behaviour has also been demonstrated on the macroscopic scale by rod-like objects. It is very interesting to try and replicate this on a microscopic scale. The main aim of the project is to create a new class of active rods that exhibit rolling activity under chemical and optical gradients. To achieve this,

it is important to understand the mechanism of activity of rod-like objects under chemical and optical stimuli.

Experiments conducted using silica Janus rods with a Platinum layer in an aqueous solution of H2O2 give interesting results and exhibit different kinds of activity when parameters like concentration of H2O2 and aspect ratio of rods are changed. Under specific conditions, particles are capable of switching their direction of motion. Experiments done using rods covered in gold nanoparticles under an optical gradient also reveal promising results of being able to make the rods roll upon providing sufficient energy to break the symmetry and fine-tuning certain parameters.

BP 2.7   Mon 11:30   TOE 317

Active Nematic Multipoles: Flow Responses and the Dynamics of Defects and Colloids — •Alexander J. H. Houston[1,2] and Gareth P. Alexander[1,3] — [1]Department of Physics, Gibbet Hill Road, University of Warwick, Coventry, CV4 7AL, United Kingdom — [2]Department of Physics, University of York, Heslington, York YO10 5DD, United Kingdom — [3]Centre for Complexity Science, Zeeman Building, University of Warwick, Coventry, CV4 7AL, United Kingdom

Two fundamental questions in active nematics are how to extract useful work from their non-equilibrium dynamics and how to extend the topological defect-based description of dynamics that has proved useful in two dimensions to three dimensions, in which the defects form geometrically-complex loops. We introduce a general description of localised distortions in active nematics using the framework of 'active nematic multipoles'. We give the Stokesian flows for arbitrary multipoles in terms of differentiation of a fundamental flow response and describe them explicitly up to quadrupole order. This allows the identification of the dipolar and quadrupolar distortions that generate self-propulsion and self-rotation respectively and serves as a guide for the design of arbitrary flow responses. Our results can be applied to both defect loops in three-dimensional active nematics and to systems with colloidal inclusions. They reveal the geometry-dependence of the self-dynamics of defect loops and provide insights into how colloids might be designed to achieve propulsive or rotational dynamics, and more generally for the extraction of work from active nematics.

BP 2.8   Mon 11:45   TOE 317

Structure and Dynamics of Active Polymer — •Sunil Pratap Singh — Indian Institute of Science Education and Research Bhopal, India, 462066

In this talk we are going to present structural and dynamical properties of a self-propelled filament using coarse-grained Brownian dynamics simulations. We consider two kinds of self-propulsion force on polymers, in case one force is applied tangent to the filament and in another model direction of active force is considered to be random. Case one shows that chain's stiffness and radius of gyration monotonically decrease. Moreover, the radius of gyration of the filament shows universal scaling for various bending rigidities with flexure number. In the latter model, where monomers are assumed to be active Brownian particle (ABP), displays a non-monotonic behaviour of end-to-end distance with activity strength. We will discuss here the role of many-body interactions on its structure and relaxation behavior. Additional we talk about the rheological behavior of chain under linear shear-flow. Our simulations reveal that active polymer's zero-shear viscosity varies in non-monotonic fashion with the active noise. More-importantly the viscosity decreases in the intermediate regime, that is followed by an increase in the more extensive *Pe* regime. We attribute the decrease of the zero-shear viscosity in the intermediate regime is due to many-body interactions among chain monomers.

BP 2.9   Mon 12:00   TOE 317

Pumping, Mixing, and Signal Transmission in Active Pores — •Goncalo Antunes[1,2,3], Paolo Malgaretti[1,2,3], Siegfried Dietrich[2,3], and Jens Harting[1,4] — [1]Helmholtz-Institut Erlangen-Nürnberg für Erneuerbare Energien (IEK–11), Forschungszentrum Jülich, Cauer Str. 1, 91058 Erlangen, Germany — [2]Max–Planck–Institut für Intelligente Systeme, Heisenbergstr. 3, 70569 Stuttgart, ,Germany — [3]IV. Institut für Theoretische Physik, Universität Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany — [4]Department Chemie- und Bioingenieurwesen und Department Physik, Friedrich-Alexander-Universität Erlangen-Nürnberg, Fürther Straße 248, 90429 Nürnberg, Germany

Much attention is currently being given to the problem of manipulating fluids at the microscale, with successful applications to fields such as 3D fabrication and biomedical research. An intriguing technique to manipulate fluid flows in a pore is diffusioosmosis. We show both numerically and analytically that a corrugated catalytic pore can act as a micropump even when it is fore-aft symmetric. This phenomenology is possible due to a spontaneous symmetry breaking which occurs when advection rather than diffusion is the dominant mechanism of solute transport. Relaxing the condition of Stokes flow leads to unsteady flow, and persistent oscillations with a tunable frequency appear. We further include the inverse chemical reaction that consumes solute and introduces an additional timescale. Finally, we find that the flow may lose its axial symmetry and hence promote mixing in the low Reynolds number regime.

BP 2.10   Mon 12:15   TOE 317

Interacting particles in an activity landscape — •Adam Wysocki[1], Anil Kumar Dasanna[1,2], and Heiko Rieger[1,2] — [1]Department of Theoretical Physics and Center for Biophysics, Saarland University, Saarbrücken, Germany — [2]INM-Leibniz Institute for New Materials, Saarbrücken, Germany

We study interacting active Brownian particles (ABPs) with a space-dependent swim velocity. We find that, although an equation of state exists, a mechanical equilibrium does not apply to ABPs in activity landscapes. The pressure imbalance originates in the flux of polar order across the interface between regions of different activity. An active-passive patch system is mainly controlled by the smallest global density for which the passive patch can be close packed. Below this density a critical point does not exist and the system splits continuously into a dense passive and a dilute active phase with increasing activity. Above this density and for sufficiently high activity the active phase may start to phase separate into a gas and a liquid phase caused by the same mechanism as motility-induced phase separation of ABPs with a homogeneous swim velocity.

BP 2.11   Mon 12:30   TOE 317

Active phase fluctuations of Chlamydomonas axonemes — •Abhimanyu Sharma[1], Benjamin M. Friedrich[2], and Veikko F. Geyer[1] — [1]B CUBE - Center for Molecular Bioengineering, TU Dresden, Dresden, Germany — [2]Cluster of Excellence Physics of Life, TU Dresden, Dresden, Germany

Cilia and eukaryotic flagella generate periodic beat patterns by the activity of dynein motors. Earlier studies revealed active fluctuations in the ciliary beat arising presumably from small number fluctuations in the collective dynamics of the molecular motors that drive the beat. A theoretical model of the beating cilium as a system of coupled motors predicts that the fluctuations measured in terms of the quality factor of ATP oscillations scale with the number of beat-generating-motors.

To measure those fluctuations experimentally, we use in situ reactivated axonemes, the mechanical core of motile cilia isolated from the green alga Chlamy-

domonas. To modulate the number of motors in beating axonemes, we make use of motor mutants or partially extract molecular motors biochemically.

Using shape mode analysis and limit-cycle reconstruction, we characterize the phase fluctuations in the beat and report for the first time the relation between beat parameters and the motor number in Chlamydomonas axonemes. We experimentally infer scaling relations for the beat frequency, mean beat amplitude, and the quality factor. Further, using mass spectrometry, we identify specific dynein motors and infer their role in regulating the beat fluctuations.

BP 2.12   Mon 12:45   TOE 317

Lattice dynamics of pulsating active particles — •Alessandro Manacorda and Étienne Fodor — University of Luxembourg

Cells in epithelial tissues can drastically deform their shapes and volume giving rise to collective behavior such as size oscillation and wave propagation. These phenomena have a strinking impact in many biological contexts such as embryonic development, cardiac arrhythmias and uterine contraction.

The theoretical models describing the emergence of contractile waves so far consider the cells as motile particles, where activity is represented by self-propulsion; however this ingredient is questionable in dense systems where particles barely move. We therefore introduce a novel class of active matter where the activity is the ability to change an internal degree of freedom at the single-particle level e.g. particles' size. The collective behavior of active particles is investigated in a lattice model, where the interplay between pulsation and synchronization gives rise to emergent behavior such as wave propagation. Fluctuating hydrodynamic equations can be obtained from microscopic dynamics and their predictive power is shown in comparison with numerical simulations.

We highlight the minimal ingredients needed for the complex behavior abovementioned and point out future directions in the growing field of pulsating active matter.

Elucidating the Binding Process of a Disordered Protein to a Membrane Containing Ionic Lipids via Atomistic Simulations: a Case Study of LKB1 — •Azadeh Alavizargar and Andreas Heuer — Institute of Physical Chemistry, University of Muenster, Corrensstr. 28/30, 48149 Muenster, Germany

Liver kinase LKB1 is a serine/threonine kinase, which apart from from playing a significant role in many biological processes such as cell proliferation and polarity, it functions also as a downregulator in tumors. In this work, we probe the significance of phosphatidic acid (PA) lipids as well as the poly-basic region for the binding of the C-terminus of the protein to the membrane, using molecular dynamics simulations. It was revealed that PA lipids are essential for the protein-membrane binding and that the mutation of the first three lysine residues does not abolish the binding. We specifically show the details of the protein-membrane binding at the atomic resolution using various amount of PA lipids in the membrane. Importantly, it was also found that the protein-membrane binding is dynamic and gives rise to structural changes of the protein as a result of the interaction and the accumulation of PA lipids in the membrane, which is beyond the accessible resolution in the corresponding experiments. Furthermore, we quantified the significance of each polar amino acid in the poly-basic region of the protein. These results provide important insights into the understanding and mechanism of the interaction of disordered proteins with membranes including ionic lipids.

BP 3.2   Mon 9:45   BAR 0106

Migration of oxygen in the human bc1 complex and the behavior of QH2 and Q cofactors inside it — •Katarina Kretschmer, Malena Kottke, and Ilia Solov'yov — Insitue of Physics, University of Oldenburg, Oldenburg, Germany

The dimeric bc1-complex embedded in the inner membrane of mitochondria is a relevant part of the respiratory chain in a mitochondrial cell of eukaryotes. Through different electron transfers that include oxidation and reduction reactions of the substrate molecules at the Qo- and Qi-site in this protein complex, it contributes to the metabolic system of the cell. Specifically, the complex facilitates proton transfers across the membrane to maintain an electrostatic potential, which is in turn used to drive ATP synthesis. This molecular machinery, however, is suspected to be a source of superoxide and is believed to be one of the factors in cellular aging.

Through molecular dynamics simulations, we have investigated the migration of molecular oxygen in the bc1-complex in order to identify possible reaction sites that could lead to superoxide formation. The investigation follows an earlier study of the bc1-complex from Rhodbacter capsulatus and reveals several

important differences. Specifically, we investigate further into the behavior of the cofactors Ubiquinol (QH2) and Ubiquinone (Q) in both monomers in the bc1-complex and determine the oxygen diffusion pathways that could lead to the sites where O2 could be efficiently converted to superoxide, thereby disturbing the regular functioning of the bc1-complex.

BP 3.3   Mon 10:00   BAR 0106

On the road to cellular digital twins of in vivo tumors — •Eric Behle[1], Julian Herold[2], and Alexander Schug[1] — [1]NIC Research Group Computational Structural Biology, Jülich Supercomputing Centre, Jülich Research Center, Jülich, Germany — [2]Steinbuch Centre for Computing, KIT, Karlsruhe

To this day, cancer remains an insufficiently understood disease plaguing humanity. In particular, the mechanisms driving tumor invasion still require extensive study. Current investigations address collective cellular behavior within tumors, which leads to solid or fluid tissue dynamics. Furthermore, the extracellular matrix (ECM) has come into focus as a driving force facilitating invasion. To complement the experimental studies, computational models are employed, and advances in computational power within HPC systems have enabled the simulation of macroscopic tissue arrangements. We hereby present our work using Cells in Silico (CiS), a high performance framework for large-scale tissue simulation previously developed by us. CiS is capable of simulating tissues composed of tens of millions of cells, while accurately representing many physical and biological properties. Our ultimate aim is to build a cellular digital twin of an in vivo tumor. Unfortunately, current in vivo measurement methods lack the required resolution for directly parameterizing our simulations. Therefore, we aim to parameterize CiS via a bottom-up approach, utilizing experimental data from multiple in vitro systems. We focused our first studies on tumor spheroids, a main workhorse of tumor analysis. Towards this, we developed a novel method to compare spatial features of spheroids in 3D.

BP 3.4   Mon 10:15   BAR 0106

Resolving hierarchical interactions of proteins in phase-separated condensates by multi-scale simulations — •Lukas Stelzl[1,2,3], Kumar Gaurav[1,2,3], Xiaofei Ping[1,2,3], Arya Changiarath Sivadasan[1,2,3], René Ketting[3], and Dorothee Dormann[3,4] — [1]Institute of Physics, JGU Mainz, Germany — [2]Faculty of Biology, JGU Mainz, Germany — [3]IMB Mainz, Germany — [4]Institute of Molecular Physiology, JGU Main, Germany

Liquid-liquid phase separation and the resulting phase-separated condensates of proteins help to organize cellular processes in time and space. At same time, dysregulation of phase separation is implicated in the development of neurodegenerative diseases. Using particle-based multi-scale simulations we are elucidating

how phase-separated condensates can provide for specific molecular recognition and thus cellular regulation and how this specificity is lost in diseases. With simulations we are elucidating how a hierarchy of interactions such as strong interactions of folded domains and weak and multivalent interactions between disordered regions of proteins determine phase behavior. With our multi-scale methods we can simulate condensates with atomic resolution and resolve molecular details of "sticker"-"sticker" interactions, their kinetics and how these provide for specific recognition and cellular function. We also show how mutations and biochemical modifications can shift the conformational equilibria of proteins and their interactions in phase-separated condensates and favor the formation of toxic aggregates in neurodegenerative diseases.

Invited Talk BP 3.5 Mon 10:30 BAR 0106

Resolving gating and allosteric modulation in ion channels through simulations and small-angle neutron scattering — •ERIK LINDAHL — Dept. Biophysics & Biochemistry, Science for Life Laboratory, Stockholm University

Pentameric ligand-gated ion channels (pLGICs) perform electrochemical signal transduction in organisms ranging from bacteria to humans. In addition to their normal gating cycle, pLGICs are highly sensitive to allosteric modulation where small compounds such as barbiturates, benzodiazepines or alcohols influence the gating kinetics by binding in separate sites, either in the transmembrane or extracellular domain. Despite a wealth of new experimental structures, it has been challenging to understand the gating kinetics, in particular since the channels rapidly undergo transitions to a desensitized nonconducting state rapidly after opening. I will present our recent combined experimental and computational work on a number of prokaryotic and eukaryotic pLGICs from the team, and how we are trying to combine low-resolution experimental techniques such as SANS (small-angle neutron scattering) with simulations to model channels under realistic conditions. In addition, I will show how we have been able to resolve structures in all separate functional states, their state-specific interactions with lipids, and not least how we are beginning to understand the properties of the desensitized state.

Clustering Molecular Dynamics Trajectories using Density and Flux — •JAYASHRITA DEBNATH[1] and GERHARD HUMMER[1,2] — [1]Max Planck Institute of Biophysics, Frankfurt am Main, Germany — [2]Goethe University, Frankfurt am Main, Germany

Molecular dynamics (MD) simulations are a powerful tool for studying a wide range of molecular systems and processes, with applications ranging from materials science to biology and medicine. Analyzing these simulations often involves finding a low-dimensional representation of the trajectory data and clustering the sampled configurations into kinetically relevant metastable states. The steady growth in the time and length scales of MD simulations, and in the complexity of their molecular systems, necessitates the development of new analysis tools that do not rely entirely on chemical or physical intuition. Here, we propose a neural network based unsupervised algorithm that can identify states using the static and dynamic information encoded in the trajectories. The network identifies metastable states by modeling a probability distribution of the data in a reduced dimensional space and learns the state boundaries by minimizing the flux between states. Furthermore, it can learn the optimal number of states from single long equilibrium trajectories or multiple short ones. After demonstrating the effectiveness of this method for a toy potential, we apply it to trypsin-benzamidine unbinding as a model of drug binding kinetics, to and folding-unfolding transitions of the villin headpiece subdomain.

Enhancing Traction-Force Microscopy with Machine Learning — •FELIX S. KRATZ, LARS MÖLLERHERM, and JAN KIERFELD — TU Dortmund University, Germany

Traction patterns of adherent cells provide important information on their interaction with the environment, cell migration or tissue patterns and morphogenesis. Traction Force Microscopy is a method aimed at revealing these traction patterns for adherent cells on engineered substrates with known constitutive elastic properties from deformation information obtained from substrate images. Conventionally, the substrate deformation information is processed by numerical algorithms of varying complexity to give the corresponding traction field via solution of an ill-posed inverse elastic problem. We explore the capabilities of a deep convolutional neural network as a computationally more efficient and robust approach to solve this inversion problem. We develop a general purpose training process based on collections of circular force patches as synthetic training data, which can be subjected to different noise levels for additional robustness. The performance and the robustness of our approach against noise is systematically characterized for synthetic data, artificial cell models and real cell images, which are subjected to different noise levels. A comparison to state-of-the-art Bayesian Fourier transform traction cytometry reveals the precision, robustness, and speed improvements achieved by our approach, leading to an acceleration of Traction Force Microscopy methods in practical applications.

BP 3.8 Mon 11:45 BAR 0106

Finding pathways in molecular dynamics simulations using machine learning and graph methods — •STEFFEN WOLF[1], MIRIAM JÄGER[1], VICTOR TÄNZEL[1], SIMON BRAY[1,2], MATTHIAS POST[1], and GERHARD STOCK[1] — [1]Biomolecular Dynamics, Institute of Physics, University of Freiburg, 79104 Freiburg, Germany — [2]Bioinformatics Group, Institute of Informatics, University of Freiburg, 79110 Freiburg, Germany

Understanding the mechanisms of biomolecular systems and complexes, e.g., of protein-ligand (un)binding, requires the understanding of paths such systems take between metastable states. In MD simulation data, paths are usually not observable per se, but need to be inferred from simulation trajectories. Here we present novel approaches to cluster trajectories according to similarities. These approaches include neighbor-nets allowing to correct for input data ambiguity [1] and an unsupervised learning approach employing only a single free parameter [2]. We demonstrate how such clusters of trajectories correspond to pathways, and how the approaches help in the identification of reaction coordinates for a considered process. Last, we present a theoretical framework how potentials of mean force can be calculated for individual pathways, and how these potentials and kinetics along paths can be combined into a comprehensive complete free energy profile and process kinetics.

BP 3.9 Mon 12:00 BAR 0106

Artificial Intelligence for Molecular Mechanism Discovery — •HENDRIK JUNG[1], ROBERTO COVINO[2], A ARJUN[3], CHRISTIAN LEITOLD[4], PETER G BOLHUIS[3], CHRISTOPH DELLAGO[4], and GERHARD HUMMER[1] — [1]Max Planck Institute of Biophysics, Frankfurt, Germany — [2]Frankfurt Institute for Advanced Studies, Frankfurt, Germany — [3]University of Amsterdam, Amsterdam, The Netherlands — [4]University of Vienna, Vienna, Austria

We present a machine learning algorithm to extract the mechanism of collective molecular phenomena from computer simulations. The algorithm combines transition path sampling (TPS), deep learning (DL), and statistical inference to simultaneously enhance the sampling and understanding of complex molecular reorganizations without human intervention. TPS is a Markov Chain Monte Carlo method in trajectory space that samples the rare transition trajectories connecting meta-stable states. In our algorithm a DL model is selecting the configurations from which the new trial trajectories are generated using shooting moves, i.e., the trajectories are propagated according to the physical model of the simulated system. By iteratively training on the outcomes of the shooting moves, the model simultaneously increases the efficiency of the rare-event sampling and gradually reveals the underlying mechanism of the transition. In a second step we distill the knowledge about the transition encoded in the DL model into a simplified mathematical expression. With this algorithm we study a diverse set of molecular systems ranging from the association of ions in solution to the oligomerization of a transmembrane alpha helix dimer.

MD simulations of n-alkanes in a phospholipid bilayer: CHARMM36 vs. Slipids — •ANIKA WURL and TIAGO FERREIRA — Institute of Physics, Martin-Luther Universität Halle-Wittenberg

The incorporation of n-alkanes into phospholipid bilayers is a convenient starting point for studying the molecular behavior of linear, (purely) hydrophobic molecules in lipid membranes. Here, we perform atomistic molecular dynamics simulations using two state-of-the-art lipid force fields, CHARMM36 [1] and Slipids [2], to systematically investigate how the miscibility of n-alkanes in dipalmitoylphosphatidylcholine (DPPC) bilayers depends on alkane chain length. The two force fields show a distinct behavior: Slipids simulations predict an effect of chain length on miscibility, while for CHARMM36 simulations this is not the case for the alkanes studied. A comparison with ^{2}H NMR spectra shows that the accuracy of the two force fields is dependent on alkane length. CHARMM36 performs well for the shorter chains, while Slipids models the longer alkanes better. Slipids chains are more flexible, due to reduced electrostatic 1-4 interactions compared to CHARMM36. By scaling these 1-4 interactions, CHARMM36 can be adapted to model longer alkanes and lipid acyl tails better. The presented results are of general interest for future studies of other long and flexible hydrophobic molecules inside lipid membrane environments, and show that n-alkane/lipid mixtures should be taken into account for optimization of force fields designed to model lipid membranes. [1] Jämbeck et al.; J Phys Chem B 2012, 116, 3164-3179 [2] Klauda et al.; J Phys Chem B 2010, 114, 7830-7843

BP 3.11 Mon 12:30 BAR 0106

Scission criteria upon proteins X-ray absorption — •CARLOS ORTIZ-MAHECHA[1], LUCAS SCHWOB[2], SADIA BARI[2], and ROBERT MEISSNER[1,3] — [1]Technische Universität Hamburg, Hamburg, Germany — [2]Deutsches Elektronen-Synchrotron, Hamburg, Germany — [3]Helmholtz-Zentrum Hereon, Geesthacht, Germany

Dynamic protonation in a protein lead to conformational changes which could be studied by challenging near-edge X-ray absorption mass spectrometry (NEX-

AMS) experiments and computationally expensive quantum mechanical (QM) calculations. Less demanding assessment is essential for interpreting the underlying electronic density changes in proteins. Those density changes in the amino-acid (AA) non-covalent environment are evaluated by *in-silico* X-ray spectra and their chemical-physical properties by the pair interaction energy decomposition analysis (PIEDA) method. In order to represent a protein X-ray absorption spectra as a summation of their smaller protein fragments X-ray spectra, we first assess its electronic neighboring influence to establish a scission criteria. For that, we propose a pattern involving the change of excited-state transition energy probability in a two-body AA localized density population and the charge transfer energy change from PIEDA as a function of the non-covalent interaction distance. In this way using this criteria, the X-ray absorption spectra of proteins could potentially be represented as a composition of X-ray spectra of their smaller fragments, which would be computationally more efficient.

BP 3.12   Mon 12:45   BAR 0106
Fluid deformable surfaces, the influence of surface viscosity in fluid membranes — Veit Krause and •Axel Voigt — Institute of Scientific Computing, Technische Universität Dresden, Germany
We consider a fluid-solid duality of membranes, with in-plane fluid properties and out-of-plane solid (bending) properties. In such systems any tangential flow induces shape deformationas and any change in morphology induces tangential flow. This numerically challanging surface problem is solved by surface finite elements and we explore the dynamics towards equilibrium states in various settings, ranging from transitions from biconcave to dumbell shapes, coarsening of two-component surface fluids under the influence of curvature and wrinkling in fluid membranes.

Nonlinear and active rheology of cell tissues — •Charlie Duclut[1,2], Joris Paijmans[2], Mandar M. Inamdar[3], Carl D. Modes[4], and Frank Jülicher[2] — [1]Laboratoire Physico-Chimie Curie, Paris, France — [2]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [3]Indian Institute of Technology Bombay, Mumbai, India — [4]Max Planck Institute for Molecular Cell Biology and Genetics, Dresden, Germany
Tissues are assemblies of large numbers of cells which form a soft active material. In amorphous solids as in tissues, neighbour exchanges (or T1 transitions) can relax local stresses and allow the material to flow. In tissues, in addition to these passive events, energy consumption at the microscopic level allows cells to perform active neighbour exchanges that can shape the tissue into a prescribed geometry. In my talk, I will consider an anisotropic vertex model to study T1 rearrangements in polygonal cellular networks. I will consider two different physical realizations of the active anisotropic stresses, that can be both observed in experiments: (i) anisotropic bond tension and (ii) anisotropic cell stress. Interestingly, the two types of active stress lead to patterns of relative orientation of T1 transitions and cell elongation that are different. Using the lens of a continuum description of the tissue as an anisotropic active material, I will discuss the energetics of the dynamic tissue and express the energy balance in terms of internal elastic energy, mechanical work, chemical work and heat. This allows us to define active T1 transitions that can perform mechanical work while consuming chemical energy.

Hydraulic and osmotic control of lumen coarsening — •Mathieu Le Verge Serandour[1,2] and Hervé Turlier[2] — [1]School of Natural Sciences, Technical University of Munich, Germany — [2]Center for Interdisciplinary Research in Biology, Collège de France, PSL Research University, Paris, France
The blastocoel formation is a keystone in the morphogenesis of the pre-implantation mammalian embryo, yet the physical mechanism for its emergence remained unclear. The blastocoel is a fluid-filled cavity (or lumen) that positions the first axis of symmetry of the embryo. We showed that, in the mouse embryo, the blastocoel results from micron-sized lumens, nucleating at the adhesive basolateral side of embryonic cells and coarsening in a process akin to Ostwald ripening. We investigate the collective dynamics of a one-dimensional chain of lumens as a minimal model for the blastocoel formation, taking the osmotic effects into account. We include the permeation of water and osmolyte through the cellular membrane. We show that the coarsening of the chain is reminiscent of dewetting films, with a scaling law for the number of lumens controlled by a screening length associated with water permeation, while the influence of osmotic inhomogeneities remains limited. Finally, we consider active osmolyte pumping that may rescue the chain from collapse. We find a new scaling law controlled by active pumping emerging from the coalescence of lumens, which may also direct the position of the final lumen.

BP 4.3   Mon 15:30   BAR Schö
Mechanical Properties of the Premature Lung — •Jonas Naumann[1], Nicklas Koppe[1], Ulrich Thome[2], Mandy Laube[2], and Mareike Zink[1] — [1]Research Group Biotechnology & Biomedicine, Peter Debye Institute for Soft Matter Physics, Leipzig University, 04103 Leipzig, Germany — [2]Center for Pediatric Research Leipzig, Department of Pediatrics, Division of Neonatology, Leipzig University, 04103 Leipzig, Germany
Premature infants are often reliant on mechanical ventilation to survive. However, prolonged ventilation and associated mechanical stress may cause subsequent pulmonary diseases of the immature lung. To study the mechanical properties of fetal rat lungs on macroscopic scale, we performed rheology experiments under compression and tension using different velocities. Fetal lung tissue showed a hyperelastic behavior and became significantly stiffer with increasing deformation velocities. In fact, fetal lung tissue under compression showed clear viscoelastic features even for small strains. A higher Young's modulus of fetal lungs compared to adult controls clearly pointed towards altered tissue characteristics. In addition, the influence of a hydrostatic pressure difference on the electrophysiology of primary fetal distal lung epithelial cells was investigated on microscopic scale. We observed a strong impact of hydrostatic pressure on the activity of the epithelial sodium channel and the sodium-potassium pump. Vectorial sodium transport, crucial for alveolar fluid clearance, was significantly impaired.

BP 4.4   Mon 15:45   BAR Schö
'Forcing' changes in health and disease: New access into bioengineered skeletal muscle mechanics for preclinical screening — •Arne Hofemeier[1,2], Till Muenker[2], Mariam Ristau[2], Timo Betz[2], and Wolfram Zimmermann[1] — [1]University Medical Center, Göttingen, Germany — [2]Third Institute of Physics, Göttingen, Germany
Mechanical properties of skeletal muscles are tightly related to proper functionality, which makes experimental access to the biomechanics of skeletal muscle tissue essential to advance our understanding of muscle function, development and disease. Recently devised in vitro culture systems allow for raising 3D muscle tissues using single cells from patients. However, these systems are inherently incompatible with high resolution microscopy and precise mechanical in-plate measurements. Here, we present a new chamber design that allows real-time high resolution 3D microscopy and non-invasive quantification of global contractile forces and tissue tension during muscle formation. Surprisingly, we found that bioengineered muscles, derived from patients suffering from Duchenne muscular dystrophy, develop under higher tension although they appear weaker upon stimulation. Duchenne is caused by loss of a membrane linker protein, dystrophin, which we therefore dedicate an important novel role as a molecular tension sensor. Testing an individualized gen therapy for a subset of Duchenne patients, we were able to demonstrate that not just the contractile strength of the bioengineered muscles was restored, but also the elevated tissue tension was decreased again.

BP 4.5   Mon 16:15   BAR Schö
Harnessing active viscoelasticity for synthetic epithelial morphogenesis — •Nimesh Ramesh Chahare[1,2], Adam Ouzeri[2], Tom Golde[1], Thomas Wilson[1,3], Pere Roca-Cusachs[1], Marino Arroyo[2,3], and Xavier Trepat[1,4] — [1]Institute for Bioengineering of Catalonia, Barcelona, Spain — [2]Universitat Politècnica de Catalunya, Barcelona, Spain — [3]Centre Internacional de Mètodes Numèrics en Enginyeria, Barcelona, Spain — [4]Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain
Epithelial sheets are active viscoelastic materials that form specialized 3D structures suited to their physiological roles, such as branched alveoli in the lungs, tubes in the kidney, and villi in the intestine. How epithelial shape arises from active viscoelasticity and luminal pressure remains poorly understood. Here we developed a microfluidic setup to engineer 3D epithelial tissues with controlled shape and pressure. Through this approach, we subject the tissues to a range of lumen pressures at different rates and probe the relation between strain and tension in different regimes. Slow pressure changes relative to the timescales of actin dynamics allow the tissue to accommodate large strain variations. However, under sudden pressure reductions, the tissue buckles and folds to store excess tissue area. This behavior is well captured by a 3D computational model that incorporates the turnover, viscoelasticity, and contractility of the actomyosin cortex. Informed by this model, we harness the active behavior of the cell cortex to pat-

tern epithelial folds by rationally directed buckling. Our study establishes a new approach to engineering epithelial morphogenetic events.

BP 4.6   Mon 16:30   BAR Schö

Continuum Mechanics of Cell Intercalation in *Tribolium* — •Maryam Setoudeh[1,3] and Pierre A. Haas[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Straße 38, 01187 Dresden, Germany — [2]Max Planck Institute of Molecular Cell Biology and Genetics, Pfotenhauerstraße 108, 01307 Dresden, Germany — [3]Center for Systems Biology Dresden, Pfotenhauerstraße 108, 01307 Dresden, Germany

Deformations of tissues during development often involve cell intercalations and cell neighbour exchanges, but a general continuum description of such plastic rearrangements in tissues is still lacking.

Here, we combine morphoelasticity and plasticity theory to develop a continuum framework of tissue mechanics combining cell intercalations, intrinsic deformations such as tissue contraction, and elastic deformations of the tissue.

We apply our theory to the development of the beetle *Tribolium* [1] during which a layer of cells, the serosa, closes over the embryo. Cells deintercalate from the rim of the serosa into its bulk, thus reducing the number of cells at the boundary and closing the serosa. This is associated with actomyosin contraction at the rim of the serosa [1].

We model this process by the axisymmetric closure of a circular hole in a flat elastic sheet contracting near the hole. Our analytical and numerical results show how intercalation reduces the contraction required for serosa closure and hint at the importance of an additional force exerted by the embryo at the rim of the serosa.

Tracking and comprehending single cell dynamics in Drosophila dorsal closure using machine learning — •Daniel Härtter[1,3], Yuxi Long[2], Janice Crawford[2], Daniel P. Kiehart[2], and Christoph F. Schmidt[1] — [1]Department of Physics and Soft Matter Center, Duke University, USA — [2]Department of Biology, Duke University, USA — [3]Department of Pharmacology and Toxicology, Göttingen University Medical Center

Dorsal closure in Drosophila melanogaster embryos is a key model system for cell sheet morphogenesis and wound healing. We pursue a data-driven approach to understand the emergence of organized behavior on tissue level from the stochastic dynamics of single cells across scales. We developed DeepTissue, a deep-learning-based algorithm to automatically and robustly detect and temporally track various single cell features: cell shapes, cell junction lengths, myosin intensities, and tissue topology. Epithelial cells in dorsal closure exhibit oscillations and contribute to progressive cell sheet movements, while showing a large variability in individual shapes, dynamics, and fates. Based on high-quality

multi-parametric trajectories of 1000s of single cells, we use unsupervised machine learning techniques to detect and classify behavioral and structural phenotypes. Further we study how the behavior of single cells throughout closure is driven by deterministic and/or stochastic factors, with the aim to predict singular cell ingression events.

The role of intermediate filaments in stress resistance in 3D epithelial structures — •Tom Golde[1], Marco Pensalfini[2], Nimesh Chahare[1], Marino Arroyo[1,2], and Xavier Trepat[1,3,4] — [1]IBEC, Barcelona, Spain — [2]UPC, Barcelona, Spain — [3]UB, Barcelona, Spain — [4]ICREA, Barcelona, Spain

The safety belt hypothesis states that IFs are protecting cells from large and rapid deformations. However, typical experiments for stretching epithelial tissues only reach maximum strains of around 0.3. We developed a microfluidic device where an epithelial monolayer is grown on a porous surface with circular low adhesion zones. Upon applying hydrostatic pressure, the monolayer delaminates into a spherical cap (dome), generating tissue strains of more than 1 while individual cells are stretched up to strains of 9. We can image these 3D epithelial domes with high resolution, determine the tissue tension via Laplace law, and control the rate of inflation and deflation.

Using this approach with MDCK cells, we observed a striking reorganization of the keratin IF rim-and-spoke network into a central knot with thick, radially oriented bundles. Previous results by us and others hereby indicate a crucial role of actin-IF interactions. To better understand the mechanical principles of such transitions, we developed a multiscale computational model that simulates the interactions of keratin IFs with the nucleus, desmosomes, and the actin cortex. Combining experiments and simulations, we can now conclusively test the safety belt hypothesis in controlled and unparalleled large 3D tissue deformations

BP 4.9   Mon 17:15   BAR Schö

Instabilities in hexanematic models of epithelia — •Josep-Maria Armengol-Collado, Livio Carenza, and Luca Giomi — Instituut-Lorentz, Leiden Institute of Physics, Universiteit Leiden, P.O. Box 9506, 2300 RA Leiden, The Netherlands

Epithelial tissues, whose study remain fundamental to understand processes such as cancer progression, have revealed to exhibit multiscale orientational order. While the large scale dynamics is ruled by the nematic symmetry, hexatic order instead controls the behaviour of small clusters of cells. By considering a hydrodynamic approach, we investigate the stability of hexanematic liquid crystals identifying the role of activity and flow alignment in the generation of spontaneous flows, which also reflect the interplay between different length scales. We finally address possible consequences when confining such a fluid in a channel, connecting this phenomenology with recent observations of metastatic cell invasion.

BP 5: Focus Session NanoAgents

Repurposing nucleic acids as high-resolution force sensors: From fundamental mechanotransduction to translational biophysics — •Khalid Salaita — Emory University, Department of Chemistry, Atlanta, Georgia, USA

Cells are highly dynamic structures that are constantly converting chemical energy into mechanical work to pull and push on one another and on their surroundings. These pulls and pushes are mediated by tiny molecular forces at the scale of tens of piconewtons. For context, 7 pN applied a distance of 1 nm is ~1 kcal/mol. Nonetheless, these forces can have profound biochemical consequences. For example, the rapidly fluctuating forces between immune cells and their targets can drastically tune immune response and function. Despite the importance of mechanics there are limited methods to study forces at the molecular scale and particularly within living cells.

In this talk, I will discuss my group's efforts at addressing this gap in knowledge by developing tools to map the molecular forces applied by cells. I will describe the development of a suite of DNA tension probes which offer significant improvements in S/N and lead to enhanced spatial and temporal resolution. I will also describe a series of force-triggered reactions that enable signal amplification. Fluorescence polarization spectroscopy and super-resolution imaging offer the highest resolution maps of cell traction forces reported to date. Finally, armed with these new tools, I will describe the advent of translational mechanobiology where we predict the bleeding risk in patients by measuring the mechanical activity of their platelet adhesion receptors.

BP 5.2   Mon 15:30   TOE 317

Remodelling DNA filaments for bottom-up synthetic biology — •Maja Illig[1], Kevin Jahnke[1,2], Marlene Scheffold[1], Hauke Drechsler[3], Stefan Diez[3], and Kerstin Göpfrich[1] — [1]MPI for Medical Research, Heidelberg,

Germany — [2]Harvard University, School of Engineering and Applied Sciences (SEAS), Cambridge, MA, USA — [3]TU Dresden, Center for Molecular Bioengineering (B CUBE), Dresden, Germany

The control of filamentous cytoskeletal systems is one of the dedicated aims of bottom-up synthetic biology to engineer self-dividing synthetic cells and equip them with mechanical cell-to-cell communication pathways. A molecular engineering approach to achieve specific functionality from the nanoscale to the microscale requires programmability in order to design self-assembly.

This work reinforces how DNA nanotechnology paves the way to create biocompatible nanostructures that can mimic cellular entities. Here, we demonstrate the remodelling of entirely synthetic filaments made from DNA nanotubes: (i) Towards bottom-up synthetic cell division, we can rationally design a ring structure made from bundled filaments. We can control the ring formation by engineering of a synthetic crosslinking peptide and we further constrict the ring diameter by external triggers. (ii) Towards mechanotactic synthetic cells, a transmembrane signalling pathway enables the reconfiguration of the cytoskeleton made from DNA filaments. The stimulus-induced clustering of transmembrane entities results in mechanical remodelling of the internal DNA cytoskeleton (Jahnke, Illig et al. Biorxiv 2022).

DNA origami agents for the efficient treatment of solid tumors — •Johann Moritz Weck[1], Merve-Zeynep Kesici[1], Cornelia Monzel[2], and Amelie Heuer-Jungemann[1] — [1]Max Planck Institut für Biochemie, Am Klopferspitz 18, 82152 Martinsried — [2]Heinrich Heine Universität Düsseldorf, Universitätsstraße 1, 40225 Düsseldorf

We previously used DNA origami as a platform to pre-cluster Fas ligands (FasL) of the tumor necrosis factor receptor superfamily (TNFRSF) with nanometer precision in varying patterns and presented those to HeLa cells in a 2D cell culture model. We found up to a 100x increase of potency upon pre-clustering FasL in hexagonal geometries, a high sensitivity towards inter-ligand distance and a dependency on linker rigidity. In order to use this knowledge for the advancement of TNRSF ligand-based therapeutics, we investigated the interactions of DNA origami nanoagents with solid tumors. Certain aspects of cancer cell biology, such as the complex biological environment of solid tumors cannot be efficiently simulated in regular 2D cell culture systems. Using a 3D tumor spheroid model, we here show that FasL-DNA origami nanoagents are able to strongly affect the growth of 3D tumor spheroids. Partial dissolution of 3D tumoroids is observed after exposure to the nanoagents. We provide insights into DNA origami tumor spheroid penetration ability as well as a threshold like behavior of signaling initiation, and design rules for nanomaterial based therapeutics.

BP 5.6   Mon 16:45   TOE 317

Monitoring the Switching dynamics of Photolipid Membranes with Plasmonic Nanorods — •Jinhua Zhang, Francis Schuknecht, Ludwig Habermann, Alexander Pattis, Stefanie Pritzl, and Theobald Lohmüller — Chair for Photonics and Optoelectronics, Nano-Institute Munich, Department of Physics, Ludwig-Maximilians-Universität, Königinstraße 10, 80539 Munich, Germany

Photoswitchable lipids (i.e. photolipids) are intriguing nanoagents for controlling lipid membrane properties with light. However, analyzing the switching dynamics in a single lipid bilayer locally and in situ is challenging due to a lack of sensitive tools for detecting the very small changes in membrane thickness (< 1 nm). Here, we demonstrate a new approach to monitor the photoisomerization of photolipid membranes on the nanoscale via plasmonic sensing.

In our experiment, gold nanorods are deposited on a glass substrate and coated with a supported photolipid bilayer. The photosensitive azobenzene group in the lipid tails is switched between a trans and cis form by an illumination sequence with UV and blue light, while scattering spectra of individual nanorods are simultaneously measured. We find that the photoisomerization process of azobenzene leads to a reversible shift of the nanorod's plasmon resonance over many switching cycles. Our study shows that single nanorods may thus be used as sensitive probes to study isomerization dynamics and photostationary states of photolipid bilayer membranes within nanoscale environments.

Bio-inspired Magnetic Nanoprobes For Subcellular Manipulation Studies in Single Cells — •Andreas Neusch[1], Iuliia Novoselova[1], Liesa Zitzke[1], Sarah Sadik[1], Michael Farle[2], Ulf Wiedwald[2], and Cornelia Monzel[1] — [1]Heinrich-Heine-University, Düsseldorf — [2]University of Duisburg-Essen, Duisburg

Probing and manipulating biological functions requires tools to target and modify the proteins involved in the respective process. In recent years Magnetogenetics emerged as an approach where magnetic nanoparticles (MNPs) and external magnetic fields are used to realize such manipulation (Lisse et al., Adv. Mater., 29, 1700189 (2017)). The advantages of this combination lies within the deep tissue penetration of magnetic fields and the possibility to apply stimuli on nanoscales leading to spatial redistribution, force application, or heat generation of proteins. However, a precise active perturbation requires MNPs to be monodisperse, biocompatible, tunable with regard to their magnetic properties, as well as exhibiting a modifiable molecular shell (Monzel et al., Chem. Sci. 8, 7330-7338 (2017)). Here, we synthesize a bioinspired semisynthetic MNP - Magnetoferritin (MFt) -, which fulfils these demands. MFt is based on the globular iron storage protein complex ferritin that converts iron ions to a ferrihydrite core but can be synthetically loaded with a magnetic iron oxide core (Novoselova et al., Nanomaterials, 11, 2267 (2021)). MFt was chemically, physically and magnetically characterized both in vitro and in vivo. We demonstrate how MFt can be used to target proteins on living cells as well as to spatially manipulate MFts in a single cell environment.

BP 5.8   Mon 17:15   TOE 317

Precise micro-manipulations via multiplexed feedback-controlled thermoviscous flows — •Elena Erben[1], Nicola Maghelli[1], Weida Liao[2], Antonio Minopoli[1], Eric Lauga[2], and Moritz Kreysing[1] — [1]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany — [2]DAMTP, University of Cambridge, UK

Methods for precise micro-manipulation are highly relevant for many problems in biological research such as cell patterning and controlled droplet fusion. Thermoviscous flows [1] hold great potential for manipulations in biological systems since they can be induced optically and enable non-invasive in-vivo perturbations [2]. Recently, we developed a novel optofluidic manipulation method based on feedback-controlled thermoviscous flows. This technique facilitates the automatic positioning of a single micro-particle, with a precision of up to 24 nm [3]. Our approach can be multiplexed to the parallel manipulation of multiple particles, thus facilitating dynamic micropatterning. Furthermore, we found that positioning of multiple particles can be greatly accelerated by leveraging highly complex flow patterns that result from multiplexing. We anticipate that combining our approach with elaborate theoretical modelling will increase the precision and speed of this manipulation method even more, facilitating translation onto applications in the life sciences and beyond.

BP 6: Bacterial Mechanics

Time: Monday 15:00–17:15   Location: BAR 0106

BP 6.1   Mon 15:00   BAR 0106

Antigenic variation modulates attractive forces between bacteria and affects antibiotic tolerance — •Isabelle Wielert[1,3], Sebastian Kraus-Römer[1,3], Paul Higgins[2,3], and Berenike Maier[1,3] — [1]Institute for Biological Physics, University of Cologne, Germany — [2]Institute for Medical Microbiology, Immunology and Hygiene, University of Cologne, Germany — [3]Center for Molecular Medicine Cologne

Type 4 pili (T4P) are multifunctional surface exposed polymers involved in adhesion, force generation, surface motility, aggregation and act as major antigens. During antigenic variation, the human pathogen Neisseria gonorrhoeae varies the primary structure of the pilin, the major subunit of the T4P fibre, to escape from immune surveillance. But it is unclear how pilin antigenic variation impacts other T4P functions. We addressed this question by replacing the pilin of a laboratory strain by pilins from various clinical isolates. By performing dual

laser trap experiments, we found that the pilin variant strains clustered into two groups with different attractive forces. Variants with interaction forces exceeding 40 pN formed colonies while weakly interacting bacteria retained a planktonic lifestyle. All pilin variants supported surface motility, yet the planktonic variants moved faster. Previous studies indicated that bacterial aggregation results in higher tolerance against antibiotic treatment. To test whether pilin antigenic variation affects tolerance, we carried out bacterial survival assays and showed that indeed colony-forming variants are more tolerant. We conclude that pilin variation enhances bacterial fitness beyond immune escape.

Stress anisotropy in confined populations of growing rods — Jonas Isensee[1,2], Lukas Hupe[1,2], Ramin Golestanian[1,2,3], and •Philip Bittihn[1,2] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, Göttingen University — [3]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, UK

A central feature of living matter is its ability to grow and multiply. The mechanical activity associated with growth produces both macroscopic flows shaped by confinement, and striking self-organization phenomena, such as orientational order and alignment, which are particularly prominent in populations of rod-shaped bacteria due to their nematic properties. However, how active stresses, passive mechanical interactions and flow-induced effects interact to give rise to global alignment patterns remains elusive. Here, we study in silico colonies of growing rod-shaped particles confined in channel-like geometries. A spatially resolved analysis of the stress tensor reveals a strong relationship between near-perfect alignment and an inversion of stress anisotropy for particles with large length-to-width ratios. In quantitative agreement with an asymptotic theory, strong alignment can lead to a decoupling of active and passive stresses parallel and perpendicular to the growth axis, respectively. We demonstrate the robustness of these effects to perturbations and for weaker confinement. Our results illustrate the complexity arising from the inherent coupling between nematic order and active stresses in growing active matter, modulated by geometric and configurational constraints due to confinement.

BP 6.3   Mon 15:30   BAR 0106

Magnetic fields help magnetotactic bacteria navigate complex environments — Agnese Codutti[1,2], Mohammad Charsooghi[1], Konrad Marx[3], Elisa Cerda-Donate[1], Omar Munoz[3], Paul Zaslansky[1], Vitali Telezki[3], Tom Robinson[1], Damien Faivre[1,4], and •Stefan Klumpp[3] — [1]MPI of Colloids and Interfaces, Potsdam — [2]TU Munich — [3]University of Göttingen — [4]Aix-Marseille Université, CEA, CNRS, BIAM, Saint Paul lez Durance, France

To study swimming of magnetotactic bacteria in a near-realistic sediment environment resembling those in their natural habitat, we produced microfluidic channels that contained sediment-mimicking obstacles. These obstacle channels were produced based on microCT reconstructions of sediment samples. We characterized the swimming of magnetotactic bacteria through these channels and found that swimming throughput was highest for intermediate magnetic fields. This observation was confirmed by extensive computer simulations using an active Brownian particle model, parameterized based on experimental trajectories. The simulations indicate that swimming at strong field is impeded by the trapping of bacteria in corners that require transient swimming against the magnetic field for escape. At weak fields, the direction of swimming is almost random, making the process inefficient as well. We confirmed the trapping effect in our experiments and showed that lowering the field strength allows the bacteria to escape.

BP 6.4   Mon 15:45   BAR 0106

Mechanical strain sensing and growth of rod-shaped Escherichia coli independent of cell wall synthesis — •Lars Renner[1], Felix Wong[2], Ariel Amir[2], Yuki Kitahara[3], and Sven van Teeffelen[3] — [1]Leibniz Institute of Polymer Research, Dresden — [2]Harvard University, Cambridge, USA — [3]Universite de Montreal, Canada

One of the central questions in bacterial cell biology is how specific shapes evolved and are maintained. It is remarkable how bacteria can precisely control the cellular processes regulating cell shape. However, many of the underlying biophysical cues are largely unknown. We set out to understand how mechanical stress affects rod-shape maintenance. Specifically, we combine microfabrication tools and mathematical modelling to identify a stress-based mechanism that regulates shape in rods. We then examined the influence of the biomolec-

ular machinery that builds the cell wall and found that rod-shaped cells retain the ability to expand their envelopes differentially in response to locally varying mechanical forces. Thus, cell-wall cleaving enzymes appear to represent an alternative pathway for coupling cell envelope growth to mechanical forces that is distinct from cell wall insertion.

Mechanical and electrical properties of bacterial biofilms modulate antibiotic tolerance — •Berenike Maier — Institute for Biological Physics and Center for Molecular Medicine Cologne, University of Cologne

Aggregation into colonies and biofilms can enhance bacterial survivability under antibiotic treatment. Yet, the transition between the life as an individual cell and life within a biofilm is poorly understood. We investigate this transition using the human pathogen *Neisseria gonorrhoeae* (gonococcus). Within minutes, these bacteria self-assemble into spherical colonies comprising thousands of cells. We show that freshly assembled colonies are reminiscent of liquid droplets whose viscosity can be tuned by the pilus-mediated attractive force between bacterial cells. The viscosity correlates with antibiotic tolerance. Next to mechanical properties, we investigate the electrical properties of gonococcal colonies. We show that once the colonies have reached a critical size, the membrane polarization transitions from uncorrelated to collective dynamics. The spatial polarization pattern correlates with patterns of distict growth rates and antibiotic tolerance. In summary, both mechanical and electrical properties of bacterial colonies affect survivability under external stresses.

Acclimatization of filamentous cyanobacteria to light and pH - from individual to colony-scale — •Franziska Papenfuss, Sarah Haeger, Maximilian Kurjahn, Antaran Deka, and Stefan Karpitschka — MPI for Dynamics and Self-Organization, Göttingen, Germany

Photoautotrophic cyanobacteria contribute about 10 % to the net primary production of earth's biosphere. Acclimatization to fluctuating environmental conditions supported their sustained existence over a few billion years, but the underlying mechanisms remain elusive. Here, we investigate three species of filamentous cyanobacteria, cultivated for three weeks at different light-intensities (0.25-8 μE) and pH buffered to specific values between 6.8-8.4 or unbuffered. During cultivation, micro-scale parameters like the abundance of photopigments and the velocity of single filaments as well as macro-scale parameters like growth rate, pH and colony morphology were tracked. In unbuffered cultures, pH varies between 6.5-10, depending on light driven photosynthesis. Filaments start to aggregate at high densities but mainly independent of illumination and pH. Neither is the growth rate influenced by pH, however it is positively correlated to illumination. Nevertheless, in some species, pH seems to influence the filament gliding velocity and photopigmentation. Thus, our investigations show that pH is not only a consequence of the photosynthetic activity, but also influences the acclimatization of the cyanobacteria in a regulating feedback mechanism.

BP 6.7   Mon 17:00   BAR 0106

Molecular Dynamics Simulation of the Polymer Layering on the Surface Layer Proteins of Methanosarcina acetivorans — •Jonathan Hungerland[1], Aitolkyn S. Uali[2], Po-Heng Lee[3], and Ilia A. Solov'yov[1] — [1]Dept of Physics, University of Oldenburg — [2]Dept of Chemistry, Gumilyov Eurasian National University — [3]Dept of Civil and Environmental Engineering, Imperial College London

The archaea of the type Methanosarcina can produce Methane in an efficient, anaerobic, symbiotic process with Geobacter metallireducens. Their symbiosis is a so-called direct interspecies electron transfer (DIET), which is not limited by diffusion and has potential application in prospective energetically net-positive, anaerobic waste-water treatment. However, the mechanisms underlying DIET are yet unclear. The Methanosarcina species that coat themselves in layers of Methanochondroitin polymers were found to be capable of DIET. Therefore, the polymers might be crucial for the DIET of Methanosarcina species. The performed molecular dynamics simulations generate an atomistic picture of the Methanochondroitin layers accounting for the porous surface layer proteins aiming to suggest potential charge-transfer mechanisms into the cell and might reveal the role of the surface layer pores.

Chiral motion of actively driven objects in discrete steps towards a remote target — •ANDREAS M. MENZEL — Otto-von-Guericke-Universität Magdeburg, Magdeburg, Germany

We address the motion of chiral actively driven objects that move in discrete steps on a flat substrate [1]. While closed polygon-shaped trajectories are found in the case of unperturbed motion, the dynamics becomes surprisingly rich and nonlinear, if the objects additionally head for a fixed remote target. In that situation, cycloidal-like, straight, zigzag-type, doubled zigzag, quadrupled zigzag, and further period-doubled types of trajectory emerge, besides chaotic behavior. Additionally, we investigate the motion of crowds of such objects under explicit mutual alignment interaction. In the absence of fluctuations, collective orientational ordering occurs also in the chaotic regime, in combination with spatial gathering of the particles. Conversely, fluctuations and polydispersity in target alignment counteract orientational ordering. Our results may apply to various types of actively driven objects, for instance, light-responsive bacteria, laser-controlled colloidal particles, or hoppers on vibrated substrates.

Polar flocks with discretized directions: the active clock model approaching the Vicsek model — •MATTHIEU MANGEAT, SWARNAJIT CHATTERJEE, and HEIKO RIEGER — Universität des Saarlandes, Saarbrücken, Germany

We study the off-lattice two-dimensional q-state active clock model (ACM) [EPL **138**, 41001 (2022)] as a natural discretization of the Vicsek model (VM) [PRL **75**, 1226 (1995)] describing flocking. The ACM consists of particles able to move in the plane in a discrete set of q equidistant angular directions, as in the active Potts model (APM) [EPL **130**, 66001 (2020); PRE **102**, 042601 (2020)], with a local alignment interaction inspired by the ferromagnetic equilibrium clock model. A collective motion emerges at high densities and low noise. We compute phase diagrams of the ACM and explore the flocking dynamics in the region, in which the high-density (polar liquid) phase coexists with the low-density (gas) phase. We find that for a small number of directions, the flocking transition of the ACM has the same phenomenology as the APM, including macrophase separation and reorientation transition from transversal to longitudinal band motion as a function of the particle self-propulsion velocity. For a larger number of directions, the flocking transition in the ACM becomes equivalent to the one of the VM and displays microphase separation and only transverse bands, i.e. no reorientation transition. Concomitantly also the transition of the $q \to \infty$ limit of the ACM, the active XY model, is in the same universality class as the VM. We also construct a coarse-grained hydrodynamic description akin to the VM.

BP 7.3 Mon 15:30 ZEU 160

Tracer-induced temperature difference in motility-induced phase separation — •LUKAS HECHT, IRIS DONG, and BENNO LIEBCHEN — Institut für Physik kondensierter Materie, Technische Universität Darmstadt, Hochschulstr. 8, D-64289 Darmstadt, Germany

Previous studies of overdamped active Brownian particles (ABPs) mixed with passive tracers have shown that self-propulsion can induce motility-induced phase separation (MIPS) for large enough particle density and self-propulsion speed [1]. Here, we present our study on overdamped ABPs mixed with inertial passive tracers. We show that MIPS features different kinetic temperatures in the dense and the dilute phase if the passive tracers are sufficiently heavy (inertial). Remarkably, unlike for underdamped ABPs [2,3], neither the overdamped ABPs nor the passive tracers alone would feature such a temperature difference in coexisting phases. The observed temperature difference is accompanied by a violation of the equipartition theorem and strongly depends on the self-propulsion speed and the particle density. This allows us to tune the temperature difference from a cold dense and hot dilute phase to the counterintuitive opposite case in which the dense phase is hotter than the dilute phase. These findings open a route to create active materials with a persistent temperature profile by inserting active particles and tuning their self-propulsion speed accordingly.

Collective motion in two-dimensional colloidal systems with effective (active) self-propulsion due to time-delayed feedback — •ROBIN A. KOPP and SABINE H. L. KLAPP — ITP, TU Berlin, Berlin, Germany

In recent years, delayed feedback in colloidal systems has become an active and promising field of study [1,2], key topics being history dependence and the manipulation of transport properties. Here we study the dynamics of a two-dimensional colloidal suspension, subject to time-delayed feedback, where time-

delayed feedback can be interpreted as a mechanism of effective self-propulsion, i.e., activity [3]. To this end we perform overdamped Brownian dynamics simulations, where the particles interact through a Weeks-Chandler-Andersen potential. Furthermore, each particle is subject to a Gaussian, repulsive feedback potential, that depends on the difference of the particle position at the current time, and at an earlier time. We observe and quantitatively study the emergence of dynamical clustering and collective motion characterized by a nonzero mean velocity and provide a possible explanation for the underlying mechanism combining single-particle and mean-field-like effects.

Inverted Sedimentation of Active Particles in Unbiased ac Fields — •JOSÉ CARLOS UREÑA MARCOS and BENNO LIEBCHEN — Institut für Physik Kondensierter Materie, TU Darmstadt, Darmstadt, Germany

Biological microswimmers can steer autonomously and use this ability to perform sophisticated tasks. Synthetic microswimmers do not yet reach the same degree of autonomy, and need to be controlled externally if they are to carry out tasks such as targeted cargo delivery or microsurgery. While much progress has been made recently to control their motion based on external forces or gradients, e.g. in light intensity, which have a well-defined direction or bias, little is known about how to steer APs in situations where no permanent bias can be realized.

Here, we show that ac fields with a vanishing time average provide an alternative route to steering APs. We exemplify this route for inertial APs in a gravitational field, observing that a substantial fraction of them persistently travels in the upward direction upon switching on the ac field, resulting in an inverted sedimentation profile at the top wall of a confining container. Our results offer a generic control principle which could be used in the future to steer active motion, to direct collective behaviors and to purify mixtures.

Long-range communications enable the hierarchical self-organization of active matter — •IGOR ARONSON[1], ALEXANDER ZIEPKE[2], IVAN MARYSHEV[2], and ERWIN FREY[2] — [1]Pennsylvania State University, USA — [2]Ludwig-Maximilians-University, Munich, Germany

The most distinct markers of life are the ability to move (locomotion), consume energy (metabolism), process information, and form multi-cellular aggregates. Many biological systems exhibit long-range signaling strategies for evolutionary advantage. We explore the multi-scale self-organization of interacting self-propelled agents that locally process information transmitted by chemical signals. The communication capacity dramatically expands their ability to form complex structures, allowing them to self-organize through a series of collective dynamical states at multiple hierarchical levels.

The consequent study shows that information exchange by acoustic waves between the self-propelled units creates a slew of multifunctional structures. Each unit is equipped with an acoustic emitter and a detector in this realization. The swarmers respond to the resulting acoustic field by adjusting their emission frequency and migrating toward the strongest signal. We find self-organized structures with different morphology, including snake-like self-propelled entities, localized aggregates, and spinning vortices. Our results provide insights into the design principles of communicating active particles capable of performing complex tasks.

BP 7.7 Mon 17:00 ZEU 160

Arrested by heating — •CORINNA C. MAASS[1,2], PRASHANTH RAMESH[2,1], and MAZIYAR JALAAL[3] — [1]University of Twente, Enschede, Netherlands — [2]MPI for Dynamics and Self-organization, Göttingen, Germany — [3]Universiteit van Amsterdam, Amsterdam, Netherlands

Active droplets are a class of microswimmers driven by chemical reactions at the droplet interface. Typically, the activity is powered by an advection-diffusion instability in the chemohydrodynamic fields around the droplet that is characterised by the Péclet number Pe of chemical transport. With increasing Pe, higher hydrodynamic modes at the interface cause the droplet to transition from inactivity, to steady, to reorienting, to fully unsteady motion. Here, we demonstrate that it is possible to change Pe reversibly and in situ by thermally activated changes in the chemical enviroment, and thereby to control the motility of the droplet.

Chiral active particles with non-reciprocal couplings: results from particle-based simulations — •Kim L. Kreienkamp and Sabine H. L. Klapp — Technische Universität Berlin, Germany

Non-reciprocal interactions manifest their drastic impact on the collective dynamics of active matter systems by changing, for example, the general type of observed instabilities [1] and leading to time-dependent states [2,3]. In particular, the combination of non-reciprocity and chirality in terms of intrinsically rotating chiral active particles ("circle swimmers") reveals intriguing non-trivial time-dependent collective dynamics [1].

After having developed an understanding of the collective dynamics on the continuum level in previous work [1], we here present first results of particle-based simulations of chiral active particle systems with non-reciprocal alignment couplings. Indeed, quantitative predictions from continuum approaches are somewhat limited by the approximations made during the coarse-graining process. Thus, the first goal of our particle-based simulations is to explore the validity of the previously obtained continuum results regarding the overall state diagram. Second, we aim at investigating microscopic aspects of the various time-dependent states. Finally, we discuss possibilities to characterize the thermodynamic behavior of the non-reciprocal chiral system based on the stochastic trajectories obtained in particle-resolved simulations.

Lattice-induced freezing in active systems unveils dynamic crystallites with square ordering — •Aritra K. Mukhopadhyay[1], Peter Schmelcher[2,3], and Benno Liebchen[1] — [1]Technische Universität Darmstadt, 64289 Darmstadt, Germany. — [2]Zentrum für Optische Quantentechnologien, Universität Hamburg, Luruper Chaussee 149, 22761 Hamburg, Germany. — [3]The Hamburg Centre for Ultrafast Imaging, Universität Hamburg, Luruper Chaussee 149, 22761 Hamburg, Germany.

Active matter, comprising self-propelled particles like bacteria, colloidal microswimmers, or granular microflyers is currently attracting enormous attention for its ability to self-organize into complex nonequilibrium structures. In this work, we report on a new state of dynamic active crystallites, which occurs when exposing active particles to a spatially periodic potential. These crystallites require activity to emerge, adopt the structure of the underlying lattice (e.g.

square rather than hexagonal close packing), and are continuously in motion. This new phase unifies the structural properties of crystals with the dynamical properties of disordered fluids. Our work thus unveils a route to creating a new state of active materials with an intrinsic structure that can be externally controlled.

BP 7.10   Mon 17:45   ZEU 160

Shape-dependent collective motion: cohesive groups and cargo transport of colloidal rods — Philipp Stengele, •Anton Lüders, and Peter Nielaba — Universität Konstanz, Konstanz, Deutschland

In active toy model systems where colloids interact via predefined social interaction rules as well as steric collisions, the shape of the individual particles strongly influences emerging collective behavior. We study this based on two example systems using Brownian dynamics simulations (without hydrodynamic interactions). Firstly, we investigate a simple perception model in which colloidal rods move actively if predefined visual stimuli exceed a certain threshold. Here, we find an aspect ratio range where the rods form a dilute cohesive group with a time-independent particle distribution. If the aspect ratio surpasses this range, the rods slowly drift apart. Secondly, we look into the cargo capture and transport of a passive rod using a dense swarm of active spheres which form a hexagonal cage with a cavity for the cargo. Again, the aspect ratio of the rod proves to be crucial, as we find geometric restrictions that must be met to stabilize the cavity. Our work underlines that the shape (here, the aspect ratio) of the particles in active matter systems must be carefully considered while defining interaction rules to perform specific tasks.

BP 7.11   Mon 18:00   ZEU 160

Active Chiral Nematics — •Rüdiger Kürsten[1,2,3] and Demian Levis[1,2] — [1]Departament de Física de la Matèria Condensada, Universitat de Barcelona, Barcelona, Spain — [2]Universitat de Barcelona Institute of Complex Systems (UBICS), Barcelona, Spain — [3]Institut für Physik, Universität Greifswald, Greifswald, Germany

We study inherently chiral self-propelled particles in two dimensions that are subjected to nematic alignment interactions and rotational noise. By means of both, homogeneous and spatially resolved mean field theory we identify various different flocking states. We confirm the presence of the predicted phases using agent-based simulations. We emphasize that special care has to be taken within the simulations in order to avoid artifacts. We present a non-standard simulation technique in order to avoid those artifacts.

Chiral flows can drive pattern formation in viscoelastic surfaces — •Eloy de Kinkelder[1,2], Elisabeth Fischer-Friedrich[3,4], and Sebastian Aland[1,2] — [1]TU Bergakademie Freiberg, Freiberg, Germany — [2]HTW Dresden, Dresden, Germany — [3]TU Dresden, Dresden, Germany — [4]BIOTEC, Dresden, Germany

During division in animal cells, the actomyosin cortex has been found to exhibit counter-rotating cortical flows along the axis of division. These are also known as chiral flows. Notably, the chiral flows were shown to influence cellular rearrangements and drive the left-right symmetry breaking in developing organisms. At the current state, no numerical simulations have been done to study the influence of chiral flows on the cell cortex shape. To deepen the insight on that matter, we present here a numerical study of an axi-symmetric viscoelastic surface embedded in a viscous fluid. On this surface we impose a generic counter rotating force field to investigate its influence on the surface shape and material transport. Notably, we find that a large areal relaxation time results in flows towards the equator of the surface. These flows assist the transport of a surface concentration during the forming of a contractile ring. Accordingly, we show that chiral forces by themselves can drive pattern formation and stabilise contractile rings at the equator.

BP 8.2   Tue 9:45   BAR Schö

Neutrophil mechanotransduction during durotaxis — •Fatemeh Abbasi[1], Matthias Brandt[2], and Timo Betz[1] — [1]Third Institute of Physics,Biophysics, Georg August University Göttingen — [2]Institute of Cell Biology, ZMBE, University of Münster

In Vivo, cells experience complex tissue environments with various chemical and physical features. 3D confinement is one of the major physical obstacles for cells in their natural environment. Neutrophils are among the most abundant immune cells in our body, which have to cope with various physical constrictions on their way from production to the infection site. In addition to confinement, the stiffness of the microenvironment is another mechanical feature these rapidly moving cells are exposed to. Neutrophils experience various tissue stiffness, from 1 kPa (bone marrow) to 20 MPa (bone). Previous studies have demonstrated that

these cells are responsive to their microenvironment stiffness by adjusting their adhesion and spreading. Based on this knowledge we decided to combine confinement and stiffness change and investigate the impact of 3D stiffness gradient on cell behaviour and migration, a fact called durotaxis. We hypothesized that stiffness gradient might be a triggering factor of neutrophil migration toward the infection site. We confine neutrophils in between 2 layers of polyacrylamide hydrogels with 2 different stiffness and keep this distance stable for the desired period of time to investigate cell mechanotransduction during durotaxis from different points of view. Our preliminary results regarding the neutrophil durotaxis show a surprising and transient force peak on the soft substrate during cell shifting.

BP 8.3   Tue 10:00   BAR Schö

Red blood cell lingering modulates hematocrit distribution in the microcirculation — •Yazdan Rashidi[1], Greta Simionato[2], Qi Zhou[3], Thomas John[1], Alexander Kihm[1], Mohammed Bendaoud[1], Timm Krueger[3], Miguel o. Bernabeu[3], Lars Kaestner[1], Mattias w. Laschke[2], Michael d. Menger[2], Christian Wagner[1], and Alexis Darras[1] — [1]Experimental Physics, Saarland University, 66123 Saarbruecken, Germany — [2]Institute for Clinical and Experimental Surgery, Saarland University, 66421 Homburg, Germany — [3]School of Engineering, University of Edinburgh, Edinburgh EH9 3FD, United Kingdom

The distribution of red blood cells (RBCs) in the microcirculation determines how oxygen is delivered to tissues and organs. This process relies on the partitioning of RBCs at successive microvascular bifurcations. It is known that RBCs partition disproportionately to the blood flow rate, therefore leading to heterogeneity of the hematocrit in microvessels. Usually, downstream of a bifurcation, the vessel branch with a higher fraction of blood flow receives a higher fraction of RBC flux.

However, deviations from this phase-separation law have been observed in recent works. Here, we quantify how the microscopic behavior of RBCs lingering influences their partitioning, through combined in vivo experiments and in silico simulations. We quantify the cell lingering at capillary-level bifurcations and

demonstrate that it correlates with deviations from the phase-separation process from established empirical predictions by Pries et al.

Mechanical fingerprint of the intra-cellular space — •Till M. Muenker, Bart E. Vos, and Timo Betz — University of Göttingen, Göttingen, Germany
Many important cellular functions such as organelle positioning and internal cargo transport are dependent on the viscoelastic intracellular mechanical properties of cells. A range of different mechanical models has been proposed to describe these properties. Whilst simple models such as Maxwell or Kelvin-Voigt models don't seem sufficient to capture the full complexity of cells, more elaborate models like generalized Kelvin-Voigt models require a huge number of parameters. This hinders the comparison and interpretation of experimental findings. Further, from a physics perspective, cells are systems out of thermodynamic equilibrium, permanently consuming metabolic energy to carry out mechanical work. The level of "non-equilibrium" can be proposed as an indicator for cell type, cell state or even diseases. To determine both, the viscoelastic properties and the cellular activity, we use optical tweezers based active and passive microrheology in a diverse group of 9 different cell-types. Surprisingly, despite differences in origin and function, the complex moduli of all cell types can be described using a 4 parameter based fractional Kelvin-Voigt model. Additionally, the frequency dependent activity can be described with a simple power law. This approach allows to reduce those complex and frequency dependent properties down to a fingerprint of 6 parameter. Further principal component analysis shows that only 2 of them may be sufficient to characterize the mechanical intracellular state.

Microtubule Lattice Dynamics — Subham Biswas[1], Rahul Grover[2], Cordula Reuther[2], Mona Grünewald[1], Stefan Diez[2], and •Laura Schaedel[1] — [1]Saarland University, Saarbrücken, Germany — [2]TU Dresden, Germany
Microtubules are dynamic cytoskeletal filaments that grow and shrink by subunit addition or removal at their tips. In contrast, the microtubule lattice far from the tips was long considered to be static. The discovery of subunit loss and incorporation along the lattice far from the tips - termed lattice dynamics - led to a paradigm shift and revealed a new dimension of microtubule dynamics.

Microtubule lattice dynamics occur in vitro as well as in living cells and contribute to microtubule organization and resilience to mechanical stress. Yet, it is largely unknown which cellular mechanisms are involved in their regulation. Recent discoveries suggest that microtubule-associated proteins (MAPs), which control a variety of properties of intracellular microtubules, are a key factor in the regulation of lattice dynamics. Here, we take a closer look at MAP-regulated microtubule lattice dynamics.

Force generation in human blood platelets by filamentous actomyosin structures — •Anna Zelena[1], Johannes Blumberg[2], Ulrich S. Schwarz[2], and Sarah Köster[1] — [1]Institute for X-Ray Physics, Georg-August-University of Göttingen, Germany — [2]Institute for Theoretical Physics, University of Heidelberg, Germany
Blood platelets are central elements of the blood clotting response after wounding. Upon vessel damage, they adhere to the surrounding matrix of the vessel and contract the emerging blood clot, thus helping to restore normal blood flow. The blood clotting function of platelets has been shown to be directly connected to their mechanics and cytoskeletal organization. The reorganization of the platelet cytoskeleton during spreading occurs within minutes and leads to the formation of contractile actomyosin bundles, but it is not known how this structure formation corresponds to force generation. In this study, we combine fluorescence imaging of the actin structures with traction force measurements in a time-resolved manner. We find that force generation is localized in few hotspots, which spatially align very closely with the visualized end points of the fibrous actin structures and do not change much with time. Moreover we show that force generation is a very robust mechanism independent of changes in the amount of added thrombin in solution or fibrinogen coverage on the substrate, suggesting that force generation after platelet activation is a threshold phenomenon that ensures reliable blood clot contraction in diverse environments.

How to build muscle? Sarcomeric pattern formation by non-local interactions — •Francine Kolley[1,2], Clara Sidor[3], Frank Schnorrer[3], and Benjamin M. Friedrich[1,2] — [1]Physics of Life, TU Dresden — [2]cfaed, TU Dresden — [3]IBDM,Aix Marseille University
Striated muscles drive all voluntary movements and are highly organized in crystal-like structures, comprising different filament types on a micrometer scale. The specific size of a sarcomere is set by the giant protein titin. Titin links the molecular motor myosin in the middle of a sarcomere to the so-called Z-disc, which is rich in actin crosslinkers at the sarcomere boundary. Despite the impor-

tance of the repeated structures of theses sarcomeres for muscle functionality, it is poorly understood how they self-assemble during muscles development.To investigate this question, we introduce theoretical models based on putative mechanism. We can show with a minimal Mean-field model that a non-local interaction between the key proteins is sufficient for the emergence of periodic patterns. Agent-based simulations of this model reveal the influence of small-number fluctuations. We can expand this model to include additional properties, such as different myosin bindings or the catch-bond behavior of the Z-disc crosslinker α-actinin. In addition, from analyzing images of the *Drosophila* flight muscles during early developmental stages, provided by Schnorrer Lab, we are able to identify α-actinin and titin as the first proteins forming periodic patterns with myosin, while actin follows later, constraining possible models.

Impact of oxidative stress on the mechanical properties of isolated mitochondria — •Yesaswini Komaragiri[1,2], Muzaffar H Panhwar[1,2], Bob Fregin[1,2], Gayatri Jagirdar[3], Carmen Wolke[3], Stefanie Spiegler[1,2], and Oliver Otto[1,2] — [1]Institut für Physik, Universität Greifswald, Friedrich-Ludwig-Jahn-Str. 15a, 17489 Greifswald, Germany — [2]DZHK, Greifswald, Universitätsmedizin Greifswald, Fleischmannstr. 42, 17489 Greifswald, Germany — [3]Universitätsmedizin Greifswald, Ferdinand-Sauerbruch-Strasse, 17475 Greifswald, Germany
Mitochondria are essential in various physiological processes, including the homeostasis of reactive oxygen species (ROS) as key intracellular signaling molecules. While it is already established that mechanical properties are a crucial parameter in characterizing and comprehending biological systems such as cells and tissues, little is known about the significance of organelle mechanics for cell function. Here, we demonstrate the application of real-time fluorescence and deformability cytometry for the label-free and high-throughput analysis of mitochondria isolated from C6 glial cells. Our data on several thousands of viable mitochondria indicate that their deformation is shear stress dependent. We studied the effect of exogenously and endogenously generated ROS on mitochondria mechanics in two proof-of-concept studies. Under both conditions, we observed a decrease in size while the deformation increased relative to a control condition. The results suggest a general biophysical mechanism of how mitochondria respond to oxidative stress.

New applications for the direct method in 3D traction force microscopy — •Johannes Blumberg[1,2], Simon Brauburger[1,2], and Ulrich Schwarz[1,2] — [1]Institute for Theoretical Physics, Heidelberg University — [2]Bioquant, Heidelberg University
Traction force microscopy (TFM) estimates the mechanical forces of cells adhering to an elastic substrate by measuring by the movement of embedded marker beads. It has become a standard tool to study the mechanobiology of single cells or cell monolayers on flat two-dimensional (2D) substrates, but three-dimensional (3D) setups provide new challenges. Although the inverse method of force inference by minimization of a loss function has become the standard method for 2D TFM, for 3D TFM the direct method of directly calculating stress and surface traction from strain becomes an attractive alternative, for example when performing 3D TFM with elastic beads in organisms, tumor spheroids or organoids. We explain how this method works in practice and how it compares to the inverse method.

Profilin Regulating the Polymerisation Velocity of Actin — •Lina Heydenreich and Jan Kierfeld — TU Dortmund University, 44227 Dortmund, Germany
F-Actin, as a part of the cytoskeleton, drives crucial biological processes like cell motility, where the control of the polymerisation speed is essential. Experiments in [1] show a maximal polymerisation speed of F-actin at high concentrations of profilin and actin.

We present a kinetic model of F-actin growth in the presence of profilin and obtain an exact result for the mean growth velocity which is in agreement with stochastic simulations, and explains the experimental data. The maximal growth speed is limited by the release rate of profilin from filamentous actin. In the limit where nearly all actin monomers are bound to profilin, the polymerisation speed follows the Michaelis-Menten kinetics.

By analysing the presented model, we can examine the influence of an external force and the influence of profilin on the fluctuations and precision of the polymerisation. Additionally we can give constraints on the concentrations to obtain a saturation of the growth velocity.

Development of a platform for accessing the membrane tension of cells in microchannels — •Eric Sündermann, Bob Fregin, Doreen Biedenweg, Stefanie Spiegler, and Oliver Otto — ZIK HIKE, University of Greifswald, Greifswald, Germany

The development of high-throughput methods for cell mechanical research is becoming increasingly important in biology, medicine and physics as the analysis of large samples opens up possibilities for basic science and clinical use. Currently, various techniques are available, but hardly any can discriminate between membrane and bulk contributions to the mechanical properties of a cell.

Here, we combined deformability cytometry with fluorescence lifetime imaging microscopy (FLIM) to study the response of membrane tension to hydrodynamic stress. Myeloid precursor cells were first stained with Flipper-TR®, a fluorescent dye with a lifetime proportional to the membrane tension, and then flushed through the constriction of a microfluidic chip, where they deform under a shear stress. Under steady-state conditions, our data shows that the membrane tension of cells increases with increasing hydrodynamic stress, as expected. Exposing cells to methyl-ß-cyclodextrin to reduce the amount of cholesterol in the cell membrane leads to a reduction in membrane tension while the bulk Young's modulus is not affected.

These results highlight the potential of microfluidic technologies to quantify the contribution of different cell components to its overall mechanical phenotype.

Gliding motility and reorientation of flagellated microbes on curved surfaces — •Alexandros Fragkopoulos[1], Nicolas Fares[1,2], and Oliver Bäumchen[1] — [1]University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — [2]University of Bordeaux, CNRS, LOMA, UMR 5798, 33400 Talence, France

The model organism *Chlamydomonas reinhardtii*, a unicellular biflagellated microalga, can adhere and colonize almost any surface under particular light conditions. Once the cells attach to a surface, an intraflagellar transport machinery translocates the cell body along the flagella, which are oriented in a 180° configuration. This motion is known as gliding motility. Even though the cells firmly adhere to surfaces, they are able to reorient through different physical mechanisms [1]. With the use of the orientation autocorrelation function, we find that cells exhibit large reorientation events shortly after their initial attachment to a surface, while at longer time scales they are primarily constrained to 1D motion. On cylindrical surfaces, the large reorientations cause the cells to predominantly align in the direction of the minimum principle curvature. We quantify the curvature-induced alignment using the nematic order parameter and reveal that the minimum surface curvature required for cell alignment is comparable to the static flagella curvature.

Efficiency of navigation strategies for active particles — •Lorenzo Piro[1], Ramin Golestanian[1,2], and Benoit Mahault[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford, United Kingdom

Optimal navigation in complex environments is a problem with multiple applications ranging from designing efficient search strategies to engineering microscopic cargo delivery. When motion happens in presence of strong external forces, route optimization is particularly important as active particles may encounter trapping regions that would substantially slow down their progress.

Here, considering a self-propelled agent moving at a constant speed, we study the efficiency of Zermelo's classical solution. Investigating both cases of motion on the plane and on curved surfaces, we focus on the regime where the external force exceeds self-propulsion in finite regions. There, we show that, despite the fact that most trajectories following the trivial policy of going straight get arrested, the Zermelo policy allows for a comprehensive exploration of the environment.

However, our results also indicate an increased sensitivity of the Zermelo strategy to initial conditions, which limits its robustness and long-time efficiency, particularly in presence of fluctuations. These results suggest an interesting trade-off between exploration efficiency and stability for the design of control strategies to be implemented in real systems.

BP 9.3 Tue 10:00 TOE 317
Run with the Brownian Hare, Hunt with the Deterministic Hounds — •Davide Bernardi[1] and Benjamin Lindner[2,3] — [1]Italian Institute of Technology, Ferrara, Italy — [2]Bernstein Center for Computational Neuroscience, Berlin, Germany — [3]Institut für Physik, Humboldt-Universität zu Berlin

Pursuit and evasion are vital to most animal species and play an important role in many human activities. Traditionally, chase-and-escape models have been studied in the framework of game theory, or in detailed models that can be studied only through numerical simulations and that lack generalization power.

Here, we present analytic results for the mean time and energy used by a pack of deterministic hounds to capture a prey that undergoes Brownian diffusion. Depending on the number of chasers, we find that the mean capture time as a function of the prey's diffusion coefficient can be monotonically increasing, decreasing, or attain a minimum at a finite value. Furthermore, an optimal speed and number of chasing hounds exist, that depend on the baseline power consumption and drag coefficient of each chaser.

The present model can be seen as an analytically tractable basis for the theoretician's perspective on the growing field of smart microswimmers and autonomous robots.

Function of Morphodynamics in Foraging *Physarum polycephalum* — •Lisa Schick[1], Mirna Kramar[2], and Karen Alim[1] — [1]School of Natural Sciences, Technical University of Munich, Germany — [2]Institute Curie, Paris, France

How network-forming fungi structure and reorganize their network morphology and thereby the carbon flows in the soil is key to understanding climate - yet hidden from us due to the long time scales of network dynamics and the soil itself. Here, the network-forming slime mold *Physarum polycephalum* serves as a model of network dynamics of a foraging network-forming life. We follow and quantify the network migration velocity and morphology of foraging *P. polycephalum*. We identify three distinct morphological states characterized by network compactness and density of moving fronts. Estimating the energetic cost of distinct states, we find that morphological variability allows the organism to balance the energetic costs of foraging and search strategy. Our observations allow us to project how resource availability might shift the balance and thereby affect network extension in foraging network-forming organisms.

BP 9.5 Tue 10:30 TOE 317
Unraveling the migratory behavior of a large single-celled organism — •Lucas Tröger, Florian Goirand, and Karen Alim — School of Natural Sciences, Technical University of Munich, Germany

Many cells face search problems, such as finding food, conspecifics, or shelter, and different search strategies can provide different chances for success. In contrast to most single-celled organisms the slime mold *Physarum polycephalum* forms a giant network-shaped cell while foraging for food. Which advantage does the giant cell at the verge to multicellularity provide? We experimentally investigate and quantify the long-time migratory behavior of small networks of *P. polycephalum* in the absence and in the presence of food, and develop a simple mechanistic model that successfully describes its migration. We find that *P. polycephalum* performs a run-and-tumble-like motion modified by self-avoidance to achieve superdiffusive migration. Furthermore, it tunes its short-time dynamics in order to adapt to environments with different amounts of available nutrients, while its long-time dynamics remain unchanged. This work shows how *P. polycephalum* controls the inherent stochasticity of its movement by simple rules, which may represent an evolutionary advantage.

BP 9.6 Tue 11:00 TOE 317
Controlling active turbulence by activity patterns — •Arghavan Partovi-fard, Josua Grawitter, and Holger Stark — Institute of Theoretical Physics, Technische Universität Berlin, Hardenbergstraße 36, 10623 Berlin, Germany

Active fluids exhibit spontaneous and chaotic flow patterns which are known as active turbulence [1]. One of the current challenges in active matter is controlling and harnessing these flow patterns for powering processes at small scales [2]. As a simple realization of an active fluid, we consider a semi-dilute solution of active rods and study it within a numerical simulation of the governing equations that are formulated in terms of velocity and the orientational order tensor parameter fields.

We find that for a solution of pusher active rods there is a critical magnitude of activity above which the initially isotropic solution develops locally varying nematic order and turbulent-like fluid flow. Aiming to control the turbulent flow state, we pattern the activity with a square lattice of circular inactivity spots. We find that for a specific range of lattice parameters the flow field develops lanes of unidirectional flow with alternating directions while between them a row of corotating vortexes emerges; We call this state the laning state and it is multistable since different realizations of the random initial state of rods lead to dif-

ferent configurations of the laning state with various widths of the lanes. In this state, the director field develops nematic domains oriented toward the Leslie angle with respect to the flow.

Active matter: From spontaneous to controlled phenomena. — •DANIEL PEARCE — University of Geneva
Active matter is the study of materials able to move themselves. During this talk I will discuss how we can take advantage of the interplay between topological defects, geometry and topology to exercise control over active materials. By studying active nematic fluids on a curved surface, we can influence the position and orientation of topological defects according to their charge. This means specific nematic textures can be generated. By studying active contractile actomyosin gels, it is possible to show that only active topological defects with charge +1 can generate curvature, and the sign is related to the phase of the defect. This frees the process from the constraints of the Poincare-Hopf theorem and allows complex surfaces to be generated. This is demonstrated by recreating the shape of a freshwater hydra from the positions of the topological defects

BP 9.8   Tue 11:30   TOE 317
Nucleation of chemically active droplets — •NOAH ZIETHEN and DAVID ZWICKER — Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany
Liquid-liquid phase separation emerged as a crucial organizing principle inside biological cells giving rise to a plethora of intracellular compartments. Unique to the cellular context, these condensates can consist of only a few hundred molecules and are affected by non-equilibrium processes. In particular, active chemical conversion between condensate material and proteins in the surrounding cytoplasm can control multiple aspects of the condensates. Yet, it is unclear how these reactions affect the spontaneous nucleation and dissolution associated with low particle numbers. Here, we investigate the influence of chemical reactions on the bistable region of active droplets using a stochastic field theory. We find an effective increase in the energy barrier and thus decelerated transitions between the homogeneous and the droplet state. Using classical nucleation theory, we approximate the full dynamics by diffusion in a free energy potential described by an analytical expression only depending on droplet radius and reaction rate. This analogy also allows us to determine the equivalence of the binodal line, so we can propose an extension of the equilibrium phase diagram to capture driven chemical reactions. Cells might use these effects to control the nucleation of intracellular droplets.

BP 9.9   Tue 11:45   TOE 317
Hydrodynamic description and transport coefficients in a model of active cellular aggregates — •SUBHADIP CHAKRABORTI[1,2] and VASILY ZABURDAEV[1,2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [2]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany
Complex multicellular aggregates consisting of a large number of interacting cells are ubiquitous in biology, ranging from bacterial biofilms to organoids, cell spheroids, and tumors. We consider colonies of *N. gonorrhoeae* bacteria as a prototypical example of cells that use retractile cell appendages to actively interact with a substrate and with each other. We construct a microscopic model on a 1D lattice taking into account the non-equilibrium bacterial motility driven by two crucial forces – cell-substrate and cell-cell interactions. We observe a

phase transition from a homogeneous state to a clusterized state upon tuning the density and activity parameters. Using macroscopic fluctuation theory (MFT), we analytically derive hydrodynamics for the model system and calculate two density-dependent transport coefficients – the bulk-diffusion coefficient and the conductivity. The behavior of these transport coefficients successfully explains the non-equilibrium phase transition. We support our analytical findings with the results obtained numerically. Our theory provides a general framework for studying the non-equilibrium collective behavior of other dense cellular aggregates also, in the context of dynamics and their transport properties.

BP 9.10   Tue 12:00   TOE 317
Flocking of unfriendly species: The two-species Vicsek model — •SWARNAJIT CHATTERJEE[1], MATTHIEU MANGEAT[1], CHUL-UNG WOO[2], HEIKO RIEGER[1], and JAE DONG NOH[2] — [1]Saarland University, Saarbrücken, Germany — [2]University of Seoul, Seoul, Korea
We consider the two-species Vicsek model (TSVM) consisting of two kinds of self-propelled particles, A and B, that tend to align with particles from the same species and to anti-align with the other. The model shows a flocking transition that is reminiscent of the original Vicsek model [1]: it has a liquid-gas phase transition and displays micro-phase separation in the coexistence region where multiple dense liquid bands propagate in a gaseous background. The novel feature of the TSVM is the existence of two kinds of bands, one composed of mainly A-particles and one mainly of B- particles and the appearance of two dynamical states in the coexistence region: the PF (parallel flocking) state in which all bands of the two species propagate in the same direction, and the APF (anti-parallel flocking) state in which the bands of species A and species B move in opposite directions. When PF and APF states exist in the low-density part of the coexistence region they perform stochastic transitions from one to the other. The system size dependence of the transition frequency and dwell times shows a pronounced crossover that is determined by the ratio of the band width and the longitudinal system size. Our work paves the way for studying multispecies models with heterogeneous alignment interactions.

BP 9.11   Tue 12:15   TOE 317
Two-potential model for molecular motors — •SOPHIE KLEMPAHN and HELMUT SCHIESSEL — Cluster of Excellence Physics of Life, Technical University of Dresden, Germany
Molecular motors are highly efficient biological machines, which drive systems away from equilibrium and realise key biological processes. For the description of the molecular motor action, discrete jump processes as well as energy barriers with height differences can be used. However, these models are based on symmetric conditions or unidirectional motion and therefore do not capture real biological systems with fuel gradients or where the motion is not unidirectional. To predict the effect of molecular motors on the density distribution of cargo particles in one dimension, we introduce a two potential model. This model represents the cargo particles as active particles, in which the binding of molecular motors to the cargo particle causes the active part of motion. Furthermore, we use two different energy landscapes for jumps to the left or right side, to include motors moving back- and forward, asymmetric environment or two different molecular motors acting on the same cargo particle in different directions. The solution of a master equation with different energy landscapes for jumps to the left and right side results in specific extremal points in the probability density of the cargo particles and shows a ratchet effect in case of periodic potentials.

BP 10: Evolution and Origin of Life

Invited Talk   BP 10.1   Tue 9:30   BAR 0106
Protein evolution in sequence landscapes: from data to models and back — •MARTIN WEIGT — Sorbonne University, Paris, France
In the course of evolution, proteins diversify their sequences via mutations, while keeping their 3D structure and biological functions remarkably conserved. Modern sequence databases provide us with increasingly large samples for this sequence diversity. In my talk, I will describe how these samples can be used to infer data-driven protein sequence landscapes, using approaches borrowed from statistical physics or machine learning. In turn, we can model the interplay between mutation and selection in protein evolution as a stochastic process in these landscapes. I will illustrate these ideas in three examples: (i) the prediction of the effect of individual mutations in proteins, (ii) the modeling of experimental protein evoltuion, and (iii) the statistical design of artificial but functional proteins.

BP 10.2   Tue 10:00   BAR 0106
Non-equilibrium approaches to the origin of life — THOMAS MATREUX[1], PAULA AIKKILA[1], CORINNA KUFNER[2], DOMINIK BUCHER[3], ALMUTH SCHMID[1], WOLFGANG ZINTH[1], DIETER BRAUN[1], and •CHRISTOF MAST[1] — [1]LMU, Munich, Germany — [2]Harvard, Cambridge, USA — [3]TUM, Munich, Germany
Life is an out-of-equilibrium process, so its emergence must also have been decisively shaped and driven by the non-equilibrium systems present 4 billion years ago. We investigated how simple heat fluxes through geological networks of interconnected chambers created chemical niches from complex mixtures of prebiotically relevant substances, each with different prevailing concentration ratios. These "micro-labs" could thus enable a wide variety of prebiotic reactions and massively increase their yield and selectivity compared to bulk systems. We further measured the sequence selectivity of UV radiation on pseudo-genomes built from subsets of codon sequences. Comparison with existing chronologies for codon and amino acid evolution suggests the importance of UV light as a selection pressure during the evolution of early life.

BP 10.3 Tue 10:15 BAR 0106

Unpredictable repeatability in evolutionary dynamics — •Suman Das and Joachim Krug — Institute for Biophysics, University of Cologne, Germany

Biological evolution proceeds through occurrence and fixation of mutations. But how repeatable are evolutionary trajectories? Is the evolution of specific well-adapted genotypes largely a matter of chance, or should we expect the same genotypes to evolve repeatedly? The answer depends in part on the probability distribution of mutational effect sizes. Repeatability is itself a random variable, and for light-tailed distributions it converges to its mean value in the limit of a large number of available mutations. However, for heavy-tailed distributions, we show that the repeatability is much higher but the distribution remains broad, and consequently the repeatability cannot be predicted based on the distribution. This non-self averaging effect is similar to those observed in certain disordered systems, and arises from the fact that the fixation process is dominated by a few mutations even in the limit of infinite mutation number. We discuss the behavior in various heavy-tailed regimes, and illustrate it with applications to empirical data on drug resistance evolution.

BP 10.4 Tue 10:30 BAR 0106

Kinetics of Information Content in a Virtual Circular Genome — •Ludwig Burger, Tobias Thun, and Ulrich Gerland — Technical University of Munich

We study the kinetics of information content in an ensemble of oligonucleotides that undergo hybridization, dehybridization, non-enzymatic templated ligation and single-strand cleavage. The stability of hybridized complexes depends on the sequence because the dehybridization rate depends on the free hybridization energy. Mismatches are possible, but they lead to a thermodynamic and kinetic penalty. The information that is supposed to be "stored" in the ensemble is a circular genome as well as its complementary strand. Therefore, the oligonucleotides in the initial ensemble are chosen such that every element in the ensemble is part of the true genomic sequence. In most investigated scenarios, the initial ensemble loses its information content and no information amplification can be observed. Depending on the choice of ligation and cleavage rate, the loss of information can be driven by cleavage or ligation. Information loss by ligation is caused by templated ligation processes that produce long strands that do not resemble the true genomic sequence. This is the case if the hybridization site is too short or contains too many mismatches to guarantee correct alignment of template and ligated strands. Even though information amplification appears to be difficult to achieve, the timescale of information loss can be extended by tuning the hybridization energy or the concentration of short oligomers.

BP 10.5 Tue 11:00 BAR 0106

Evolutionary rescue of resistant mutants is governed by a balance between radial expansion and selection in compact populations — Serhii Aif[1,2], Nico Appold[1,2], Lucas Kampmann[3], Oskar Hallatschek[3,4], and •Jona Kayser[1,2] — [1]MPI für die Physik des Lichts, Erlangen, Germany — [2]MPZ für Physik und Medizin, Erlangen, Germany — [3]University of California, Berkeley, USA — [4]Leipzig University, Leipzig, Germany

Mutation-mediated treatment resistance is one of the primary challenges for modern antibiotic and anti-cancer therapy. Yet, how slower-growing resistant lineages may escape purifying selection via continued evolution is still unclear. Here, we introduce a system of fluorescence-coupled synthetic mutations to track the entire evolutionary trajectory of thousands of resistant lineages in expanding yeast colonies. We uncover that an underlying quasi-stable equilibrium between the opposing forces of radial expansion and natural selection, a phenomenon we term inflation-selection balance, enhances the evolutionary rescue of resistant lineages. Tailored computational models and agent-based simulations corroborate the fundamental nature of the observed effects and demonstrate the potential impact on drug resistance evolution in cancer. The described phenomena should be considered when predicting multi-step evolutionary dynamics in any mechanically compact cellular population, including pathogenic microbial biofilms and solid tumors. The insights gained will be especially valuable for the quantitative understanding of response to treatment, including emerging evolution-based therapy strategies.

BP 10.6 Tue 11:15 BAR 0106

Heat flows drive ionic and pH gradients — •Thomas Matreux[1], Almuth Schmid[1], Paula Aikkila[1], Kristian Le Vay[2], Johannes Raith[3], Bernhard Altaner[3], Bettina Scheu[4], Ulrich Gerland[3], Hannes Mutschler[2], Dieter Braun[1], and Christof B. Mast[1] — [1]Systems Biophysics, LMU Munich, Germany — [2]Biomimetic systems, TU Dortmund, Germany — [3]Physics of Complex Biosystems, TU Munich, Germany — [4]Earth and Environmental Sciences, LMU Munich, Germany

The first steps in the emergence of life on Earth occurred on rocks and their constituent phases with a feedstock of simple molecules. Our aim is to combine this background with physical non-equilibria such as thermal gradients, offering unique opportunities for molecular selection on all levels.

In this scenario, ions leached from mineral samples are selectively accumulated by heat flows through water-filled fractures. In contrast to up-concentration by dehydration or freezing, this actively alters the Magnesium:Sodium ratio to an extent that permits key ribozyme activities.

Simple mixtures of formic acid and sodium hydroxide, exposed to thermal gradients, drive pH gradients which can be understood and predicted by a separation of timescales. Such proton gradients can locally acid-dissolve Apatite, a presumably abundant phosphate mineral that is close to insoluble at physiological pH. By thermal fractionation, significant concentrations of phosphate are provided at neutral pH.

BP 10.7 Tue 11:30 BAR 0106

Evolution Mechanics: a Framework of Hierarchy Formation in Evolving Systems — •Yunus Sevinchan — Science of Intelligence Cluster, Technische Universität Berlin, Berlin, Germany — Institute for Theoretical Biology, Humboldt-Universität zu Berlin, Berlin, Germany — Institute of Environmental Physics, Universität Heidelberg, Heidelberg, Germany

The structures we observe around us are of a wide diversity and complexity, ranging from simple cells to intricate ecosystems and human societies. The question how these hierarchically modularized structures can arise from simpler ones is of central importance when desiring to understand our world.

I present the Evolution Mechanics framework [1] which aims to find a concise description of the mechanisms by which evolutionary systems unfold into hierarchically organized modules. Key elements of this conceptual framework are a so-called Self-Replicator and a set of processes that need to occur in order for an Evolutionary Transition in Individuality to take place, thus leading to a new hierarchical level. While inspired by the evolution of biological life, Evolution Mechanics is abstracted from it and takes a more general perspective, providing a consistent language to address the fundamental processes giving rise to the complexity we observe.

Sequence distributions in coexisting phases — •Ivar Svalheim Haugerud[1], Giacomo Bartolucci[2], and Christoph A. Weber[1] — [1]University of Augsburg, Augsburg, Germany — [2]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Phase separation, sequence, and length distributions of heteropolymers such as RNA and DNA are essential in regulating functions and spatial organization in living cells and at the molecular origin of life. Here, we theoretically investigate the interplay between phase separation, polymer sequence, and length at non-dilute conditions. To this end, we developed a thermodynamic description for the reversible polymerization of different monomeric units. In the model, polymers can grow, shrink and phase separate from each other and the solvent. We show that growth in length facilitates phase separation already at low concentrations. Our key finding is that the distribution of sequences is entirely different in each phase. These results suggest that condensed phases can act as hubs for functionalities that rely on the sequence-specificity of RNA or DNA.

BP 10.9 Tue 12:00 BAR 0106

Controlling Alkaline Vent Morphologies in Microfluidic Models by pH and Fluid Flow — •Maximilian Weingart[1], Siyu Chen[2], Clara Donat[2], Dieter Braun[1], and Karen Alim[2] — [1]Systems Biophysics, Ludwig-Maximilians Universität München, Amalienstraße 54, 80799 München, Germany — [2]CPA and Department of Biosciences, School of Natural Sciences, Technische Universität München, Ernst-Otto-Fischer-Straße 8, 85748 Garching b. München, Germany

Alkaline vents provide the unique chemical composition for the precip- itation of alkaline fluids in acidic, metal-ion containing ocean water, thereby providing the necessary gradients to drive molecular reactions at the origin of life. Yet, the 3D chimney-like structure of vents pre- vents any visualization of potentially reaction fueling gradients. Here, we develop a microfluidic model of alkaline vents permitting spatio-temporal visualization of precipitate formation and morphology. Varying concentration and inflow rate of an alkaline solution into a flat microfluidic-chamber pre-filled with an acidic Fe(II)-solution we observe a diverse set of precipitate morphologies. Visualizing the pre- cipitation pattern we identify for which physical parameter vent mor- phologies allow for gradients in pH and molecular composition to arise. We establish our microfluidic model as a framework to investigate the potential of gradients across a permeable bound- ary for early compart- mentalisation and molecular reactions at the Origin of life. The 2D microfluidic alkaline vent model shows that disordered precipitate mor- phologies allow for the formation of strong pH gradients.

Reinforcement Learning: Optimizing Target-search in a homogeneous environment — •Harpreet Kaur, Michele Caraglio, and Thomas Franosch — Institute for Theoretical Physics, Universität Innsbruck, Innsbruck, Austria.

The target-search problem is an interdisciplinary problem comprising several scales, ranging from bacteria looking for food to robots collecting garbage. Generally, in target search we make decisions in an uncertain and often complex environment with the aim of finding a target as efficiently as possible. The key feature that efficient searching agents have in common is the ability to self-propel. Being able to develop efficient search strategies is crucial, as the time needed to discover a target is often a limiting resource. Here, we address the problem of how a smart microswimmer finds a randomly located target in a homogeneous environment by resorting on machine-learning techniques, particularly Reinforcement Learning. We aim to show that learned strategies are optimal and enable minimization of the search time. Also, our work will provide a better understanding of bacteria behavior and biological foraging.

BP 11.2   Tue 12:30   P1

A study of bacteria entrapment using multiparticle collision dynamics — •Pierre Martin and Holger Stark — Technische Universität, Berlin, Germany

The purpose of the current study is to investigate entrapment of bacteria near surfaces. Mechanisms to control trapping of bacteria near solid surfaces is of utmost interest to many medical and biotechnological applications. Trapping leads to enhanced attachement, facilitates the proliferation of cells and ultimately the formation of bacterial biofilms on the surface. Bacteria such as Escherichia coli (E. coli) propel themselves by rotating a bundle of helical flagella. They can change direction by reversing the rotation of a flagella, a process known as tumbling. The motion of bacteria near surfaces induces hydrodynamic interactions with the substract, aligning the cell almost parallel to the surface. This creates an attractive force from the bacteria to the surface, moving and trapping the bacteria along it.

We currently implement a realistic model of E. coli including its tumbling motion within a computer code where we couple it to fluid flow at low Reynolds numbers. The fluid flow is simulated using the method of multi-particle collision dynamics, an efficient solver of the Navier-Stokes equations. Our first goal is to simulate non-tumbling numerical strain of E.coli under shear flow. We will analyse the importance of rheotaxis and Jefferey orbits for near surfaces motility and trapping.

BP 11.3   Tue 12:30   P1

Collective dynamics of multicellular systems in curved geometries — •Tom Brandstätter[1,2], David Brückner[3], YuLong Han[4], Ricard Alert[5], Ming Guo[4], and Chase Broedersz[1,2] — [1]Arnold-Sommerfeld-Center for Theoretical Physics, Ludwig-Maximilians-Universität München — [2]Department of Physics and Astronomy, Vrije Universiteit Amsterdam — [3]Institute of Science and Technology Austria — [4]Department of Mechanical Engineering, Massachusetts Institute of Technology — [5]Max Planck Institute for the Physics of Complex Systems

The multicellular organization of diverse systems, including embryos, intestines, and tumors relies on coordinated cell migration in curved environments. In these settings, cells establish supracellular patterns of motion, including collective rotation and invasion. While such collective modes are increasingly well understood in 2D flat systems, the consequences of geometrical and topological constraints on collective cell migration in 3D curved tissues are largely unknown. Here, we discover a collective mode of cell migration in rotating spherical tissues manifesting as a propagating single-wavelength velocity wave. This wave is accompanied by a pattern of incompressible cellular flow across the spheroid surface featuring topological defects. Using a minimal active particle model, we reveal that this collective mode originates from the active flocking behavior of a cell layer confined to a curved surface. Our results identify curvature-induced velocity waves as a generic active matter mode, impacting the dynamical organization of 3D curved tissues.

Self-propulsion of Janus particles at small laser powers and the impact of salt — •Franziska Braun and Regine von Klitzing — Institute for Condensed Matter Physics, Technische Universität Darmstadt, D-64289 Darmstadt

The anisotropy in the architecture allows Janus particles to create an out-of-equilibrium state around the particle in the solvent, which is a necessary condition for triggering self-propulsion. One possible propulsion mechanism is thermophoretic self-propulsion. When laser light (λ = 532 nm) illuminates a gold-capped particle, a local temperature gradient is generated along the particle surface due to surface plasmon excitation of the gold cap. This gradient perturbs the equilibrium conditions of the surrounding medium and leads to self-propulsion.

This contribution focuses on an intensive study of the self-propulsion behavior of self-thermophoretic Janus particles. For this purpose, the movement of the Janus particles is tracked in real-time with dark-field microscopy (DFM). First, the thermophoretic velocity of Au-PS particles is investigated focusing on very low laser powers below 10 mW. Surprisingly, the study shows a deviation of the thermophoretic velocity from the expected linear behavior in the low laser power regime. Secondly, the influence of salt ions on the self-propulsion behavior of such Au-PS particles is described.

BP 11.5   Tue 12:30   P1

An omnipresent material that still suprises: Anomalous stress relaxation of polydimethylsiloxane (PDMS) — Philipp Lach, Erdem Bondan, Pierre-Louis Cramer, Nan Xue, Robert W. Style, Stefanie Heyden, •Charlotta Lorenz, and Eric R. Dufresne — Department of Materials, ETH Zürich, Vladimir-Prelog-Weg 1-5/10, 8093 Zürich, Switzerland

Polydimethylsiloxane (PDMS) is an elastomer which finds ubiquitous use as a model system in experimental settings, as well as in engineering applications. It is easy to fabricate and tune over a large stiffness range. Recent applications in soft robotics have stimulated a closer look at its mechanical properties. Here, we report anomalous responses of PDMS networks to deformation. In one set of experiments, PDMS becomes stiffer after repeated cycles of deformation. In another, PDMS has a non-monotonic stress relaxation in response to a step-strain. Together, these results suggest a mechano-chemical coupling in PDMS where deformed networks are capable of forming new cross-links.

Complex formation between Polyethylenimine and mRNA — •Jonas Lehnen[1], Giovanni Settanni[2], and Friederike Schmid[1] — [1]KOMET 1, Institute of Physics, JGU Mainz, Germany — [2]Faculty of Physics and Astronomy, Ruhr University Bochum, Germany

Messenger RNA vaccines have proven invaluable in the fight against the COVID-19 pandemic. Among the vehicles for non-viral gene delivery Polyethylenimine (PEI) has attracted attention due to its high transfection efficiency. PEI binds to negatively charged mRNA forming polyplexes. These are nanoparticles (NP) of different sizes, depending on the pH used for their assembly as well as salt, PEI and RNA concentration. Small NP have been shown to be critical for high transfection efficiency. We use coarse-grained molecular dynamics simulations to examine the effects of the various factors determining polyplex size and gain a better understanding of the processes involved in their formation, with a special interest on the effects of PEI concentrations way above the amount necessary to neutralize the mRNA, following up on recent experimental results. Experimental and atomistic simulation data were used to tune our model with the aim of finding the mechanism responsible for controlling the size of NPs and give a description of the formation process.

BP 11.7   Tue 12:30   P1

Long-Term Stability, Biocompatibility and Magnetization of Suspensions of Isolated Bacterial Magnetosomes — F. Mickoleit[1], C. Jörke[2], •R. Richter[3], S. Rosenfeldt[4], S. Markert[1], I. Rehberg[3], A. S. Schenk[5], O. Bäumchen[3], D. Schüler[1], and J. H. Clement[2] — [1]Dept. Microbiology, University of Bayreuth, D-95447 Bayreuth, Germany — [2]Dept. Hematology and Medical Oncology, Jena University Hospital, D-07747 Jena, Germany — [3]Experimental Physics V, University of Bayreuth, D-95447 Bayreuth, Germany — [4]Physical Chemistry I, University of Bayreuth, D-95447 Bayreuth, Germany — [5]Physical Chemistry - Collidal Systems, University of Bayreuth, D-95447 Bayreuth, Germany

Magnetosomes are magnetic nanoparticles biosynthesized by magnetotactic bacteria. Due to a genetically strictly controlled biomineralization process, the ensuing magnetosomes have been envisioned as agents for biomedical and clinical applications. In the present work, we examine the stability parameters of magnetosomes isolated from *Magnetospirillum gryphiswaldense* upon storage as a suspension in a buffer solution at 4°C and N_2 atmosphere for one year in the absence of antibiotics. The magnetic potency, measured by the saturation magnetization of the particle suspension [1], drops by 2/3 within this year - about ten times slower than at ambient air and room temperature. The particle size distribution, the integrity of the surrounding magnetosome membrane, the colloidal stability, and the biocompatibility turn out to be not severely affected by long-term storage. — [1] Mickoleit F., et al. (2018). ACS Appl. Mater. Interfaces 10(44), 37898.

The change of DNA radiation damage upon hydration: In-situ observations by near-ambient-pressure XPS — •Marc Benjamin Hahn[1], Paul M. Dietrich[2], and Jörg Radnik[1] — [1]undesanstalt für Materialforschung und -prüfung, Berlin, Germany. — [2]SPECS Surface Nano Analysis GmbH, Berlin, Germany

X-ray photoelectron-spectroscopy (XPS) allows simultaneous irradiation and damage monitoring. Although water radiolysis is essential for radiation damage, all previous XPS studies were performed in vacuum. [1] Here we present near-ambient-pressure XPS experiments to directly measure DNA damage under water atmosphere. They permit in-situ monitoring of the effects of radicals on fully hydrated double-stranded DNA. Our results allow us to distinguish direct damage, by photons and secondary low-energy electrons (LEE), from damage by hydroxyl radicals or hydration induced modifications of damage pathways. The exposure of dry DNA to x-rays leads to strand-breaks at the sugar-phosphate backbone, while deoxyribose and nucleobases are less affected. In contrast, a strong increase of DNA damage is observed in water, where OH-radicals are produced. In consequence, base damage and base release become predominant, even though the number of strand-breaks increases further. [1] Hahn, M.B., Dietrich, P.M. & Radnik, J. In situ monitoring of the influence of water on DNA radiation damage by near-ambient pressure X-ray photoelectron spectroscopy. Commun Chem 4, 50 (2021).

BP 11.9   Tue 12:30   P1

A NAP-XPS-study on X-ray radiation damage: Chemical changes to Gene-V Protein — •Dorothea C Hallier[1,2,3], Jörg Radnik[2], Paul M Dietrich[4], Harald Seitz[1,3], and Marc Benjamin Hahn[2] — [1]Fraunhofer Insitute for Cell Therapy and Immunology, Branch Bioanalytics and Bioprocesses, Potsdam, Germany — [2]Federal Insitute for Materials Research and Testing BAM Berlin, Berlin, Germany — [3]Univerity of Potsdam, Institute for Biochemistry and Biology, Potsdam Germany — [4]SPECS Surface Nano Analysis GmbH, Berlin, Germany

Single-stranded DNA-binding proteins such as Gene-V Protein (G5P/GVP) are involved in maintaining the DNA metabolism after exposure to ionizing radiation, i.e. after radiation therapy in cancer treatment. X-ray photoelectron spectroscopy (XPS) was used to analyze the chemical damage of ionizing radiation to G5P itself. Direct and indirect damage was detected through combined vacuum XPS and near-ambient pressure (NAP) XPS measurements under water and nitrogen atmosphere. The x-ray irridation leads to degradation i.e. via dehydrogenation, decarboxylation, dehydration and deamination. A strong increase of protein damage was observed in water as compared to vacuum.

BP 11.10   Tue 12:30   P1

FTIR and SRE spectra analysis for supported lipids bilayers (SLB's) with dry incorporation of Gramicidin A — •D. Saavedra[1], N. Moraga[1], N. Gomez-Vierling[1], M. Cisternas[2], R. Rodriguez[1], S. Rojas[2], and U.G. Volkmann[1] — [1]Institute of Physics and CIEN-UC, Pontificia Universidad Catolica de Chile — [2]School of Industrial Engineering, Universidad de Valparaiso, Santiago, Chile

A dry method for SLB's assembling was developed in our group, without use of solvents and in vacuum [1], with the aim of synthesizing stable platforms for biosensors. For characterization, FTIR spectrum was analyzed for the detection of functional groups of DPPC and DSPC phospholipids in the range of 800 - 4000 1/cm. Using the SRE spectrum of DPPC and DSPC, their phase transitions were studied as a function of temperature. The SLB's/Gramicidin interaction at different concentrations were analyzed in order to optimize the growth of the biomolecules. These results would allow to evaluate the use of spin-probes in Gramicidin for the study of ion channel formation [2] and as a prototype for insertion of larger proteins.

BP 11.11   Tue 12:30   P1

Detection of Gramicidin by DPH fluorescence technique in supported phospholipids bilayers (SLB's) on SiO2 substrate — •D. Saavedra[1], M. Soto-Arriaza[2], N. Moraga[1], N. Gomez-Vierling[1], M. Cisternas[3], and U.G. Volkmann[1] — [1]Institute of Physics and CIEN-UC, Pontificia Universidad Catolica de Chile — [2]Faculty of Medicine and Science, Universidad San Sebastian, Santiago, Chile — [3]School of Industrial Engineering, Universidad de Valparaiso, Santiago, Chile

An unconventional method to manufacture supported lipid bilayers (SLB's) was developed in our laboratory: without solvents, dry [1,2] and in the absence of gases, with the aim of synthesizing stable biosensor platforms. In this work we use our physical fabrication method for the incorporation of specific signal transmitters that have selective sensitivity.

The fluorescence emission spectra of Gramicidin, with DPH as extrinsic probe and fluorescence resonant energy transfer (FRET) techniques, seeks to detect its incorporation into the SLB's.

A series of samples were prepared in absence and presence of Gramicidin and the extrinsic probe DPH. Detection was realized using a single time-correlated spectrofluorimeters photon counting (TCSPC).

BP 11.12   Tue 12:30   P1

Homogenization of DPPC films deposited from the gas phase onto silicon substrates — •N. Moraga[1], D. Saavedra[1], N. Gomez-Vierling[1], M. Cisternas[2], M.J. Retamal[3], and U.G. Volkmann[1] — [1]Institute of Physics and CIEN-UC, Pontificia Universidad Catolica de Chile, Santiago, Chile — [2]School of Industrial Engineering, Universidad de Valparaiso, Santiago, Chile — [3]Engineering Faculty, Universidad Finis Terrae, Santiago, Chile

Supported lipid bilayers (SLBs) are stable structures that allow us to gain insight into the physical behavior of cell membranes through thin film characterization techniques. In this work, DPPC SLBs are made through Physical Vapor Deposition (PVD) technique on silicon substrates without using any solvent [1]. The film thickness was monitored in situ by high-resolution ellipsometry. The DPPC deposition rate, substrate temperature during deposition and post deposition membrane annealing temperature in vacuum and in dry air are used as parameters. Homogeneity of the phospholipid bilayer is observed through the topographical analysis and Young modulus by AFM. Lower deposition rates and a slight increase of substrate temperature led to more homogeneous films. The right annealing temperature and time further improve membrane quality to favor protein insertion [2].

Foam-like properties of bundled polymer networks — •Lukas Paul Weise, Tobias Alexander Kampmann, and Jan Kierfeld — TU Dortmund University, Germany

We simulate systems of mutually attractive semiflexible harmonic chain polymers in quasi-two dimensions with the event chain algorithm. An isotropic initialization of the system evolves into a network of densely packed bundles of polymers. The resulting structure aims to minimize the overall bundle length which gives rise to properties reminiscent of foams. We examine the applicability of laws and relations characterizing the structure of foams to the bundled polymer networks in order to assess to what extent the networks behave foam-like. The dynamics of the bundled networks are found to be very sensitive with respect to details of the polymer interactions via friction terms albeit qualitative resemblance to foams remains.

BP 11.14   Tue 12:30   P1

Self-assembled Peptides Structure Mediated by Solid Interfaces. — •Leila Sahebmohammadi[1], Regine von Klitzing[1], Markus Mezger[2], and Pol Besenius[3] — [1]Soft Matter at Interfaces, Department of Physics, Technical University of Darmstadt, Hochschulstraße 8, 64289 Darmstadt, Germany — [2]Dynamics of condensed systems, Faculty of Physics, Universität Wien, Währinger Straße 38-42, 1090 Wien, Austria — [3]Department of Chemistry, Johannes Gutenberg-Universität Mainz, Duesbergweg 10-14D-55128 Mainz, Germany

In situ QCM-D reveal a layer-by-layer absorption of the oppositely charged peptides, forming a multilayer. The total amount of adsorbing peptides is derived by the adsorbed temperature and increases with increasing temperature. Exposure to high or low pH (12 or 2) removes the peptide stacks apparently due to reduced electrostatic interaction. AFM result shows the distribution pattern is nanorod-like. These experiments prove stable switchable blocks on the surface that can carry biological and colloidal materials.

BP 11.15   Tue 12:30   P1

Investigations of the Fusion Process of Lipid-Based Nanoparticles with Model Endosomal Membranes Using Coarse-Grained Molecular Dynamics Simulations — •Thomas Kolbe[1], Friederike Schmid[1], and Giovanni Settanni[1,2] — [1]Physics Department, Johannes Gutenberg University Mainz — [2]Faculty of Physics and Astronomy, Ruhr University Bochum

Lipid based nanoparticles have proven to be viable choices for the delivery of genetic material inside a living organism. Compared to the more traditionally used non-pathogenic viruses they attract through potentially much lower costs and milder effects on the immune system. Yet, the exact mechanisms of the endosomal escape - the process with which the delivered drug enters the cell - requires more thorough examination. We simulate the related fusion of a DNA-lipid based nanoparticle with a model endosomal membrane, using coarse-grained molecular dynamics to gain more insights into the underlying processes. By modeling the drop of the system's pH in the various stages of the endosome with different degrees of ionization in our nanoparticle, we can see that the better part of transfections happen at a late stage, confirming that cationic lipids are a main driver of the transfection process. Further, we observe that the size and structure of the nanoparticles have substantial influence on the transfection efficiency.

BP 11.16 Tue 12:30 P1

Machine Learning Guided RNA Contact Prediction — •Utkarsh Upadhyay[1], Oskar Taubert[2], Christian Faber[3], and Alexander Schug[4] — [1]Forschungszentrum Jülich, Jülich, Germany — [2]Karlsruher Institut für Technologie, Karlsruhe, Germany — [3]Forschungszentrum Jülich, Jülich, Germany — [4]Forschungszentrum Jülich, Jülich, Germany

For around 50 years, the primary focus of genomic research has been the development of efficient and accurate methods to predict the structure of proteins, which led to the birth of better sequencing techniques and databases. About 98% of the human genome(RNA, DNA) during this action was overlooked.

RNA is not merely a messenger for making proteins, in the past few years, studies have revealed the existence of many non-coding RNAs which catalyse various biological processes; to gain detailed insights into these roles, we require the appropriate structure. Recent years have led to breakthroughs in protein structure prediction via Deep Learning. The scarcity of RNA structures, however, makes a direct transfer of these methods impossible.

We predict contact maps as a proxy to understand and predict RNA structure, they provide a minimal representation of the structure. We have worked on methods that took accuracy from 47%(DCA) to 77%(CoCoNet) and now to 87%(Barnacle). Further, we are trying to create more efficient neural networks for working with limited data, using statistical physics and ML techniques, to substantially reduce the sequence-structure gap for RNA.

BP 11.17 Tue 12:30 P1

Neighbor list artifacts in molecular dynamics simulations — •Hyuntae Kim — Max Planck Institute for Biophysics — International Max Planck Research School on Cellular Biophysics

Molecular dynamics simulations are widely used in biophysics. To aid non-expert users, most simulation packages provide default values for key input parameters. We found that the default setting of the neighbor list cut-off rlist in the GROMACS package is not sufficient to prevent various artifacts in certain systems. Beyond an already known significant energy drift, we observed catastrophic box deformations of large membrane systems with a semi-isotropically coupled Parrinello Rahman (PR) barostat, rapid oscillations in the pressure, and asymmetric deformations of the box shape. We traced the cause of these artifacts to infrequent neighbor-list updates resulting in missed long-range Lennard-Jones interactions that are systematically attractive. We find that for the small molecular systems commonly simulated, these effects tend to be masked. We present measures to diagnose the problem and guidelines for practitioners.

BP 11.18 Tue 12:30 P1

Sequential resource-sharing speeds up replication in *Plasmodium falciparum* — •Patrick Binder[1,2], Severina Klaus[3], Markus Ganter[3], Ulrich S. Schwarz[2], Thomas Höfer[1], and Nils B. Becker[1] — [1]German Cancer Research Center (DKFZ), Heidelberg — [2]Institute for Theoretical Physics and Bio-Quant, Heidelberg University — [3]Center for Infectious Diseases, Heidelberg University Hospital

The malaria-causing pathogen *Plasmodium falciparum* is a eukaryotic parasite with a complex life cycle that includes proliferation within red blood cells. After invasion of a red blood cell, the parasite undergoes several rounds of nuclear division and after two days releases around 20 daughter parasites. Although nuclei reside in a shared cytoplasm, using fluorescent imaging, we observe that these cycles desynchronize during multiplication, and do so more rapidly than expected for independent nuclei. To explain the observed asynchrony, we introduce a branching model for allocation of a shared enzyme to the different nuclei. The model encompasses parallel and sequential DNA replication modes. We find that when the shared enzyme is limiting, a sequential replication utilizes resources more efficiently than parallel, which result in faster completion of nuclear multiplication. Overall, our findings suggest that *Plasmodium falciparum* has evolved optimal resource utilization by exploiting a sequential sharing of replication machinery.

BP 11.19 Tue 12:30 P1

Semantic Segmentation for Single Particle Tracking in Noisy Data — •Mattias Luber, Mohammad Amin Eskandari, and Timo Betz — Third Institute of Physics - University of Göttingen

The quantitative analysis of particle motion critically depends on the quality of particle trajectory detection. Especially the position detection of particles in fluorescence microscopy images is an important task faced in biophysics. Trajectories are used to study processes like intra-cellular transport, protein diffusion within and through membranes and the reconstruction of force fields driving the particle motion. In such settings, high spatial and temporal resolution are desired. However, in practice those factors have contradictory measurement requirements. High temporal resolution requires short exposure times, which limits the photon budget and thus lead to low signal to noise ratios. This work proposes an approach to reconstruct the particle position from noisy images by applying U-NET based deep learning models to fluorescence microscopy images. Further it is shown that this method can successfully track particles with shorter exposure times, compared to traditional approaches.

BP 11.20 Tue 12:30 P1

Mathematical modelling of Nippostrongylus brasiliensis helminth infection: from single worm motility to tissue load dynamics — •Soham Mukhopadhyay[1], Jonathan Pollock[2], David Voehringer[2], and Vasily Zaburdaev[1] — [1]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — [2]Department of Infection Biology, University Hospital Erlangen, Friedrich-Alexander University Erlangen-Nuremberg, Germany

Helminth infections affect a large proportion of the world's population and cause significant morbidity. There are no vaccines against helminths, and the mechanisms by which the body fights off helminth infections are not well-understood. To better understand the immune system response we aim to develop a mathematical model describing the helminth load in different organs of the host as a function of time. As an experimental system, we use murine helminth infection by N. brasiliensis worms, where primary, secondary, and infections of mice with altered immune systems could be studied. We model the progression of infection as a system of coupled, time-delayed equations which allow us to link the larvae starting the infection on the skin of mice to the number of eggs shed to the environment by adult worms from the intestine and compare the predictions of the model to the data. For a more microscopic insight into the behaviour of larvae at different developmental stages we carry out biophysical characterisation of larval motility in in vitro settings. Combining these results we aim to achieve a quantitative description of the infection progression in the host.

BP 11.21 Tue 12:30 P1

RNA G-quadruplex folding is a multi-pathway process with a variety of short-lived intermediate states — •Marijana Ugrina[1], Ines Burkhart[2], Diana Müller[2], Harald Schwalbe[2], and Nadine Schwierz[1] — [1]University of Augsburg, Augsburg, Germany — [2]Goethe University, Frankfurt am Main, Germany

The folding kinetics of regulatory RNAs is crucial for their function. Here, we provide molecular insights into the folding pathways of a G-quadruplex from telomeric repeat-containing RNA by combining all-atom molecular dynamics and coarse-grained simulations with circular dichroism experiments. The ion atmosphere surrounding the highly charged quadruplex plays a crucial role in folding. To correctly capture the electric double-layer in implicit solvent coarse-grained simulations, we develop a matching procedure based on all-atom simulations in explicit water. This procedure allows us to provide quantitative agreement between the experiments and simulations as judged by the number of native contacts at different salt concentrations and temperatures. Folding of the quadruplex is on the timescale of minutes and the coarse-grained simulations using the three-interactions site model are therefore ideal to resolve the folding pathways and intermediate states. The results reveal that the folding is sequential with each pathway passing through two transient, on-pathway intermediates: A hairpin and a triplex or double hairpin state. Since these intermediates are degenerate with at two to four alternative conformations per state, quadruplex folding is a multi-pathway process with high conformational entropy.

BP 11.22 Tue 12:30 P1

OCTOPOS.jl: A user-friendly tool for synonymous genetic code optimization — •Simon Christ[1], Jan-Hendrik Trösemeier[2], Christel Kamp[2], and Sophia Rudorf[1] — [1]Leibniz Universität, Hannover — [2]Paul-Ehrlich-Institut, Langen

Synonomous genetic code optimization takes advantage of the fact that aminoacids can be encoded by different nucleotid triplets. It attempts to influence the translation process by synonomous substitutions to alter characteristics such as the protein expression.

OCTOPOS.jl is the reimplementation of the java desktop applicapion OCTOPOS in the julia programming language as a web application.

OCTOPOS combines detailed mechanistic mathematical modeling of in-vivo protein synthesis with machine learning to predict protein expression levels based on codon choice and can generate optimized synonymous mRNA sequences for enhanced heterologous gene expression in different host organisms.

The aim of this reimplementation is to enhance the accessibility of this tool for the community.

BP 11.23 Tue 12:30 P1

Self-regulation of mRNA expression via LNP-based incoherent feed-forward loops — •Judith A. Müller and Joachim O. Rädler — Ludwig-Maximilians-Universität, Munich

Lipid Nanoparticles (LNPs) have revolutionized the delivery of nucleic acid to living cells, including messenger RNAs (mRNAs) and small non-coding RNAs. However, at the single cell level, delivery of LNPs is heterogeneous and the expression level and timing is poorly controlled. A frequently occurring motif in natural gene regulation are incoherent feedforward loops (iFFLs) consisting of simultaneous initiation of activating transcription factors and down-regulating micro-RNAs. Here we realize lipid nanoparticles containing iFFL by ratiometric codelivery of eGFP coding mRNA and eGFP targeting siRNA. We find faster and more homogenous expression in eGFP time courses using Live Imaging on Single Cell Arrays (LISCA). The steady states levels show power law decrease

as a function of siRNA/RNA ratio. Our approach demonstrates self-regulated expression via iFFL-LNP based genetic programs.

BP 11.24   Tue 12:30   P1

How not to lose spikes: inference methods for spike-count neurons — •Tobias Kühn and Ulisse Ferrari — Institut de la Vision, Sorbonne Université, IN-SERM, CNRS, F-75012 Paris

Maximum-entropy models have been successfully applied to neuronal data stemming from diverse areas like cortex, hippocampus or the retina. Despite this success, it features the major drawback of being restricted to describing every neuron to be in one out of two states: in a given time bin, either there was at least one spike or not. This property does not only limit the statistics that can be matched, but also prevents capturing the neurons' behavior when the firing rate is high, that is when the amount of transmitted information is large. The spike-count model we are suggesting provides a solution to both of these caveats. We are assuming the single-neuron probability distribution to be given in Boltzmann form with energy functions of the shape $E(n) = h \cdot n + J \cdot n^2 + \epsilon \cdot n^3 + \mathcal{O}(n \ln(n))$, where n is the spike count in the respective time bin and ϵ is a small negative hyper parameter guaranteeing that the probability is well-defined for all J. To account for pairwise covariances, we extend the independent neuron case by including an Ising-like interaction term that couples neurons in the network. To infer the model parameters, we develop Monte-Carlo and mean-field methods. We are confident that these techniques will prove useful in the further investigation of neuronal data, in particular in the search for second-order phase transitions.

BP 11.25   Tue 12:30   P1

Parameter Optimization for 1D-0D Coupled Blood Flow Models: Physics-Informed Neural Networks versus Kernel Methods — •Tobias Köppl[1], Benedikt Hoock[1,3], and Gabriele Santin[2] — [1]Technische Universität München, School of Computation, Information and Technology — [2]Digital Society Research Center, Fondazione Bruno Kessler, Italy — [3]Support by Computing Facilities of Leibniz-Rechenzentrum München

The understanding of blood perfusion of organs is essential to improve motion therapy. Here, numerical simulations of the blood flow on the human arteries network have already come up to augment in-vivo measured data. A common approach is the coupled 1D-0D hydrodynamic model combining the simplified incompressible Navier-Stokes equations with the Windkessel model. Fine-tuning the free model parameters such as the resistance and capacity is computationally expensive so it is beneficial to find a simpler surrogate. To this purpose we apply two different machine-learning techniques: physics-informed neural networks and kernel-based methods. The first simultaneously minimizes the quadratic loss to existent reference data and the residuals of a physical system of differential equations by a neural network. The second builds a model from kernel functions and is purely data-driven. We refine these approaches to predict the blood pressure from the 1D-OD model in a single vessel at varying resistance, capacity and heart beat, sampled over time and space. Comparing them in terms of the training and test error and their run time, we conclude that they are equally applicable to be now integrated into quantum optimization.

BP 11.26   Tue 12:30   P1

From in vitro to in silico: a pipeline for the generation of 3D-cell culture simulations from real image data — Elina Nürnberg[1,2,3], Felix Romer[1], •Mario Vitacolonna[2,3], Rüdiger Rudolf[2,3], and Simeon Sauer[1] — [1]Institut für mathematisch-naturwissenschaftliche Grundlagen, Mannheim University of Applied Sciences, Mannheim, Germany — [2]Institute of Molecular and Cell Biology, Mannheim University of Applied Sciences, Mannheim, Germany — [3]Center for Mass Spectrometry and Optical Spectroscopy, Mannheim University of Applied Sciences, Mannheim, Germany

Immunofluorescence labelling, optical tissue clearing and confocal laser scanning microscopy enable the visualization of whole, intact 3D-cell culture models on a single cell level, without loss of 3D spatial information. However, a manual extraction of quantitative information from the entire sample is cumbersome and often only performed on a subset of the data. Moreover, due to lack of computational resources, appropriate statistical methods or theoretical models, this data is often analyzed only qualitatively. In order to overcome these obstacles and improve exploitation of available data beyond quantitative image analysis, we propose a 3D-image analysis pipeline, consisting of image segmentation and 3D-feature extraction to gain quantitative information on cell morphology and protein distribution. Subsequently, this information is used to statistically define prototypical cell types, which are implemented into a basic 3D simulation based on the cellular potts model, which aims to recreate in-silico the in-vitro 3D cell culture, and which can be further adapted to specific research questions.

BP 11.27   Tue 12:30   P1

Determinants of lipid-based nanoparticle structure and stability investigated using molecular dynamics simulations — •Jonas Paulus[1] and Giovanni Settanni[1,2] — [1]Department of Physics, Johannes Gutenberg University Mainz, Germany — [2]Faculty of Physics and Astronomy, Ruhr University Bochum, Germany

mRNA-based therapeutics represent an effective tool to fight several diseases including viral infections, as demonstrated by the COVID-19 vaccination campaign, and cancer. To protect the mRNA from the harsh conditions in a human body, the polyanion is packed into a lipid-based nanoparticle (LNP). This delivery vehicle, although effective, still presents some problems like strict storage requirements, low fraction of successfully delivered mRNA as well as undesirable reactions in some patients. The source of these problems as well as solution approaches are topic of a promising research field. Here we use molecular dynamics simulations to provide a characterization of the internal structure of LNPs and lipid-based nanomaterials for the delivery of RNA. In particular we measure how several observables obtained from different lipid formulations, like the flexibility of bilayers, the tendency to phase separation, the pattern of interactions or behavior under different pH values are related to experimentally measured physico-chemical characteristics as well as to the transfection efficiency. Such structural information could help design more effective lipid formulations for mRNA delivery.

On European Robin cryptochrome 4 interaction with membranes — •Maja Hanic[1], Marta Majewska[2], Izabella Brand[2], and Ilia Solov'yov[1,3,4] — [1]Department of Physics, Carl von Ossietzky University of Oldenburg, Carl-von-Ossietzky Straße 9-11, 26129, Oldenburg, Germany — [2]Department of Chemistry, Carl von Ossietzky University of Oldenburg, Carl-von-Ossietzky Straße 9-11, D-26111, Oldenburg, Germany — [3]Research Centre for Neurosensory Sciences, Carl von Ossietzky University of Oldenburg, Carl-von-Ossietzky Straße 9-11, 26111, Oldenburg, Germany — [4]Department of Physics, Center for Nanoscale Dynamics (CENAD), Carl von Ossietzky University of Oldenburg, Ammerländer Heerstr. 114-118, 26129 Oldenburg

Since the 19th century it was postulated that migratory birds use the geomagnetic field for navigation. Exactly how a migratory bird is able to migrate long distances has become a scientific interdisciplinary question. Recently, cryptochrome 4a from night-migratory songbird European Robin (ErCry4) has been expressed and shown to be sensitive to magnetic field. The sensitivity of ErCry4 to the Earth's magnetic field could be explained by uniform alignment of the ErCry4 protein in bird's eye cells. The possible interaction of ErCry4a with the model membrane mimicking the one found in the outer part of the cone cells was investigated both experimentally and computationally. The experimental and computational results indicate that the ErCry4 does interact with the model lipid membrane. This is the first known observation that ErCry4 interacts with a cell membrane, which could be a key step for ErCry4 to propagate the signal as a magnetoreceptor.

Heat flows through rock cracks purify >50 building blocks of life — •Paula Aikkila, Thomas Matreux, Dieter Braun, and Christof Mast — Systems Biophysics, LMU Munich, Germany

A crucial step during the origins of life is the emergence of biopolymer building blocks. However, the optimal reaction pathways for their formation usually require feedstocks of pure reactants and defined purification and mixing steps to suppress unwanted side reactions and allow for high product yields. We show that heat flows through thin crack-like compartments purify complex mixtures of prebiotically relevant building blocks with high selectivity by bringing together geomaterials, chemistry and microfluidics in a realistic environment. This non-equilibrium process differentially enriches prebiotically relevant building blocks, and distinguishes even mass-identical molecules. Using the experimentally determined thermophoretic properties, we model geologically plausible networks of connected heat flow compartments. Our results show how geologically driven non-equilibria could purify compounds and implement downstream mixing for the origin of life.

Theory of adaptation to a moving optimum — •Sakshi Pahujani and Joachim Krug — Institute for Biological Physics, University of Cologne, Zülpicher Straße 77, D-50937 Köln, Germany

We study the evolution of a polygenic trait under changing environment using a theory of adaptation formulated by Michael Kopp and Joachim Hermisson [1]. This theory treats the changing environment as a fitness optimum moving in the phenotypic space. Within this framework, we work with the assumption of instantaneous fixation of beneficial mutations. Consequentially, we view adaptation as a walk in the phenotypic space, the dynamics of which are governed by the selection coefficient and the dimensionless speed of the optimum. We investigate the conditions pertaining to the existence of a stationary distribution of the phenotypic lag of the population from the optimum and the dependence of the distribution of adaptive substitutions on the distribution of phenotypic effect sizes available to the population. Further, we go beyond the linear dependence of the optimum on time to non-linear dependencies and incorporate this into the theory to answer questions about the time until first passage through a fitness threshold which potentially leads to the extinction of the population.

(De)hydration can speed up chemical process — Ivar Haugerud, •Pranay Jaiswal, and Christoph Weber — Mesoscopic Physics of Life, Institute of Physics, Universitätsstr. 1, Augsburg, Germany

Under early earth conditions, wet-dry cycles and phase separated droplets are separately believed to facilitate chemical processes. Recent experimental studies suggest that chemical reactions can accelerate when subject to non-equilibrium conditions of hydration or dehydration. We develop a theoretical model studying the interplay between wet-dry cycles, phase separation, and chemical processes. We find that hydration and dehydration can significantly increase chemical reaction rates and are further magnified with increasing oscillation amplitudes. Repeated cycles keep the system out of equilibrium, allowing for persistent chemical activity. Furthermore, resonance behaviour in the cycle frequency maximizes the chemical turnover. Our findings show under what conditions the physics of wet-dry cycles could have accelerated chemical reactions in prebiotic soups, similar to enzymes in living cells.

Spontaneous engulfment of microparticles by giant unilamellar vesicles — •Clément Marque and Antonio Stocco — Institut Charles Sadron, Strasbourg, France

Giant unilamellar vesicles (GUVs) are micrometer sized concentric phospholipid bilayers, containing an aqueous medium and constituting simple and controllable model systems to study interaction mechanisms of cells. Adhesion, membrane tension and bending are involved in the engulfment of microparticles and a balance between these contributions is necessary to observe particle wrapping by a GUV membrane. In this context, we mimic the particle endocytosis process by using two types of (1 - 2 microns diameter) colloids interacting with GUVs: uniform silica microparticles and Janus microparticles, half coated with gold nanoparticles (10 - 100 nm) and fabricated by a bottom-up microfluidic self-assembly approach. For this purpose, we aim at controlling particle engulfment in absence of any applied external force. By tuning only membrane properties, we define the critical parameters to observe spontaneous engulfment of microparticles by GUVs. We focus our attention on membrane tension, membrane spontaneous curvature and lipid composition. Membrane spontaneous curvature is tuned by addition of salt, adsorbing onto the outer bilayer surface. Membrane composition is adjusted, as well, to tune lipid fluidity, and membrane surface charge. Finally, Janus microparticle-vesicle interaction will be investigated in out of equilibrium conditions when microparticles are able to self-propel and impart an effective force on the membrane by light exploiting the photothermal properties of gold nanoparticles.

BP 11.33   Tue 12:30   P1

Impact of biomolecular condensates on endocytosis — •Tyler Harmon[1], Max Ferrin[2], and Frank Jülicher[3] — [1]Leibniz Institute for Polymer Research, Dresden, Germany — [2]University of California, Berkeley, USA — [3]Max Planck Institute for the Physics of Complex Systems

Endocytosis is a mechanism that cells use to import material from outside the cell without allowing it immediate access to the cytoplasm. This process involves a section of a cell membrane that is folded inward and then separated into a membrane coated sphere containing the cargo called a vesicle. The process involves recruiting many different protein components to the membrane. We model this recruitment as the formation of a small droplet (biomolecular condensate) located on the membrane. We show using a theoretical model that the presence of a droplet has two major impacts. It creates an additional barrier to initializing endocytosis and it accelerates the process once started. Importantly, the magnitude of this barrier is reduced as droplets get larger. Taken together, droplets are ideal for improving the robustness of endocytosis. It provides a natural checkpoint where cells can ensure they are ready to proceed with endocytosis and, once started, helps ensure that it doesn't stop halfway.

BP 11.34   Tue 12:30   P1

Investigation of thermal fluctuations and elastic properties of lipid bilayers via molecular dynamics simulations — •Clara Rickhoff, Azadeh Alavizargar, and Andreas Heuer — Institute of Physical Chemistry, University Münster, Münster, Germany

As cell membranes consist to a large part of a lipid bilayer and are essential for living cells by forming a barrier between different compartments of cells, which needs to be stable on the one hand but also ductile for processes like cell division on the other hand, the mechanical properties of lipid bilayers are of interest for a better understanding of the behaviour of cell membranes. One important quantity is the bending modulus, which can be extracted from the thermal fluctuation of the bilayer in an equilibrium state and thus from molecular dynamics simulations (MD simulations) and generally can be, due to similar length and time scales, also compared to neutron spin echo spectroscopy (NSE).

In this work, we first performed atomistic MD simulations on a pure DMPC-system and a DPPC-system in order to compare the resulting bending modulus and effective bending modulus with available data from literature. Those simulations were then compared with the results of coarse-grained MD-simulations

(CG-simulations), which offer the possibility to examine larger systems and also investigate the impact of transmembrane domains on those quantities.

BP 11.35   Tue 12:30   P1

phospholipids diffusion on the surface of model lipid droplets — •Shima Asfia, Ralf Seemann, and Jean-Baptiste Fleury — Universität des Saarlandes, Experimental Physics and Center for Biophysics, 66123 Saarbrücken, Germany

Lipid droplets (LD) are organelles localized in the membrane of the Endoplasmic Reticulum (ER) that play an important role in metabolic functions. Many studies have focused on the biophysical properties of these LDs. However, despite numerous efforts, we are lacking information on the mobility of phospholipids on the LDs surface, although they may play a key role in the protein distribution. In this article, we developed a microfluidic setup that allows the formation of a triolein*buffer interface decorated with a phospholipid monolayer. Using this setup, we measured the motility of phospholipid molecules by performing Fluorescent Recovery After Photobleaching (FRAP) experiments for different lipidic compositions. The results of the FRAP measurements reveal that the motility of phospholipids is controlled by the monolayer packing decorating the interface [1].

BP 11.36   Tue 12:30   P1

SAXS measurements during polychromatic illumination of photoswitching in azobenzene lipid vesicles — •Matthias Lösche[1], Benedikt Baumgartner[2], Benjamin Ajanovic[1], Oliver Thorn-Seshold[2], and Bert Nickel[1] — [1]Faculty of Physics and CeNS, Ludwig-Maximilians-Universiät München, Geschwister-Scholl-Platz 1, Munich 80539, Germany — [2]Department of Pharmacy, Ludwig-Maximilians-Universität München, Butenandtstraße 5-13, Munich 81377, Germany

Photoswitchable molecules are envisioned to be used in the field of nanomedicine. Here we study photoswitchable azobenzene lipids which switch to predominantly cis-state at 365 nm wavelength illumination and to trans-state at 465 nm illumination. The conformational change of the lipid induces different vesicle membrane thicknesses, which can be read out by small-angle x-ray scattering, as established by us before. What is not yet known is how azobenzene lipid vesicles behave when irradiated at other wavelengths. We illuminate lipid vesicles with 16 different wavelengths (generated by high-power LEDs) which cover the whole visible light region. We follow the kinetics of the switching process by SAXS. This establishes an action spectrum that correlates the different photostationary states with illumination wavelength.

BP 11.37   Tue 12:30   P1

Two-photon 3D laser printing inside synthetic cells — •Tobias Abele[1,2], Tobias Messer[3], Kevin Jahnke[1,2], Marc Hippler[3], Martin Bastmeyer[3], Martin Wegener[3], and Kerstin Göpfrich[1,2] — [1]Max Planck Institute for Medical Research, Heidelberg, Germany — [2]Heidelberg University, Heidelberg, Germany — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany

Towards the ambitious goal of manufacturing synthetic cells from the bottom up, various cellular components have already been reconstituted inside of lipid vesicles. However, the deterministic positioning of these components inside the compartment has remained elusive. Here, by using two-photon 3D laser printing, 2D and 3D hydrogel architectures were manufactured with high precision and nearly arbitrary shape inside of preformed giant unilamellar lipid vesicles (GUVs). The required water-soluble photoresist is brought into the GUVs by diffusion in a single mixing step. Crucially, femtosecond two-photon printing inside the compartment does not destroy the GUVs. Beyond this proof-of-principle demonstration, early functional architectures were realized. In particular, a transmembrane structure acting as a pore was 3D printed, thereby allowing for the transport of biological cargo, including DNA, into the synthetic compartment. These experiments show that two-photon 3D laser microprinting can be an important addition to the existing toolbox of synthetic biology.

Self-patterning of polyelectrolyte multilayer films: the roles of PSS molecular weight, the top layer, and post-preparation treatment — Amir Azinfar and •Christiane A. Helm — Institute of Physics, University of Greifswald, Germany

The self-patterning of thin films is relevant both for fundamental research and applications. We investigate polyelectrolyte multilayer films made from poly(diallyldimethylammonium) and poly(styrene sulfonate) (PDADMA/PSS). Various PSS with low molecular weight are used. Invariably, the film thickness increases exponentially with the number of deposited PDADMA/PSS bilayers. The separation and height of the domains increase significantly with each deposited PDADMA/PSS bilayer, as AFM images show. At the end of the exponential growth regime, either a parabolic (and then a linear) or a linear growth regime follows, depending on the selected PSS molecular weight. In the non-exponential growth regimes, the domain separation changes less during film growth than in the exponential growth regime.

PSS is more strongly bound to the film than PDADMA. PSS-terminated films show the same domain distance in water and air. However, when PDADMA-

terminated films are dried, the domain distance in the air increases while the domain height decreases, causing a reduction in total area. In the air, the surface energy is greater than in water, and a highly textured surface costs a lot of energy. We propose the changed surface pattern is attributable to energy minimization. Furthermore, the domains are stable when exposed to 1 M NaCl solution but shrink in 2 M NaCl.

Membranes with large phospholipid asymmetries — •Martin Girard — Max-Planck-Institut für Polymerforschung, Ackermannweg 10, 55128 Mainz

Plasma membranes in cells are asymmetric, an observation that dates 40 years. Recent observations suggest that these membranes present large lipid number asymmetries, with almost twice as many phospholipids on one of the leaflet than the other. Simulations provide an excellent avenue to probe behavior of these membranes. Here, I discuss the behavior of such membranes, in particular with respect to chemical asymmetries in the membrane. The work required to establish the phospholipid number asymmetry is also discussed, a quantity that is directly related to the work done on lipids by the so-called flippases and floppases proteins responsible for asymmetry homeostasis.

BP 11.40   Tue 12:30   P1

Wetting-effects of liquid-liquid condensates on lipid membranes — Chae Yeon Kang, Yoohyun Chang, and •Katja Zieske — Max Planck Institute for the Science of Light, Erlangen

Liquid-liquid condensates are supramolecular assemblies of proteins and RNA molecules and have been studied extensively, due to their ability to spatially structure cells and to spatially confine biological reactions. However, little is known about the interactions of liquid-liquid condensates with lipid membranes and the consequences of these interactions on cellular length scales.

Here, we used a cell-free bottom-up approach to reconstitute liquid-liquid condensates at lipid membranes. Our results demonstrate how lipid membranes and liquid-liquid condensates interact under various experimental conditions and point towards an important role of wetting-effects in intracellular organization.

A preparative mass spectrometer to deposit intact large native protein complexes — •Paul Fremdling[1], Tim K. Esser[1], Bodhisattwa Saha[1], Alexander A. Makarov[2,3], Kyle L. Fort[2], Maria Reihnhardt-Szyba[2], Joseph Gault[1], and Stephan Rauschenbach[1,4] — [1]Chemistry Research Laboratory, University of Oxford, 12 Mansfield Road, Oxford OX1 3TA, UK — [2]Thermo Fisher Scientific, Bremen, 28199, D — [3]Bijvoet Center for Biomolecular Research, University of Utrecht, Padualaan 8, 3584 CH Utrecht, NL — [4]MPI for Solid State Research, Heisenbergstrasse 1, Stuttgart, 70569, D

Electrospray ion-beam deposition (ES-IBD) is a tool to study structure and reactivity of nonvolatile molecules. It ionises molecules gently, purifies and deposits them onto a substrate. In combination with imaging techniques, direct structural information can be obtained.

There are only a small number of custom ES-IBD instruments worldwide, with no commercial ones. We present a module that adds ion-beam deposition capabilities to a commercial MS (Thermo ScientificTM Q ExactiveTM UHMR).

We characterise beam intensity, landing-energy control, and deposition spot size for a broad range of molecules. In combination with atomic force microscopy (AFM) and transmission electron microscopy (TEM), we distinguish near-native from unfolded proteins and show retention of native shape of protein assemblies after dehydration and deposition. Further, we use an enzymatic assay to quantify activity of a non-covalent protein complex after deposition on a dry surface.

Tracking the Electron Transfer Cascade in European Robin Cryptochrome 4 Mutants — •Daniel Timmer[1], Anders Frederiksen[1], Daniel C. Lünemann[1], Anitta R. Thomas[1], Jingjing Xu[1], Rabea Bartölke[1], Jessica Schmidt[1], Tomas Kubar[2], Antonietta De Sio[1], Ilia A. Solov'yov[1], Henrik Mouritsen[1], and Christoph Lienau[1] — [1]University of Oldenburg, Germany — [2]Karlsruhe Institute of Technology, Germany

The ability of some birds to sense weak earth-strength magnetic fields for navigation is thought to rely on the quantum mechanical radical pair (RP) mechanism [1]. Here, cryptochrome proteins, located in the birds retina, can undergo consecutive electron transfers after blue light photo-excitation of a bound flavin chromophore with a nearby chain of four tryptophan amino acid residues. This leads to the formation of a long-lived RP, which can interconvert between the singlet and triplet state due to hyperfine interactions. Spin-selective signaling state populations can eventually be influenced via a weak external magnetic field [1]. Using pump-probe spectroscopy on wildtype cryptochrome protein of the European robin and a series of mutants, where we selectively blocked the electron transfer along the chain with redox-inactive phenylalanine, we are able to track RP formation step by step and extract the electron transfer times and yields [1]. Our experimental study is supported by theoretical modeling of the electron

transfer cascade using a mixed quantum mechanical/molecular mechanical approach. [1]: Xu, Jingjing, et al., Nature 594.7864, 535-540 (2021). [2]: Timmer, Daniel, et al., arXiv preprint arXiv:2205.10393 (2022).

BP 11.43   Tue 12:30   P1

Nonlinear Transmission of FUS Protein Solution at 0.5 THz — •Quang Minh Thai[1], Igor Ilyakov[2], Manthan Raj[1], Daniel Dornbusch[2], Atiqa Arshad[2], Thales de Oliveira[2], Marcus Jahnel[1,3], Jan-Christoph Deinert[2], Alexey Ponomaryov[2], Sergey Kovalev[2], and Ellen M. Adams[1,2] — [1]Cluster of Excellence Physics of Life (PoL), TU Dresden, Dresden, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Dresden, Germany — [3]Center for Molecular and Cellular Bioengineering, Biotechnology Center, TU Dresden, Dresden, Germany

Water possesses strong absorption in the THz range due to intermolecular vibrational modes in a network of hydrogen-bonded water molecules. Its THz response is also sensitive to the coupling of water to other molecules, i.e. the hydration shell of a protein. Probing the nonlinear properties of hydration water can provide insight into protein solvent dynamics, and in the case of intrinsically disordered proteins, its subsequent role in the liquid-liquid phase separation (LLPS). Such characterization at low THz frequencies (< 3 THz) remains yet limited, due to the scarcity of brilliant light sources in this range. Here, we present the nonlinear characterization at 0.5 THz of water and FUS protein solution in a liquid transmission cell, using a THz time-domain spectroscopy (THz-TDS) setup with the TELBE free electron laser source at HZDR. Our results show that the nonlinear absorption and refractive indices of the FUS protein solution differ from that of water, indicating a perturbed hydrogen bonding network.

BP 11.44   Tue 12:30   P1

Bio-SAXS of Single-Stranded DNA-Binding Proteins: Radiation Protection by the Compatible Solute Ectoine — •Marc Benjamin Hahn[1], Dorothea C. Hallier[1,2,3], Glen J. Smales[2,3], and Harald Seitz[1] — [1]Bundesanstalt für Materialforschung und prüfung (BAM), 12205 Berlin, Germany — [2]Fraunhofer Institute for Cell Therapy and Immunology, Branch Bioanalytics and Bioprocesses (IZI-BB), 14476 Potsdam, Germany — [3]Universität Potsdam, Institut für Biochemie und Biologie, 14476 Potsdam, Germany

Small-angle X-ray scattering (SAXS) can be used for structural determination of biological macromolecules and polymers in their native states. To improve the reliability of such experiments, the reduction of radiation damage occurring from exposure to X-rays is needed. One method, is the use of scavenger molecules that protect macromolecules against radicals produced by radiation exposure. In this study we investigate the feasibility to apply the compatible solute, osmolyte and radiation protector Ectoine (THP(B)) as a scavenger throughout SAXS measurements of single-stranded DNA-binding protein Gene-V Protein (G5P/GVP). Therefore we monitor the radiation induced changes of G5P during bio-SAXS. The resulting microscopic energy-damage relation was determined by particle scattering simulations with TOPAS/Geant4. The results are interpreted in terms of radical scavenging as well as post-irradiation effects, related to preferential-exclusion from the protein surface. Thus, Ectoine provides an non-disturbing way to improve structure-determination of proteins via bio-SAXS in future studies.

BP 11.45   Tue 12:30   P1

Molecular Dynamics Simulations of Large Proteins in Vaccum and during Surface Adsorbtion — •Alpcan Önür[1,2], Tim K. Esser[2], Christoph Globisch[1], Christine Peter[1], and Stephan Rauschenbach[2,3] — [1]Departement of Chemistry, University of Konstanz, Konstanz, Germany — [2]Departement of Chemistry, University of Oxford, Oxford, UK — [3]Max Planck Institute for Solid State Research, Stuttgart, Germany

Knowledge of protein structures is crucial for biological and medical research in for instance metabolism, drug discovery and diseases. Cryogenic electron microscopy (cryo-EM) recently became a dominant method of protein structure determination. One of the main challenges with cryo-EM measurements lies in the protein preparation with many pitfalls which can destroy the native structure of proteins due to surface effects. The combination of electrospray ion beam deposition (ESIBD) and native mass-spectrometry creates chemically selective cryo-EM samples. This method has the potential to overcome many conventional cryo-EM sample preparations. However, the native ESIBD-CryoEM approach prepares and images dehydrated gas-phase proteins, which have collided with a surface. This can affect the native protein fold and hence influence the cryo-EM obtained structure, for instance reducing the resolution or inducing deviations. In this work we will present first steps towards understanding structural changes of proteins in electrospray ion beams, after surface interactions, and during dehydration in ultra-high vacuum by utilizing molecular dynamics simulations.

BP 11.46   Tue 12:30   P1

Dynamics of Tau protein studied with X-ray photon correlation spectroscopy (XPCS) — •Sebastian Retzbach[1], Nimmi Das Anthuparambil[2,5], Anita Girelli[3], Kevin Pounot[4], Sonja Timmermann[2], Maximilian D. Senft[1], Marvin Kowalski[2], Michelle Dargasz[2], Nafisa Begam[1], Fabian Westermeier[5], Anastasia Ragulskaya[1], Fajun Zhang[1], Christian Gutt[2], and Frank Schreiber[1] — [1]Universität Tübingen, Germany — [2]Universität Siegen, Germany — [3]Stockholm University, Sweden — [4]ESRF, Grenoble, France — [5]DESY, Hamburg, Germany

Proteins exhibit a rich phase behavior, including the formation of amyloid fibrils, which have been linked to many diseases, e.g. Alzheimer's disease. Understanding the dynamics associated with amyloid fibril formation and beyond, such as liquid-liquid phase separation, nucleation and gel-formation, is thus of substantial interest. X-ray photon correlation spectroscopy (XPCS) is a state-of-the-art method to study matter over a broad range of time- and length scales, which was successfully used to study protein systems [1]. Here, we use this method to follow the dynamics and the structural changes of the Alzheimer associated, amyloid fibril forming, protein Tau. After inducing the fibrillation with Heparin, at a Tau concentration of 100 mg/ml, and waiting for 22 hours, a fractal structure with a characteristic length of around 200 nm has evolved. The dynamics exhibited ballistic behavior that show similarities to the dynamics in gels.

Upconversion-nanoparticle optical trapping for ultraresolution motor protein measurements — •Aleksandr Kostarev and Erik Schäffer — Universität Tübingen, ZMBP, Tübingen, Deutschland

Molecular machines are essential for many cellular processes. For example, kinesin motor proteins transport cargo along microtubule cytoskeletal filaments. The stepping and force generation of single motors can be measured using optical tweezers. However, the spatiotemporal resolution achieved with common optical tweezers probes is insufficient to detect fast steps in particular at low forces. To improve the resolution, nanoparticles are required as optical tweezers probes. Upconversion nanoparticles trapped near resonance of their electric susceptibility have the highest reported trapping efficiency and are chemically stable. Yet, they have not been used for biophysical measurements. To use them, we have integrated a near-resonance trapping laser, detector, and laser steering system in an optical tweezers system. Calibration measurements show that the upconversion nanoparticles indeed have a very high trapping efficiency when trapped with a laser near resonance compared to off-resonance trapping. Once functionalized with the motors, trapping experiments will shed light on how weak kinesin motors step and diffuse on microtubules. In the long term, upconversion-nanopartical optical trapping will improve the spatiotemporal resolution of optical tweezers and shed light on the working mechanism of a wide range of molecular machines.

BP 11.48   Tue 12:30   P1

Diffusive anchorage of molecular motors facilitates robust cargo transport — •Rachele Catalano[1], Gina A. Monzon Monzon[1,2], Rahul Grover[1], Ludger Santen[2], and Stefan Diez[1,3] — [1]B CUBE - Center for Molecular Bioengineering, TU Dresden — [2]Center for Biophysics, Department of Physics, Saarland University — [3]Cluster of Excellence Physics of Life, TU Dresden

Intracellular transport of vesicles and organelles is carried out by teams of molecular motor proteins moving cargo along polar intracellular filaments. Multiple-motors are coupled to each other via a fluid membrane that allows motors to diffuse along the cargo surface. How the number of involved motors and the diffusivity of motors on the cargo surface influence such transport is not well understood. Here we use a combined experimental and theoretical approach to investigate the impact of motor number and motor-cargo interaction on the motility parameters of kinesin-driven cargoes moving along microtubules. We found that the velocities of cargoes with highly diffusive motors decrease with an increase in motor number. Cargoes with non-diffusively bound motors moved with velocities independent of the motor number. Numerical simulations reveal that diffusive motor-cargo binding results in higher numbers of microtubule-bound motors, which increases steric hindrance associated with cargo slow down. Additionally, the higher number of microtubule bound motors enhances cargo run length and increases transport robustness. Our results demonstrate that loose mechanical coupling of multiple motors by diffusive membrane anchorage leads to robust transport at the cost of lower velocity.

BP 11.49   Tue 12:30   P1

Amplified self-stabilization of cell adhesions under load — •Julia Müllner[1,2] and Benedikt Sabass[1,2] — [1]Institute for Infectious Diseases and Zoonoses, Department of Veterinary Sciences, LMU München — [2]Department of Physics, LMU München

Cell adhesion is crucial for the structural organization of living organisms. Experimentally, it was found that planar cell-matrix adhesions respond to an increase in shear force by growing in size in order to maintain structural stability. As part of this process, the protein vinculin binds to force-activated binding sites of talin and to actin, thereby strengthening the cluster. However, it is not fully understood how mechanical forces induce adhesion molecules to drive adhesion growth. We present a minimalist model to explore the dynamics of an adhesion cluster under shear force. The system is reduced to a single adapter molecule species (talin) that can undergo conformational changes when being stretched. As in an open system, molecules are exchanged between a reservoir and the adhesion cluster. To account for adhesion growth upon molecule unfolding, we expand the reservoir rate to be proportional to the number of unfolded molecules. Simulation results show that the number of adhesion bonds rises with increasing shear force, as seen in experiments. A state diagram is constructed, delineating regimes of adhesion stabilization from unbounded growth and adhesion rupture. An analytical mean-field model yields solutions that are in good agreement with the simulation results. Overall, we describe and characterize a mechanism that amplifies self-stabilization of cellular adhesions under load.

BP 11.50   Tue 12:30   P1

Is sensory adaptation generally limited by the energy-speed-accuracy trade-off? — •Vansh Kharbanda[1,2] and Benedikt Sabass[1,2] — [1]Institute for Infectious Diseases and Zoonoses, Department of Veterinary Sciences, LMU München — [2]Department of Physics, LMU München

Sensory adaptation is vital to all living organisms. An adaptive sensory system can be modelled as a stochastic, nonlinear feedback network. Using a generic framework, we study the accuracy of adaptive mechanisms and its energetic cost. Recently, it has been suggested that the steady-state dissipation rate associated to maintenance of an adaptive state increases logarithmically with the adaptation accuracy. We present results that demonstrate that this logarithmic scaling does not hold generally, but appears to be linear when the state of the system is close to the phase-space boundaries. Our numerical results also suggest that boundaries in the phase space of system variables limit the capacity of the system to dissipate. Moreover, we conjecture a new empirical expression relating the steady-state dissipation rate and the strength of the input signal if the state lies in the vicinity of the boundaries. Finally, the combined adaptation accuracy of two linearly coupled systems is studied. We show that a coupling of the outputs of the systems deteriorates the overall adaptation accuracy while the associated energy cost is also reduced. In contrast, a coupling of the control elements reduces the dissipation rate without compromising on the adaptation accuracy.

BP 11.51   Tue 12:30   P1

Three-compartment model describes coarsening of biomolecular condensates in Meiosis — •Marcel Ernst and David Zwicker — Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany

During meiosis, crossovers between the female and male chromosomes mix genetic information. Experimental observations consistently reveal two key findings: First, the number of crossovers per chromosome is at least one and usually small, between one and three. Second, there is crossover interference, which prevents nearby crossovers on a single chromosome. A recently suggested model proposes biomolecular condensates that coarsen by exchanging material along chromosomes to determine crossovers. We extend this model by including the exchange with the surrounding nucleoplasm, leading to a three-compartment model. We validate the model by comparing numerical results with various experimental data in Arabidopsis. In particular, we explain the behavior of a mutant without the axial structure linking the chromosome pairs. Moreover, we derive scaling laws, analogous to Lifshitz-Slyozov-Wagner theory, predicting the final number of crossovers, and their spatial structure as a function of coarsening time, chromosome length, and the initial amount of material. In summary, our model reveals how meiotic crossovers are regulated in wild-type and in mutants.

Investigation on the learning ability of the single-celled slime mould *P. polycephalum* — •Adrian Büchl, Lisa Schick, and Karen Alim — School of Natural Sciences, Technical University of Munich, Germany

The slime mould *Physarum polycephalum* is well known for its ability to store information and perform complex problem-solving despite being just a single, gigantic, network-shaped cell. Yet, can we consider such complex behaviour learning? Using bright-field microscopy observations we investigate how *P. polycephalum* networks react to repetitive negative blue light stimuli. We vary stimuli duration and the concentration of the growth medium in the substrate to probe how training time and migration speed impact *P. polycephalum*'s ability to follow trained behaviour.

Can iron-phthalocyanines, Fe-Pc, on CrI3 imitate active site of hemoglobin? — •Cihan Bacaksiz and Maria Fyta — Computational Biotechnology, RWTH Aachen University, Aachen, Germany

The metallo-phthalocyanines (M-Pc) molecules are studied for their chemical, magnetic, and optoelectronic properties. They can function in a wide range of applications, such as gas sensors, field effect transistors, organiclight-emitting diodes, and data storage devices. More specifically, the core of iron-phthalocyanines (Fe-Pc) resembles structurally the active site of hemoglobin

(heme), which is responsible of holding the oxygen and carbon dioxide. Motivated by this potential, we have studied the oxygen-capture and -release properties of Fe-Pc on top of magnetic monolayer CrI3 using first-principle simulations. The interplay between the magnetic properties of Fe-Pc on CrI3 and its chemical activity are investigated. It is found that the surface effects on the molecule accompanied with the magnetic interactions between Fe and Cr atoms can be used to manipulate - even control - the oxygen capture-release properties of Fe-Pc.

Band formation of red blood cells by density gradient centrifugation — •Luca David Hastenteufel, Felix Milan Maurer, and Christian Wagner — Experimentalphysik, Universität des Saarlandes, Saarbrücken

Percoll is a commercial density medium consisting of coated silicia particles, which show a non-toxicity to cells and low surface charge. Nowadays, Percoll is the standard medium for density separation of erytrocytes, leukocytes and other subcellular particles. The distribution of red blood cells after centrifugation in a self-forming Percoll gradient is characterized by a heterogeneous structure of discrete bands. We established a one dimensional particle model and a set of experiments to show that band formation is caused by aggregation. We also developed a continuum model describing the development of the RBC volumetric density under influence of a pair interaction. It shows also discrete solutions in the shape of band patterns. Understanding the band patterns gives information on the aggregation energy and disease severeness.

BP 11.55 **Tue 12:30** **P1**

Exploiting Onsager regression in passive measurements to reveal active mechanics of living systems — Till Muenker, Gabriel Knotz, Matthias Krüger, and •Timo Betz — Faculty of Physics, Georg-August-University Göttingen

Understanding life is arguably among the most complex scientific problems faced in modern research. From a physics perspective, living systems are complex dynamic entities that operate far from thermodynamic equilibrium. This active, non-equilibrium behaviour, with its constant hunger for energy, allows life to overcome the dispersing forces of entropy, and hence drives cellular organisation and dynamics at the micrometer scale. Unfortunately, most analysis methods provided by the powerful toolbox of statistical mechanics cannot be used in such non-equilibrium situations, forcing researchers to use sophisticated and often invasive approaches to study the mechanistic processes inside living organisms. Inspired by Onsager's regression hypothesis, we introduce here a Mean Back Relaxation (MBR) observable, which detects active motion in purely passive measurements of particle fluctuations. The MBR, which is based on three point probabilities, is theoretically and experimentally shown to exhibit markers of non-equilibrium, i.e., of detailed balance breaking dynamics. We furthermore observe an astonishing relation between the MBR and the effective non-equilibrium energy in living cellular systems. This is used to successfully predict the viscoelastic response function and the complex shear modulus from a purely passive approach, hence opening the door for rapid and simple passive mechanics measurements even in active systems.

BP 11.56 **Tue 12:30** **P1**

Theory of rheology and aging of protein condensates — •Ryota Takaki[1], Louise Jawerth[2], Marko Popovic[1], and Frank Jülicher[1] — [1]Max Planck Institute for the Physics of Complex Systems — [2]Leiden University

Biological polymeric materials form liquid droplets through liquid-liquid phase separation, referred to as biological condensates. Although the material properties of biological condensates are deemed to play essential roles in cellular functions, quantitative studies of condensates' rheology became available very recently. Particularly the experiments found the glass-like material property of condensates, showing slow relaxation, termed "aging" in the glass field. In this study, we develop a rheological model of biological condensates from the physical pictures: diffusion and stochastic binding of proteins inside condensates. We obtain the constitutive equation for the material property of protein condensates showing aging behavior observed in experiments. We elucidate how aging manifests in the experimental observations in microrheology, both in active and passive rheology. We develop a novel method for active rheology to compute the time-dependent property of aging materials. We derive generalized fluctuation-response relations to bridge the mean squared displacement of diffusing elements inside aging Maxwell fluid to the time-dependent material properties, which can be used in passive rheology.

Mitochondrial dynamics control cellular anti-viral responses in the innate immune system — •Felix J. Meigel[1] and Steffen Rulands[2,1,3] — [1]MPI for the Physics of Complex Systems, Dresden, Germany — [2]Arnold Sommerfeld Center for Theoretical Physics, Department of Physics, Ludwig-Maximilians-Universität, München, Germany — [3]Center for Systems Biology Dresden, Germany

The inflammation response of mammalian cells to infection with RNA viruses (e.g. coronaviruses or influenza A) is mediated by the signaling pathway around the protein MAVS. For an efficient inflammation response, MAVS proteins need to form large homo-oligomers on the mitochondrial membrane. Here, we discuss how mitochondrial fusion and fission assists the formation of large membrane-bound protein aggregates by inducing density fluctuations among mitochondria. We demonstrate how the dynamic compartmentalization of the protein aggregation dynamics by steady organelle fusion and fission qualitatively alters the extreme value statistics of the aggregate size distribution beyond a limit set by the Vigil-Ziff criterion. We develop a thermodynamic framework, that allows us to asses under which conditions dynamic compartmentalization affects the aggregate size distribution and facilitates the formation of large aggregates. In this work, we not only emphasize the importance of mitochondrial dynamics for efficient immune responses but also introduce a framework to discuss the non-equilibrium thermodynamics of multi-scale systems in the context of dynamic compartmentalization.

Monodominance in tropical forests: modelling the influences of biological mechanisms on cluster formation — •Julia Meyer[1], Pia Backmann[2], and Alexander K. Hartmann[1] — [1]Institute of Physics, University of Oldenburg, Germany — [2]University of Leipzig, Germany

Monodominance in tropical forests describes the formation of patches dominated by a single tree species, i.e., *clusters*, in an otherwise highly species-rich forest. The reasons for its emergence are not fully understood yet, probably multiple causes exist [1], depending on the specific forest.

Recently, a statistical-mechanics model was introduced [2] which allowed for an analysis of the cluster formation process. A phase transition between a non-percolating and a monodominated percolating phase could be observed, and analyzed by finite-size scaling techniques. The properties of this system, such as the morphology of clusters, are quite distinct from standard percolation. Here, we numerically [3] further investigate extensions of the model by including different biological mechanisms, like shade tolerance, that are believed to potentially favor monodominance. We analyze how the properties of this phase transition change for the modified model.

Phase segregation and microemulsion module of DNA oligo based nano-motifs — •Rakesh Chatterjee[1], Mai P. Tran[2], Yannik Dreher[2], Julius Fichtler[2], Kevin Jahnke[2], Xenia Tschurikow[3], Aaron Gadzekpo[3], Lennart Hilbert[3], Kerstin Göpfrich[2], and Vasily Zaburdaev[1] — [1]Friedrich-Alexander- Universität Erlangen-Nürnberg, Germany — [2]Max Planck Institute for Medical Research, Heidelberg, Germany — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany

DNA can be used as a programmable material by designing the base sequences to drive self-assembly. The technology of forming macromolecular droplets through sequence design of DNA-like biopolymers could provide insights into the mechanisms of liquid-like droplet formation via liquid-liquid phase separation. In two experimental setups we study how the process of phase segregation of two motifs is affected by confinement and how the dispersal of the aggregated phase is controlled by addition of amphiphiles. To quantify this process theoretically we use a versatile lattice-gas model in two dimensions with cross-shaped particles that can closely mimic the shape of synthetic nano-motifs and their interaction valencies as well as account for their translational and rotational diffusion. With our numerical results we can recapitulate the observed effects of the slowing down phase segregation in confinement and the dose response of the aggregate dispersal by addition of amphiphile components.

Delay time of erythrocyte sedimentation rate — •Jan Fischer, Thomas John, Lars Kaestner, Christian Wagner, and Alexis Darras — Experimental Physics, Saarland University; D-66123 Saarbrücken, Germany

In many suspensions of microscopic particles, ranging from cosmetic creams to food dough to oil paints, the suspended sate is only transient. Indeed, unless the densities of particles and fluid are perfectly matched, gravity eventually separates the two phases. In many practical cases with a high concentration of particles, this separation happens as a sudden "collapse" after a long period (sometimes months or years) where no separation was observed. This phenomenon actually defines the life span of many practical products.

Our group recently demonstrated that red blood cells (aka erythrocytes) follow the same behavior on short time scales. This has practical application, since their average sedimentation rate is used as a medical parameter. However, while it is known that the collapse delay time has an intrinsic random component for thermal suspensions, it is not clear whether it is the case for red cells, which are mainly athermal.

For the first time, we characterized the variability of the delay time for a given suspension of red blood cells. Moreover, the influence of various parameters

unique to red blood cells, such as cell shape and rigidity, has been studied and correlated with the microstruture of the red blood cells aggregates.

BP 11.61   Tue 12:30   P1
Modeling of protein condensates — •Kathrin Hertäg and Joshua Robinson — ITP4, Stuttgart, Deutschland

Phase separation in systems driven away from thermal equilibrium has recently attracted substantial interest, in particular for motile active matter and protein condensates in cells. The latter are characterized by a finite size that can be stable *in vivo* over the whole cell cycle while *in vitro* the same proteins undergo conventional phase separation that coarsens towards a fully phase-separated state. The physical processes that control the condensate size are largely unexplored. Here we apply methods from active liquid theory to study and assess possible mechanisms.

BP 11.62   Tue 12:30   P1
Cumulative refractoriness in Calcium signaling — •Lukas Ramlow[1], Martin Falcke[1,2], and Benjamin Lindner[1] — [1]Physics Department of Humboldt University, Berlin, Germany — [2]Max Delbrück Center for Molecular Medicine, Berlin, Germany

Stochastic spiking and adaptation are two essential feature of calcium signaling. The stochasticty stems from the punctate calcium release from the ER into the cytosol by IP3R channel clusters. The adaptation is due to the depletion and slow replenishment of the ER. To capture calcium spike generation, we adopt the popular stochastic adaptive integral-and-fire (IF) model from neuroscience. Our model describes i) activity of IP3R clusters and ii) dynamics of the global calcium concentrations in the cytosol and ER. Cluster activity is modeled by a Markov chain, capturing the puff. The calcium concentrations are described by a two-variable IF model driven by the puff current. While it has been known for decades that the activity of IP3R clusters is random, a method to derive the noise acting on the cytosolic calcium is lacking. We close this gap using a time scale separation to approximate the puffing current by a white Gaussian noise with analytically accessible intensity. This results in a nonlinear IF model with and multiplicative noise. Assuming fast replenishment the IF model generates a renewal spike train and we can derive analytical expressions for the mean and coefficient of variation of the interspike interval (ISI). Taking into account ER depletion, the model displays cumulative refractoriness and can be used to infer otherwise inaccesible parameters from experimental data.

BP 11.63   Tue 12:30   P1
Protein induced lipid demixing in homogeneous membranes — •Piotr Nowakowski[1,2], Bernd Henning Stumpf[3], Ana-Sunčana Smith[1,3], and Anna Maciołek[2,4] — [1]Institut Ruđer Bošković, Zagreb, Croatia — [2]Max Planck Institute for Intelligent Systems, Stuttgart, Germany — [3]Friedrich–Alexander–Universität Erlangen–Nürnberg, Erlangen, Germany — [4]Instytut Chemii Fizycznej Polskiej Akademii Nauk, Warszawa, Poland

We study a model of a lipid bilayer membrane with two order parameters: the chemical composition described using the Gaussian model and the spatial configuration described with the elastic deformation model of a membrane with a finite thickness, or equivalently, for an adherent membrane. We assume a linear coupling between the two order parameters. Using the exact solution, we calculate the correlation functions and order parameters profiles. We also study the domains that form around inclusions on the membrane. We propose and compare several distinct ways to quantify the size of such domains. Despite its simplicity, the model has many interesting features like Fisher–Widom line and two distinct critical regions.

Self-organized criticality in animal collectives — •Yunus Sevinchan[1,2], David Bierbach[1,3,4], Luis Gómez-Nava[1,2], Jens Krause[1,3,4], and Pawel Romanczuk[1,2] — [1]Science of Intelligence, TU Berlin, Berlin, Germany — [2]Institute for Theoretical Biology, HU Berlin, Berlin, Germany — [3]Leibniz-Institute of Freshwater Ecology and Inland Fisheries, Berlin, Germany — [4]Thaer-Institute, HU Berlin, Berlin, Germany

Collective biological systems – such as animal groups or neuronal networks – are presumed to operate at or near so-called critical points at which they exhibit maximal sensitivity towards environmental cues. We have studied large fish shoals of sulphur mollies (*Poecilia sulphuraria*) which perform collective diving cascades as a response to predation. We previously found these shoals to operate close to criticality, allowing near-optimal propagation of information through the collective [1]. By analyzing a large video dataset of surface waves originating as a response to bird attacks or various synthetic stimuli, we relate wave characteristics to the macroscopic state of the shoal and varying environmental contexts. These results help in better understanding the fundamental mechanisms allowing collectives to self-tune their distance to criticality and navigate the robustness-sensitivity tradeoff.

BP 11.65   Tue 12:30   P1
Electro-thermodynamics of coacervate interfaces — •Arghya Majee[1], Christoph A. Weber[2], and Frank Jülicher[1,3,4] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Institute of Physics, University of Augsburg, Germany — [3]Center for Systems Biology Dresden, Germany — [4]Cluster of Excellence Physics of Life, TU Dresden, Germany

Biological condensates are assemblies of proteins and nucleic acid that provide biochemical compartments in the cell. Such condensates can form by coacervation since many condensate components are charged and condensate properties vary with salt concentration. While the thermodynamic description based on short ranged interactions is well established, a theory accounting for the role of electrostatic interactions in the presence of salt is lacking. Here, we propose an electro-thermodynamic theory of such systems taking into account the role of electrostatics. We find that two or even more charged layers can form at the interface, where charge neutrality is locally not obeyed. Depending on the values of parameters, such charge profiles and associated electrostatic potential profiles imply either reflection or attraction of single molecules diffusing across the interface. Such interface properties could also account for a varying tendency of droplets to fuse and be of relevance for chemical reactions inside biological condensates by selectively recruiting reacting components by charge.

BP 11.66   Tue 12:30   P1
Mean-field theory for fibrillar aggregation and nematic-isotropic phase separation — •Kafa Alameh[1,2] and Christoph Weber[1] — [1]Mesoscopic Physics of Life, Institute of Physics, Universitätsstr. 1, Augsburg, Germany — [2]Center for Systems Biology Dresden, Pfotenhauerstr. 108, 01307 Dresden, Germany

Cells use droplet-like compartments to spatially organize their interior into subcompartments, known as membrane-less organelles. Such organelles are liquid condensates and provide distinct physical environments for chemical processes. Recently, it has been shown that various proteins with beta-sheet structures, such as FUS, are involved in protein aggregation diseases such as ALS and Alzheimer's. Moreover, FUS-rich condensates were shown to undergo aberrant "phase transition," leading to fibrillar, solid-like aggregates. Several theoretical studies have focused on how phase-separated compartments affect the irreversible aggregation of dilute monomers; however, the interplay between aggregation and phase separation at non-dilute conditions remains elusive. Such conditions are particularly relevant at the condensate interface, where aggregates are often nucleated and enriched. Here, we propose a mean-field theory accounting for the interplay between aggregation, condensate formation, and phase transition at condensate interfaces. We find a rich phase behavior; three coexisting phases differing in density and the degree of order: disordered-dilute, disordered-dense, and nematic-dense phases. Our theory suggests the possibility of finding ordered membrane-less organelles in regulatory pathways of neurodegenerative diseases.

BP 11.67   Tue 12:30   P1
Density fluctuation analysis of living matter — •Conrad Möckel[1,2,3], Kyoohyun Kim[1,2], Abin Biswas[1,2,4], Simone Reber[4], Vasily Zaburdaev[1,2,5], and Jochen Guck[1,2,3] — [1]Max Planck Institute for the Science of Light, 91058 Erlangen, Germany — [2]Max Planck Zentrum für Physik und Medizin, 91058 Erlangen, Germany — [3]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91054 Erlangen, Germany — [4]IRI Life Sciences, Humboldt-Universität zu Berlin, 10115 Berlin, Germany — [5]Department of Biology, Mathematics in Life Sciences, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91054 Erlangen, Germany

The characterisation of the dynamical properties of living matter plays an important role in unraveling its complexity. Here we present the combination of quantitative phase imaging with differential dynamic microscopy in order to probe and evaluate its inherent density fluctuations. By employing theoretical models, this approach allows for the determination of the time- and length scale dependent viscoelastic properties of optically transparent systems as demonstrated for high speed supernatant (HSS) Xenopus laevis egg extract. We find that HSS exhibits distinct dynamics at two time scales which can be explained by diffusion in a diffusing potential.

BP 11.68   Tue 12:30   P1
Optimal navigation of smart active particles in complex landscapes — •Mischa Putzke and Holger Stark — Technische Universität Berlin, Institut für Theoretische Physik, Straße des 17. Juni 135, 10623 Berlin, Germany

The field of active matter, and in particular microswimmers, is finding more and more applications. Synthetic microswimmers are potentially used for microsurgery and the targeted transport of drugs and genes. This requires smart active particles that can process information.

The mentioned applications require the optimal navigation in complex environments where the self-propelled microswimmer only changes its orientation but not its velocity. Machine learning is often used to solve optimization problems. We employ Q-learning to train the agent to move towards a target while it receives information about the direction and distance of the target. To model the smart active particle we use Langevin dynamics.

We show that the microswimmer with its limited information is able to navigate in complex landscapes such as potential barriers and wells but also in vortical flow and find the fastest trajectories. We also show that the navigation optimization is stable against thermal fluctuations by including thermal noise in the orientation during training. For potential wells and vortical flow, it can also be observed that during training not the entire set of existing trajectories is covered by the microswimmer, thus optimal solutions can remain hidden.

BP 11.69   Tue 12:30   P1

Evaluation of nanoparticle resistance development of microorganisms — •Stefanie Schuba, Julian Schütt, Jürgen Fassbender, and Denys Makarov — Helmholtz-Zentrum Dresden-Rossendorf

Over the last century, antibiotics against bacterial infections have led to increased life expectancy and quality of people worldwide. Yet the WHO has brought attention to the increasing resistance development of bacterial pathogens against antibiotics - many bacteria are already multi-resistant. In the search of alternatives to classical antibiotics, nanotechnology and nanoparticles (NP) are moving into the focus of scientific research. Particular attention is paid to the Nanosilver (Ag-NP), which has experienced an immense upswing in recent years and is used in many medical products such as wound dressings or consumer products. However, are Ag-NPs safe for health and environment? To tackle this challenge, conventional methods have been used to explore nanoparticle resistance. Conversely, these methods have proven to be limited in terms of labor, cost, and statistical power. In our work, we intend to overcome these barriers by developing a droplet-based microfluidic analytical platform as a tool to elucidate the impact and biological influence of nanoparticles on living microorganisms with high statistical evaluation and detection efficiency. This method allows the separation of bacteria into single droplets, the generation of individual bioreactors, and the screening of the bacterial metabolism in the presence of Ag-NP.

BP 11.70   Tue 12:30   P1

Traffic Slowdown by Antibiotics — •Johannes Keisers, Luca Ciandrini, and Phillippe Fuchs — Centre De Structurale Biologe (CBS), Montpellier, France

The transcription and translation process are amongst the most fundamental processes in biology. In both processes, the flow of RNAP or ribosomes determines the biosynthesis rate. Here, we model this flow with a unidimensional traffic model called the Totally Asymmetric Simple Exclusion Process or TASEP. In particular, we are interested in understanding the role of ribosome pausing states induced by sublethal doses of antibiotics. These pausing states give furhter insights in the dynamics between different antibiotics and the translation process. The final goal is to model how antibiotics change the translation rate by adding a pausing state to the ribosomes and extend the previously derived solution to the open boundary case.

BP 11.71   Tue 12:30   P1

The Influence of pegRNA Variations on Prime Editing Kinetics — •Nathalie Schäffler[1], Julian Geilenkeuser[2], Dong-Jiunn Jeffery Truong[2], Gil Westmeyer[2], and Joachim Rädler[1] — [1]LMU München, Deutschland — [2]ISBM, Helmholtz-Zentrum München, Deutschland

A key development in recent CRISPR technology is the "Search and Replace" system, also called Prime Editing (PE). Right now, the optimization of this is an active research field, which could lead to interesting new possibilities like approaches for biocomputing. However, current studies focus primarily on endpoint measurements with FACS.

In our research we compare different pegRNA variations and their editing efficiency via collective and single cell timelapse measurements. We transfect a HEK293T cell line, which stably expresses a blue shifted mGreenLantern (bsmGL), with the two PE components: pegRNA and Cas9-complex. With this, the cells gain the ability to edit their bsmGL DNA back to the original green mGL sequence. We track the fluorescence-time courses of this signal with Live-cell Imaging of Single Cell Arrays (LISCA) and use kinetic rate equations to better understand the defining processes in the timing of those edits.

This allows us to have a closer look into the kinetics of PE.

Steady-state operation of a cell-free genetic band-detection circuit — •Anna C. Jäkel, Lukas Aufinger, and Friedrich C. Simmel — Technichal University of Munich, Munich, Germany

Synthetic gene networks have been used extensively to explore principles of biological pattern formation as they play a decisive role during biological growth and development processes. Here, we report on a bottom-up approach to design and analyze a cell-free genetic circuit based on an incoherent feed forward loop (IFFL-2), which is expected to produce a three-stripe pattern in response to an input gradient. In our work, we first simulated the behavior of the circuit and explored relevant parameters using a genetic algorithm. We then tested our circuit in a bacterial cell-free gene expression system and found that our circuit is only functional under non-equilibrium conditions in microfluidic ring reactors, whereas it fails to perform in bulk experiments in closed reactors. Hence, we concluded that non-equilibrium conditions are of necessity to establish the double-repression cascade which was the essential element of the genetic cir-

cuit. We used six neighboring ring reactors to establish a 'virtual' morphogen gradient by supplying the reactors with decreasing amounts of the transcription factor sigma28, corresponding to the different positions within an exponential morphogen gradient. We finally demonstrated that our IFFL-2 circuit, when operated in the microfluidic system, shows the correct gene expression response that is required for stripe-formation in a spatial context.

BP 11.73   Tue 12:30   P1

Steady-state operation of a cell-free genetic band-detection circuit — •Anna C. Jäkel, Lukas Aufinger, and Friedrich C. Simmel — Technichal University of Munich, Munich, Germany

Synthetic gene networks have been used extensively to explore principles of biological pattern formation as they play a decisive role during biological growth and development processes.

Here, we report on a bottom-up approach to design and analyze a cell-free genetic circuit based on an incoherent feed forward loop (IFFL-2), which is expected to produce a three-stripe pattern in response to an input gradient. In our work, we first simulated the behavior of the circuit and explored relevant parameters using a genetic algorithm. We then tested our circuit in a bacterial cell-free gene expression system and found that our circuit is only functional under non-equilibrium conditions in microfluidic ring reactors, whereas it fails to perform in bulk experiments in closed reactors. Hence, we concluded that non-equilibrium conditions are of necessity to establish the double-repression cascade which was the essential element of the genetic circuit. We used six neighboring ring reactors to establish a 'virtual' morphogen gradient by supplying the reactors with decreasing amounts of the transcription factor sigma28, corresponding to the different positions within an exponential morphogen gradient.

We finally demonstrated that our IFFL-2 circuit, when operated in the microfluidic system, shows the correct gene expression response that is required for stripe-formation in a spatial context.

A first approach for mimicking guided axon-growth by electrical circuits — •Bakr Al Beattie, Sebastian Jenderny, Karlheinz Ochs, and Dennis Michaelis — Ruhr University Bochum, Chair of Digital Communication Systems, Bochum, Germany

The self-organization aspect of electrical circuits mimicking neuronal networks often only focuses on synapses. Besides the adjustment of synaptic coupling strength, the guidance of growing axons is another important principle for the biological wiring process of neurons. In particular, guidance cues determine the growth direction and thus which neurons interconnect with each other. Up to now, only mathematical models of this process exist. Our aim hence is to provide an ideal electrical circuit mimicking fundamental principles of guided axon growth. For this purpose, we use memristors in combination with sensors. Here, the sensors represent the sensing of guidance cues, while the memristors form the non-volatile signal transmission paths. We then develop a corresponding wave digital model to verify our circuit approach.

BP 11.75   Tue 12:30   P1

Mimicking axon-growth by a bio-inspired memristive circuit — Sebastian Jenderny, •Bakr Al Beattie, and Karlheinz Ochs — Ruhr University Bochum, Chair of Digital Communication Systems, Bochum, Germany

Hardware implementations of neuronal networks are already very powerful. In terms of e.g. energy efficiency, however, they are still far inferior to biological neuronal networks. For this purpose, a better understanding of the general principles that shape these networks can contribute to the development of improved electrical circuits. One principle often neglected is the growing of axons, which has, up to now, only been considered for technical abstract circuit realizations. In this context, our aim is to develop a more bio-inspired circuit model mimicking axon growth in a way that can be compared to the biological process. To this end, we utilize Morris-Lecar oscillators as axon segments and memristors for implementing the growth mechanism. A wave digital emulation then successfully verifies our circuit approach for an axon growth example taken from biology.

BP 11.76   Tue 12:30   P1

RNA Contact Prediction by Data Efficient Deep Learning — •Oskar Taubert[1], Fabrice Lehr[2], Alina Bazarova[3,4], Christian Faber[3], Philipp Knechtges[2], Marie Weiel[1,4], Charlotte Debus[1,4], Daniel Coquelin[1,4], Achim Basermann[2], Achim Streit[1], Stefan Kesselheim[3,4], Markus Götz[1,4], and Alexander Schug[3] — [1]Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Deutsches Zentrum für Luft- und Raumfahrt, Köln, Germany — [3]Forschungszentrum Jülich, Jülich, Germany — [4]Helmholtz AI

On the path to full understanding of the structure-function relationship or even design of RNA, structure prediction would offer an intriguing complement to experimental efforts. Any deep learning on RNA structure, however, is hampered by the sparsity of labeled training data. Utilizing the limited data available, we here focus on predicting spatial adjacencies (*contact maps*) as a proxy for 3D

structure. We explore the space of self-supervised learning for RNA multiple sequence alignments and focus on downstream contact prediction from latent attention maps.

Boosted decision trees in particular prove an advancement in contact prediction quality that can be further enhanced by finetuning the pretrained backbone. We name our model BARNACLE. Our conceptional advance is reflected by a considerable increase of precision and other metrics for contact prediction, thus promising to decrease the sequence-structure gap for RNA.

BP 11.77 Tue 12:30 P1

Influence of Contact Map Topology on RNA Structure Prediction — •Christian Faber and Alexander Schug — Forschungszentrum Jülich, Germany

The available sequence data of RNA molecules have highly increased in the past years. Unfortunately, while computational power is still under exponential growth, the computer prediction quality from sequence to final structure is still inferior to the labour intensive experimental work. Therefore, various attempts have been made to improve computer generated structure predictions.

Although an end-to-end procedure has been developed for proteins in the form of Alphafold2, such a breakthrough is not yet available for RNA molecules. The current strategy entails two steps: (i) predicting potential contacts in the form of a contact maps from evolutionary data, and (ii) simulating the molecule with a physical force field while using the contact map as restraint. However, the quality of the structure prediction crucially depends on the quality of the contact map.

Until now, only the proportion of true positive contacts was considered as a quality characteristic. We propose to also include the distribution of these contacts, and have done so in our recent studies. We observed that the distribution into clusters (typical for ML) leads to poor results. Therefore, we propose a new quality criterion for contact maps that can be easily incorporated into existing ML algorithms. We have introduced this criterion into Barnacle, a recent, very strong ML algorithm especially designed for RNA contact prediction.

BP 11.78 Tue 12:30 P1

Combined cell and nanoparticle models for TOPAS to study radiation dose enhancement by Monte-Carlo based particle scattering Simulations — •Marc Benjamin Hahn[1] and Julian Mateo Zutta Villate[2] — [1]Bundesanstalt für Materialforschung und -prüfung, 12205 Berlin, Germany — [2]Pontificia Universidad Javeriana, Bogota, Colombia

Dose enhancement by gold nanoparticles (AuNP) increases the biological effectiveness of radiation damage in biomolecules and tissue. To apply them effectively during cancer therapy their influence on the locally delivered dose has to be determined.[1] Hereby, the AuNP locations strongly influence the energy deposit in the nucleus, mitochondria, membrane and the cytosol of the targeted cells. In this work, two newly developed continuous and discrete-geometric models for simulations of AuNP in cells are presented.[2] We apply the presented models in Monte-Carlo particle scattering simulations to characterize the energy deposit in cell organelles by radioactive 198AuNP. They emit beta and gamma rays and are therefore considered for applications with solid tumors. Differences in local dose enhancement between randomly distributed and nucleus targeted nanoparticles are compared. Hereby nucleus targeted nanopinarticels showed a strong local dose enhancement in the radio sensitive nucleus.[1] J.M. Zutta Villate and M.B. Hahn, Eur. Phys. J. D. 73 (2019) 95. [2] M.B. Hahn and J.M. Zutta Villate, Sci Rep 11 (2021) 6721.

Interaction of laminin and brain cells with ion implanted titania nanotube scaffolds — •Jan Frenzel[1,2,3], Astrid Kupferer[1,2], and Stefan Mayr[1,2] — [1]Leibniz Institute of Surface Engineering (IOM), 04318 Leipzig, Germany — [2]Division of Surface Physics, Faculty of Physics and Earth Sciences, Leipzig University — [3]Research Group Biotechnology and Biomedicine, Faculty of Physics and Earth Sciences, Leipzig University

Brain-machine interfaces enable symptomatic treatment of neurodegenerative diseases by modulating neural activities and enjoy great popularity when brain tissue is assessed ex vivo. However, current-use interface materials are troubled by numerous challenges concerning loss of long-term adhesion, rejection reactions, and glial scarring. We show that ion-implanted titania nanotube scaffolds (TNS) are a promising candidate for dealing with these issues because they combine high biocompatibility with adequate electrical conductivity. Based on our experiments, we explain how changes in the adsorption of laminin and the viability/adhesion of neurons and glial cells caused by ion implantation can be described by alterations in surface characterisics. The high neuron viability observed on all TNS, but suppressed glial cell formation on implanted TNS, demonstrates the potential as a future interface material. We acknowledge funding by SMWK (100331694). Reference: Frenzel et al., Nanomaterials 2022, 12, 3858. https://doi.org/10.3390/nano12213858

BP 12.2 Wed 9:45 TOE 317

Fiber-based femtosecond 3D printing — •Claudia Imiolczyk[1], Andy Steinmann[1], Moritz Flöss[1], Zhen Wang[1], Michael Heymann[2], Andrea Toulouse[3], and Harald Giessen[1] — [1]4th Physics Institute, Research Center SCoPE, University of Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany — [2]Institute of Biomaterials and Biomolecular Systems, University of Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany — [3]Institute of Applied Optics, Research Center SCoPE, University of Stuttgart, Pfaffenwaldring 9, 70569 Stuttgart, Germany

Ultrashort laser pulses are often used in medical applications, for instance for soft-tissue surgeries. However, the progress on using such laser pulses for tissue structuring is rather marginal so far. Therefore, we aim to realize an endoscopic fiber-based femtosecond 3D printer to minimally invasively surgically repair organ damage on a micrometer scale. For this, high-power femtosecond laser pulses are required, in order to 3D print desired geometries with a microfluidic bio-ink using two-photon-lithography. We utilize ruled reflective diffraction gratings to pre-chirp laser pulses, as dispersion in optical fibers broadens these femtosecond laser pulses. We report on measurements of pulse duration, spectrum, compression, and nonlinear effects. These resulting 3D printed structures should be colonized with endogenous cells, analogous to the extracellular matrix. This could open a new area of endoscopic 3D printing of biomaterials inside the human body to revolutionize plastic micro-surgery, such as repairing defects in the heart of embryos or even repairs behind the eardrum at the auditory ossicles.

BP 12.3 Wed 10:00 TOE 317

DNA-encoded viscoelastic matrices for cell and organoid culture — •Elisha Krieg — Leibniz-Institut für Polymerforschung Dresden e.V. — Technische Universität Dresden

The recent advances in mechanobiology and the physics of life have driven an immense interest in mechanically programmable viscoelastic materials for cell and organoid culture. Here I describe a class of soft hydrogels based on novel DNA libraries that self-assemble with synthetic polymers.[1] This dynamic DNA-based matrix (DyNAtrix) provides computationally predictable, systematic, and independent control over key cell-instructive properties by merely changing DNA sequence information without affecting the compositional features of the system. This approach enables: (1) thermodynamic and kinetic control over network formation; (2) adjustable heat activation for the homogeneous embedding of mammalian cells; and (3) dynamic tuning of stress relaxation times to precisely recapitulate the mechanical characteristics of living tissues. DyNAtrix is self-healing, printable, exhibits high stability, cyto- and hemocompatibility, and controllable degradation. DyNAtrix-based 3D cultures of human mesenchymal stromal cells, pluripotent stem cells, canine kidney cysts, and placental organoids exhibit high viability, proliferation, and morphogenesis over several days to weeks. DyNAtrix thus represents a programmable and versatile precision matrix, paving the way for advanced approaches to biomechanics, biophysics, and tissue engineering.

Invited Talk BP 12.4 Wed 10:15 TOE 317

Materials properties of bacterial biofilms. — •Cécile M. Bidan — Max Planck Institute of Colloids and Interfaces, Department of Biomaterials, Potsdam, Germany

As bio-sourced materials are raising interest for their sustainability, using bacteria to produce biofilms made of a protein and polysaccharide matrix has become a new strategy to make engineered living materials with various functionalities. Our group contributes to this emerging field by clarifying how bacteria adapt biofilm materials properties to the environment. For this, we culture E. coli producing curli amyloid and phosphoethanolamine-cellulose fibers on nutritive agar substrates with varying physico-chemical properties and study the growth, morphology and mechanical properties of the resulting biofilms. We demonstrated that changing the properties of the agar substrate with polyelectrolyte coatings or by varying the water content the bulk properties of the agar affects E. coli biofilm growth, morphology and mechanical properties. We also used E. coli producing only amyloid fibers and focus on the matrix structural and functional changes at the molecular scale. To assess the contribution of each matrix component to the macroscopic biofilm materials properties, we compared the characteristics of biofilms produced by a collection of E. coli mutants differing in the matrix they produce. The results indicate that E. coli biofilm matrix is a composite made of rigid and brittle curli amyloid fibers assembled within a mesh of soft and adhesive phosphoethanolamine-cellulose fibers. Finally, we

explored how treating biofilms with ionic solutions can help tuning further their properties.

BP 12.5 Wed 10:45 TOE 317

The migration and search behavior of immune cells — Reza Shaebani and •Franziska Lautenschläger — Saarland University, Saarbrücken

Immune cells have a variety of tasks in the body. For example, dendritic cells act as the *sentinels* searching for pathogens. For this search, the cells need to scan a certain area in an effective way. Here, we investigate how cells optimize the search of such area. We have shown before that all cell types show a correlation of migration speed and persistence [1]. We later found that cells which strongly correlate these two parameters are particularly good at searching objects [2]. Interestingly, we found that cells do not keep the memory of their speed as long as the memory of their persistence [3]. Now, we investigate how we can disturb this migration and search behavior, preferable by altering the cytoskeleton [4].

BP 12.6 Wed 11:00 TOE 317

Molecular motors from a 3D perspective: how do kinesins organize microtubules? — •Laura Meissner[1], Jonas Bosche[2], Ludger Santen[2], and Stefan Diez[1,3,4] — [1]B CUBE - Center for Molecular Bioengineering, TU Dresden, Dresden, Germany — [2]Center for Biophysics, Department of Physics, Saarland University, Saarbrücken, Germany — [3]Cluster of Excellence Physics of Life, TU Dresden, Dresden, Germany — [4]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany

Kinesins are ubiquitous motor proteins that are essential for intracellular transport processes. In addition, several kinesins act within the mitotic spindle by sliding and crosslinking microtubules. Some of those kinesins not only move longitudinally on the microtubule filament but also display an axial component in their motion. So far, the effect of this axial motion on motility and force generation within the mitotic spindle has not been explored deeply. Using a 3D motility assay, we show that the antagonistic motor proteins kinesin-5 and kinesin-14 drive the rotation of microtubules around each other. We characterize their motility parameters, including velocity and pitch. Further, we determine the extension of the motors, which reveals the conformation of the motors in microtubule overlaps. To investigate the rotational force (torque) that the motors could produce during microtubule sliding, we developed a microtubule coiling assay. Here, both kinesin-5 and kinesin-14 bent and coiled microtubules, indicative of the generation of significant torque. We hypothesize that this behavior serves to organize spindle fibers and to provide robustness to the spindle.

15 min. break

BP 12.7 Wed 11:30 TOE 317

3D stimulated Raman spectral imaging of water dynamics associated with pectin-glycocalyceal entanglement — •Moritz Floess[1], Tobias Steinle[1], Florian Werner[1], Yunshan Wang[1], Willi L. Wagner[2], Verena Steinle[2], Betty S. Liu[3], Yifan Zheng[3], Steven J. Mentzer[3], and Harald Giessen[1] — [1]4th Physics Institute, University of Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany — [2]Department of Diagnostic and Interventional Radiology, University Hospital of Heidelberg, Im Neuenheimer Feld 420, 69120 Heidelberg, Germany — [3]Laboratory of Adaptive and Regenerative Biology, Brigham & Women's Hospital, Harvard Medical School, Boston MA

Pectin, a heteropolysaccharide, is an ideal biomaterial for medical applications such as serosal wound healing and visceral tissue repair. It forms strong mechanical bonds with the underlying tissue. The extraordinary adhesive properties of pectin on organ surfaces are highly water-dependent and most likely result from a microstructural entanglement of pectin polysaccharide chains with the similarly textured glycocalyx, a glycoprotein coat, covering mammalian cell surfaces. We employ label-free 3D stimulated Raman scattering (SRS) microscopy to investigate the hydrophilicity of pectin hydrogel without the altering effects of sample fixation, dehydration, or tissue staining. In particular, we quantify the time scales, on which two different hydration mechanisms take place. Furthermore, the transition zone between pectin and porcine serosal tissue is imaged to obtain quantitative insights into the entanglement between pectin and mammalian glycocalyx.

BP 12.8 Wed 11:45 TOE 317

Quantifying optomechanical properties of phase separated protein condensates — •Timon Beck[1], Lize van der Linden[2], Raimund Schlüssler[2], Kyoohyun Kim[1], Simon Alberti[2], and Jochen Guck[1] — [1]Max Planck Institute for the Science of Light, Erlangen, Germany — [2]Biotec TU Dresden, Dresden, Germany

The organization of intracellular material is a complex task and cells have different strategies for compartmentalization. One way is the formation of membraneless organelles that are involved, for example, in metabolic control and DNA repair. The underlying process of phase separation and percolation is tightly controlled by many parameters as temperature, ion and protein concentration, as well as crowding conditions. Changes in these parameters have an impact on the intermolecular interactions and accordingly tune optical and viscoelastic characteristics of the condensates. Despite the dynamic development of the research field in the last years, there is a lack of tools to quantitatively measure such physical properties. A combination of Brillouin microscopy with quantitative phase imaging, providing information about refractive index and density, gives access to a set of optical and mechanical quantities and in particular the longitudinal modulus. By varying temperature and ion conditions, we were able to tune intermolecular interactions within phase separated protein droplets and found that the introduced variations are reflected in the optomechanical properties of the condensates.

BP 12.9 Wed 12:00 TOE 317

Confinement-induced fractionation and liquid-liquid phase separation of polymer mixtures — •Arash Nikoubashman[1] and Miho Yanagisawa[2] — [1]Institute of Physics, JGU Mainz, Germany — [2]Graduate School of Science, The University of Tokyo, Japan

The formation of (bio)molecular condensates via liquid-liquid phase separation in cells has received increasing attention, as these coacervates play important functional and regulatory roles within biological systems. However, the majority of studies focused on the behavior of pure systems in bulk solutions, thus neglecting confinement effects and the interplay between the numerous molecules present in cells. To advance our knowledge, we perform simulations of binary polymer mixtures in droplets, considering both monodisperse and polydisperse molecular weight distributions for the longer polymer species. We find that confinement induces a spatial separation of the polymers by length, with the shorter ones moving to the droplet surface. This partitioning causes a distinct increase of the local polymer concentration in the droplet center, which is more pronounced in polydisperse systems. Consequently, the systems exhibit liquid-liquid phase separation at average polymer concentrations where bulk systems are still in the one-phase regime.

BP 12.10 Wed 12:15 TOE 317

Branching morphogenesis in the silica cell wall of diatoms — •Iaroslav Babenko[1,2,3], Benjamin M. Friedrich[1,2], and Nils Kröger[1,3] — [1]Cluster of Excellence Physics of Life, TU Dresden, 01062 Dresden, Germany. — [2]Center of Advancing Electronics Dresden, TU Dresden, 01062 Dresden, Germany. — [3]Center for Molecular and Cellular Bioengineering, 01307 Dresden, Germany.

Diatoms live in a glass house: these common single-celled algae fascinated evolutionary biologists, chemical engineers and inspired artists for their ability to produce intricately nano- and micropatterned silica schells. The valve of the cell wall is formed in a planar intracellular compartment termed silica deposition vesicles (SDVs). The physical mechanism that guides the self-assembly of species-specific silica patterns is unknown. Here, we address this question by studying the formation of the silica rib patterns in the cell wall of the model diatom *Thalassiosira pseudonana* by combining theory and electron microscopy of nascent silica valves. We propose a minimal model of branching morphogenesis based on a non classical Turing reaction-diffusion system to quantitatively account for the time course of experimentally observed rib patterns. We introduce a novel mechanism of branching morphogenesis, which relies on a transition from soluble to insoluble silica phases inside the SDV and the concurrent release of an inhibitor that hinders this transition. Moreover, our minimal model is capable of producing a wide range of rib patterns, suggesting that this model may be applicable for describing branching morphogenesis in other diatom species and potentially, in other organisms.

BP 12.11 Wed 12:30 TOE 317

Reimplementing the formation and dispersal of transcriptional clusters with synthetic DNA-nanomotifs and Langevin-dynamics simulations — •Aaron Gadzekpo[1], Xenia Tschurikow[1], Mai Tran[2], Rakesh Chatterjee[3,4], Vasily Zaburdaev[3,4], Kerstin Göpfrich[2], and Lennart Hilbert[1] — [1]Karlsruhe Institute of Technology — [2]Max Planck Institute for Medical Research — [3]Max Planck Zentrum für Physik und Medizin — [4]Friedrich-Alexander Universität Erlangen-Nürnberg

Spatial organisation of the genome is emerging as a crucial aspect of gene transcription. In pluripotent cells, self-interacting molecular factors, such as RNA polymerase II, form microphase-separated domains, which become increasingly dispersed due to amphiphilic effects of newly transcribed genes. To under-

stand the principles that lead to this behaviour, we designed synthetic DNA-nanomotifs that form droplets due to self-interaction and allow for the addition of an amphiphilic tail of thymines. Time-lapse microscopy, titration experiments and analysis of the resulting distributions of droplet properties demonstrate that the synthetic system reproduces the dispersal of phase-separated domains found for increasing transcription levels. Simulations based on Langevin-dynamics equally reproduce this behaviour after tuning interaction strengths and number ratios. Our findings illustrate how model-guided design of DNA-based systems can elucidate the mechanisms that control spatio-temporal compartmentalisation in cells.

BP 12.12   Wed 12:45   TOE 317

Partition complex structure can arise from sliding and bridging of ParB dimers — •Lara Connolley[1], Lucas Schnabel[2], Martin Thanbichler[2], and Sean Murray[1] — [1]Max Planck Institute for Terrestrial Microbiology, Marburg, Germany — [2]University of Marburg, Marburg, Germany

Chromosome segregation is vital for cell replication and in many bacteria is controlled by the ParABS system. A key part of this machinery is the association of ParB proteins to the parS-containing centromeric region to form the partition complex. Despite much work, the formation and structure of this nucleoprotein complex has remained unclear. It was recently discovered that CTP binding allows ParB dimers to entrap and slide along the DNA, as well as leading to more efficient condensation through ParB-mediated DNA bridging. Here, we use semi-flexible polymer simulations to show how these properties of sliding and bridging can explain partition complex formation. We find that transient ParB bridges can organise the DNA into either a globular state or into hairpins and helical structures, depending on the bridge lifetime. Upon coupling with stochastic sliding simulations to form a unified sliding and bridging model, we find that short-lived ParB bridges do not hinder ParB sliding and the model can reproduce both the ParB binding profile and the condensation of the nucleoprotein complex. Overall, our model clarifies the mechanism of partition complex formation and predicts its fine structure.

BP 13: Signaling, Biological Networks

Time: Wednesday 9:30–11:00   Location: BAR 0106

Invited Talk   BP 13.1   Wed 9:30   BAR 0106
Biological signal processes across scales — •Steffen Rulands — Ludwig-Maximilians Universität München, Arnold Sommerfeld Center ffor theoretical Physics, Theresienstr. 37, 80333 München — Max-Planck-Institute for theoretical Physics, Nöthnitzer Str. 38, 01187 Dresden
In contrast to many physical systems, biological systems have the remarkable architecture of being organized into a spatial hierarchy of non-equilibrium processes: from molecules embedded into sub-cellular compartments to cells interacting in tissues. In my talk, I will show how biological systems manipulate the transmission of noise and information between and across these scales in order to perform biological functions. By combining theory and experiments I will first describe a general theory describing the propagation of noise and signals in multi-scale non-equilibrium systems. I will then apply these insights to show how cells make use of the propagation of fluctuations on the subcellular scale to perform biological signal processing: by establishing a low-pass filter of concentration fluctuations in the regulation of cell death and by facilitating a gelation phase transition in the innate immune response.

BP 13.2   Wed 10:00   BAR 0106
Protein Dynamics in the Complex Physical Environment of the Synapse — •Simon Dannenberg, Sarah Mohammadinejad, and Stefan Klumpp — Institut für Dynamik komplexer Systeme Georg-August-Universität Göttingen, Göttingen, Germany
The synapse is a complex environment that is densely packed with proteins and has an internal geometry structured by membranes. This affects the mobility of proteins involved in signal transmission and hence, their availability at corresponding reaction sides.

In our work we use dynamic Monte Carlo simulations to investigate the influence of different physical features of the synapse on protein mobility. The simulations are parameterized by mobility measurements via FRAP experiments. Our approach revealed an unexpectedly high sensitivity of the experiments on the geometry of the synapses as well as dependence of protein fluxes on synaptic features such as axon diameter and synapse size.

BP 13.3   Wed 10:15   BAR 0106
How can a single neuron influence behavior? Hints from integrate-and-fire network models — •Davide Bernardi[1] and Benjamin Lindner[2,3] — [1]Italian Institute of Technology, Ferrara, Italy — [2]Bernstein Center for Computational Neuroscience, Berlin, Germany — [3]Institut für Physik, Humboldt-Universität zu Berlin
Recent experiments challenge the established view that only large neuronal populations can reliably encode information, as is argued on the basis of the large noise and chaotic dynamics of cortical networks. One striking example is that awake rats can be trained to respond to the stimulation of a single cell in the barrel cortex. Here, this problem is framed theoretically by studying how the stimulation of a single neuron can be detected in large networks of integrate-and-fire neurons.

Combining numerical simulations and analytical calculations, we illustrate a simple strategy to detect the single neuron stimulation in the activity of a read-out subpopulation or in a second network, which is both more realistic and more efficient. Furthermore, a readout network tuned to approximate a differentiator circuit can detect the single-neuron stimulation in a more biologically detailed model. In this case, the detection probability increases significantly upon injection of an irregular current, in agreement with experiments.

Our models show how inhibitory synapses could make it possible for the sensitivity to single-neuron perturbation to coexist with a stable asynchronous spontaneous activity, that is, through a mild selective imbalance in the topological (spatial) and temporal sense.

BP 13.4   Wed 10:30   BAR 0106
Towards statistical models of activity recordings from stem cell derived neuronal networks — •Sebastian Willenberg[1], Elijah R. Shelton[1], Paulina M. Wysmolek[2], Filippo D. Kiessler[1], Achim Brinkop[1], and Friedhelm Serwane[1,2,3] — [1]Faculty of Physics and CeNS, LMU, Munich, Germany — [2]MPI for Medical Research, Heidelberg, Germany — [3]Munich Cluster for Systems Neurology, Munich, Germany
Analysis of neuronal activity is the key to understanding the principles of brain circuitry. Theoretical models have been applied on many different scales, ranging from the analysis of single neuron activity to the collective behaviour of large groups of neurons. Models from statistical physics describe the behaviour of networks across spatial and temporal scales with a minimal amount of parameters. Until now, those models have mainly been applied to datasets recorded via 2D electrode arrays. This makes accessing 3D network morphology challenging. I will present our first steps applying statistical models to neuronal recordings of stem cell derived neuronal networks obtained using lightsheet[1] or confocal microscopy. To model the collective firing we map single neuron activity to two states and apply a maximum entropy model to calculate the entropy and energy following the approach of Tkačik et al.[2]. Using this approach, we seek a minimal model describing the firing activity which allows us to understand and predict the collective behaviour of *in vitro* neuronal networks.

BP 13.5   Wed 10:45   BAR 0106
Inference of dynamical networks connectivity with Recurrent Neural Networks — •Pablo Rojas, Marie Kempkes, and Martin E Garcia — Theoretical Physics, University of Kassel, Germany
The inference of directed links in networks of interacting systems is a problem spanning many disciplines. Systems out of equilibrium represent a special case, where samples are not independent but structured as timeseries. In this context, Recurrent Neural Networks (RNN) have attracted recent attention, due to their ability to learn dynamical systems from sequences. We introduce a method to infer connectivity of a network from the timeseries of its nodes, using a RNN based on Reservoir Computing (RC). We show how modifications of the standard RC architecture enable a reliable computation of the existence of links between nodes. While the method does not require information about the underlying mathematical model, its performance is further improved if the selection of hyperparameters is roughly informed by knowledge about the system. The method is illustrated with examples from different complex systems, ranging from networks of chaotic Lorenz attractors to biological neurons. Using simulations of these systems, we demonstrate its power and limitations under a variety of conditions, such as noise levels, delayed interactions, size of the network and hidden variables.

BP 14: Focus Session: From Inter-individual Variability to Heterogeneous Group Dynamics and Disorder in Active Matter (joint session DY/BP/CPP)

The study of active particle dynamics has developed into a vibrant field of multidisciplinary research, including such diverse systems as bacterial colonies, cellular self-organization, synthetic colloids and microrobots as well as macroscopic systems like locusts, flocks of birds, schools of fish or pedestrians. Whereas many studies in the past focused either on the random transport of individual particles or on the interplay of temporal fluctuations (noise) and interactions (velocity alignment or attraction/repulsion), there is now an increasing interest in the question how structural disorder and inter-individual variability, i.e., different motility characteristics of individuals, shape the active particle dynamics and emergent pattern formation of groups. The presence of structural or quenched disorder raises furthermore the immediate question how to bridge data and models based on (short time) tracking data, given the simultaneous presence of temporal fluctuations. With this focus session, we aim at bringing researchers from statistical physics and biophysics together to discuss this interdisciplinary topic and exchange ideas on common challenges arising in different application areas.

Organized by Robert Großmann (Potsdam)

BP 15: Tissue Mechanics II

Time: Wednesday 10:30–12:15　　　　　　　　　　　　　　　　　　　　　　　　　　　　　Location: BAR Schö

BP 15.1　Wed 10:30　BAR Schö
Hydrostatic pressure and lateral actomyosin tension control stretch and tension of the basement membrane in epithelia — •Karla Yanin Guerra Santillan[1,3], Elisabeth Fischer-Friedrich[1,2], and Christian Karla Yanín[1,3] — [1]Cluster of Excellence Physics of Life, Technische Universität Dresden, Dresden, Germany. — [2]Biotechnology Center, TU Dresden, Tatzberg, 01307 Dresden, Germany — [3]School of Science, Technische Universität Dresden, Dresden, Germany

The shaping of epithelial tissues into functional organs often depends on asymmetries in mechanical tension present at the apical and basal sides of cells. Contraction of an actomyosin meshwork underlying the apical side of cells is known to generate apical tension. The basal side of cells is also associated with an actomyosin meshwork, but it is, in addition, connected to a specialized extracellular matrix, the basement membrane. However, how basal tension is generated, and the role of the basement membrane in this process, are often disregarded and not well understood. Here, using atomic force microscopy, we measure mechanical tension in the basal surface of the wing disc epithelium of Drosophila. We find that basal tension depends crucially on the basement membrane with additional contributions of the actomyosin cytoskeleton. Further, performing localized optogenetic activation of actomyosin contractility and osmotic shocks, we deduce that elastic basement membrane stretch is generated by intracellular hydrostatic pressure and lateral actomyosin contractility.

BP 15.2　Wed 10:45　BAR Schö
Noisy growth and buckling in soft tissues — •Rahul G. Ramachandran[1], Ricard Alert[1,2], and Pierre A. Haas[1,2,3] — [1]Max Planck Institute for the Physics of Complex System, 01187 Dresden, Germany — [2]Center for Systems Biology Dresden, 01307 Dresden, Germany — [3]Max Planck Institute of Molecular Cell Biology and Genetics, 01307 Dresden, Germany

The generation of curved tissue shapes such as the villi of the gut or the gyrations of the brain has been associated with buckling instabilities that release elastic stresses accumulated by constrained growth. However, most mechanical theories for these morphogenetic processes assume homogeneous growth and mechanical properties, while these parameters often exhibit strong fluctuations in biological systems. Here, we therefore study a minimal mechanical model of these fluctuations: We analyze the buckling of a growing, neo-Hookean rod through nonlinear finite-element simulations. Fluctuations are introduced as spatial inhomogeneities of the growth tensor and the material parameters. Our results show that stronger growth fluctuations promote buckling by decreasing the buckling threshold. We interpret these results using strain energy distribution from homogenous, patterned and random growth simulations and validate them using analytical calculations.

BP 15.3　Wed 11:00　BAR Schö
Viscoelastic measurements in glioblastoma-infiltrated cerebral organoids — •Michael Frischmann[1], Elijah Shelton[1], Sofia Kalpazidou[2], Jovica Ninkovic[2,3], and Friedhelm Serwane[1,3] — [1]Faculty of Physics and Center for NanoScience, LMU Munich, Germany — [2]Biomedical Center, LMU Munich, Germany — [3]Munich Cluster for Systems Neurology, Munich, Germany

The glioblastoma is a malignant neuroepithelial brain tumor with median survival rates of a few months without treatment. One reason is the rapid infiltrative growth with active destruction of brain tissue and the resulting necrotic debris. Glioblastomas are well described from a molecular biology perspective. However, little is known about their mechanical properties which directly affect the tumor's ability to spread into adjacent tissues. I will present measurements of mechanical properties of glioblastoma and its surrounding tissue. To study tumor biophysics in an accessible in vitro system, we use cerebral organoids grown from induced pluripotent stem cells (iPSCs) with implantet glioblastoma cells. To determine the mechancial properties of the tumor and its microenvironment, we use magnetic microdroplets that we inject into the tissue via microneedles. Actuated by a homogeneous magnetic field, the droplet deforms and its deformation is recorded via a confocal microscope. The dynamic deformation is used to infer the viscoelastic properties of physiological and pathological tissue, as well as boundary regions. The recorded data allows us to establish a viscoelastic model of glioblastoma and to develop a mechanical understanding how brain tumors infiltrate their environment.

15 min. break

BP 15.4　Wed 11:30　BAR Schö
Density-dependent active flow transition of biological tissues — •Mathieu Dedenon[1,2], Carles Blanch-Mercader[3], and Karsten Kruse[1,2] — [1]Department of Biochemistry, University of Geneva, 1211 Geneva, Switzerland — [2]Department of Theoretical Physics, University of Geneva, 1211 Geneva, Switzerland — [3]Laboratoire Physico-Chimie Curie, Institut Curie, Université PSL, Sorbonne Université, CNRS UMR168, Paris, France

Biological tissues of elongated cells can spontaneously flow thanks to active stresses, as predicted by 2D generalized hydrodynamics. This effect has been recently confirmed experimentally with confined C2C12 myoblasts.

Under circular confinement, those cells are observed to undergo tissue rotation at confluence. Cells have maximal orientational order at the disc periphery, forming a spiral +1 topological defect. However at a later stage, cell density increases and the tissue ceases rotational motion. This transition is accompanied by a reorientation of cells along the radial direction, transforming the +1 defect into a static aster.

To understand density-dependent spiral-aster transitions, we generalize the previously used 2D polar active fluid description to incorporate a generic passive coupling between cell density and polarity fields. Using symmetry arguments, several energy terms are allowed and we explore systematically how such couplings affect the spontaneous flow transition, under which conditions they promote a spiral-aster transition. This work shows that collective motion is not only driven by tissue active stress but is also sensitive to cell density.

BP 15.5　Wed 11:45　BAR Schö
Capturing the mechanosensitivity of cell proliferation in models of epithelium — •Maxime Hubert[1], Kevin Höllring[1], Lovro Nuić[2], Luka Rogić[2], Sara Kaliman[1], Simone Gehrer[1], Florian Rehfeldt[3,4], and Ana-Sunčana Smith[1,2] — [1]FAU Erlangen-Nürnberg, Erlangen, Germany — [2]Ruđer Bošković Institute, Zagreb, Croatia — [3]University of Göttingen, Göttingen, Germany — [4]University of Bayreuth, Bayreuth, Germany

The proliferation of epithelial cells, the process of cell growth and cell division, is affected by the mechanical properties of the surrounding environment. While

an extensive literature covers single cell mechanoresponse, information about tissue-wide mechanoresponse are scarce. It is only known that high cell density restricts proliferation and eventually leads to homeostasis. In this presentation, we aim at completing the existing literature by addressing the role of both cell density and extracellular stiffness in the proliferation of cells in epithelial monolayer. Using MDCK-II epithelial tissues stained with EdU we are able to measure the fraction of dividing cells at a given cell density and quantify mechanoresponse. We build a cell-level theory of proliferation based on a two-population description which is compared successfully to the experiments and implemented into simulations. Using experiments and simulations, we also address the role of proliferation in the large scale growth of tissues. A tissue-scale theory of epithelial growth based on the cell-level findings is finally presented. This work provides a first step towards a complete description of proliferation at the tissue scale and its influence on its compartmentalization.

Quantitative 3D live-imaging of self-organisation in embryonic organoids — •Valentin Dunsing, Sham Tlili, Claire Chardès, Léo Guignard, and Pierre-François Lenne — IBDM & CENTURI, Aix-Marseille University/ CNRS, Marseille, France

The emergence of asymmetries within a mass of equivalent cells is the starting event in the development of embryos, resulting in the formation of the main body axes. Despite its fundamental role, the mechanisms that induce symmetry breaking remain largely unknown because they are difficult to probe in vivo, particularly in mammalian embryos. A promising in vitro model to study such mechanisms are embryonic organoids, which undergo gastrulation-like movements similar to those observed in embryos. We aim to use live imaging to disentangle the interplay between signaling, cell differentiation and mechanics underlying self-organized symmetry breaking. Currently available imaging platforms are limited to low-throughput 3D or high-throughput 2D imaging. To overcome this limitation, we establish multi-view single-objective lightsheet microscopy, allowing us to image tens of organoids over hours to days with cellular resolution and sufficient temporal sampling to track cells in 3D. We present ongoing efforts using deep learning based segmentation and quantitative image analysis to correlate cellular dynamics and rearrangements with the expression of key differentiation markers during polarization of aggregates. We thereby analyze how spatially localized expression domains and collective cell movements establish symmetry breaking. Finally, we analyze the variability of spatiotemporal patterns across multiple specimen.

BP 16: Systems Biophysics

Invited Talk   BP 16.1   Wed 11:15   BAR 0106

Systems biophysics of bacterial response to cell wall-targeting antibiotics — Rebecca Brouwers[1], Shareareh Tavaddod[1], Leonardo Mancini[2], Jacob Biboy[3], Elizabeth Tatham[1], Pietro Cicuta[2], Waldemar Vollmer[3], and •Rosalind Allen[1,4] — [1]School of Physics & Astronomy, University of Edinburgh, Edinburgh, UK — [2]Cavendish Laboratory, University of Cambridge, Cambridge, UK — [3]Centre for Bacterial Cell Biology, University of Newcastle, Newcastle, UK — [4]Theoretical Microbial Ecology, Faculty of Biological Sciences, University of Jena, Germany

Antibiotics are central in modern medicine, yet bacterial infections are increasingly becoming resistant to antibiotics. To use antibiotics more effectively, we need to understand better how they work. We have used a combination of microbiological and biophysical experiments, and theoretical modelling, to probe how the antibiotic mecillinam, which targets bacterial cell wall synthesis, kills the bacterium Escherichia coli. Comparing killing dynamics under conditions of rich and poor nutrients we conclude that the balance between the rates of creation of cell surface area and volume plays a crucial role in the fate of cells when exposed to this antibiotic.

Cell size distribution: an analytical comparison between lineage and population experiments — •Arthur Genthon — ESPCI, Université PSL, Paris, France (until december 2022) — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany (from january 2023)

In the past decade, new microfluidic devices, like the mother machine, have been designed to monitor single lineages of cells for many generations with great precision. In classical bulk cultures where full populations are grown, cells with high reproductive success lead to larger populations of offsprings, while no such selection effect is present in single-lineage experiments. Quantifying the statistical bias between these two families of experiments is at the basis of a universal notion of natural selection, which can be defined for any branching tree, not just in cell biology. In this work, we thus compute analytical lineage-population biases for the cell size distribution, in the context of size-controlled cells. The role of stochasticity, both in single-cell growth and in volume partitioning at division, is explored, and we show how it can cancel the lineage-population bias. In addition, in simple cases we show how we can learn the laws of cell growth and division from mother machine steady state size distributions. The parameters of the model, such as the single-cell growth rate, the strength of the size control or the asymmetry of division are obtained by fitting analytical distributions to Escherichia coli data.

Tuning pattern formation of *E. coli* Min proteins *in vivo* — Ziyuan Ren[1], •Henrik Weyer[2], Laeschkir Würthner[2], Erwin Frey[2], and Suckjoon Jun[1] — [1]Department of Physics & Section of Molecular Biology, Division of Biological Sciences, University of California San Diego, 9500 Gilman Dr. La Jolla, CA 92093, USA — [2]Arnold Sommerfeld Center for Theoretical Physics and Center for NanoScience, Department of Physics, Ludwig-Maximilians-Universität München, Theresienstraße 37, D-80333 München, Germany

The Min protein system of *Escherichia coli* bacteria is crucial for their proliferation. The Min proteins ensure symmetric cell division by positioning the cell-division machinery at midcell. This spatial templating is achieved by the

self-organized pole-to-pole oscillation of the Min proteins, suppressing FtsZ ring formation at the cell poles. We experimentally study the robustness of Min pattern formation under changes in the total protein content of MinD and MinE by genetically modifying their expression in live *E. coli* bacteria. This uncovers a remarkable robustness of Min patterns *in vivo* comparable with previous findings *in vitro*. Moreover, this study reveals that the protein concentrations determine the pattern type, and both standing-wave and traveling-wave patterns form in filamentous cells. We show that the same reaction–diffusion model based on the conformational switch of MinE introduced earlier for the *in vitro* system explains both the robustness and the pattern characteristics *in vivo*. Thus, common principles underlie Min pattern formation *in vivo* and *in vitro*.

BP 16.4   Wed 12:15   BAR 0106

Stochastic dynamics of cell shape during cellular state transitions — •Wolfram Pönisch[1], Iskra Yanakieva[1], Aki Stubb[2], Guillaume Salbreux[3], and Ewa Paluch[1] — [1]Dept. of Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK — [2]Stem Cells and Metabolism Research Program, University of Helsinki, Helsinki, Finland — [3]Dept. of Genetics and Evolution, University of Geneva, Geneva, Switzerland

The development of an organism is characterized by a series of cellular state transitions where cells become increasingly specialized. Such state transitions are often accompanied by morphological changes and there are strong indications of coupling between a cell's shape and state. Here, we present a pipeline to quantify and analyse cell shapes as cells undergo the epithelial-to-mesenchymal transition (EMT). We apply our analysis pipeline to study how shape and fate are coupled during the EMT of MDCK cells. We confirm that cell morphology is closely associated with the state: While epithelial cells display spherical shapes, mesenchymal cells undergo spreading. After defining the distinct cellular shapes corresponding to cell states, we study how exactly the morphological features of a cell evolve during EMT. To this aim, we investigate trajectories of the morphological features of individual cells in a low-dimensional morphospace and describe the evolution of cellular shape as a Langevin process, allowing us to entangle the role of deterministic and stochastic morphogenetic forces. By integrating morphometric analysis into studies of cell state transitions, we aim to better understand the crosstalk between cell state and shape.

Sensitivity of Boolean attractors to small network changes and implications for the inference of microbial interaction networks — •Jyoti Jyoti and Marc-Thorsten Hütt — Jacobs university, Bremen, Germany

Sensitivity of dynamics on graphs under small topological changes has been studied for diverse types of dynamics and in relation with a wide range of applications. Here we extend this direction of research by studying (and deciphering) the change of attractors in Boolean threshold dynamics under single and multiple edge switches. By evaluating differences in attractor sets, we can, with high accuracy, predict the structural change in the network. This is of high relevance for network inference, e.g., inferring microbial interactions from abundance patterns: Current approaches, where interaction networks are inferred from attractors [1], often fail to provide networks, which in turn can reproduce the initial attractor set. Evaluating the differences in attractor sets (initial set vs. the one produced by the inferred network) and estimating topological differences from

them can pave the way towards better inference algorithms. We briefly discuss the implications of our findings for microbiome analyses.

BP 16.6   Wed 12:45   BAR 0106
Information storage allows for optimal adaptation in chemical signalling networks out-of-equilibrium — •Daniel Maria Busiello[1] and Giorgio Nicoletti[2] — [1]Max Planck Institute for the Physics of Complex Systems, Germany — [2]University of Padua, Italy

Living systems process information and exhibit dynamical adaptation. We propose a chemical model for sensing that encompasses only necessary ingredients: energy consumption, information storage, and negative feedback. Indeed, equilibrium constraints limit the efficiency of information processing, and storage is an unavoidable energy-consuming step to exploit information. Our model architecture is informed by experimental observations that found negative feedback to be ubiquitous. We show that the presence of information storage and negative feedback leads to finite-time memory, essential for dynamical adaptation. Surprisingly, adaptation is associated with both an increase in the mutual information between external and internal variables and a reduction of dissipation in the internal chemical processes. This twofold advantage comes at an energetic cost. By simultaneously optimising energy consumption and information processing features, we find that far-from-equilibrium sensing dominates in the low-noise regime. Finally, we employ our model to shed light on the adaptation of neurons in zebrafish larvae subjected to periodic visual stimuli. We find striking similarities between predicted and observed behaviours, quantifying dissipation and information-processing performance. Our theory provides a stepping stone towards the idea of highlighting crucial ingredients for information processing starting from a chemical description.

BP 17: Protein Structure and Dynamics

Computational Approaches to Liquid-Liquid Phase Separation of Partially Disordered RS-Proteins — •Yannick Witzky[1], Stephan Hobe[2], Andreas Wachter[2], Arash Nikoubashman[1], and Friederike Schmid[1] — [1]Institute of Physics, Johannes Gutenberg University — [2]Institute for Molecular Physiology, Johannes Gutenberg University

RS-proteins are a class of proteins that contribute to light-activated gene regulation (via an alternative splicing mechanism) in plant morphogenesis. It has been hypothesized that liquid-liquid phase separation (LLPS) plays an important role for the regulation mechanism. Studying these proteins is challenging because they contain both intrinsically disordered regions (IDRs) - which presumably control the LLPS - as well as folded domains that contain the functionally important RNA binding sites. Here we use and compare different coarse-grained models to study the condensation and phase behavior of RS proteins: Commonly used IDP models [1,2] as well as the structure predictive UNRES model [3]. We specifically focus on the on the single-chain conformations, phase behavior and the accessibility of RNA binding site.

BP 17.2   Wed 15:15   BAR 0106
Key Role of the Solvent in Driving Liquid-Liquid Phase Separation — •Ellen Adams[1,2], Jonas Ahlers[3], Verian Bader[3], Simone Pezzotti[3], Konstanze Winkhofer[3], Jörg Tatzelt[3], and Martina Havenith[3] — [1]Technische Universität Dresden — [2]Hemholtz Zentrum Dresden Rossendorf — [3]Ruhr Universität Bochum

In recent years the importance of the aqueous solvent in influencing protein structure, function, and dynamics has been recognized. Coupling of water molecules to the protein surface creates an interfacial region in which water molecules within this region have distinctly different properties than bulk water. Yet, the structure and dynamics within this interfacial region are still not easy to access experimentally. Terahertz (THz) spectroscopy has been shown to be a powerful tool to investigate solvent dynamics in bulk solutions and is directly sensitive to changes in the low frequency collective intermolecular hydrogen-bonding vibrations of water. Here the role of solvation dynamics in the liquid-liquid phase separation (LLPS) of the intrinsically disordered protein fused in sarcoma (FUS) is probed. Characterization of the hydrogen bonding network reveals that water solvating hydrophobic groups is stripped away in the membrane-less FUS biomolecular condensates. Additionally, water left inside of the biomolecular condensates is highly constrained, indicative of a population of bound hydration water. These results uncover the vital role of hydration water in LLPS: the entropically favorable release of unfavorable hydration water serves as a driving force for LLPS.

BP 17.3   Wed 15:30   BAR 0106
Local structure and dynamics of water molecules in FUS protein molecular condensates. — Daniel Chavez Rojas[1], •Joseph Rudzinski[1,2], and Martin Girard[1] — [1]Max Planck Institute for Polymer Research, Mainz, Germany — [2]Institut für Physik, Humboldt-Universität zu Berlin, Berlin, Germany

There is evidence that molecular condensates of the FUS protein play a role in the development of some neurodegenerative diseases like ALS. For this reason, understanding the molecular mechanism by which these condensates form at an atomistic level is of therapeutic interest. However, the molecular structure and water-protein interactions of these condensates is poorly understood. In this work, we utilize a multi-scale approach to generate FUS condensates at a suffi-cient scale with a coarse-grained model, followed by investigation of the atomic scale with shorter, fully-atomistic molecular dynamics simulations. As a result, we are able to efficiently characterize water-protein hydrogen bonding interactions, contacts, and water ordering around the individual amino acids of FUS proteins in the condensate versus in solution. The characterization of water-protein and protein-protein structure provides insights about the driving forces that promote the formation of these molecular condensates.

BP 17.4   Wed 15:45   BAR 0106
Structural dynamics of the intrinsically disordered SNARE proteins at the membrane interface: Recent insights by NMR spectroscopy — Tobias Stief[1,2], Mirko Kraus[1,2], Katharina Vormann[1,2], Reinhard Jahn[3], Angel Perez-Lara[4], and •Nils-Alexander Lakomek[1,2] — [1]Forschungszentrum Jülich, Jülich, Germany — [2]Heinrich-Heine-Universität, Düsseldorf, Germany — [3]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [4]University of Granada, Granada, Spain

SNARE proteins play a crucial role during neurotransmitter release by eliciting the fusion of the synaptic vesicle membrane with the presynaptic plasma membrane. In their pre-fusion state, the SNARE proteins are intrinsically disordered. They do not exhibit a well-defined structure and show high internal flexibility, being membrane-anchored. However, the mode of interaction between the SNARE proteins and the lipid membrane needs to be better understood.

We use the SNARE proteins as a model system for developing novel NMR methods to characterize the inner and conformational dynamics of intrinsically disordered proteins interacting with lipid membranes or being membrane-anchored. Therefore, we address a large range of timescales, from pico- to milliseconds, employing both solution NMR and solid-state NMR methods. The aim is to better describe the conformational space of intrinsically disordered proteins at the lipid membrane interface. At the conference, we will present recent (unpublished) insights into the structural dynamics of the SNARE protein synaptobrevin-2 at the lipid membrane interface.

BP 17.5   Wed 16:00   BAR 0106
Single-chain and condensed-state behavior of intrinsically disordered nuclear proteins in bulk and confinement — •Janka Bauer[1], Lukas Stelzl[1,2,3], Dorothee Dormann[2,3], and Arash Nikoubashman[1] — [1]Institute of Physics, JGU Mainz, Germany — [2]Biocenter, Institute of Molecular Physiology, JGU Mainz, Germany — [3]Institute of Molecular Biology, Mainz, Germany

The liquid-liquid phase separation of intrinsically disordered proteins plays an integral part for the formation of membraneless organelles in cells, which in turn have key functional and regulatory roles. To better understand the complex relation between the sequence and self-assembly of these heteropolymers, we perform molecular simulations of the low-complexity domains of heterogeneous nuclear ribonucleoprotein A1 (hnRNPA1) and Fused in Sarcoma (FUS). For hnRNPA1, we systematically analyze how the conformation and phase behavior are affected by the number of aromatic residues within the examined sequences in both single-chain and condensed state simulations. Our observations strongly support the hypothesis that aromatic residues play a dominant role for condensation, which is further corroborated by a detailed analysis of the intermolecular contacts. To mimic more closely conditions prevalent in cellular environments, we perform simulations of hnRNPA1 and FUS in spherical confinement, where we systematically vary the fraction of the crowding agent polyethylene glycol.

Efficiency and selectivity in the self-assembly of SAS-6 rings on a surface — •Santiago Gomez Melo[1], Dennis Wörthmüller[1], Pierre Gönczy[2], Niccolo Banterle[3], and Ulrich Schwarz[1] — [1]Heidelberg University, Heidelberg, Germany — [2]EPFL, Lausanne, Switzerland — [3]EMBL, Heidelberg, Germany

Centrioles are large cylindrical structures that organize various microtubule-based processes in cells, including the formation of cilia and spindles. Their characteristic nine-fold symmetry results from rings that are formed by dimers of the protein SAS-6. Recently it was observed that the self-assembly of SAS-6 rings is strongly facilitated on a surface. Moreover, a fraction of non-canonical symmetries (i.e., different from nine) was observed. To better understand the factors that determine the efficiency and selectivity of this process, we have performed Brownian Dynamics computer simulations with patchy particles, in which we varied interaction energies and angular binding range. For weak interaction energies and large angular range, we find that the assembly kinetics can be described well by the coagulation-fragmentation equations in the reaction-limited approximation. In contrast, large interaction energies and small angular range lead to kinetic trapping and diffusion-limited assembly. Comparison with experimental data suggests that the SAS-6 system combines a weak binding energy with a small angular range in order to avoid kinetic trapping and favor the desired nine-fold symmetry.

BP 17.7   Wed 16:45   BAR 0106

Alphafold predicts the most complex protein knot and composite protein knots — Maarten Brems[1], Robert Runkel[1], Todd Yeates[2], and •Peter Virnau[1] — [1]Institut für Physik, Staudingerweg 9, JGU Mainz — [2]UCLA-DOE Institute for Genomics and Proteomics, University of California Los Angeles (USA)

The computer artificial intelligence system AlphaFold has recently predicted previously unknown three-dimensional structures of thousands of proteins. Focusing on the subset with high-confidence scores, we algorithmically analyze these predictions for cases where the protein backbone exhibits rare topological complexity, i.e. knotting. Amongst others, we discovered a 7_1-knot, the most topologically complex knot ever found in a protein, as well as several 6-crossing composite knots comprised of two methyltransferase or carbonic anhydrase domains, each containing a simple trefoil knot [1]. These deeply embedded composite knots occur evidently by gene duplication and interconnection of knotted dimers. Finally, we report two new five-crossing knots including the first 5_1-knot. Our list of analyzed structures forms the basis for future experimental studies to confirm these novel knotted topologies and to explore their complex folding mechanisms.

Multi-state Unfolding Processes: Discrimination of protein domains by urea-induced thermal shift — •Ji Young Yang[1,2], Oliver Burkert[2], Boris Mizaikoff[1], and Jens Smiatek[3,4] — [1]Institute for Analytical and Bioanalytical Chemistry, University of Ulm, Ulm, Germany — [2]Boehringer Ingelheim Pharma GmbH & Co. KG, Analytical Development Biologicals, Biberach(Riss), Germany — [3]Boehringer Ingelheim Pharma GmbH & Co. KG, Development NCE, Biberach (Riss), Germany — [4]Institute for Computational Physics, University of Stuttgart, Stuttgart, Germany

Co-solute induced molecular denaturation and aggregation mechanisms related to stability changes for multi-domain proteins like mAbs are often hard to monitor experimentally. In addition, a thorough theoretical explanation is often missing. We performed intrinsic fluorescence (IF) measurements of monoclonal antibody (mAb) samples for different aqueous urea concentrations under thermal denaturation. Our results show that the denaturing effect of urea on individual mAb domains can be explained by linear mapping of the thermal shifting curve to the actual urea concentration. Notably, the achieved thermal shifting curves can be assigned to certain protein domains, which enables discrimination of overlapping denaturation processes. Our approach highlights the benefits of direct monitoring of co-solute effects on the conformational stability of mAb domains and its colloidal stability. We will discuss the experimental approach and present the corresponding outcomes in terms of the underlying molecular mechanisms.

BP 17.9   Wed 17:15   BAR 0106

X-ray damage to Gene-V Protein: NAP-XPS analysis of Chemical changes to Proteins in Water — •Dorothea C Hallier[1,2,3], Jörg Radnik[2], Paul M Dietrich[4], Harald Seitz[1,3], and Marc Benjamin Hahn[2] — [1]Fraunhofer Insitute for Cell Therapy and Immunology, Branch Bioanalytics and Bioprocesses, Potsdam, Germany — [2]Federal Insitute for Materials Research and Testing BAM Berlin, Berlin, Germany — [3]Univerity of Potsdam, Institute for Biochemistry and Biology, Potsdam Germany — [4]SPECS Surface Nano Analysis GmbH, Berlin, Germany

X-ray photoelectron spectroscopy (XPS) was used to analyze the chemical damage of ionizing radiation to a single-stranded DNA-binding protein: Gene-V Protein (G5P/GVP) and its most abundant amino acids (Alanine, Arginine, Cysteine, Glycine, Lysine, Methionine, Tyrosine). This protein plays a crucial role in maintaining the DNA metabolism, especially DNA replication, recombination and repair. Vacuum measurements were combined with near-ambient pressure (NAP) XPS measurements under water and nitrogen atmosphere to detect both direct and indirect radiation damage and corresponding damage pathways. The exposure of proteins and aminoacids to x-rays leads to degradation i.e. via dehydrogenation, decarboxylation, dehydration and deamination. A strong increase of protein damage was observed in water as compared to vacuum.

Comparison of fitting strategies to extract the diffusion coefficient in microrheological experiments — •Sten Leipnitz, Christian Wagner, and Thomas John — Experimental Physics, Saarland University, Saarbrücken

Tracking of small particles undergoing a Brownian motion in liquids is a widespread method in passive microrheology to extract the diffusion coefficient D, the viscosity of the sample respectively. The mean-squared displacement (MSD) is determined from particle positions as a function of the timelag $MSD(\tau) = \sigma_0^2 + 2nD\tau + v_{\text{drift}}^2\tau^2$, where v_{drift} is a possible drift velocity and σ_0 is an offset due to position detection noise in experiments. We present: the extracted parameters depend strongly on the used number of fitting points in the MSD-relation. Surprisingly, considering only the beginning of the MSD-relation in the fitting procedure leads to the best expectation value of the diffusion coefficient. This is shown by numerical simulations of the Brownian motion as well as from experimental data.

BP 18.2   Wed 15:15   ZEU 250

Non-monotonic behavior of timescales of passage in heterogeneous media: Dependence on the nature of barriers — Moumita Dasgupta[1], •Sougata Guha[2], Leon Armbruster[1], Dibyendu Das[2], and Mithun K. Mitra[2] — [1]Department of Physics, Augsburg University, USA — [2]Department of Physics, IIT Bombay, India

Usually time of passage across a region may be expected to increase with the number of barriers along the path. Can this intuition fail depending on the special nature of the barrier? We study experimentally the transport of a robotic bug which navigates through a spatially patterned array of obstacles. Depending on the nature of the obstacles we call them either entropic or energetic barriers. For energetic barriers we find that the timescales of first passage vary non-monotonically with the number of barriers, while for entropic barriers first passage times increase monotonically. We perform an exact analytic calculation to derive closed form solutions for the mean first passage time for different theoretical models of diffusion. Our analytic results capture this counter-intuitive non-monotonic behaviour for energetic barriers. We also show non-monotonic effective diffusivity in the case of energetic barriers. Finally, using numerical simulations, we show this non-monotonic behaviour for energetic barriers continues to hold true for super-diffusive transport. These results may be relevant for timescales of intra-cellular biological processes.

BP 18.3   Wed 15:30   ZEU 250

Phase behavior and finite-size effects in biology — •Felix Herrmann, Burkhard Duenweg, and Martin Girard — Max-Planck Institut fuer Polymerforschung (MPI-P), Mainz, Germany

Phase behavior observed in biology remains puzzling. For instance, the plasma membrane of cells exhibits signs of criticality, as it is controlled to remain near a demixing point. This membrane contains thousand of components, and it is largely unclear how its composition is controlled. Beyond this, one can ask whether cells should obey the traditional thermodynamic picture, given their small size, large number of components and the presence of non-equilibrium processes.

Here, we study toy systems, lattice models containing many (>30) components. We show that these systems exhibit strong finite-size effects. These manifest as behavior that appears similar to traditional critical behavior, but vanish logarithmically with system size. We examine scaling laws, and whether traditional paradigms from macroscopic thermodynamics can be broken in such systems.

BP 18.4　Wed 15:45　ZEU 250

Hierarchical interactions in complex ecosystems — •Lyle Poley[1], Joseph W. Baron[3], and Tobias Galla[1,2] — [1]Theoretical Physics, Department of Physics and Astronomy, School of Natural Sciences, The University of Manchester, Manchester M13 9PL, UK — [2]Instituto de Física Interdisciplinar y Sistemas Complejos IFISC (CSIC-UIB), 07122 Palma de Mallorca, Spain — [3]Laboratoire de Physique Statistique, École Normale Supérieure (ENS), Paris Sciences et Lettres (PSL) Research University, Sorbonne Université, 75005 Paris, France

In the analysis of complex ecosystems it is common to use random interaction coefficients, often assumed to be such that all species are statistically equivalent. We relax this assumption by imposing hierarchical inter-species interactions, which we incorporate into a generalised Lotka-Volterra dynamical system. These interactions impose a hierarchy in the community. Species benefit more, on average, from interactions with species below them in the hierarchy than from interactions with those above.

Using analytical tools from the theory of disordered systems, most notably path-integrals and dynamic mean-field theory, we demonstrate that a stronger hierarchy stabilises the community by reducing the number of species in the surviving community. We will also show that the probability of survival for a given species is dependent on its position in the hierarchy.

Quantifying information content in continuous attractor networks — •Tobias Kühn[1,2] and Rémi Monasson[1] — [1]Laboratoire de Physique de l'Ecole Normale Supérieure, ENS, Université PSL, CNRS, Sorbonne Université, Université Paris Cité, F-75005 Paris — [2]Institut de la Vision, Sorbonne Université, INSERM, CNRS, F-75012 Paris

Attractor networks are a theme with long tradition to model information storage in the brain. Continuous attractor neural networks (CANN), in particular, have been employed to describe the storage of information about space and orientation. However, it stays controversial how useful this paradigm really is to explain actual processes, for example the representation of space in grid and place cells in the entorhinal cortex and the hippocampus, respectively.

A common criticism is that the disorder present in the connections might deteriorate the system's capability to reliably preserve the information of a certain pattern. In order to investigate if this criticism is valid, a measure is needed to objectively quantify the information content of a given neural network. Using the replica-trick, we compute the Fisher information for a network receiving space-dependent input whose connections are composed of a distance-dependent and a disordered component. We observe that the decay of the Fisher information is slow for not too large disorder strength, indicating that CANNs have a regime in which the advantageous effects of connectivity on information storage outweigh the detrimental ones.

BP 18.6　Wed 16:15　ZEU 250

Gift of gab: Probing the limits of dynamic concentration-sensing across a network of communicating cells — •Mohammadreza Bahadorian[1,2], Christoph Zechner[1,2,3], and Carl D. Modes[1,2,3] — [1]Max Planck Institut for Molecular Cell Biology and Genetics (MPI-CBG), 01307 Dresden, Germany — [2]Center for Systems Biology Dresden (CSBD), 01307 Dresden, Germany — [3]Cluster of Excellence Physics of Life, TU Dresden, 01069 Dresden, Germany

Many systems in biology and other sciences employ collaborative, collective communication strategies for improved efficiency and adaptive benefit. One such paradigm of particular interest is the community estimation of a dynamic signal, when, for example, an epithelial tissue of cells must decide whether to react to a given dynamic external concentration of stress-signaling molecules. At the level of dynamic cellular communication, however, it remains unknown what effect, if any, arises from communication beyond the mean field level. What are the limits and benefits to communication across a network of neighbor interactions? What is the role of Poissonian versus super-Poissonian dynamics in such a setting? How does the particular topology of connections impact the collective estimation and that of the individual participating cells? In this article we construct a robust and general framework of signal estimation over continuous-time Markov chains in order to address and answer these questions.

Low-Temperature and Water-Based Biotemplating of Nanostructured Foam-Like Titania Films using ß-Lactoglobulin — •Julian E. Heger[1], Wei Chen[1], Shanshan Yin[1], Nian Li[1], Volker Körstgens[1], Calvin J. Brett[2,3], Wiebke Ohm[2], Stephan V. Roth[2,3], and Peter Müller-Buschbaum[1,4] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]DESY, Hamburg, Germany — [3]Royal Institute of Technology KTH, Stockholm, Sweden — [4]MLZ, TUM, Garching, Germany

Energy-related applications such as solar cells, batteries, and the photocatalytic production of hydrogen are broadly built up on titania nanostructures. A tailored titania morphology is necessary to match the required charge diffusion lengths and the crystallinity beneficial for efficient performance. In the context of large-scale fabrication, the aspect of sustainability becomes essential. Biopolymer templating based on ß-Lactogobulin (ß-lg) and spray deposition promotes low-temperature and water-based synthesis of nanostructured, crystalline, foam-like titania films. During spray deposition, the ß-lg biopolymer matrix sterically directs the titania morphology. Afterwards, the biotemplate is removed by UV-light exposure. To understand the kinetics of film formation during the spray deposition on the nano and crystalline length scale, we simultaneously perform in situ grazing-incidence small-angle and wide-angle X-ray scattering (GISAXS/GIWAXS). Together with scanning electron microscopy (SEM), the results explain the role of ß-lg as a biotemplate.

Structural changes in cellulose nanofibril-colloid hybrid films during humidity cycling — •Stephan V. Roth[1,2], Calvin J. Brett[1,2], Alexandros Alexakis[2], Lucas P. Kreuzer[3], Martin Mansson[2], Sarah Rogers[4], Eva Malmström[2,5], Peter Müller-Buschbaum[3,5], and L. Daniel Söderberg[2] — [1]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]KTH Royal Institute of Technology, Stockholm, Sweden — [3]TUM School of Natural Sciences, Chair for Functional Materials, Garching — [4]ISIS-STFC, Rutherford Appleton Laboratory, Chilton, Oxon OX11 0QX, UK — [5]MLZ, TUM, Garching, Germany

Biocompatible cellulose nanofibrils (CNFs) are an ideal material for sustainable biomaterial templates. Combined with latex colloids, the resulting hybrid colloid-CNF functional materials are excellent candidates for bio-inspired structural colors. Due to the hydrophilic nature of CNFs, we investigate the stability against humidity cycling in terms of reversible/irreversible structural rearrangements. We applied depth sensitive grazing incidence small-angle neutron scattering to evaluate the humidity-induced rearrangements in hybrid latex colloid:CNF templates in situ during cyclic humidification. After the first humidity cycle, a change in morphology on the scale of several 10 nm was observed, which is attributed to latex particles which diffused in the network and enlarged the pores of the network. The measured kinetics resolve the time- and depth-dependence of the differently sized colloids' penetration into the porous CNF network.

Fluorescence correlation spectroscopy for studying the aggregation of nanoplastics in model biofilm substances — •Tobias Guckeisen, Rozalia Orghici, and Silke Rathgeber — Universität Koblenz, Deutschland

Nanoplastics in the environment are a growing problem. Pollutants can adhere to their surfaces and therefore be easily transported into the natural systems. Biofilms are found everywhere in the environment; they are formed by microbial communities that produce a matrix of extracellular polymeric substances. The interaction between nanoplastics and biofilms can lead to aggregation and sedimentation of nanoparticles and determines the transport and fate of nanoplastics. A better understanding of the transport and fate of nanoplastics is important to improve our ability to predict risks associated with these ubiquitous contaminants. In this project, we use fluorescence correlation spectroscopy (FCS) to study the aggregation and interactions of nanoplastics with model biofilm substances. Protein-polysaccharide mixing ratio and pH-dependent aggregation studies show that it is crucial to consider correlative effects between multiple biofilm components to better understand the impact biofilms have on nanoplastic aggregation. Biofilm model systems with only one component, as commonly considered, may lead to an incorrect assessment of the tendency to aggregation.

Ensemble inequivalence and negative extensibility in a wormlike chain with fluctuating bending stiffness — •Panayotis Benetatos — Department of Physics, Kyungpook National University, Republic of Korea

Many semiflexible polymers exhibit fluctuations in the local bending stiffness along their contour. This may be due to intrinsic conformational changes (e.g., denaturation bubble formation in double stranded DNA or helix-coil transition in polypeptides) or to the reversible adsorption and desorption of molecules from the polymer's environment. In this presentation, we analyse the tensile elasticity of a strongly stretched wormlike chain which consists of N concatenated segments, where each segment can be in one of two states, A and B, which differ

in bending stiffness. We call this model the reversible wormlike chain (rWLC) model. In the Gibbs (fixed-force, isotensional) ensemble, we obtain analytic expressions for the force-expression relation and the mean fraction of B segments. We show that, under certain conditions, there is a tension-induced crossover from a mostly A to a mostly B rWLC. In the Helmholtz (fixed-extension, isometric) ensemble, we obtain analytic expressions up to a summation. We show that, for finite N, there is marked ensemble inequivalence. Remarkably, in the Helmhlotz ensemble, the rWLC can exhibit negative extensibility and multiple peaks.

BP 19.5 Wed 17:30 MER 02

Aging and compressed exponential stress relaxation in mechanorespon-sive hydrogels — •Geonho Song[1,2], Wouter Ellenbroek[3], and Kerstin Blank[1,2] — [1]Johannes Kepler University Linz, Linz, Austria — [2]Max Planck Institute of Colloids and Interfaces, Potsdam, Germany — [3]Eindhoven University of Technology, Eindhoven, The Netherlands

Biological materials, such as the extracellular matrix (ECM), are viscoelastic and exhibit stress relaxation. Stress relaxation in the ECM is linked to cellular behavior and needs to be considered as a design parameter when developing bioinspired materials for cell culture and tissue engineering. Here, we introduce a collagen-inspired hydrogel with tunable crosslink kinetics. We utilize collagen-mimetic peptides with controlled association and dissociation rates to crosslink star-shaped polyethylene glycol. We show that ultraslow crosslink dissociation rates cause a distinctive relaxation behavior that is reminiscent of soft glassy ma-terials, showing out-of-equilibrium properties. In particular, subjecting the networks to a sequence of pre-stress and aging causes uncommon compressed exponential relaxation. This unique phenomenon has previously only been reported for a small number of soft glassy systems where compressed exponential relaxation was related to ultraslow dynamics that prohibited the release of internal stresses. In such systems, slow crosslink dissociation delays network relaxation until an external trigger is applied. In future work, we aim to investigate the interplay between locally generated stresses, such as cellular traction forces, and network relaxation properties.

BP 19.6 Wed 17:45 MER 02

Nonaffinity controls critical slowing down and rheology near the onset of rigidity — •Abhinav Sharma[1], Jordan Shivers[2], and Fred MacKintosh[2] — [1]Leibniz institute for polymer research, Dresden — [2]Rice University, Houston, Texas

Fluid-immersed networks and dense suspensions often reside near a boundary between soft (or fluid-like) and rigid (or solid-like) mechanical regimes. This boundary can be crossed either by varying the concentration or by deformation. Near the onset or loss of rigidity, dissipation-limiting nonaffine rearrangements dominate the macroscopic viscoelastic response, giving rise to diverging relaxation times and power-law rheology. Here, we derive a simple relationship between nonaffinity and excess viscosity in fluid-immersed amorphous materials. We then demonstrate this relationship and its rheological consequences in simulations of stress relaxation in strained filament networks and dense suspensions.

Imaging DNA-Origami with Low Energy Electron Holography — •Moritz Edte[1], Hannah Ochner[1], Luigi Malavolti[1], and Klaus Kern[1,2] — [1]Max-Planck-Institute for Solid State Research, Stuttgart, Germany — [2]École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

Our low-energy electron holography (LEEH) approach makes use of a coherent low-energy electron wave (energies in the range of 50 to 150 eV) for imaging biomolecules with high contrast [1]. Hence, the method allows true single-molecule imaging of large three-dimensional molecules and can map conformational variability of flexible molecules [2]. I will show LEEH measurements of individual DNA-Origami molecules on single layer graphene, demonstrating that LEEH is capable of imaging this class of molecules without introducing perceptible structural changes on the time scale of the measurements and on the spatial scale defined by our current resolution limit.

[1] J.-N. Longchamp, et al., PNAS, 2017, 114, 1474-1479. [2] H. Ochner, et al., PNAS, 2021, 118, e2112651118

Spectral and nanolocal discrimination of crosslinked from single fibril-lar actin using mid-IR photoinduced force microscopy (PiF-IR) — Jesvin Joseph[1,2], Dijo Moonnukandathil Joseph[1,2], Lukas Spantzel[2,3], Katharina Reglinski[1,2], Christoph Krafft[1,2], Christian Eggeling[1,2], Rainer Heintzmann[1,2], Michael Börsch[2,3], and •Daniela Täuber[1,2] — [1]Leibniz Institute of Photonic Technology, Jena — [2]Friedrich Schiller University Jena — [3]Jena University Hospital, Jena, Germany

Fibrillar actin is one of the major structural components in cells. Consequently, pathogenic alterations in cell functionality may be revealed by monitoring the re-arrangement of F-actin. However, discriminating protein aggregation in the range below 10 nm is challenging even by high resolution fluorescence microscopy. This gap can be addressed by recently developed mid-IR photo-induced force microscopy (PiF-IR). PiF-IR spectra obtained from fibrillar and monomeric actin match the corresponding FTIR spectra. The high spectral resolution of PiF-IR provides simplified access to IR spectroscopic signatures from secondary protein structure. The intensity of bands at 1655 cm-1 and 1685 cm-1 associated to α-helices and intermolecular β-sheets, respectively, varied within the scan image. Furthermore, PiF-IR hyperspectra obtained form single fibrillar actin appear more homogeneous than those from cross-linked F-actin. These first results are very promising for using PiF-IR to discriminate F-actin structures to study pathogenic alterations in cells and tissue ex vivo.

BP 21.3 Thu 10:00 BAR Schö

Cryo-EM samples of gas-phase purified protein assemblies using native electrospray ion-beam deposition (ES-IBD) — •Tim Esser[1], Lukas Eriksson[2], Paul Fremdling[2], and Stephan Rauschenbach[2] — [1]Thermo Fisher Scientific, 1 Boundary Park, Hemel Hempstead, HP2 7GE, UK — [2]Department of Chemistry, University of Oxford, Oxford OX1 3TF, UK

Combining native mass spectrometry (MS) with cryo electron microscopy (cryo-EM) allows to correlate information on homogeneity, stoichiometry, shape, and interactions of native protein complexes, complementary to high-resolution protein structures. Cryo-EM samples are conventionally made by coating TEM grids with a protein-containing solution, blotting, and plunge freezing in liquid ethane, quenching proteins in their native state, embedded in ultra-thin films of vitreous ice. Reliable sample preparation remains a major challenge, in particular for heterogeneous samples. Here we demonstrate mass-selective cryo-EM sample preparation via native electrospray ion-beam deposition (ES-IBD), as a direct link between native MS and cryo-EM. Protein complexes are brought into the gas phase, mass-selected, and deposited on TEM grids with thin carbon films at defined temperature. By controlling interactions in solution, gas-phase, and on the surface, we probe protein conformations between native solution-phase and native-like gas-phase structures. We show sub-nanometer EM density maps obtained using native ES-IBD and discuss its potential to extend the scope of cryo-EM in structural biology.

CRISPR activation screen to improve the optical properties of living tissues — •Susan Wagner, Venkat Krishnaswamy, Kaushikaram Subramanian, Heike Petzold, Benjamin Seelbinder, Rico Barsacchi, and Moritz Kreysing — Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany

Today, optical microscopes deliver unprecedented resolution allowing discoveries down to the molecular level. Nevertheless, optical access of living biological samples by microscopes is usually restricted to the outer most surface owing to tissue-induced light scattering.

Using directed evolution, we successfully improved the optical properties of mammalian cells. We aim to fully understand this optical plasticity of cells, and genetically clear living mammalian tissues by targeting responsible genes. We are conducting a genome-wide CRISPR activation screen to find genes which confer transparency. This contribution seeks to report on progress, challenges, and opportunities of this technology for biophotonics research, and more generally its potential towards a system level understanding of cellular biophysics.

As a next step, we are investigating how improved optical properties of individual cells influence the optical properties of 3D cell clusters, such as spheroids,

using interspersed external fluorescent microspheres to quantify unbiased imaging quality.

Understanding the full potential of the optical plasticity of a tissue bears the potential of providing us with a broad toolkit, so that different genetic strategies can be applied depending on the specific nature of the various biological samples.

Optical characterization of biological material across scales using interferometric microscopy — •DANIEL MIDTVEDT — Department of Physics, University of Gothenburg

The physicochemical properties, such as size, mass, and composition, of biological matter generally impact its function. However, quantitative characterization of these parameters across the many length-, time-, and mass scales relevant for biology is challenging. Interferometric imaging techniques, such as holographic imaging and interferometric scattering microscopy (iSCAT), provide quantitative measurements of the light scattering properties of biological objects, and are promising techniques for achieving such characterization. However, although iSCAT provides exquisite sensitivity, quantitatively relating the measured signal to physicochemical properties is straightforward only for small (Rayleigh) scatterers. The holographic signal, on the other hand, can be quantified across arbitrary length scale, but due to poor signal-to-noise ratio it is typically restricted to particles larger than the illuminating wavelength. In this talk, I will showcase some of our recent results combining interferometric imaging techniques with deep learning, enabling pushing the limit of mass quantification in holographic imaging toward the Rayleigh limit, thereby bridging a gap in optical characterization of small particles. With our technique, we are able to characterize biological matter across four orders of magnitude in length, four order of magnitude in time, and ten orders of magnitude in mass. I will highlight the key steps that have enabled us to make this development, and discuss its potential impact on life science research.

BP 21.6 Thu 10:45 BAR Schö
Adaptive optics in Confocal microscopy and Fluorescence correlation spectroscopy — •JULIUS TRAUTMANN, PHILIPP KELLNER, and CHRISTIAN EGGELING — Institute for Applied Optics and Biophysics, Friedrich-Schiller University Jena, Philosophenweg 7, 07743 Jena

For more than three decades adaptive optics have been widely used in astronomical applications, but only in recent years it has established itself as an important feature for high resolution microscopy. The abillity to correct for optical aberrations can be useful for any kind of setup but it proved particularly useful when imaging samples with inhomogeneous refractive index structures such as cells and especially cell tissue.

The most established adaptive optic elements include deformable mirrors (DMs) and spatial light modulators (SLMs) which can dynamically correct for aberrations.

This talk will cover the basic idea of including a deformable mirror (DM) in a confocal microscope within a fluorescence correlation spectroscopy (FCS) setup. A comparison of placing the deformable mirror in the excitation or detection beam path will take place.

Visualizing the inner life of microbes — •ULRIKE ENDESFELDER — Institute for Microbiology and Biotechnology, Bonn University, Germany

Microbes, as unicellular organisms, are crucial model systems for the study of cellular mechanisms and functions. With the advent of modern fluorescence microscopy techniques, we can now visualize the inner workings of microbes at the molecular level, e.g. the dynamics of single molecules and the molecular architecture of sub-cellular structures. By quantifying the molecular characteristics of microbes in vivo, we thus can create detailed, spatially and temporally resolved maps of their molecular makeup, allowing us to understand the dynamic heterogeneity and sub-populations at the sub-cellular level. In this talk, I will discuss the potential of single-molecule biophysical approaches for microbiology, using examples from our own research and outlining our future visions.

BP 21.8 Thu 11:45 BAR Schö
A Minimal Model of CD95 Signal Initiation Revealed by Advanced Molecular-Sensitive Imaging — •NINA BARTELS[1], NICOLAAS TM VAN DER VOORT[2], CLAUS AM SEIDEL[2], and CORNELIA MONZEL[1] — [1]Experimental Medical Physics, Heinrich-Heine University, Düsseldorf, Germany — [2]Molecular Physical Chemistry, Heinrich-Heine University, Düsseldorf, Germany

The spatio-temporal organization and dynamic interactions of receptors in the plasma membrane are fundamental for our mechanistic understanding of cell signal initiation. A paradigm of a cell signal initiation process is the ligand-induced oligomerization of TNF (tumor necrosis factor) receptor CD95 in the signaling pathway for apoptosis. Here, we scrutinize proposed CD95 oligomerization models in the cell plasma membrane by applying a molecular sensitive imaging toolkit with up to nanometric resolution including time-resolved FRET

spectroscopy, confocal Photobleaching Step Analysis, STED microscopy, and FCS. Covering a wide range of parameters, CD95 interactions are probed over the whole dynamic range from μs to hours, molecular to cellular scales, and with particular focus on quantifying molecular concentrations. Our multiscale study reveals a minimal oligomerization model to trigger apoptosis efficiently, where only ~8-17% CD95 monomers assemble into dimers/trimers after ligand binding. Further, we highlight the importance of combining complementary techniques for a full understanding of transient and potentially localized processes such as a cell signal initiation.

Investigating human lung tissue by propagation-based phase-contrast X-ray tomography — •JAKOB REICHMANN[1], STIJN VERLEDEN[2], MARK KÜHNEL[3], JAN-CHRISTOPHER KAMP[3], LAVINIA NEUBERT[3], JAN-HENDRIK MÜLLER[1], THANH QUYNH BUI[1], DANNY JONIGK[3], and TIM SALDITT[1] — [1]Institute for X-ray Physics, University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen — [2]Anatomy and Research Centre, University of Antwerp, Universiteitsplein 1, 2610 Wilrijk, Belgium — [3]Institute of Pathology, Hannover Medical School, Carl-Neuberg-Straße 1, 30625 Hannover

The lung is a perfect example of how the function of an organ is enabled by its three-dimensional structure, here formed by intricate and intertwined networks of ventilation and vasculature. In this work we study the structure of lung tissues over multiple scales down to the sub-cellular level by phase-contrast computed tomography (PCCT). We show how human lung tissues with their largely air-filled compartments and small vessels can be imaged non-destructively with a scalable, isotropic resolution and quantitative density. Three-dimensional reconstructions with varied voxel sizes down to 130nm are obtained by advanced phase retrieval and tomographic reconstruction, shedding light on the three-dimensional cytoarchitecture. Morphometric parameters are extracted by automated image processing, and used to quantify the degree of pathological alterations. This offers unique potential to extend histology and pathohistology to study e.g. SARS-CoV-2 infected tissue or other lung degrading diseases such as COPD or cystic fibrosis, as we show with first applications of the method.

BP 21.10 Thu 12:15 BAR Schö
Dynamic allometry of nuclei and cell size in early embryos of a model organism — ROLF FICKENTSCHER[1], TOMOKO OZAWA[2], AKATSUKI KIMURA[2], and •MATTHIAS WEISS[1] — [1]Experimental Physics I, University of Bayreuth, Germany — [2]Cell Architecture Laboratory, National Institute of Genetics, Mishima, Japan

Allometric relations between two observables are a widespread phenomenon in biology. The volume of nuclei, for example, has frequently been reported to be linearly related to the cell volume, but also conflicting, sublinear power-law correlations have been reported. Given that nuclei are vital organelles that harbor and maintain the cells' DNA, an understanding of the allometric scaling of nuclear volumes, which eventually defines the concentration and accessibility of chromatin, is of high interest. Using the model organism Caenorhabditis elegans, we show here that the allometry between cell and nucleus volumes is a dynamically adapting phenomenon with an asymptotic linear scaling. The adaption rate of the nucleus volume also scales with cell size. Our experimental data are well captured by a simple and supposedly generic model based on a diffusion-limited liberation of chromatin sites which drives decompaction and hence nucleus growth. Extrapolating our results to the general case of growing and proliferating cells suggests an isometric scaling of cell and nucleus volumes as the generic case.

BP 21.11 Thu 12:30 BAR Schö
Mechanical and electrophysiological recordings of neural organoids — ELIJAH SHELTON[1], PAULINA WYSMOLEK[2], FILIPPO KIESSLER[1], ACHIM BRINKOP[1], SEBASTIAN WILLENBERG[1], MICHAEL FRISCHMANN[1], and •FRIEDHELM SERWANE[1,2,3] — [1]Faculty of Physics & CeNS, LMU Munich, Germany — [2]MPI for Medical Research, Heidelberg, Germany — [3]Munich Cluster for Systems Neurology, Munich, Germany

Stem-cell derived organoids have made the exploration of neuronal network function accessible in vitro and are now allowing disease modelling. Both biochemical and mechanical signals, such as the elastic modulus, modulate the underlying behaviour of neurons to connect to networks. My group is developing tools for the mechanical and electrophysiological characterization of neuronal organoids. I will present a minimal-complexity setup for 3D imaging of their network activity (Wysmolek et al., Sci Rep 12, 20420, 2022). To extract Ca-signals we combine a lightsheet microscope as an add-on to a standard inverted microscope with computational tools. We created a 3D connectivity map by imaging spontaneous activity. As a next step, we apply statistical models to characterize the network behaviour. Changes in the tissue mechanical properties are one biophysical hallmark of tumour formation in vivo. We map the mechanical properties of tumor-forming cerebral organoids using ferrofluid droplets as mechanical actuators. Our measurements performed in neural organoids could inform researchers about the interaction between mechanics and function in the central nervous system.

BP 21.12   Thu 12:45   BAR Schö
Multi-scale X-Ray phase contrast tomography from the whole cochlea to single cells — •Jannis Justus Schaeper[1], Christoph Kampshoff[2], Bettina Wolf[2], Daniel Keppeler[2], Tobias Moser[2], and Tim Saldditt[1] — [1]Institut für Röntgenphysik, Georg-August-Universität Göttingen — [2]InnerEarLab, Universitätsmedizin Göttingen

The cochlea is the receptor organ of the inner ear which transduces sound into neuronal activity. Both fundamental aspects of signal transduction and neurophysiology as well as biomedical research (implant technology, hearing loss and disorders) require 3D imaging techniques capable to quantify the microanatomy (1).

We present multi-scale 3D imaging of small-animal cochleae by X-ray phase-contrast tomography (XPCT) using both synchrotron radiation (SR) and lab μ-CT to assess the morphology of the cochlea, orientation of cochlear implants (CIs), and the number and density of spiral ganglion neurons (SGNs). Due to optimization in sample preparation, image acquisition and phase retrieval we achieve high contrast for unstained soft tissue. Without extensive sample preparation, shape and volume of every SGN in the entire organ can be identified. In the high-resolution PC-CT, and in the parallel beam, we reach cellular resolution in the organ of Corti. Lab μ-CT is suitable to analyze cochlear morphology and to assess the correct positioning of CIs and resulting (non-)optimal signal transduction.

Reduced stochastic models of drifting assemblies in plastic neuronal networks — •Sven Goedeke, Christian Klos, Yaroslav Felipe Kalle Kossio, and Raoul-Martin Memmesheimer — University of Bonn, Bonn, Germany

In a standard model, associative memories are represented by assemblies of strongly interconnected neurons. It has recently been proposed that these assemblies are not static but drift freely in neural circuits. On the level of single neurons, assembly drift is reflected by characteristic dynamics: relatively long times of stable assembly membership interspersed with fast transitions. How can we mechanistically understand these dynamics? Here we answer this question by proposing simplified, reduced models. We first construct a random walk model for neuron transitions between assemblies based on the statistics of synaptic weight changes measured in simulations of spiking neural networks exhibiting assembly drift. It shows that neuron transitions between assemblies can be understood as noise-activated switching between metastable states. The random walk's potential landscape and inhomogeneous noise strength induce metastability and thus support assembly maintenance in the presence of ongoing fluctuations. In a second step, we derive an effective random walk model from first principles. In this model, a neuron spikes at a fixed background rate and with an input weight-dependent probability when its current or another assembly reactivates. The approach can be applied generally to networks of drifting assemblies, irrespective of the employed neuron and plasticity models.

BP 22.2   Thu 9:45   TOE 317
Fluctuation-dissipation relations for spiking neurons — •Benjamin Lindner — Bernstein Center for Computational Neuroscience Berlin, Philippstr. 13, Haus 2, 10115 Berlin, Germany — Physics Department of Humboldt University Berlin, Newtonstr. 15, 12489 Berlin, Germany

Spontaneous fluctuations and stimulus response are essential features of neural functioning but how they are connected is poorly understood. I derive fluctuation-dissipation relations (FDR) between the spontaneous spike and voltage correlations and the firing rate susceptibility for i) the leaky integrate-and-fire (IF) model with white noise; ii) an IF model with arbitrary voltage dependence, an adaptation current, and correlated noise. The FDRs can be used to derive thus far unknown statistics analytically [model (i)] or the otherwise inaccessible intrinsic noise statistics [model (ii)].

BP 22.3   Thu 10:00   TOE 317
Current fluctuations in nanopores: origin and breakdown of 1/f noise — •Paul Robin, Mathieu Lizee, Alessandro Siria, and Lydéric Bocquet — ENS, Université PSL, CNRS, Sorbonne Université, Université Paris-Cité, Paris, France

Ion transport through nanometric pores is key to many biological processes, from osmoregulation to neurotransmission, yet this process is known to occur under strong fluctuations. The power spectrum of this current noise is known to scale like 1/f at low frequency, according to the long-standing yet empirical Hooge law. Modelling attempts generally rely on complex assumptions such as self-organized criticality or microscopic disorder - in contrast with the apparent universality of 1/f pink noise. In this talk, I will present a simple theoretical model accounting for the presence of 1/f fluctuations in ionic currents through nanopores regardless of their microscopic structure. In particular, I will show how pink noise can emerge from diffusive processes alone, rather than necessitating complex conductance switching mechanisms. This prediction also explains why pink noise can be observed for frequencies much lower than that of microscopic processes. Lastly, I will discuss under which conditions this description is expected to break down. Notably, chemical processes on the pore's walls can alter ion dynamics and slow down diffusion, leading to memory effects and deviations to Hooge's law. I will compare these predictions to experimental data on artificial nanofluidic pores with various surface properties and reactivities.

BP 22.4   Thu 10:15   TOE 317
Selective alignment force in schooling fish linked to leader-follower interactions given by relative speeds of neighbours — •Andreu Puy[1], Palina Bartashevich[2,3], and Pawel Romanczuk[2,3] — [1]Departament de Física, Universitat Politècnica de Catalunya, Barcelona, Spain — [2]Institute for Theoretical Biology, Humboldt-Universität zu Berlin, Germany — [3]Excellence Cluster Science of Intelligence, Technische Universität Berlin, Germany

Collective motion is commonly assumed to emerge when individuals in a group interact with neighbours via some combination of attraction, repulsion and alignment forces. Alignment has been the most elusive and controversial force to study in experimental setups, with previous works differing about its existence. Here we revisit the topic by introducing a force map technique depending on the relative velocities of neighbours. In contrast to commonly used force maps, our technique demonstrates evidence for experimental data of schooling fish of a selective alignment force when individuals move at slower speeds than their neighbours and an antialignment force when they move at higher speeds. We employ a simple model with alignment to demonstrate the validity and robustness of the proposed force map. Including a selective interaction where individuals only interact with faster neighbours allowed us to reproduce the alignment interactions in the experimental data. Finally, we link this idea to leader-follower interactions, justifying that faster individuals act as leaders with respect to their neighbours.

Invited Talk   BP 22.5   Thu 10:30   TOE 317
Statistical Physics of Spatially Organized Catalytic Particles — •Ulrich Gerland — Technical University of Munich, Germany

Catalytic particles are spatially organized in a number of biological systems across different length scales, from enzyme complexes to metabolically coupled cells. Despite operating on different scales, these systems all feature localized reactions involving partially hindered diffusive transport, which is determined by the collective arrangement of the catalysts. We explore how different arrangements affect the interplay between the reaction and transport dynamics, which ultimately determines the flux through the reaction pathway. Two fundamental trade-offs arise, the first between efficient inter-catalyst transport and the depletion of substrate, and the second between steric confinement of intermediate products and the accessibility of catalysts to substrate. We find that the question of optimal catalyst arrangements generalizes the well-known Thomson problem of electrostatics [1]. Furthermore, we map the problem of optimally arranging enzymes to an economic investment problem, which helps to formulate and understand a possible design principle for synthetic biomolecular systems [2].

BP 22.6   Thu 11:15   TOE 317
Collective Dynamics of Multi-Scale Interacting Complex Systems — •Fabrizio Olmeda[1,2] and Steffen Rulands[1,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]IST Austria, Vienna, Austria — [3]Ludwigs-Maximilians-Universitat Munchen, Arnold Sommerfeld Center for Theoretical Physics, Munich, Germany

Understanding the conditions under which complex systems are stable is pivotal for understanding their response to perturbations. Theoretical work has shown that for global interactions between components a minimal complex system is stable if the standard deviation of linearised interaction rates is sufficiently small. In biological systems, which often contain a small number of important and in-

teractions are mediated by diffusing agents, stochasticity and non-locality may influence stability. Here, we generalise these results to stochastic, spatial systems with interaction on multiple length scales. Starting from a microscopic description we derive a coarse-grained field theory and identify a transition between a regime defined by giant density fluctuations and one exhibiting a spatial instability with a finite wave length. The latter is suppressed by non-reciprocity in the interactions between components. Our work provides a rigorous framework to infer collective dynamics and stability in complex systems, with applications ranging from ecosystems to morphogenesis.

BP 22.7 Thu 11:30 TOE 317
Physical mechanism of erythrocytes sedimentation rate — •Alexis Darras, Thomas John, Lars Kaestner, and Christian Wagner — Experimental Physics, Saarland University; D-66123 Saarbrücken, Germany
Red blood cells (or erythrocytes) sedimentation rate (ESR) is a physical parameter of blood which is often checked in medical diagnosis. It is indeed well known that in case of inflammation, the increase in fibrinogen and other proteins induces a higher ESR.

Until recently, researchers thought that the increase of fibrinogen accelerates the ESR by creating bigger aggregates of red blood cells (RBC). Fibrinogen is indeed an aggregation agent of RBCs, and bigger aggregates tend to sediment faster in Stokes regime. However, modeling the ESR measurements with this hypothesis is challenging and often requires physical assumptions specific to this system.

Besides, modern colloidal science has shown that attractive particles, in suspensions with a high volume fraction, form percolating aggregates, as wide as the container. The sedimentation of those colloids then follows a so-called "colloidal gel collapse" regime, governed by the geometry of the percolating aggregate acting as a porous material. In this talk, we show that RBCs actually follow the same behavior. We also demonstrate that a porous-material model naturally leads to an efficient description the RBC sedimentation, which also provides a long-sought dependency of the ESR as a function of the initial RBC volume fraction (i.e. the hematocrit).

BP 22.8 Thu 11:45 TOE 317
Stochastic wavelength selection and pattern fixation — •Tom Burkart[1,2], Anastasiia Petrova[2,3], Laeschkir Würthner[1,2], Claudia Veigel[2,3], and Erwin Frey[1,2,4] — [1]Arnold Sommerfeld Center for Theoretical Physics (ASC), Department of Physics, LMU München, Munich, Germany — [2]Center for NanoScience, LMU München, Munich, Germany — [3]Department of Cellular Physiology, Biomedical Center (BMC), LMU München, Planegg-Martinsried, Germany — [4]Max Planck School Matter to Life, Munich, Germany
Biological pattern-forming processes are typically driven by a chemical fuel (out-of-equilibrium systems) or by a relaxation towards a thermodynamic equilibrium (phase separation). In these cases, pattern wavelength selection results from translational shifts of high-density regions and mass redistribution in between such regions. Here, we study how a pattern with a characteristic wavelength can form when high-density regions can only grow, but neither mass redistribution nor translation are allowed. The corresponding wavelength selection mechanism relies on thermal fluctuations, irreversible fixation of randomly occurring high-density regions, and long-ranged interactions between these regions. To model the density dynamics and the long-ranged interaction, we derive a set of reaction-diffusion equations from a free energy functional. In addition, we derive the statistics of pattern wavelengths from order statistics, emphasising the stochastic nature of the underlying mechanism. Our results constitute an alternative path to pattern formation next to out-of-equilibrium dynamics and phase separation processes.

BP 22.9 Thu 12:00 TOE 317
Control of non-equilibrium chemical reactions via phase separation — •Sudarshana Laha[1,2], Jonathan Bauermann[1,2], Tyler S. Harmon[3], Frank Jülicher[1,2], Thomas C.T. Michaels[4], and Christoph A. Weber[5] — [1]Max Planck Institute for the Physics of Complex Systems Dresden , Germany — [2]Center for Systems Biology Dresden , Germany — [3]IFW Dresden, Germany — [4]ETH Zürich, Switzerland — [5]Institute of Physics, University of Augsburg, Germany
Fuel-driven out-of-equilibrium chemical reactions are spatially organized using compartments in living cells. To what extent the properties of chemical reactions are altered by the compartments relative to homogeneous systems and the underlying physical principles are less explored. Here, we derive a theoretical framework to study such chemical reactions in the presence of compartments. We highlight the different governing kinetic equations for the reactants in diffusion-limited and reaction-limited regimes. We show that for two-state

transition processes, the turnover of the product can be significantly affected in the limit of infinitely fast diffusion of the components. We can further derive the optimal compartment volume analytically which shows how phase separation parameters can affect the turnover. We further observe that the initial rate can be strongly modified for enzymatic and nucleation processes. These aspects allow us to understand better the control of such processes and exemplify the role of enzymes in compartments to speed up the reaction. This understanding is crucial for synthetically designing of cells as compartments and establishing communication between them.

BP 22.10 Thu 12:15 TOE 317
Microphase separation of living cells — •François Detcheverry, Adrien Carrère, Joseph d'Alessandro, Olivier Cochet-Escartin, Julie Hesnard, Nasser Ghazi, Charlotte Rivière, Christophe Anjard, and Jean-Paul Rieu — University of Lyon, Université Claude Bernard Lyon 1, CNRS, Institut Lumière Matière, F-69622, VILLEURBANNE, France
Self-organization of cells is key to a variety of biological systems and physical concepts inspired from condensed matter have proven essential in understanding some of their properties. Here we demonstrate that microphase separation, long known in polymeric materials and other inert systems, has a natural counterpart in living cells. When placed below a millimetric film of liquid nutritive medium, a quasi two-dimensional population of *Dictyostelium discoideum* cells spontaneously self-assembles into compact domains. Their typical size of 100 μm is governed by a balance between competing interactions: an adhesion which acts as a short-range attraction and promotes aggregation, and an effective long-range repulsion stemming from aerotaxis in near anoxic condition. We present a combination of experimental data, analytical modelling and cell-based simulations that all support this scenario. Our findings establish a generic mechanism for self-organization of living cells and highlight oxygen regulation as an emergent organizing principle for biological matter.

BP 22.11 Thu 12:30 TOE 317
Hydrationa and crowding effects on SOD1 sequestration into FUS biocondensates — Luis Enrique Coronas[1], Emeline Laborie[2], Stepan Timr[2], Fabio Sterpone[2], and •Giancarlo Franzese[1,3] — [1]Interdisciplinary and Statistical Physics Section–Department of Condensed Matter Physics, Physics & Institute of Nanoscience and Nanotechnology (IN2UB), Universitat de Barcelona, Barcelona, Spain — [2]CNRS Laboratoire de Biochimie Théorique, Institut de Biologie Physico-Chimique, Université Paris Denis Diderot, Paris, France — [3]Max Planck Institut für Physik Komplexer Systeme, Dresden, Germany
Superoxide Dismutase 1 (SOD1) is a protein related to amyotrophic lateral sclerosis that, under Heat Stress (HS), is sequestered into Stress Granules in vivo and Fused in Sarcoma (FUS) biomolecular condensates in vitro. Experiments show that an in vitro cytomimetic medium, using Bovine Serum Albumin (BSA) as crowder, decreases the SOD1 partition coefficient (PC) even after 60 min of HS. Implicit-water OPEP simulations show no preferential interactions of SOD1 with BSA. Here, by combining the OPEP with a coarse-grained water model, accounting for water contributions to the interactions in large biological systems, we show that SOD1 has one preferred associative state in FUS but three in BSA, whose transition rates and residency times are controlled by their hydration. We conclude that the SOD1 PC's decrease in FUS condensate, when BSA crowders are present, is due to the hydration entropy increase in BSA, a mechanism possibly relevant also in vivo.

BP 22.12 Thu 12:45 TOE 317
Stochastic heat production in phase-separated systems out of equilibrium — •Kathrin Laxhuber, Jonathan Bauermann, and Frank Jülicher — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany
Phase-separated multi-component systems in the presence of chemical reactions provide interesting examples of non-equilibrium systems. We complement the dynamics of phase separation by a heat transport equation which is coupled to diffusive matter transport. On a microscopic scale, fluctuations become relevant, which we include by developing a stochastic lattice model that we link to the macroscopic continuum dynamics. We then implement this model in a kinetic Monte Carlo simulation of spatial flows of energy and matter as well as local reactions. By coupling to reservoirs or by fueling reactions, a system can be driven out of equilibrium. Using a toy system of a single phase-separated droplet, we discuss how temperature fluctuations affect the droplets' dynamics and the noise in the system. We furthermore show how the fluxes due to the driving give rise to a stochastic production of latent heat and reaction heat. The systems we discuss serve as models for biological condensates and the study of energetics in cells.

Conformational dynamics of SARS-CoV-2 spike protein modulates the binding affinity to ACE2 — Fidan Sumbul[1], Claire Valotteau[1], Prithwidip Saha[1], Ignacio Fernadez[2], Annalisa Meola[2], Eduard Baquero[2], Dorota Kostrz[3], James R Portman[3], François Stransky[3], Pablo Guardado Calvo[2], Charlie Gosse[3], Terence Strick[3], Felix Rey[2], and •Felix Rico[1] — [1]Aix-Marseille Univ, CNRS, INSERM, LAI, CENTURI, Marseille, France — [2]Institut Pasteur, Department of Virology, CNRS UMR 3569, Paris France — [3]Ecole Normale Superieure, Institut de Biologie, CNRS, INSERM, PSL, Paris, France

SARS-CoV-2 spike protein (S) interacts with angiotensin-converting enzyme 2 (ACE2) to enter host cells. Protein S forms a homotrimer with three receptor-binding domains (RBD) adopting open and closed conformations. The (un)binding of S to ACE2 may be affected by these conformational dynamics. Here, we used single molecule force spectroscopy to probe the binding strength and affinity of the S-trimer/ACE2 interaction and high-speed atomic force microscopy (HS-AFM) to visualize the RBD opening dynamics of S-trimers. HS-AFM imaging revealed dynamic S-trimers with the three RBDs stochastically and independently switching between open and closed conformations. This modulates binding to ACE2 of S-trimers, but not unbinding. Experimental opening rates and a simple conformational binding model explain the modulation of the binding affinity. Our results shed light on the molecular basis of coronavirus infection.

BP 23.2   Thu 10:00   BAR 0106
ion-specific DNA adsorption at mica mediated by monovalent and divalent metal cations — •Ibrahim Mohd[1], Max Lallemang[2], Bizan N Balzer[2], and Ibrahim Mohd[1] — [1]University of Augsburg, 86159 Augsburg, Germany — [2]universitätsstraße 1

Ion mediated attraction between biomolecules and solid substrates plays a crucial role in a broad range of biotechnological applications. In this work, we combine molecular dynamics simulations and single-molecule atomic force microscopy experiments to characterise the desorption properties of single-stranded DNA at mica surface mediated by the alkali and alkaline earth metal ions Li+, Na+, K+, Cs+, Mg2+ and Ca2+. Our results show that both monovalent and divalent ions induce an attractive interaction between DNA and the negatively charged mica surface. DNA adhesion is caused by two effects: Firstly, ion-specific adsorption of the monovalent cations compensates the negative charge and induces a long-ranged attraction. In addition, the surface adsorbed cations form inner-sphere contacts with the oxygen atoms of the DNA backbone. Both effects depend on the type of cation: Cs+ and K+ ions lead to loosely associated DNA with high surface mobility and low rupture forces. Na+, Li+, and divalent ions lead to a stronger association of DNA with low surface mobility and high rupture forces. By comparing the force-extension curve shapes from experiments and simulations we could provide atomistic insights into the desorption mechanisms and identify the dominant interactions involved in the desorption process.

BP 23.3   Thu 10:15   BAR 0106
Understanding the molecular determinants of chitin-protein interactions in the arthropod cuticle - a single-molecule approach — •Ayesha Talib[1,2], Yael Politi[2], and Kerstin G. Blank[1,3] — [1]Max Planck Institute of Colloids and Interfaces, Potsdam, Germany — [2]Technische Universität Dresden, CMCB, B CUBE, Dresden, Germany — [3]Johannes Kepler Universität, Institute of Experimental Physics, Linz, Austria

In the cuticle of arthropods, structural proteins and chitin fibers form a composite material with anisotropic mechanical properties. The molecular parameters that define the chitin-protein interaction are largely unknown. To answer the fundamental question of what controls cuticle mechanical properties, a molecular strategy is employed that integrates protein engineering with single-molecule force spectroscopy. Chitin binding domains (CBDs) from the spider Cupiennius salei have been identified and expressed recombinantly to qualitatively and quantitatively compare the strength of the protein-chitin interaction. For one CBD present in all spider tissues, we investigated the three partly overlapping consensus motifs RR-1, RR-2 and CB-4. Pull-down assays and single-molecule force spectroscopy suggest that the shortest RR-1 motif does not bind to chitin, whereas similar binding strength is observed for the longer sequences RR-2 and CB-4. We observe a fast dissociation rate, suggesting that CBDs facilitate energy dissipation upon deformation. Our ultimate goal is to correlate molecular properties with the mechanical function of the composite and to synthesize artificial analogues with tunable mechanical properties.

Complex unfolding, refolding and DNA association of the relaxase TrwC — •César Augusto Quintana-Cataño[1], •Miriam Schramm[1], Ekaterina Vorobevskaia[1], Andreas Hartmann[1], and Michael Schlierf[1,2] — [1]B

CUBE - Center for Molecular Bioengineering, TU Dresden, Germany — [2]Cluster of Excellence Physics of Life, TU Dresden, Germany

Referred as "bacterial sex", bacterial conjugation is a process in which a donor cell transfers DNA to a recipient cell. Conjugation is a main driver for spreading of antibiotic resistance genes. The relaxase TrwC associated to the type 4 secretion system is a multi-domain model enzyme essential for bacterial conjugation. It serves multiple purposes: DNA recognition, nicking and unwinding in the donor cell; and re-ligation of ssDNA in the receptor cell. For this last step a mechanical unfoldase denaturates TrwC, which then refolds in the receptor cell. TrwC is a multi-domain protein consisting of 966 amino acids with a 55 amino acids long intrinsically disordered C-terminus. Here, we studied unfolding and folding mechanics of TrwC using single-molecule magnetic tweezers force spectroscopy. We show that the subdomains of TrwC unfold at distinct, different force regimes ranging from ~10 pN to 90 pN and TrwC refolds in a complex multistep reaction. Using our data, we can quantify the folding energetics of TrwC. We have further discovered complex DNA binding events of monomers and dimers using fluorescence correlation spectroscopy, allowing us to build a model of DNA association. We anticipate that our data helps to understand a key enzyme of DNA conjugation and its multifold activities.

Superpower behavior of the budding yeast kinesin-8 — •Anita Jannasch, Brent Fielden, Michael Bugiel, and Erik Schäffer — Universität Tübingen

Kinesin-8 motor proteins can regulate microtubule dynamics and their length. Furthermore, they can crosslink microtubules and slide them relative to each other. These properties make the motor important for cell division. The budding yeast kinesin-8, Kip3, depolymerizes microtubule in a collective, force and length-dependent manner. The latter is due to the motor's very high processivity. Recently, we found that contrary to the depolymerization activity of multiple motors, a single Kip3 motor stabilizes microtubules. Compared to conventional kinesin, Kip3 is more than 10x slower and can generate about a 5x lower maximum force suggesting that it is a low power motor. Surprisingly, using high-precision optical tweezers, we observed that single Kip3 bound via a nanobody to optically trapped microspheres occasionally moved about 6x faster generating 3x higher forces compared to its usual behavior. This superpower behavior is almost comparable to conventional kinesin, but it is unclear whether it is related to one of its biological functions. The nanobody coupling also reduced the compliance of the system and thereby improved the spatiotemporal resolution. With the improved resolution, we were able to detect 4-nm mechanical substeps of the motor. In the long term, a better understanding of the various talents of Kip3 on the molecular level will have implications for cell division and associated diseases.

BP 23.6   Thu 11:00   BAR 0106
Thermodynamic inference for molecular motor models based on non-invasive conditioned waiting-time measurements — •Benjamin Ertel, Jann van der Meer, and Udo Seifert — II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany

Molecular motors are one example of biophysical systems operating far from equilibrium. For the description of their dynamics in motor-bead assays, three classes of models have been proposed. The first class, discrete Markov networks, emphasizes the configurational changes of the motor where the bead enters the transition rates. The second class of models focuses on the motion of the bead, which is described by an overdamped Langevin equation. The third class of models, hybrid motor-bead complexes, describes the full dynamics of the motor-bead assay by combining discrete and continuous models from the two previous classes. In this work, we develop a thermodynamic inference scheme that can be used to distinguish qualitatively between the different classes of models. Since this inference scheme is based on the observation of waiting times for conditioned transitions of the bead trajectory only, it is non-invasive and operationally accessible in experiments. Various characteristics of the motor, like its driving affinity, can be inferred without further information. We have obtained these results through analytical derivations and extensive numerical calculations.

A variance sum rule and its entropy production estimation — •Ivan Di Terlizzi[1,2], Marta Gironella[3], Marco Baiesi[3], and Felix Ritort[2] — [1]Max Planck Institute for the Physocxs of complex systems — [2]University of Padua — [3]University of Barcelona

Nonequilibrium steady states, from the planetary scale to biological processes, are characterized by entropy production via energy dissipation to the environment, which is often challenging to measure. A novel variance sum rule sets a new resource for exploiting fluctuations to measure physical quantities in stochastic systems. In particular, we focus on the formula it gives for estimating the entropy production rate from trajectories of positions and forces. We describe this method with analytically solvable models and we show its robustness and usefulness in practical applications to experimental data. By introducing a model-dependent fitting procedure, the method is also adapted to deal with conditions where not all degrees of freedom are experimentally accessible. For example, by analysing traces of flickering red blood cells, we obtain estimates of the entropy production rate in line with values obtained with totally different thermodynamic techniques.

BP 23.9   Thu 12:00   BAR 0106

Lattice defect sites accelerate microtubule severing by spastin — •Cordula Reuther[1], Paula Santos-Otte[1], Rahul Grover[1], and Stefan Diez[1,2,3] — [1]B CUBE - Center for Molecular Bioengineering, TU Dresden, Dresden, Germany — [2]Cluster of Excellence Physics of Life, TU Dresden, Dresden, Germany — [3]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany

Length regulation of microtubules and their organization into complex arrays occurs through the activity of polymerases, depolymerases as well as severing enzymes such as katanin and spastin. The latter hexamerize on the microtubule lattice, pull out single tubulin dimers in an ATP-dependent manner and eventually generate internal breaks in the microtubule. For both enzymes it was shown that the severing activity is regulated by tubulin posttranslational modifications. So far, however, only katanin has been reported to exhibit a lattice-defect- or crossover-sensing activity. Here, we determined whether lattice defects in GMPCPP-stabilized microtubules also affect the severing activity by spastin. In controlled in vitro assays we characterized microtubules with defects next to control microtubules. Defect sites were introduced either through specific polymerization conditions or by end-to-end annealing of microtubules. We found that (i) the presence of defects accelerated the onset of the severing process and (ii) severing occured twice as often in microtubule segments with defect sites as compared to random lattice segments. Furthermore, we quantified the correlation of the fluorescence signal of GFP-labelled spastin along the microtubule lattice to the severing sites as a function of time.

BP 23.10   Thu 12:15   BAR 0106

Keratin filament mechanics and energy dissipation are determined by metal-like plasticity — •Charlotta Lorenz[1], Johanna Forsting[1], Robert W. Style[2], Stefan Klumpp[3], and Sarah Köster[1] — [1]Institute for X-Ray Physics, University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

— [2]Department of Materials, ETH Zürich, Vladimir-Prelog-Weg 1-5/10, 8093 Zürich, Switzerland — [3]Institute for the Dynamics of Complex Systems, University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Cell mechanics is determined by an intracellular biopolymer network, including intermediate filaments that are expressed in a cell-type specific manner. A prominent pair of intermediate filaments are keratin and vimentin as the epithelial-to-mesenchymal transition is associated with a switch from keratin to vimentin. The transition coincides with a change in cellular mechanics, and thus dynamic properties of the cells. This observation raises the question of how the mechanical properties already differ on the single filament level. Here we use optical tweezers and a computational model to compare the stretching and dissipation behavior of the two filament types. We find that keratin and vimentin filaments behave in opposite ways: keratin filaments elongate, but retain their stiffness, whereas vimentin filaments soften, but retain their length. This finding is explained by fundamentally different ways to dissipate energy: viscous sub-units sliding within keratin filaments and non-equilibrium α helix unfolding in vimentin filaments.

BP 23.11   Thu 12:30   BAR 0106

The single-strand annealing protein RAD52 can form a stable nucleoprotein filament — •Carolina Carrasco[1], Laura Muras[1], Tobias Jachowski[1], Sivaraman Subramaniam[2], Francis Stewart[2], and Erik Schäffer[1] — [1]Center for Plant Molecular Biology (ZMBP), University of Tübingen, Tübingen, Germany — [2]Department of Genomics, Biotechnology Center, TU Dresden, Dresden, Germany

Genome maintenance requires the repair of DNA double-strand breaks. It can be mediated among others by the single-strand annealing. RAD52 proteins form rings that are thought to promote the annealing. How RAD52 interacts with and anneals DNA strands remains unclear. We have investigated the dynamic interaction of RAD52 with DNA by force spectroscopy using optical tweezers. Upon stretching single DNA molecules in the presence of RAD52, we have observed elongation steps in DNA extension that are consistent with either dissociation, unwrapping, or opening of individual DNA-bound rings. Upon relaxation, reverse steps of similar amplitude were detected. Under constant force, step sizes were uniform. Surprisingly, the disruption forces followed a gamma distribution suggesting that the RAD52-DNA dissociation process consists of multiple stochastic steps. Successive stretch-relax cycles at high forces promoted DNA softening and a melting-force increase because of an intercalation and sealing mechanism on DNA. The final DNA-RAD52 hysteresis-free nucleoprotein filament is consistent with a flexible helical structure in which RAD52 monomers, and not rings, mediate strand annealing.

BP 23.12   Thu 12:45   BAR 0106

Assessing biomolecular interactions across scales using optical tweezers — •Roman Renger, Nicholas Luzzietti, and Philipp Rauch — Paalbergweg 3, 1105 AG Amsterdam, Netherlands

Biological processes involving proteins interacting with nucleic acids, cell membranes or cytoskeletal filaments are key to cell metabolism and hence to life in general. Detailed insights into these processes provide essential information for understanding the molecular basis of physiology and the pathological conditions that develop when such processes go awry. The next scientific breakthrough consists in the direct, real-time observations and measurements of the most fundamental mechanisms involved in biology Single-molecule technologies offer a powerful opportunity to meet these challenges and to study dynamic protein function and activity in real-time and at the single-molecule level. Here, we present our efforts for further enabling discoveries in the field of biology and biophysics using the combination of optical tweezers with correlative fluorescence microscopy (widefield, TIRF, confocal and STED) and label-free Interference Reflection Microscopy (IRM). We present several examples in which our technology has enhanced the understanding of basic biological phenomena, ranging from protein structure to intracellular organization. Furthermore, we show that advances in hybrid single-molecule methods can be turned into an easy-to-use and stable instrument that has the ability to open up new avenues in many research areas.

Acoustically propelled nano- and microparticles: From fundamentals to applications — •Raphael Wittkowski — Institut für Theoretische Physik, Center for Soft Nanoscience, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany

Among the existing types of artificial active colloidal particles, acoustically propelled nano- and microparticles have a particularly high potential for future ap-

plications in fields like medicine and materials science. However, despite intensive research on this type of motile particles in recent years, the understanding of their properties is still very limited. A reason for the limited understanding is that the previous research has mostly been experimental and that it is difficult to study the dependence of certain system parameters on the propulsion of the particles in experiments since the parameters can often not be varied independently of the other parameters and in ranges of reasonable size. In this talk, I will give

an overview about our theoretical investigation of the properties of acoustically propelled nano- and microparticles and the challenges that remain for future research.

BP 24.2   Thu 10:00   ZEU 160

Force on probe in a confined active fluid — Shuvojit Paul[1], •Ashreya Jayaram[2], N Narinder[1], Thomas Speck[2], and Clemens Bechinger[1] — [1]Fachbereich Physik, Universität Konstanz, 78464 Konstanz, Germany — [2]Institut für Physik, Johannes Gutenberg-Universität Mainz, 55128 Mainz, Germany

When immersed in a dispersion of smaller "depletants", a colloidal particle experiences depletion forces in the presence of another colloidal particle or under confinement. While the nature of these forces is well-established for passive systems, much less is known about the consequence of making the depletants self-propelled or "active". In this work, we consider a large, optically trapped probe under circular confinement surrounded by smaller active Janus particles. We find that the force experienced by the probe varies non-monotonically as the distance between the colloid and the confinement is increased. To rationalize this observation, we relate the measured force to the active stress and, subsequently, to the microstructure of the surrounding active fluid. Going beyond synthetic active matter, our work could shed light on the organization of intracellular entities in biological systems.

BP 24.3   Thu 10:15   ZEU 160

Symmetry-breaking refractive index profiles as a propulsion mechanism for active Brownian particles — •Julian Jeggle[1], Matthias Rüschenbaum[2], Cornelia Denz[2], and Raphael Wittkowski[1] — [1]Institut für Theoretische Physik, Center for Soft Nanoscience, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany — [2]Institut für Angewandte Physik, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany

Active Brownian particles (ABPs) have been realized with various propulsion mechanisms such as self-diffusiophoresis, self-electrophoresis or acoustic scattering. Typically, these mechanisms induce flow fields around the particles that represent a deviation from the "pure" ABP model. Here, we present a novel implementation of ABPs in the form of transparent microswimmers with a symmetry-breaking refractive index gradient. Utilizing the momentum transfer associated with light refraction as the driving force induces no flow fields beyond Stokes flow. Unlike optothermally driven particles, this archetype of ABPs also allows for sensitivity to the phase and polarization of the driving light field thus improving the spatio-temporal control of light-based propulsion mechanisms. Using non-light-absorbing particles enables bulk volume systems and allows the introduction of feedback loops, therefore making this approach a promising foundation for adaptive matter systems.

Entropy production in active turbulence — •Byjesh Nalini Radhakrishnan, Thomas Schmidt, and Etienne Fodor — Department of physics and material science, University of Luxembourg

Active particles like bacteria and sperm cells sustain a continuous intake and dissipation of energy. Consequently, they are intrinsically out of equilibrium which leads to a non-vanishing entropy production rate (EPR) even in steady states.

Quantifying how the EPR varies in different collective phases is crucial in developing a thermodynamic framework for active matter. In this work, we look at the EPR in active turbulence. We use Active Model H, a continuum model for active particles in a momentum-conserving fluid, to study turbulence in contractile scalar active systems. We measure the local EPR in numerical simulations, which unveils the role of the noise and activity parameters on the EPR in active turbulent systems.

BP 24.6   Thu 11:15   ZEU 160

Phase transitions in multicomponent active matter: a quantitative kinetic theory — •Jakob Mihatsch[1], Thomas Ihle[1], Rüdiger Kürsten[2], and Horst-Holger Boltz[1] — [1]Institute for Physics, University of Greifswald, Greifswald, Germany — [2]Departament de Física de la Matèria Condensada, University of Barcelona, Barcelona, Spain

We consider a multicomponent model of self-propelled particles with Kuramoto-type alignment interactions. Starting from the N-particle Fokker-Planck equation we observe that the usual factorization Ansatz of the probability density, often called Molecular Chaos approximation, predicts a relaxation behavior which qualitatively disagrees with agent-based simulations. Therefore, we develop a kinetic theory which takes the time-evolution of the two-particle correlation function explicitly into account, i.e. goes beyond the mean-field approximation. We show that this theory predicts the relaxation behavior of the system as well as the order-disorder transition with high precision in certain parameter ranges. In particular, the dependence of the transition threshold on the particle speed is predicted correctly.

BP 24.7   Thu 11:30   ZEU 160

Emergent collective behaviour due to virtual interactions between robotic swimmers — •Samudrajit Thapa[1,2], Bat-El Pinchasik[1,3], and Yair Shokef[1,2,3] — [1]School of Mechanical Engineering, Tel Aviv University, Tel Aviv 69978, Israel — [2]Sackler Center for Computational Molecular and Materials Science, Tel Aviv University, Tel Aviv 69978, Israel — [3]Center for the Physics and Chemistry of Living Systems, Tel Aviv University, 69978, Tel Aviv, Israel

Many organisms in nature use local interactions to realize global collective behaviour. Here we study how simple two body distance-based interactions between active Brownian particles results in collective motion. The interactions are not physical but virtual, wherein each particle senses the presence of other particles nearby and changes its behaviour accordingly. We study the radial distribution function to quantify the emergent interactions for both social and anti-social behaviour. Using Langevin dynamics simulations, we discover that under certain conditions positive correlations of the motion can emerge even in the case of anti-social behaviour. Our results might be potentially useful for designing robotic swimmers that can swim collectively just based on sensing the distance to their neighbours.

Kinetic Event-Chain Algorithm for Active Matter — •Nico Schaffrath, Thevashangar Sathiyanesan, Tobias Kampmann, and Jan Kierfeld — Physics Department, TU Dortmund University, 44221 Dortmund, Germany

We present a cluster kinetic Monte-Carlo algorithm for active matter systems of self-propelled hard particles. The kinetic event-chain algorithm is based on the event-chain Monte-Carlo method and is applied to active hard disks in two dimensions. The algorithm assigns Monte-Carlo moves of active disks a mean time based on the mean and variance of the move length in force direction. This time is used to perform diffusional rotation of their propulsion force. We show that the algorithm reproduces the motility induced phase separated region in the phase diagram of hard disks correctly and efficiently.

BP 24.9   Thu 12:00   ZEU 160

Emergent pattern formation in communicating active matter — •Robert Grossmann[1], Zahra Mokhtari[2], Robert I.A. Patterson[3], and Felix Höfling[2,4] — [1]Institut für Physik und Astronomie, Universität Potsdam — [2]Institut für Mathematik, Freie Universität Berlin — [3]WIAS Berlin — [4]Zuse Institut Berlin

Inspired by trail formation as observed in colonies of driver ants, for example, we study ensembles of agent particles that communicate via deposition and sensing of pheromones. These chemical traces are produced by the agents themselves and encode their current position and walking direction. Other agents passing by will then tend to align with the orientation inscribed in the pheromone traces. In the limit of short pheromone lifetime, the dynamics of this system reduces to the seminal Vicsek model and, thus, yields the formation of transversally moving bands. In the opposite limit, the effective agent-agent interaction represents a form of delayed feedback and yields the spontaneous formation of macroscopic, persistent trails, which are followed and reinforced by the agents [New J. Phys. **24** 013012 (2022)]. In this talk, we present large-scale simulations of the agent model and establish the phase diagram as function of the lifetime of pheromones. We rationalize our findings by analyzing mean-field equations that are systemati-

cally derived from the stochastic particle model. Combining numerical solutions of these order parameter equations and a linear stability analysis, we show how transversal bands, common in the Vicsek model, are destabilized, giving rise to the formation of "longitudinal" trails, pointing in the mean direction of motion.

BP 24.10   Thu 12:15   ZEU 160
Binary Mixture of Deforming Particles — •Yiwei Zhang, Alessandro Manacorda, and Etienne Fodor — DPhyMS, University of Luxembourg, Luxembourg, Luxembourg

Phase separation occurs in miscible liquids where components have distinct properties. In reactors, components undergo stochastic change in their properties which affect the liquid composition. While phase separation and reaction-diffusion have already been studied extensively as separate ingredients, how they combine in non-ideal reactors remains poorly understood. To bridge this gap, we consider repulsive particles with fluctuating size subject to one-body landscape and nonequilibrium synchronisation. The landscape features minima which, regarding size as reaction coordinate, distinguish three states: Particles with finite size, either A- or B-type, and point particles. In this context, synchronisation penalizes A particles in B-rich phases, and vice versa, so that the system eventually accommodates a uniform state. We report the phase diagram depending on the stability of each state and the corresponding particle sizes. Combining hydrodynamic and phenomenological arguments, we recapitulate how metastability regulates the interplay between synchronisation and repulsion. Our results reveal the role of nonequilibrium kinetic factors at play in non-ideal reaction-diffusion systems.

BP 24.11   Thu 12:30   ZEU 160
Self-organization of model catalytic cycles — •Vincent Ouazan-Reboul[1], Jaime Agudo-Canalejo[1], and Ramin Golestanian[1,2] — [1]Max Planck Institute for Dynamics and Self-Organization, Am Fassberg 17, D-37077, Göttingen, Germany — [2]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, OX1 3PU, Oxford, UK

We study analytically and numerically a model metabolic cycle composed of an arbitrary number of species of catalytically active particles. Each species converts a substrate into a product, the latter being used as the substrate by the next species in the cycle. Through a combination of catalytic activity and chemotactic mobility, the catalytic particles develop effective interactions with particles belonging to neighbouring species in the cycle. These interactions, being fully out-of-equilibrium, show some unusual features, in particular being non-reciprocal. We find that such model metabolic cycles are able to self-organize through a macroscopic instability, with a strong dependence on the characteristics of the cycle. For instance, cycles containing an even number of species are able to minimize repulsion between their component particles by aggregating all even-numbered species in one cluster, and all odd-numbered species in another. Such a grouping is not possible if the cycle contains an odd number of species, which can lead to oscillatory steady states in the case of chasing interactions.

BP 24.12   Thu 12:45   ZEU 160
Reentrant condensation transition in a model of driven scalar active matter with diffusivity edge — Berx Jonas[2], •Bose Aritra[1], Mahault Benoit[1], and Golestanian Ramin[1,3] — [1]Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany — [2]Institute for Theoretical Physics, KU Leuven, B-3001 Leuven, Belgium — [3]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford OX1 3PU, United Kingdom

A class of scalar active matter for which the effective diffusivity vanishes beyond a certain density threshold, hereby referred to as diffusivity edge, triggers the formation of a condensate when confined in a harmonic potential. The condensation transition exhibits remarkable similarities with a Bose-Einstein Condensation (BEC). Here we study the effect of a diffusivity edge in a system of scalar active matter confined by a periodic potential and driven by an external force.

We find that this system shows qualitatively distinct stationary regimes depending on the amplitude of the driving force with respect to the potential barrier. For small driving, the diffusivity edge induces a condensation analogous to the BEC-like transition reported for the nondriven case, which is characterised by a density-independent steady state current. Conversely, large external forces lead to a qualitatively different phase diagram where condensation is not possible below a density threshold and the associated transition at moderate densities above the threshold the transition is reentrant due to the existence of a subsequent evaporation transition at low effective temperatures.

BP 25: Cell Mechanics II

BP 25.1   Thu 15:00   BAR Schö
Nuclear mechanics probed by optical tweezers-based active microrheology — •Bart Vos[1], Till Müncker[1], Ivan Avilov[2], Peter Lenart[2], and Timo Betz[1] — [1]Third Institute of Physics, University of Göttingen, Göttingen, Germany — [2]Max Planck Institute for Biophysical Chemistry, Göttingen, Germany

Mechanics play a crucial role in a wide range of cellular processes, from differentiation to division and metastatic invasion. Consequently, the mechanical properties of the cytoskeleton, providing shape, motility and mechanical stability to the cell, have been extensively studied. However, remarkably little is known about the mechanical environment within the nucleus of a cell, and fundamental questions remain unanswered, such as the role of nuclear actin or the sudden "freezing" of the cell during cellular division that prevents diffusion or active mixing of the nucleus and the cytoplasm.

To address these questions, we perform optical tweezers-based microrheology in the cellular nucleus. Microrheology has proven to be a suitable tool for intracellular mechanical measurements, as it enables local, non-invasive measurements. However, although the cytoskeleton has been extensively studied this way, the cell nucleus has not been investigated, mainly due to difficulties with inserting appropriate probe particles. By using starfish oocytes that have larger dimensions than most other cell types, we are able to perform microinjection of micrometer-sized particles. We observe viscoelastic behavior of the nucleoplasm that is profoundly different from the cytoskeleton. In addition, we mechanically follow the oocyte during meiotic cell division.

Mechanosensitive binding of filamins in the actin cytoskeleton of live cells — •Valentin Ruffine and Elisabeth Fischer-Friedrich — DFG Cluster of Excellence Physics of Life, Technische Universität Dresden, Dresden, Germany

Filamins A and B are cross-linkers of the actin cytoskeleton expressed in a wide range of human cell types. In particular, filamins are crucial in actin cytoskeleton interactions with the extracellular matrix and therefore are major molecular players in cartilage and bone development. Filamins form dimers which can bind and cross-link two actin filaments and thus contribute to the mechanical integrity of cytoskeletal structures such as the actin cortex. Myosin-generated contractile tension in the actin cortex is likely translated into a tensile force on the filamin-actin bonds in cross-linking filamins. Filamin binding to actin is transient with unbinding events after a characteristic bond lifetime. This enables large reorganizations of the cytoskeleton at longer timescales. However, tensile force in filamin-actin bonds may affect their unbinding kinetics. Here, we study the binding dynamics of filamins A and B to actin, in the cortex of mitotic HeLa cells. With a set-up combining a confocal and an atomic force microscope, we measure how changes in contractile tension in the actin cortex change filamin binding dynamics. Our results suggest a substantial increase of the lifetime of filamin-actin bonds under increased tensile force. This behavior is termed "catch-binding" and may act as a fast rescue mechanism that prevents rupture of filamin-containing actin cytoskeletal structures upon sudden tension increase.

BP 25.3   Thu 15:30   BAR Schö
T-cell migration: Improving searching efficiency by targeting Microtubules — •Galia Montalvo[1,2,3], Bin Qu[3,4], and Franziska Lautenschläger[1,2,3] — [1]University of Saarland, Department of Experimental Physics — [2]University of Saarland, Center for Biophysics — [3]Biophysics, Center for Integrative Physiology and Molecular Medicine (CIPMM), School of Medicine — [4]Leibniz Institute for New Materials

Cytotoxic T lymphocytes (CTLs) are the key players in the adaptive immune system to eliminate tumor cells. Proper mobility in three-dimensional environments is a prerequisite for CTLs to execute their killing function and the cytoskeleton plays a central role in CTL migration in 3D. In dense matrices, migration and the consequent killing efficiency of CTLs is greatly impaired. Interestingly, we observed that in 3D matrices, CTLs go through narrow quasi-1D channels. Manufactured micro-channels are a recently emerged promising tool with well-defined parameters to investigate cell migration in 1D. In this project, we characterize MTs as a major cytoskeletal component regulating the migration of CTLs in micro-fabricated environments and in dense collagen matrices. To this end, we expose CTLs to MTs disturbing drugs. We studied the mechanics of treated cells and described the role of actin in the observed stiffness increase after MT depolymerization. Our main conclusion is that searching efficiency and killing capacity of CTLs is enhanced after MT depolymerization through stiffness increase.

BP 25.4 Thu 15:45 BAR Schö

Global membrane tension is independent of polyacrylamide substrate stiffness — •Eva Kreysing[1], Jeffrey McHugh[1,2], Sarah Foster[1,3], Kurt Andresen[4], Ryan Greenhalgh[1], Eva Pillai[1,5], Andrea Dimitrcopoulus[1], Ulrich Keyser[1], and Kristian Franze[1,6] — [1]University of Cambridge, UK — [2]Collège de France, Paris — [3]University of Tübingen; Germany — [4]Gettysburg College, USA — [5]EMBL Heidelberg, Germany — [6]University Erlangen/Nürnberg, Germany

Cellular processes such as cell migration or axonal pathfinding have been shown to depend strongly on mechanical properties of the cell*s environment such as stiffness. It has been shown that Piezo1 is one of the mechanosensitive ion channels that contributes to such behaviour. It is hypothesised that Piezo1 is activated by changes in membrane tension. This raises the question whether membrane tension is influenced by stiffness of the cell*s environment. We measured membrane tension as a function of substrate stiffness in different cell types with optical tweezers. To our surprise, we found that global membrane tension is independent of substrate stiffness in the physiological range. However, we found strong differences between membrane tension on compliant substrates and glass substrates. To explain these observations, this work introduces a toy model for substrate, membrane and cortex interaction.

BP 25.5 Thu 16:00 BAR Schö

Self-stabilization of cell adhesions under load — •Benedikt Sabass — LMU München

Mechanical loading generally weakens adhesive structures and eventually leads to their rupture. However, biological systems can adapt to loads by strengthening adhesions, which is essential for maintaining the integrity of tissue and whole organisms. Inspired by cellular focal adhesions, we discuss generic, molecular mechanisms that enable adhesions to harness applied loads for self-stabilization through adhesion growth. The mechanisms are based on conformation changes of adhesion molecules that are dynamically exchanged with a reservoir. Tangential loading drives the occupation of some states out of equilibrium, which, for thermodynamic reasons, leads to association of further molecules with the cluster. The self-stabilization principle can be realized in many ways in complex adhesion-state networks and we show how it naturally occurs in cellular adhesions involving the adaptor proteins talin and vinculin.

Unraveling the light activation of flagellar adhesiveness in *Chlamydomonas* — •Rodrigo Catalan[1,2], Antoine Girot[1,2], Alexandros Fragkopoulos[1,2], Simon Kelterborn[3], Darius Rauch[3], Olga Baidukova[3], Peter Hegemann[3], and Oliver Bäumchen[1,2] — [1]Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Göttingen, Germany — [2]University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — [3]Humboldt University Berlin, Institute of Biology, 10115 Berlin, Germany

Photoreceptors are essential constituents of photoactive microbes and control several biological processes, such as circadian life cycle, sexual reproduction and phototaxis. *Chlamydomonas reinhardtii*, a unicellular model organism to study light-activated microbial functionalities, exhibits light-switchable flagellar adhesion to surfaces upon blue-light exposure [Kreis *et al.*, Nature Physics 2018]. Using single-cell micropipette force spectroscopy, we compare the adhesion forces of wild-type (WT) cells and several blue-light photoreceptor-deletion mutants. We find that the wavelength response of flagellar adhesion forces in WT cells resembles the absorption spectrum of plant cryptochrome (pCRY) and animal cryptochrome (aCRY) photoreceptors. We further assess the involvement of pCRY and aCRY photoreceptors in the light-switchable adhesion of *C. reinhardtii* by means of adsorption experiments [Catalan *et al.*, arXiv:2208.01338] at the population level using photoreceptor-deletion mutants lacking either one or both CRYs.

BP 25.7 Thu 16:45 BAR Schö

Chromatin and Nucleocytoplasmic Transport Control the Nuclear Biophysical Properties during Assembly in Egg Extracts — •Omar Muñoz[1,2], Abin Biswas[1,4], Kyoohyun Kim[1,3], Simone Reber[4], Jochen Guck[1,3], and Vasily Zaburdaev[1,2] — [1]Max-Planck-Zentrum für Physik und Medizin — [2]Department of Biology, Friedrich-Alexander-Universität Erlangen-Nürnberg — [3]Max Planck Institute for the Science of Light — [4]IRI Life Sciences, Humboldt-Universität zu Berlin

Biophysical properties of the cell nucleus are important for various cellular processes from migration to stress responses, but largely are still not well understood. One fundamental example is the mass density: we observed that the nuclear mass density consistently displays a lower value than its cytoplasmic counterpart for a wide range of species, which is surprising given that it contains the highly compacted genetic material. To understand the mechanisms behind this, we measured volume and mass density of growing nuclei reconstituted in Xenopus egg extracts. Our results identified nucleocytoplasmic transport and chromatin as the main determinants for the dry mass and volume of then nucleus, and suggest a coupling of chromatin with nucleocytoplasmic transport. We propose a theoretical model informed by experiments, which incorporates active transport of proteins and balance of colloid osmotic pressure and an entropic polymer pressure exerted by chromatin. With only a few adjustable parameters, our model can fully describe the nuclear volume and mass dynamics as observed in the experiments.

BP 25.8 Thu 17:00 BAR Schö

Dyneins, unite! How a weak motor protein can drive efficient transport of large cargoes — •Simon Wieland[1,2], Christina Steininger[1], David E. Gitschier[1], Marius M. Kaiser[1], Wolfgang Gross[1], Abdullah R. Chaudhary[3], Jana Ritschar[4], Christian Laforsch[2], Adam G. Hendricks[3], and Holger Kress[1] — [1]Biological Physics, University of Bayreuth, Germany — [2]Animal Ecology I, University of Bayreuth, Germany — [3]Department of Bioengineering, McGill University, Montreal, Canada — [4]Laboratory of Molecular Parasitology, University of Bayreuth, Germany

To promote robust transport of organelles, dyneins need to work together to overcome intracellular drag forces and opposing forces of kinesins. However, current models of dynein cooperativity cannot explain how dyneins produce very high forces to power transport of large organelles with diameters of several microns. Here, we show that many dynein teams interact with multiple microtubules to drive efficient transport of large organelles. We measured retrograde transport forces of phagosomes with diameters of 1-5 μm. These forces were adapted to the cytoplasmic viscosity, enabling equally fast transport of all phagosomes. Furthermore, we labeled and quantified dyneins on isolated phagosomes. By modeling the distribution of microtubules around the phagosomes we linked the observed transport forces to the corresponding dynein numbers. We show that both dynein's cooperativity and size-dependent interactions of organelles with microtubules contribute to the production of high collective transport forces.

BP 25.9 Thu 17:15 BAR Schö

The formation of microtentacles — •Lucina Kainka[1], Reza Shaebani[2,3], Kathi Kaiser[1], Ludger Santen[2,3], and Franziska Lautenschläger[1,3] — [1]Department of Experimental Physics, Saarland University, Saarbrücken, Germany — [2]Department of Theoretical Physics, Saarland University, Saarbrücken, Germany — [3]Center for Biophysics, Saarland University, Saarbrücken, Germany

It is widely assumed that cellular stiffness decreases during cancer progression, and this is mainly attributed to changes in their actin cortex properties. It has recently been proposed that a weakened actin cortex enables the formation of so called microtentacles. Microtentacles are microtubule-based membrane protrusions that are formed by circulating tumor cells. It is assumed that microtentacles promote reattachment of circulating tumor cells to the tissue and the escape from the blood stream.In this study, we aim to understand how the actin cortex structure changes during cancer progression to enable microtentacle formation. We further ask how microtubules generate forces to protrude the cell membrane.In our experiments, we use noncancer RPE-1 cells as a model system. By treating these cells with actin affecting compounds while they are in suspension, they form microtentacles. We further can control the number and length of microtentacles by varying the concentration of compounds applied. We analyze the actin cortex and microtubule network in these cells with fluorescence and scanning electron microscopy. We further study the microtubule dynamics inside microtentacles by fluorescence recovery after photobleaching (FRAP).

BP 26: Focus Session mRNA Physics

Invited Talk   BP 26.1 Thu 15:00 TOE 317

Decoding Molecular Plasticity in the Dark Proteome of the Nuclear Transport Machinery — •Edward Lemke — JGU & IMB Mainz, GE

The mechanisms by which intrinsically disordered proteins (IDPs) engage in rapid and highly selective binding is a subject of considerable interest and represents a central paradigm to nuclear pore complex (NPC) function. Nuclear transport receptors (NTRs) can move small proteins and mRNA through the central channel of the NPC which is filled with hundreds of phenylalanine-glycine-rich nucleoporins (FG-Nups) reaching millimolar concentrations with elusive conformational plasticity. We have now developed a semi-synthetic strategy to equip

the living cell with up to three genetic codes and label FG-Nups inside functional NPCs site-specifically with small FRET probes. This allowed us to develop an experimental approach and use fluorescent lifetime imaging microscopy (FLIM) to directly decipher the plasticity of FG-Nups. Our study enabled a conformational look on the densely packed IDPs in the sub-resolution (roughly (50 nm)^3 small cavity) cavity of the NPC. We extracted the scaling exponent, which directly describes the conformations of FG-Nups at their functional status as well as the solvent quality in the cellular and even inner NPC environment. Pairing our data with coarse grained simulations enabled us to complement the missing half of protein mass that due to its dynamics are not present in even the most recent electron tomograms of the NPC.

BP 26.2   Thu 15:30   TOE 317

Decomposition of ensemble fluorescence signals from translation experiments and simulations — •Nadin Haase, Simon Christ, and Sophia Rudorf — Institute of Cell Biology and Biophysics, Leibniz University Hannover, Germany

Proteins are major components of cells and perform all kinds of tasks essential for survival. Those parts of the DNA that contain blueprints for the synthesis of proteins are transcribed to messenger RNA (mRNA). Complex biomolecular machines called ribosomes translate the mRNA by assembling the corresponding building blocks of proteins, the amino acids. This process can be studied by in-vitro ensemble experiments through monitoring time-dependent output signals such as fluorescence time traces, where the ensemble signal is a superposition of the individual signals from all molecules in the reaction. However, translation is a stochastic process and thus even for initially synchronized reactions the ensemble signal may not reflect the features in the individual signals, especially on longer time scales. Here we present an approach to decompose the ensemble signal to reveal hidden information about the individual steps of the translation process. We explore the limits of this method and study the conditions under which a meaningful solution can be gathered.

BP 26.3   Thu 15:45   TOE 317

Creating an evolution machine with 2-3-cyclic RNA — •Dieter Braun — Systems Biophysics, Ludwig Maximilian University Munich

For life to start, a simple physical non-equlibrium mechanism combined with a most robust chemistry of a few molecules had to reach the regime of Darwinian molecular evolution. We found RNA oligomerization and templated ligation from very mildly activated RNA with 2-3-cyclic phosphates [1], with wet-dry cycling at heated air-water interfaces [2]. The oligomerization operated at elevated pH 9-10 without added salts at temperatures between 4-40°C and created oligomers of all four bases with 15 percent yield. It operated in a water-poor 'dry' state. Replication was possible with templated ligation and showed with only 1mM MgCl2 a strongly base-selective templated ligation with 25 percent yield. If catalytic conditions to recycle the hydrolytically opened 2-3-cyclic phosphate from linear 2 prime or 3 prime endings wcould be found, the reaction would operate indefinitely without feeding in a thermal gradient setting. We will show preliminary experiments for local feeding, vesiculation and protein expression in the same setting. The experiments suggest a most simple scenario for the emergence of life from only two nucleotide molecules, implemented in an early Earth volcanic setting under a CO2 atmosphere. It showcases how physics and chemistry could have acted together in a geologically abundant microfluidic setting to create Darwinian evolution.

BP 26.4   Thu 16:00   TOE 317

RNA G-quadruplex folding is a multi-pathway process with a variety of short-lived intermediate states — •Marijana Ugrina[1], Ines Burkhart[2], Diana Müller[2], Harald Schwalbe[2], and Nadine Schwierz[1] — [1]University of Augsburg, Augsburg, Germany — [2]Goethe University, Frankfurt am Main, Germany

The folding kinetics of regulatory RNAs is crucial for their function. Here, we provide molecular insights into the folding pathways of a G-quadruplex from telomeric repeat-containing RNA by combining all-atom molecular dynamics and coarse-grained simulations with circular dichroism experiments. The ion atmosphere surrounding the highly charged quadruplex plays a crucial role in folding. To correctly capture the electric double-layer in implicit solvent coarse-grained simulations, we develop a matching procedure based on all-atom simulations in explicit water. This procedure allows us to provide quantitative agreement between the experiments and simulations as judged by the number of native contacts at different salt concentrations and temperatures. Folding of the quadruplex is on the timescale of minutes and the coarse-grained simulations using the three-interactions site model are therefore ideal to resolve the folding pathways and intermediate states. The results reveal that the folding is sequential with each pathway passing through two transient, on-pathway intermediates: A hairpin and a triplex or double hairpin state. Since these intermediates are degenerate with at two to four alternative conformations per state, quadruplex folding is a multi-pathway process with high conformational entropy.

BP 26.5   Thu 16:30   TOE 317

Codon position-specific engineering of translation kinetics — Judith Müller[1], Gerlinde Schwake[1], Anita Reiser[1], Daniel Woschée[1], Zahra Alirezaeizanjani[3], Joachim Rädler[1], and •Sophia Rudorf[2] — [1]Faculty of Physics, Ludwig Maximilian University of Munich — [2]Faculty of Natural Sciences, Leibniz University Hannover — [3]independent researcher

Recently, we introduced Live Imaging on Single Cell Arrays (LISCA), which combines time-lapse microscopy of single cells on microstructured surfaces with automated image analysis. LISCA enables us to observe and analyze the time-evolution of protein expression in hundreds of individual cells in parallel. Here, we combine LISCA with our software OCTOPOS, which simulates ribosome movement on the ORF and is used to generate reporter genes with varying ribosome speeds and densities. We predict and monitor the translation kinetics of synonymous variants of eGFP to determine mRNA functional lifetimes and translation rates with high accuracy in single lung tissue cells. Our approach allows us to study how provoked ribosome jams on specific positions within the ORF influence mRNA stability, thus linking ribosome dynamics and mRNA biophysics.

BP 26.6   Thu 16:45   TOE 317

The pH dependent phase transition in lipid nanoparticle cores leads to changes of protein expression in single cells — •Julian Philipp and Joachim Rädler — LMU, Munich, Germany

Lipid nanoparticles developed into the most powerful delivery platform for mRNA-based vaccination and therapies. In general, LNPs are particles exhibiting PEG-lipid and DSPC at the surface and ionizable lipid, cholesterol and mRNA in the core. However, the pH dependent changes induced by ionizable lipids in the context of endosomal release are little understood. In particular the ionizable lipids MC3, KC2 and DLin are known to exhibit remarkably different efficacy despite similar pK values. Here, we study the structural response of ionizable lipids with cholesterol as a function of pH using synchrotron X-ray scattering. All three core phases exhibit a sequence of ordered mesophases in the range of pH 7 to 4, beginning with an isotropic swollen phase above their pK value. Lowering the pH reveals transitions to inverse micellar $P6_3/mmc$ / $Fd3m$, inverse hexagonal H_{II} and bicontinous cubic $Pn3m$ phases. If polyA, as mRNA surrogate, is added to the core phases, coexistence of pure lipid phases and condensed nucleic acid lipid H_{II}^c phase occurs. We show that the observed core structures are consistent with the SAXS scattering of mRNA containing core phases and full LNP. The difference in structural features of DLin versus MC3 and KC2 phases is also consistent with the delayed onset and reduced level of GFP expression observed in single cell time courses after transfection with DLin LNPs compared to MC3/KC2. We conclude that pH dependent core phase transitions trigger endosomal release.

BP 26.7   Thu 17:00   TOE 317

pH-dependent behavior of ionizable cationic lipids in mRNA-carrying lipoplexes investigated by molecular dynamics simulations — •Giovanni Settanni[1,2], Wolfgang Brill[3], Heinrich Haas[3], and Friederike Schmid[1] — [1]Department of Physics, Johannes Gutenberg University Mainz, Germany — [2]Faculty of Physics and Astronomy, Ruhr University Bochum, Germany — [3]BioNTech SE, Mainz, Germany

Lipid-based nanoparticles and lipoplexes are successful nanocarriers for mRNA-based therapies. The molecular structure of these assemblies is still not fully understood. Lipoplexes including the ionizable lipid 2-dioleyloxy-N,N-dimethyl-3-aminopropane (DODMA), under specific conditions, have a pH-dependent lamellar structure, where lipid bilay- ers are separated by mRNA-rich layers. Here, the structure and dynamics of these lipoplexes are investigated at varying pH and mRNAconcentration using multiscale molecular dynamics simulations[1]. It is observed that the interaction between DODMA and RNA is slightly attractive only at low pH levels. This results into a pH-dependent relocation of the RNA inside the multilayers, from bilayer's surface at low pH to a more uniform distribution inside the hydrophilic slabs at high pH. Also, at high pH, DODMA lipids shift toward the hydrophobic part of the bilayer, thus increasing their leaflet-flipping rate, a phenomenon which may ultimately affect the fusion process of the lipoplex with the endosomal membrane.

Charge and structural properties of transfection lipid layers adsorbing mRNA — •Miriam Grava[1], Ibrahim Mohd[2,3], Julio Pusterla[1], Julian Philipp[4], Joachim Rädler[4], Olaf Soltwedel[1], Nadine Schwierz[2,3], Heinrich Haas[5], and Emanuel Schneck[1] — [1]Technische Universität Darmstadt, Germany — [2]University of Augsburg, Germany — [3]Max-Planck-Institute of Biophysics, Frankfurt am Main, Germany — [4]Ludwig-Maximilians-Universität München, Germany — [5]BioNTech Corporation, Mainz, Germany

Some of the most effective COVID-19 vaccines are based on cationic lipid-based delivery systems for messenger RNA (mRNA), a promising technology for a

broader use in biomedical applications. Its efficiency depends on pH variations and ionic conditions of the bulk phase. We combine x-ray scattering and x-ray fluorescence on monolayers of positively chargeable transfection lipid mixtures with atomistic molecular dynamics (MD) simulations in order to determine their pH-dependent structural properties and the protonation degree. While the experiments yield electron density profiles and surface charge densities, the

MD simulations yield the area per molecule, the conformation of different lipid species, and the counter-ion distributions. The analysis of experimental and simulation data provides detailed information on the transfection lipid layer characteristics. We applied the same experimental techniques to transfection lipid layers before and after mRNA adsorption, which yields insights into the structure of the adsorbed layers and the interfacial electrostatic balance.

BP 27: Computational Biophysics II

BP 27.1   Thu 15:00   BAR 0106

Spectral signatures of excess-proton waiting and transfer-path dynamics — •Florian Brünig[1], Manuel Rammler[1], Ellen Adams[2], Martina Havenith[2], and Roland Netz[1] — [1]Freie Universität Berlin, Department of Physics, 14195 Berlin, Germany — [2]Ruhr-Universität Bochum, Department of Physical Chemistry II, 44780 Bochum, Germany

Signatures of solvated excess protons in infrared difference absorption spectra, such as the continuum band between the water bend and stretch bands, have been experimentally known for a long time and have recently been used to analyze protonation dynamics in photoactive proteins. However, the theoretical basis for linking spectral signatures with the microscopic proton-transfer mechanism so far relied on normal-mode analysis.

We analyze the excess-proton dynamics in ab initio molecular-dynamics simulations of aqueous hydrochloric acid solutions by trajectory-decomposition techniques. The continuum band is shown to be due to normal-mode oscillations of temporary H_3O^+ complexes. The actual proton transfer between two water molecules, which for large water separations involves crossing of a barrier and thus is not a normal mode, is characterized by two time scales: Firstly, the waiting time for transfer to occur, which leads to a broad weak shoulder around 100 cm^{-1}, consistent with our experimental THz spectra. Secondly, the mean duration of a transfer event, which produces a rather well-defined spectral contribution around 1200 cm^{-1} and agrees in location and width with previous experimental spectra.

BP 27.2   Thu 15:15   BAR 0106

Lipid-based nanomaterials for RNA delivery investigated using molecular dynamics simulations — •David Noel Zimmer[1] and Giovanni Settanni[1,2] — [1]Physics Department University of Mainz — [2]Faculty of Physics and Astronomy Ruhr University Bochum

Lipid-based nanoparticles (LNP) are one of the most effective carriers in mRNA therapeutics. They are made of a mixture of ionizable, helper, and pegylated lipids encapsulating mRNA. While peg tends to remain on the surface of the nanoparticle, the structure of the core has not yet been well characterized. Experimental data point to a relative lack of order. The lipid composition of the formulation plays a key role in determining the effectiveness of the nano carrier. Small changes in the chemical structure of ionizable and helper lipids dramatically affect the efficiency of mRNA transfection. LNPs based on DLinDMA and DLinDAP, two ionizable lipids, showed significantly different transfection efficiencies, notwithstanding the very small difference in structure. Here, using a multiscale modeling approach, the behavior of lipid formulations based on these two lipids, cholesterol and DSPC or DOPE is examined aiming to provide an understanding of the interactions of lipids and mRNA. The simulations show that, despite DLinDAP binding affinity for mRNA is larger than DLinDMA, the overall interaction of the whole lipid formulation containing DLinDAP with mRNA is weaker, resulting in a larger average distance of the mRNA from the lipid bilayer. This shows that chemical optimization based only on mRNA-ionizable lipid interactions may not be sufficient for the development of more effective lipid formulations for RNA delivery.

Toehold-Mediated Strand Displacement in Random Sequence Pools — •Thomas Mayer, Lukas Oesinghaus, and Friedrich Simmel — School of Natural Sciences, Department of Bioscience, TU Munich, D-85748 Garching, Germany

Toehold-mediated strand displacement (TMSD) has been used extensively for molecular sensing and computing in DNA-based molecular circuits. As these circuits grow in complexity, sequence similarity between components can lead to cross-talk causing leak, altered kinetics, or even circuit failure. For small circuits, such unwanted interactions can be designed against. In environments containing a huge number of sequences, this becomes infeasible. Therefore, a general understanding of the impact of sequence backgrounds on TMSD reactions is of great interest. Here, we investigate the impact of random DNA sequences on TMSD circuits. We begin by studying individual interfering strands and use the obtained data to build machine learning models that estimate kinetics. We then investigate the influence of pools of random strands and find that the kinetics are determined by only a small subpopulation of strongly interacting strands.

Consequently, their behavior can be mimicked by a small collection of such strands. Finally, we compare two established and a novel technique that speed up TMSD reactions in random sequence pools: a threeletter alphabet, protection of toeholds by intramolecular secondary structure, or by an additional blocking strand. We expect that our insights will be useful for the construction of TMSD circuits that are robust to molecular noise.

BP 27.4   Thu 15:45   BAR 0106

comparison of molecular dynamics simulations and neutron reflectivity experiments reveals strengths and weaknesses of current force fields for ionizable Dlin-MC3-DMA lipids — •Ibrahim Mohd[1,3], Jennifer Gilbert[2], Marcel Heinz[3], Tommy Nylander[2], and Nadine Schwierz[1,3] — [1]University of Augsburg, 86159 Augsburg, Germany — [2]Lund University, SE-22100 Lund, Sweden — [3]Max-Planck-Institute of Biophysics, 60438 Frankfurt am Main, Germany

Dlin-MC3-DMA (MC3) is one the most promising ionisable lipid for designing lipid nanoparticles (LNPs), which are used as drug delivery agents. Here, we provide force field parameters for cationic and neutral MC3 compatible with the AMBER Lipid17 force field. Subsequently, we carefully assess the accuracy of the current and existing MC3 force fields by providing a direct comparison to neutron reflectivity experiments of mixed lipid bilayers consisting of MC3 and DOPC at different pH. At low pH (cationic MC3) and at high pH (neutral MC3) the newly developed MC3 parameters in combination with AMBER Lipid17 for DOPC give excellent agreement with the experiments compared to existing MC3 models. With the currently parametrized MC3 parameters we are able to simulate MC3 containing LNPs in atomistic details and gain insights into the effect of pH and RNA cargo on the LNP structure. Combining molecular dynamics simulations, neutron reflectivity experiments and other scattering techniques is therefore a valuable step to drive the advancement of accurate atomistic force fields and to unravel the detailed structure of LNPs.

Simulation-based Parameter Inference for Large Scale Tumor Simulations — •Julian Herold[1], Eric Behle[2], and Alexander Schug[2] — [1]Karlsruhe Institute of Technology, Karlsruhe, Deutschland — [2]Jülich Supercomputing Center, Jülich, Deutschland

While clinical imaging of tissues focuses on macroscopic tumors, many experiments investigate only small clusters of cells. We aim on providing a scale-bridging link by performing large scale tissue simulations. We employ highly parallelized code in an HPC setting to simulate mm-sized virtual tissues such as embryogenetic zebrafish tissue or breastcancer tumors with more than a million μm-resolved individual cells. We deploy Cells in Silico (CiS), which combines a cellular potts model with an agent based layer and is thus capable of accurately representing many physical and biological properties, such as individual cell shapes, cell division, cell motility, interactions with the extra-cellular matrix etc.

Using a model with such a strong representational capacity poses the task of adjusting a large number of parameters to reproduce experimental findings. Prior work has attempted to characterize the similarity between experimental and simulated data by extracting different features and using statistical tests to establish a distance measure. This work highlights how this difficult task can be circumvented by training neural networks to distinguish between experimental and simulated data while simultaneously optimizing the model parameters to maximize the error rate of the network.

Effects of chromatin fibers characteristics on cohesin mediated loop architecture — •Aymen Attou, TIlo Zülske, and Gero Wedemann — University of Applied Sciences Stralsund, System Engineering and Information Management, 18435 Stralsund, Germany

The spatial organization of DNA in eucaryotes starts at nucleosome chains forming chromatin loops that can cluster together establishing fundamental units called topologically associating domains (TADs). TADs are an important factor for gene regulation by facilitation or repressing long range contacts in the

genome. Those loops are formed and held together by a ring-shaped protein complex called cohesin together with the effect of CTCF. A loop has a residence time of several minutes. To clarify the spatial structure of a loop, we established a coarse-grained computer model of chromatin with a resolution of single nucleosomes integrating potentials describing CTCF and cohesin. We performed Metropolis Monte Carlo simulations combined with replica exchange procedure with regular spaced nucleosomes and experimentally determined nucleosome positions in presence of cohesin-CTCF as well as depleted systems as control for different loop sizes. We studied differences in the spatial structure and of contacts probabilities of different domains, what allowed us to understand the role of cohesin and CTCF, and their impact on the 3D structure of chromatin. This study also allowed clarifying how nucleosome positions can impact the conformations of the chromatin loops during the residence time of the loop anchor, with presumed consequences for transcriptional activity.

BP 27.7   Thu 16:45   BAR 0106

Theoretical investigations on enzyme-plasma interactions in the context of plasma-driven biocatalysis — •Hanna-Friederike Poggemann, Björn Kirchhoff, Timo Jacob, and Christoph Jung — Ulm University, Institute of Electrochemistry, D-89069 Ulm

Biocatalysis is an emerging field that has several advantages over classical catalysis. The use of enzymes as catalysts is not only more environmentally friendly, but also has potential to be more efficient than the conventional approach in industrial applications. Plasma-assisted biocatalysis is a specific subsection of this field, where a plasma source is used to provide a constant supply of the enzyme co-substrate H_2O_2 that drives the catalytic reaction. However, the use of plasma presents some challenges. The plasma species can alter the structure of the enzyme leading to changes in the catalytic reaction pathway or even deactivation of the enzyme. In a theoretical multiscale approach, we address the questions of how the plasma interacts with the enzyme and how this alters the catalytic reaction. To this end, we use reactive molecular dynamics simulations to investigate possible structural changes of the enzyme by plasma species. We also perform QM/MM hybrid simulations to further investigate the reaction pathway of the enzyme AaeUPO.

BP 27.8   Thu 17:00   BAR 0106

Diffusive properties in simulations of polydisperse sphere mixtures mimicking the inside of a cell — •Frank Hirschmann[1], Hender Lopez[2], Felix Roosen-Runge[3], and Martin Oettel[1] — [1]Institute for Applied Physics, University of Tübingen, Germany — [2]School of Physics and Optometric & Clinical Sciences, Technological University Dublin, Ireland — [3]Department of Biomedical Sciences and Biofilms-Research Center for Biointerfaces (BRCB), Malmö University, Sweden

The interiors of living cells contain a multitude of different-sized biomacromolecules at relatively high packing fractions. Diffusivity and transport properties in such crowded environments are highly influenced by hydrodynamic interactions. Thus, the time needed for proteins to come into contact with each other within the cell is determined by a complex interplay of polydispersity, size-distribution and crowding. In order to analyze such systems theoretically, we employ Brownian Dynamics (BD) simulations of polydisperse mixtures of hard spheres. Using results of Stokesian dynamics we approximate hydrodynamic interactions in our BD simulations by a simple multiplicative ansatz (equivalent to a hydrodynamic "renormalization" of the Brownian short-time diffusivity), which allows us to access the long-time limit of our system. We investigate resulting diffusion constants and survival probabilities, exhibiting non-trivial behavior.

BP 27.9   Thu 17:15   BAR 0106

Unwrapping trajectories of constant-pressure molecular dynamics simulations — •Jakob Tómas Bullerjahn[1], Sören von Bülow[2], Jérôme Hénin[3], and Gerhard Hummer[1,4] — [1]Department of Theoretical Biophysics, Max Planck Institute of Biophysics, Frankfurt am Main, Germany — [2]Linderstrøm-Lang Centre for Protein Science, Department of Biology, University of Copenhagen, Copenhagen, Denmark — [3]Laboratoire de Biochimie Théorique, Institut de Biologie Physico-Chimique, CNRS, Paris, France — [4]Institute of Biophysics, Goethe University Frankfurt, Frankfurt am Main, Germany

In molecular dynamics simulations at constant pressure, the size and shape of the periodic simulation box fluctuate with time. Special care is thus required when a particle trajectory is unwrapped from a projection into the central box under periodic boundary conditions into a trajectory in full three-dimensional space, e.g., for the calculation of diffusion coefficients. Here, we review and compare different schemes proposed for trajectory unwrapping, and specify the respective rewrapping scheme to put an unwrapped trajectory back into the central box. On this basis, we then identify a scheme in which the wrapped and unwrapped trajectory are mutually consistent and in which the statistical properties of the trajectory are preserved. We conclude with advice on best practice for the consistent unwrapping of constant-pressure simulation trajectories.

BP 28: Poster Session II

Time: Thursday 18:00–20:00   Location: P2/EG

BP 28.1   Thu 18:00   P2/EG

X-Ray Phase-Contrast Tomography Imaging of Single Cells Using an Optical Stretcher — •Jan-Philipp Burchert[1], Roland Stange[2], Madleen Busse[3], Tim Salditt[1], and Sarah Köster[1] — [1]Institute for X-Ray Physics, University of Göttingen — [2]RS Zelltechnik GmbH, Schöllnach — [3]Department of Physics and Munich School of Biomedical Engineering, Technical University of Munich

X-rays penetrate deep into matter and allow us to image structures with high spatial resolution, which makes them attractive for investigating individual biological cells. Here, we combine x-ray phase-contrast tomography with an x-ray compatible optical stretcher to image single cells in solution, thus in their physiological environment, and avoid the need for freezing, drying or embedding of the samples. The cells are trapped in a contact-free manner in a fixed position by the optical stretcher and are probed by the x-ray beam. The microfluidic flow sets the cells in slow rotational motion, which enables tomographic imaging. We apply this combination of techniques to unfixed and fixed NIH3T3 fibroblasts, which are partially stained with an x-ray contrast agent. The experimental data show that we can acquire images of these cells with our setup. Moreover, the comparison of the different preparations and two beam energies will improve the image quality in future experiments.

BP 28.2   Thu 18:00   P2/EG

Scanning small angle x-ray scattering of hydrated, keratin- rich cells in flow environment — •Boram Yu[1], Sophie-Charlotte August[1], Peter Luley[1], Manfred Burgerhammer[2], and Sarah Köster[1] — [1]Institute for X-Ray Physics, University of Göttingen, Germany — [2]European Synchrotron Radiation Facility (ESRF), Grenoble, France

Intermediate filaments (IFs), one of the three main components of the cytoskeleton, form a network that contributes to cell mechanics. Thus, collecting structural information about IF networks in their physiological setting, i.e., in whole living cells, is crucial. We study mammalian cells expressing cytokeratin, which forms bundle structures. To obtain this information, we use scanning small angle x-ray scattering (SAXS), as it provides both real space overview images with moderate resolution and reciprocal space information with a high resolution.

X-ray imaging of cells in aqueous state is challenging as their electron density contrast is low, and pronounced radiation damage and radiation-induced gas formation occurs. For this reason, we used a dedicated flow sample chamber that minimizes the thickness of liquid layer in the beam path and serves to exchange liquid continuously during scanning. Despite weak contrast and short exposure times, we are able to retrieve the local main orientation of subcellular structures, thus demonstrating how scanning SAXS offers valuable information from fixed-hydrated cells in liquid flow.

BP 28.3   Thu 18:00   P2/EG

Comparative investigation of differently prepared porcine retinal pigment ephitelium (RPE) cells using mid-IR photo-induced force microscopy (PiF-IR) — •Jesvin Joseph[1,2], Robin Schneider[1], Rowena Simon[3], and Daniela Täuber[1,2,4] — [1]Heintzmann Lab, Leibniz Institute of Photonic Technology, Jena — [2]Institute of Physical Chemistry & Abbe Center of Photonics, Friedrich-Schiller-University Jena — [3]Department of Ophthalmology, University Hospital Jena — [4]Institute of Solid State Physics, Friedrich Schiller University Jena, Germany

Age-related loss of sight caused by macular degeneration (AMD) is monitored in clinical health care using fundus autofluorescence, which investigates variations in the autofluorescence signal stemming from the retinal pigment epithelium (RPE)[1]. Nanolocal chemical characterization of RPE cells and pigment granules could deepen the understanding of involved cellular processes. Nano-infrared imaging methods can provide chemical information at a lateral resolution below 10 nm[2]. We used PiF-IR to investigate externally grown porcine RPE cells, which were dried in varied conditions. First results show spectral variations obtained from cells dried at room temperature and at 37°C. We compare these spectra to PiF-IR and conventional FTIR spectra obtained from plain retinal pigment chemicals. Funding by Profil Line Light, project pintXsum, FSU Jena, is acknowledged. BP 28.4   Thu 18:00   P2/EG

Redirecting the early embryogenesis of *Caenorhabditis elegans* by altering mechanical cues — •Vincent Borne and Matthias Weiss — Experimental Physics I, University of Bayreuth, Universitätsstr. 30, D-95447 Bayreuth, Germany

During early development, somatic and germline precursor cells of the model organism *Caenorhabditis elegans* undergo an apparently pre-determined and robust division scheme, suggesting early embryogenesis to run on autopilot. While the role of biochemical signaling in embryogenesis has long been recognized, the influence of mechanical forces for proper cell arrangement has been revealed only recently. Aiming at challenging the robustness of the organismal development mechanically, we have flattened the embryo to induce altered positioning and division timing of cells. Indeed, upon a controlled squeezing between two coverslips, the outer boundary of the embryo remained intact but cytokinesis was seen to be compromised, i.e. normal development came to a full stop. Surprisingly, nuclei still underwent division, resulting in multinucleated cells or even a syncytium-like state with up to 60 nuclei. In this state, we have monitored the growth of nuclei and their division timing. Despite the total failure of cell division, both observables are in line with experimental data and theoretical descriptions obtained from unperturbed embryos. Our results highlight how some key features for correct embryonic development prevail even under mechanically stressful conditions.

BP 28.5   Thu 18:00   P2/EG

Microfluidics-based analysis of the mobility and migration pattern of *Trypanosoma brucei* — •Hannes Wunderlich[1], Lucas Brehm[2], Jana Ritschar[2], Sebastian Krauss[1], Klaus Ersfeld[2], and Matthias Weiss[1] — [1]Experimental Physics I, University of Bayreuth, Germany — [2]Molecular Parasitology, University of Bayreuth, Germany

Trypanosoma brucei is a unicellular parasite that causes the African sleeping sickness after entering the human bloodstream via the bite of an infected tsetse fly. Active spiral movement of trypanosomes, mediated by the beating of a microtubule-driven cell-body attached flagellum, is crucial to evade the hosts immune response, i.e. swimming is a matter of survival for trypanosomes. Beyond the flagellum, microtubules also form a highly ordered, subpellicular array beneath the cell membrane, hence determining the effective elasticity of the parasite and its propulsion via the flagellum. Using soft lithography to produce well-defined two-dimensional chambers and using a temperature controlled environment, we have optimized cell tracking, shape determination, and subsequent analyses. As a result, we find that wild-type and mutant strains with altered post-translational modifications of microtubules not only feature different phenotypes but also show distinct mobility patterns, e.g. a strain-dependent swimming velocitiy and intermittency of swimming (run-and-tumble phases).

BP 28.6   Thu 18:00   P2/EG

2D polarization fluorescence imaging (2DPOLIM) - Evaluation of depolarization artifacts in fixed four channel detection — •Yunhao Mei[1,2], Asad Hafeez[1,2], Yutong Wang[1,2], Mohammad Soltaninezhad[1,2], Rainer Heintzmann[1,2], and Daniela Täuber[1,2] — [1]Heintzmann Lab, Leibniz Institute of Photonic Technology, Jena — [2]Institute of Physical Chemistry & Abbe Center of Photonics, Friedrich-Schiller-University Jena, Germany

Fluorescence polarization and anisotropy measurements are widely used in Diagnostics and Imaging in the Life Sciences. Most common is the use of linearly polarized excitation together with two-channel detection of linear polarization parallel and perpendicular to the polarization in excitation. However, when applied to anisotropic samples, the result may depend on the lab frame in respect to structural alignments within the sample, which can be preventond by collecting the sample fluorescence in more polarization angles[1]. We designed a four-channel detection for evaluating Förster Resonance Energy Transfer between similar fluorescence labels, the so-called homo-FRET or emFRET. The quantitative discrimination of FRET via tiny changes in polarization resolved fluorescence intensities requires highly sensitive cameras and well-designed and calibrated detection channels. Wire grids provide high-quality polarization properties when used in normal incidence in transmission but may introduce depolarization when implemented tilted in respect to the optical axis. We studied several possible arrangements and compared the introduced depolarizations. [1] R. Camacho et al. Adv. Mater. 2019, 1805671.

BP 28.7   Thu 18:00   P2/EG

Monitoring actomyosin flows in early Caenorhabditis elegans embryos by lightsheet microscopy — •Ivana Jeremic and Matthias Weiss — University of Bayreuth, Bayreuth, Germany

Symmetry breaking, i.e. the formation of body axes, is crucial for embryonic development as it guides the formation of highly organized tissues and consequently assures proper maturation of the organism. A convenient model system for studying such events is Caenorhabditis elegans since all body axes are fully defined already in the 8-cell stage of the embryo. Confocal fluorescence imaging on C. elegans has revealed that chiral mechanical forces, generated by the actomyosin cortex, play an important role in the left-right symmetry breaking. Con-

focal imaging, however, requires a gentle flattening of the embryo to allow for a full three-dimensional assessment of the embryo. Yet, even a gentle squeezing of the embryo can already delay cell divisions and subsequently lead to altered cell positions, suggesting that also the symmetry-breaking action of the actomyosin cortex can be affected. Using a custom-made lightsheet microscope that does not require any squeezing of the embryo, we have monitored actomyosin flows in the early embryo in three dimensions over time. Preliminary data from these experiments suggest that the previously observed chiral forces are even enhanced under these unconfined conditions.

BP 28.8   Thu 18:00   P2/EG

Organelle organization and dynamics in cells on soft substrates — •Paula Girones Paya, Florian Rehfeldt, and Matthias Weiss — Experimental Physics I, University of Bayreuth, Germany

The interior of eukaryotic cells features a highly organized and dynamically evolving set of compartments (organelles), e.g. mitochondria, the endoplasmic reticulum, or the nucleus. How these organelles self-organize to arrive at an arrangement that is beneficial for a cell is still poorly understood. Numerous studies have monitored organelle morphologies and dynamics in well-characterized culture cells grown on rigid substrates, e.g. glass coverslips. In real life, however, cells are situated in soft tissues with an elastic modulus that is five to six orders of magnitude lower. On soft substrates, actin-based stress fibers are less pronounced, and consequently cell morphologies are considerably less flattened by tensile forces, suggesting that also organelle arrangement and dynamics is altered. Here, we compare results of mitochondrial dynamics, cell nucleus volumes, and the exchange kinetics for diffusively driven transport between the nucleoplasm and the cytoplasm of cells on soft and rigid substrates.

BP 28.9   Thu 18:00   P2/EG

Quantifying Molecular Mobility, Abundance and Interactions by Fluorescence Correlation Spectroscopy — •Jana Sütterlin[1], Katharina Reglinski[1,2,3], Francisco Páez Larios[1,2], and Christian Eggeling[1,2] — [1]Institut für angewandte Optik und Biophysik, Friedrich-Schiller Universität Jena, Jena, Deutschland — [2]Leibnitz-Institut für photonische Technologien e.V., Jena, Deutschland — [3]Universitätsklinikung Jena, Jena, Deutschland

Since many biological functions rely on molecular interactions, knowledge about molecular mobility and diffusional processes are key to understand cellular signalling. To gain the desired insights, it is of utmost importance to develop and apply live-cell compatible approaches for diffusional investigations. Fluorescence Correlation Spectroscopy (FCS) is a powerful technique that enables the quantification of these dynamics.

This poster will provide an outline on how to utilise parameters acquired from FCS and dual-colour Fluorescence Cross-Correlation Spectroscopy (DC-FCCS) to quantify diffusion characteristics of particles in aqueous environments. This way, an examination of diffusional behaviour influenced by various binding conditions can be carried out.

FCS study about the peroxisomal import receptor PEX5 in live HEK cells is shown to elucidate its molecular interaction dynamics within the cytosol. Thereby the potential of FCS is exploited, highlighting its non-invasive, live-cell compatible properties. Ensuring proper function of organelles and cells, PEX5 transports cargo proteins featuring a targeting sequence, which need to be imported into peroxisomes.

BP 28.10   Thu 18:00   P2/EG

Evolution of the crowded state of cells as seen by FRET — •Avijit Kundu and Mattias Weiss — Experimentalphysik I, Universität Bayreuth, Universitätsstraße 30 95447 Bayreuth

Cells are the basic units of all living organisms. Somewhat surprisingly, however, virtually all cells feature very similar and high degrees of macromolecular crowding, with total concentrations of more than 100 mg/ml, irrespective of the species from which the cell is taken. Macromolecular crowding plays a key role in many biophysical processes and it can even alter biochemical cues by changing the binding kinetics or the steady-state frunction of associated states, suggesting that cells need to actively maintain their crowding state. Using a FRET sensor that reports on the local crowdedness in living cells, we have explored how individual cells can re-adapt their crowding state after a perturbation. Using a stepwise change of the osmotic pressure, we find that cells react rapidly to the external perturbation but aim at a relaxation back to the native state over time scales of minutes to hours.

BP 28.11   Thu 18:00   P2/EG

3D light-sheet microscopy of contracting skeletal muscle tissue — •Laura Strampe, Arne Hofemeier, Paul Maier, Jan Huisken, and Timo Betz — Third Institute of Physics - Biophysics, Georg August Universität, Göttingen

Skeletal muscle makes up the majority of human muscle tissue. Its contraction allows for controlled movements of the body, as well as being essential for maintaining posture. To understand the global and local forces at play during such contractions, occurring on the time scale of seconds, a 3D high-speed, high-resolution imaging method is necessary. We present a protocol for rais-

ing biomimetic muscle tissue anchored between two flexible mm-sized post. A full contraction cycle can be recorded through the synchronization of periodic electric stimuli and image acquisition using a custom build Flamingo light-sheet microscope. This enables us to study a wide range of questions including the influence of local contractile forces on muscle stem cell activation and contractile sarcomere dynamics.

BP 28.12   Thu 18:00   P2/EG

Screening for Pharmacologically Enhanced Tissues for Optical Microscopy. — •Venkat Raghavan Krishnaswamy, Susan Wagner, Rico Barsacchi, and Moritz Kreysing — Max Planck Institute of Molecular Cell Biology and Genetics. Dresden. Germany.

Our ability to observe the complexity of a living tissue under a light microscope is heavily impeded by the inherent light-scattering properties of the biological tissues. But remarkably some living tissues are highly transparent in nature, e.g., human retina, certain deep-sea creatures, etc. Comprehending and replicating the mechanisms by which tissue transparency is attained would unleash the full capabilities of optical microscopes. Here, we propose to unravel the molecular basis of tissue transparency in three-dimensional tissues using the immense potential of high-throughput screening and large-content image analysis tools. Specifically, we used active pharmacological compounds to screen for pathways that impact light-scattering properties in spheroids of human colorectal carcinoma cell line (HCT116). Randomly integrated multifluorescent beads within the spheroids served as an extrinsic readout factor and a conventional chemical-based clearing method was used as a positive control for assessing the optical properties of the tissue. The image analysis pipeline constructed to measure the intensities of the beads through the Z-sections clearly distinguishes cleared from uncleared spheroids. Overall, a robust assay was developed which would be employed on larger screens, to rapidly identify compounds and, further, signaling pathways that regulate the molecular mechanisms of tissue transparency.

BP 28.13   Thu 18:00   P2/EG

Imaging of vital mitochondria using Scanning Ion Conductance Microscopy (SICM) and electron microscopy methods — •Eric Lieberwirth[1], Christian Völkner[1], Regina Lange[1], Anja Schaeper[2], Magdalena Otte[2], Marcus Frank[3], Kevin Oldenburg[4], Ingo Barke[1], Simone Baltrusch[2], and Sylvia Speller[1] — [1]University of Rostock, Institute of Physics — [2]Rostock University Medical Center, Institute for Medical Biochemistry and Molecular Biology — [3]Rostock University Medical Center, Medical Biology and Electron Microscopy Center — [4]University of Rostock, Center for Interdisciplinary Electron Microscopy MV

Mitochondria are enclosed by a double membrane. While the inner membrane with many insertions creates a large surface for the respiratory chain complexes, the outer one mediates fusion, fission and degradation of the organelles in the network. In this process, pole-like interaction sites develop, which impact the surface of the outer membrane. Scanning Ion Conductance Microscopy (SICM) allows the outer membrane of immobilized vital mitochondria to be measured in a buffer solution with a spatial resolution of about 50 nm and a height resolution of a few nanometers. The outer membrane shows dynamic height fluctuations as well as spatial height variations depending on the medium. Transmembrane proteins can be made visible when labelled with nanoscopic gold particles. A complementary study of SICM topographies, Scanning Electron Microscopy (SEM) and in situ liquid Transmission Electron Microscopy (TEM) images gives insight into the spatial distribution of internal and membrane-bound structures.

BP 28.14   Thu 18:00   P2/EG

Imaging Soft-Landed DNA-Aggregates — •Isabelle Legge, Jovana Pepic, Tim Esser, Márkó Grabarics, and Stephan Rauschenbach — Department of Chemistry, University of Oxford, Oxford, United Kingdom

Deoxyribose nucleic acid (DNA) is involved in important biological processes including replication, encoding information and gene expression. The helical structure of DNA double strands is well known but the superstructure of more complex assemblies such as DNA origami can be challenging to characterise by averaging techniques. Therefore, a versatile, yet practical, sample preparation technique is needed to make DNA-based molecules accessible to high-resolution, single-molecule imaging by atomic force microscopy (AFM) or transmission electron microscopy (TEM). Here, we use electrospray ion-beam deposition (ESIBD) to produce clean samples of single- and double-stranded DNA or DNA origami to enable AFM and TEM imaging, providing information on structure, conformation and revealing the mechanical properties. We discuss the advantages and limitations of this approach to improve the understanding of the function of these molecules.

BP 28.15   Thu 18:00   P2/EG

A backward-mode optical-resolution photoacoustic microscope for functional 3D imaging — •Elisabeth Baumann[1,2], Ulrike Pohle[3], Thomas Allen[4], Holger Gerhardt[1,2], and Jan Laufer[3] — [1]MDC, Berlin, DE — [2]Charite, Berlin, DE — [3]MLU, Halle, DE — [4]UCL, London, UK

Optical-resolution photoacoustic microscopy (OR-PAM) is a biomedical imaging technique with great potential for preclinical studies of the vasculature. It can be used to obtain spatially resolved information on parameters like the blood flow speed and blood oxygen saturation. However, for many in vivo applications, backward-mode operation of the OR-PAM system is required for which conventional piezoelectric ultrasound sensors are at a disadvantage as they need to be placed far away from the signal source. Here, we present an all-optical, backward-mode OR-PAM system that fulfils the requirements for functional imaging of the vasculature. The system incorporates a novel planar Fabry-Pérot (FP) ultrasound sensor, which is transparent to the excitation light and can be placed immediately adjacent to the sample.

To demonstrate the morphological imaging capabilities of the system, we performed 3D imaging in vitro of a leaf skeleton phantom and in vivo of a zebrafish embryo in raster-scanning mode. To be able to resolve blood flow, a fast continuous-scanning mode was established and validated in imaging phantoms. To show the capabilities of the system to image blood oxygen saturation, a Raman laser was set up for multi-wavelength excitation OR-PAM of ink phantoms.

BP 28.16   Thu 18:00   P2/EG

Imaging Symmetry-Dependent Behavior of Orbital Angular Momentum Entangled States — •Juan Nicolas Claro Rodriguez[1,2] and Roberto Ramirez Alarcon[1] — [1]Centro de Investigaciones en Óptica, 37150 León-Guanajuato, México — [2]Paderborn University, 33098 Germany

Orbital angular momentum (OAM) is a degree of freedom of photons, promising for many high-dimensional quantum applications. By tuning the symmetry of OAM states using dove prisms and measuring spatially resolved interference properties, we find that fringes are produced depending on the type of the state symmetry and propose an application to achieve twice the contrast in quantum optical coherence tomography. This technique also permits high-resolution microscopy of photo-sensitive tissue.

BP 28.17   Thu 18:00   P2/EG

Quantitative imaging of Caenorhabditis elegans dauer larvae during cryptobiotic transition — •Kyoohyun Kim[1], Vamshidhar R. Gade[2,3], Teymuras V. Kurzchalia[2], and Jochen Guck[1] — [1]Max Planck Institute for the Science of Light, Erlangen, Germany — [2]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany — [3]Institute of Biochemistry, ETH Zürich, Zürich, Switzerland

Caenorhabditis elegans can survive harsh environments by entering dauer diapause with reduced metabolic activity and distinct structural changes. We employed optical diffraction tomography (ODT) to quantitatively measure the transitions of mass density distribution inside living C. elegans larvae in the reproductive and diapause stages. ODT revealed that the mass density of C. elegans larvae increased upon entry into dauer diapause, and surprisingly, the harshly desiccated dauer larvae exhibited very high refractive index values (n ~ 1.5). Moreover, mutants that are sensitive to desiccation displayed structural abnormalities in the anhydrobiotic state that were not observable by conventional microscopy. Our findings open a door to quantitatively understanding the importance of material properties of an organism on the verge of life and death.

BP 28.18   Thu 18:00   P2/EG

Shaping the embryo: blastoderm stress maps reveal early mechanical symmetry breaking — •Alejandro Jurado Jiménez, Leon Lettermann, Bernhard Wallmeyer, and Timo Betz — Drittes Physikalisches Institut, Georg-August-Universität Göttingen

In this work we present a hydrodynamical analysis of early Zebrafish development which aims to understand the mechanical state of the tissue leading to its first symmetry breaking during epiboly: the shield formation. A full mechanical characterization of the blastoderm is achieved using a combination of Light-Sheet microscopy and state-of-the-art cell tracking of the cells nuclei, viscosity measurements and polyacrylamide beads as force sensors. The extraction of stress maps in the tissue is possible thanks to a custom-made software for the analysis of the bead deformation, which is presented here a versatile tool for similar stress analyses in other biological samples.

Our experimental analysis of the mechanical state of the embryo is supported and expanded by a model-driven extraction of the stress fields using NeuronalODEs. The NODEs system only necessitates the velocity field on the blastoderm to solve the hydrodynamic problem, optimizing up to 10^5 parameters and retrieving a full dynamical description of the embryo. Both the experimental and numerical analyses expose a stress asymmetry prior and during the shield formation, from which we can learn more about the mechanical origin of the first embryonal symmetry breaking.

BP 28.19   Thu 18:00   P2/EG

Radial growth and the impact of stress on the cell division plane in the hypocotyl — •Mathias Höfler and Karen Alim — School of Natural Sciences, Technical University of Munich, Germany

The morphogenesis of plant tissue is a reliably stable and efficient process, yet individual cell shape and growth underlie high variance. Theory and experiment

show that there is a mechanical and biochemical feedback loop for plant tissue development. In fact, mechanical stresses have a pronounced effect on microtubule orientation in the tissue, thereby changing the mechanical properties and leading to anisotropic cell growth. Here, we study the effect of cell mechanics, stress patterns and feedback mechanisms on the bidirectional radial growth of the plant hypocotyl. We furthermore study the connection between mechanical stresses and the choice of cell division plane orientation. We seek to unveil the minimal biophysical requirements and relevant forces to achieve the experimentally observed morphologies. Our results show that inhomogeneous growth generates distinct stress patterns in the tissue . Introducing cell division along the direction of maximum stress furthermore gives us a first perspective on how radial growth morphologies emerge.

3D Traction Force Microscopy on engineered blood vessels — •Karim Ajmail, Fatemeh Mirzapour, and Karen Alim — School of Natural Sciences, Technical University of Munich, Germany

The endothelium lines the walls of every blood vessel the human body. By virtue of their strategic position the endothelium has to withstand a plethora of mechanical cues including shear stress, circumferential strain as well as pressure exerted by the blood flow. Therefore, the mechanobiology of endothelial cells is a particularly pivotal part for the functionality of this tissue. However, the immense complexity of the vasculature necessitates in vitro systems that can uncouple and measure these various effects. Although in vitro approaches greatly enhanced our understanding of endothelial complexity, a mechanical characterization of endothelial systems is missing so far. Here, we employ 3D Traction Force Microscopy (TFM) as state-of-the-art method to measure cellular forces in physiologically relevant environments. In particular, we use 3D TFM to measure forces in a perfusable engineered blood vessel embedded in a fibrin hydrogel. Further, the effect of different stationary as well as pulsatile flow patterns on the mechanical response of the cells is investigated. We propose 3D TFM as an additional readout parameter in future human-on-a-chip applications for a quantitative mechanical characterization of the tissue.

BP 28.21   Thu 18:00   P2/EG

Tissue tension during zebrafish development — •Ming Hong Lui[1,2], Alejandro Jurado[1], Leon Lettermann[1,3], and Timo Betz[1,2] — [1]3rd Institute of Physics - Biophysics, University of Göttingen — [2]Max Planck School Matter to Life — [3]Institute for Theoretical Physics, Heidelberg University

Understanding the morphogenesis during development is one of the emerging fields where the interaction between developmental and tissue biology with biophysics has provided a series of new insights into nature's physical working principles. In particular, during embryonic development of zebrafish, cells in the blastoderm exhibit collective migration towards the yolk in a process known as epiboly, while simultaneously shield formation and gastrulation break symmetry preceding tissue differentiation. These elegantly robust processes are facilitated by both biochemical and mechanical interactions.

To determine how mechanical tissue stresses contribute to these interactions, we use photoablation to externally break symmetry by severing connections in the enveloping layer and record the subsequent population redistribution using light sheet microscopy of the whole embryonic volume. From the analysis of the nuclei trajectories, we noted that the epiboly process is highly robust and mostly unaffected by the damage, during which there is a convergent motion of cells towards an azimuthal angle (orthogonal to the direction of epiboly) that forms the future spine. Ablations can transiently disrupt this convergence dependent on the developmental time at which the damage is introduced.

BP 28.22   Thu 18:00   P2/EG

A 3D Voronoi vertex model for fluid transport in lumenogenesis — •Anne Materne[1], Charlie Duclut[1,2], Quentin Vagne[1,3,4], Pietro Incardona[3,5,6], Ivo F. Sbalzarini[3,5,7,8], and Frank Jülicher[1,3,8] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Laboratoire Physico-Chimie Curie, Paris, France — [3]Center for Systems Biology Dresden, Germany — [4]Department of Genetics and Evolution, Université de Genève, Switzerland — [5]Faculty of Computer Science, TU Dresden, Germany — [6]Institute for Genomic Statistics and Bioinformatics, Universität Bonn, Germany — [7]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany — [8]Cluster of Excellence Physics of Life, TU Dresden, Germany

In many systems, cells collectively organise to build complex structures. In particular, in certain developmental processes the formation of a fluid-filled cavity called a lumen plays a crucial role. Various mechanisms, for example programmed cell death, are known to initiate lumen formation. However, in order to sustain lumenogenesis, cells must collectively transport water and ions into the newly forming cavity. Here, we present a 3D Voronoi vertex model to study this collective transport process at cellular resolution. Our approach involves a substantial extension of the typical Voronoi work function minimisation procedures to account for the hydraulic and mechanical mechanisms in cell volume regulation and for pressure-driven flows. Fully-parallelised and efficient for systems with many cells, our procedure allows us to study the dynamics of lumenogenesis in complex geometries.

BP 28.23   Thu 18:00   P2/EG

Dystrophin as a tension regulator in human skeletal muscles — •Mariam Ristau[1], Arne Hofemeier[1,2], and Timo Betz[1] — [1]Third Institute of Physics - Biophysics, Georg-August-University Göttingen, Germany — [2]ZMBE - Institute of Cell Biology, University of Münster, Germany

Skeletal muscles are associated with contraction, movement and force generation. They are important for maintaining posture and maintaining bone and joint stability. Muscular dystrophies such as Duchenne muscular dystrophy (DMD) result in progressive weakening of skeletal muscles. DMD is caused by the loss of the protein dystrophin which is thought to stabilize and protect muscle fibers from injury. In the progression of the disease, damaged muscle fibers degrade, muscle mass is lost and greater functional impairments develop. We have studied the contractile potential of myoblasts and reconstituted tissue derived from healthy and DMD patients, and found that they were mechanically different in muscle tension and contractility. DMD derived myoblasts exhibited an overall weaker contractility compared to healthy derived myoblasts. In contrast, DMD derived myoblasts showed an overall higher muscle tension, suggesting that dystrophin may function as a tension regulator in skeletal muscles. In order to rule out the possibility that these findings are due to patient variability we intend to establish a genetic model in which we knockout dystrophin with the CRISPR/Cas9 system in healthy myoblasts and rescue dystrophin in DMD myoblasts by integrating micro-dystrophins(μDys).

BP 28.24   Thu 18:00   P2/EG

Influence of vimentin intermediate filaments on microtubules in cells — •Anna Blob[1], Roman David Ventzke[1,2], Thomas Giacomo Nies[2], Axel Munk[2], Laura Schaedel[3], and Sarah Köster[1] — [1]Institute for X-Ray Physics, University of Göttingen — [2]Institute for Mathematical Stochastics, University of Göttingen — [3]Center for Biophysics, Saarland University

The cytoskeleton in eucaryotic cells is an intricate network of three different filamentous proteins: microtubules, actin filaments and intermediate filaments. They are essential for the mechanical properties of a cell as well as intracellular transport and division. Each filament type has its own unique features, and, in particular, microtubules, can withstand large compressive forces and show characteristic buckling and bending behavior that is still not fully understood. There is evidence for important interactions between cytoskeletal filaments: vimentin intermediate filaments stabilize microtubules in vitro and can template the microtubule network in migrating cells. Following up on this idea, we are interested in the influence of vimentin networks on microtubule mechanics. Investigating how the bending of microtubules depends on both the microtubule network itself and the vimentin network will improve our understanding of the mechanical consequences of the interaction within and between these filament systems. We compare microtubule networks in vimentin-knockout and wild-type mouse fibroblasts on micropatterns. We find that the local curvature of microtubules depends on the cellular region and increases with both increasing microtubule density and increasing vimentin density.

BP 28.25   Thu 18:00   P2/EG

Interactions between synaptic vesicles and cytoskeletal filaments — •Tiago Mimoso, Tizian Schmidt, and Sarah Köster — Institute for X-Ray Physics, University of Göttingen, Germany

Signal transmission of neurons occurs both electrically and chemically. The chemical signal is transported by synaptic vesicles(SVs) from one cell to another via the synaptic cleft to the adjacent neuron. Thus, these SVs are found in the synapse, within the so-called synaptic bouton. Here, the SVs are surrounded by cytoskeletal filaments, including dynamic microtubules that undergo rapid assembly and disassembly. There are studies that suggest an interactions between SVs and the cytoskeletal filaments, however the exact mechanisms remain unknown. Therefore, we now ask the question of whether SVs and microtubules interact and what influence the presence of SVs has on the growth rate, disassembly rate, catastrophe frequency and rescue frequency of the microtubules. We employ a reconstituted *in vitro* system and image the dynamic microtubules by total internal reflection fluorescence (TIRF) microscopy. We use a novel and fast data analysis technique based on a neural network to segment the microtubules in the microscopy pictures. This method provides the advantage of being applicable also curved microtubules and yields results that are comparable to the commonly used manual analysis method.

BP 28.26   Thu 18:00   P2/EG

Burst Mode Characteristics of an Ultrasonic Transducer for Treatment of Cancer Cells — •Rebecca Kampmann[1], Birte Sehlmeyer[1], Claus Scheidemann[2], Tobias Hemsel[2], and Mathias Getzlaff[1] — [1]Institute of Applied Physics, Düsseldorf University — [2]Dynamics and Mechatronics, Paderborn University

Head and neck squamous cell carcinoma cells and oral keratinocytes have different cell mechanics and because of that they have different natural frequencies. This characteristic is used to selectively destroy cancer cells.

For this purpose, ultrasonic waves at a resonant frequency of 90kHz were used in burst mode to achieve the largest possible deflection of the ultrasonic trans-

ducer. The ultrasonic actuators were electrically excited using a flexible ultrasonic generator developed by ATHENA Technologie Beratung GmbH, Paderborn. Investigation of the active current, which is proportional to the transducer tip velocity, showed that the active current depends on the set active time. If the active time is too low, the active current is not able to reach the desired target current. The longitudinal deflection of the ultrasonic probe in burst mode is comparable to the one in continuous mode. The setpoint current amplitude and the active time are decisive parameters. In addition, the transverse deflection was investigated, showing that this vibration is larger than the longitudinal one.

BP 28.27   Thu 18:00   P2/EG
Burst Mode of Ultrasonic Resonant Oscillations for Stimulation and Destruction of Tumor Cells — •Birte Sehlmeyer[1], Rebecca Kampmann[1], Claus Scheidemann[2], Tobias Hemsel[2], and Mathias Getzlaff[1] — [1]Applied Physics, Düsseldorf University — [2]Dynamics and Mechatronics, Paderborn University

Different types of cancer, such as prostate carcinomas, are nowadays already treated with the ultrasound-based therapy HIFU (high intensity focused ultrasound). The healthy cells, which are located in the irradiation field, cannot be spared in this process. The elasticity differences between cancer cells and healthy cells strongly influence their stimulation frequency. LIPUS (low intensity pulsed ultrasound) is used to selectively stimulate and destroy cancer cells close to their own natural frequency, while sparing locally adjacent healthy cells.

Here we report new findings on the maximum oscillation amplitude of an ultrasound unit in burst mode. In burst mode, there is only a signal output during the active times.The ultrasonic actuators were electrically excited using a flexible ultrasonic generator developed by ATHENA Technologie Beratung GmbH, Paderborn. The excitation of the ultrasonic unit was varied by setting the targets current amplitude and the active time. Regarding the characteristic stimulation frequency of tumor cells, the frequency spectrum and frequency filters are discussed. In addition to the longitudinal deflection amplitude, an oscillation in the transverse direction was observed. Finally, the transverse oscillation behavior is investigated in relation to half-wave synthesis.

BP 28.28   Thu 18:00   P2/EG
Cytoskeletal Networks in Cells Under Strain — •Ruth Meyer[1], Anna V. Schepers[1], Peter Luley[1], Jonathan Bodenschatz[2], Amaury Perez Tirado[2], Andreas Janshoff[2], and Sarah Köster[1] — [1]Institute for X-Ray Physics, University of Göttingen — [2]Institute for Physical Chemistry, University of Göttingen

The cytoskeleton of eukaryotes consists of three types of filaments: F-actin, microtubules and intermediate filaments (IFs). In contrast to microtubules and actin filaments, IFs are expressed in a cell-type specific manner, and keratins are found in epithelial cells. In certain cell types, the keratin filaments form a layer close to the membrane which may be referred to as an "IF-cortex". Furthermore, it is hypothesized that this IF-cortex arranges with radial spokes in a "rim-and-spokes" structure in epithelia. Based on this hypothesis, IFs and actin filaments might add complementary mechanical properties to the cortex. It was previously shown that single IFs remain undamaged even at high strains. We now ask the question of whether this unique force-extension behavior of single IFs is also relevant in the filament network within a cell. We designed an equibiaxial stretcher that can apply high strains to the cells. This setup is combined with fluorescence and atomic force microscopy enabling simultaneously imaging of the cells and measuring their stiffness during stretching. By quantitatively analyzing the force indentation curves and the microscopy images, we analyze the structure and the mechanical properties of actin and IF networks close to the cell membrane.

BP 28.29   Thu 18:00   P2/EG
Exploring cell-cell interactions inferred from trajectories in two-site arrays — •Emily Brieger[1], Tom Brandstätter[2], Georg Ladurner[1], Chase P. Broedersz[2], and Joachim O. Rädler[1] — [1]LMU, Munich, Germany — [2]VU Amsterdam, Amsterdam, Netherlands

Collective cell migration is a fundamental aspect to a variety of physiological processes. The migratory dynamics of these collective processes rely on cell-cell interactions that are depending on complex molecular mechanisms, such as cadherin dependent pathways. In previous work we studied the interaction behavior of two cells migrating on dumbbell-like micropattern. This geometry enforces repeated head-to-head collisions of cells and allows the distinction of interacting and noninteracting events. In this framework non-cancerous MCF10A cells and cancerous MDA-MB-231 cells clearly differ in their effective adhesion and friction terms derived from quantitative theoretical analysis. Here we use this data-driven approach to study how specific molecular alterations of surface proteins change cell-cell interactions in different cell lines. Blocking of E-cadherin and Ephrin A2 via antibodies yield distinct shifts in cell behavior space. Likewise knockouts that prevent cells from using their usual communication pathways alter the adhesive and frictional interactions. We show that the analysis yields insight into the role of E-Cadherin and Ephrin A2 in frictional and adhesive interactions as well as repulsive response known as contact inhibition of locomotion.

BP 28.30   Thu 18:00   P2/EG
A high-throughput pipeline for morphological and functional analysis of cardiomyocytes — Daniel Härtter[1,2], •Lara Hauke[1], Wolfram-Hubertus Zimmermann[1], and Christoph F. Schmidt[2] — [1]Institute of Pharmacology and Toxicology, University University Medical Center Göttingen, Germany — [2]Department of Physics, Duke University, Durham, NC, USA

Cardiomyopathies, diseases of the heart muscle, affect 1 in 500 adults in Western countries. Nevertheless, reliable knowledge about disease onset and pathogenesis is lacking. To develop effective treatment options for patients, a dynamic and quantitative understanding of cardiomyopathies is needed. We developed an assay in which individual stem-cell derived heart cells of a fluorescent sarcomere reporter cell line grow in a heart-like environment - while allowing for automated high-resolution and high-framerate imaging - using micropatterned polyacrylamide acid (PAA) gels. We analyze the time-course of cell morphology and function upon drug-induced or genetic interventions with our deep-learning-based SarcAsM (Sarcomere Analysis Multitool) software. The resulting multiparametric functional and structural trajectories of cardiac muscle cells can be used to gain novel dynamical perspectives on the time-course and interplay of structure and function in health and disease and might contribute to the discovery of novel treatments.

BP 28.31   Thu 18:00   P2/EG
A mechanical bottom-up approach of memory formation in *Physarum polycephalum* — •Mathieu Le Verge Serandour and Karen Alim — School of Natural Sciences, Technical University of Munich, Germany

Understanding the emergence of memory in artificial or living complex systems is a considerable challenge: its origin, possibly an interplay of physics, genetics, or signaling, has not yet been elucidated. *Physarum polycephalum*, a unicellular organized as a two-dimensional tubular network, exhibits hallmarks of memory formation: its adaptive morphology encodes the location of past stimuli. We propose to investigate memory formation with a bottom-up approach focusing on the physical mechanisms of vascular morphology adaptation. First, we study the mechanical properties of *Physarum* by microrheology. We measure the viscoelasticity of the network's tubes and protrusions, and the change in stiffness or viscosity exposed to external stimuli, such as light or food. At the macroscopic scale, we study the dynamics of pruning of the network and its remodeling. We find an exponential decrease in the number of tubes reproduced by a toy model based on network hierarchy. These two complementary approaches will allow us to build a solid basis for establishing physical principles to characterize information encoding and memory emergence in *Physarum polycephalum*.

BP 28.32   Thu 18:00   P2/EG
Viscoelastic response of vimentin intermediate filament networks measured via optical tweezers-based active microrheology — •Kaan Ürgüp[1], Anna V. Schepers[2], and Sarah Köster[1] — [1]Institute for X-Ray Physics, Universität Göttingen, Germany — [2]Rosalind Franklin Institute and Kennedy Institute of Rheumatology, University of Oxford, UK

The microscale mechanics of the intermediate filament (IF) cytoskeleton are relevant for many cellular processes. The properties of the IF network have been shown to influence cell motility, migration and organelle transport. On the molecular level, an IF monomer is composed of amino acids that lead to α-helical domains in the center, flanked by non-helical domains. Multiple monomers assemble laterally to unit-length-filaments and longitudinally to mature filaments. Vimentin is the most abundant IF protein in humans. Single vimentin filaments show a loading-rate dependent behavior, which can be attributed to the unfolding of α-helical structures into disordered structures and β-sheets when high strains are applied. What is unclear, however, is whether this nonlinear behavior is relevant in cellular vimentin networks. In this work, we measure strain and relaxation dynamics of *in vitro* vimentin networks via optical tweezers in the nonlinear regime. We use an active-passive calibration method based on the Onsager theorem. We measure the nonlinear response to different oscillation amplitudes, which correspond to different strains applied to the network. Our setup allows us to investigate whether the nonlinear behavior of the single filaments is preserved on the network scale.

BP 28.33   Thu 18:00   P2/EG
Traction force microscopy quantifies the contractility of laminopathic cardiomyocytes — •Valentina Kuhn[1,2], Christina Goss[1,3], Aiste Liutkute[2], Anna Zelena[1], Ulrich S. Schwarz[3], Niels Voigt[2], and Sarah Köster[1] — [1]Institute for X-Ray Physics, University of Göttingen, Germany — [2]Institute of Pharmacology and Toxicology, University Medical Center Göttingen, Germany — [3]Institute for Theoretical Physics, University of Heidelberg, Germany

Cardiomyocytes generate the contractile forces in the intact heart. In their nuclear lamina, cardiomyocytes express lamins A and C, a type of intermediate filament proteins that are encoded by the *LMNA* gene and are important for both genetic regulation and cytoskeletal organization. Patients with pathogenic *LMNA* mutations typically suffer from diseases characterized by altered cardiomyocyte contractile behavior, leading to high sudden cardiac death rates. So far, no detailed mechanistic explanation nor specific therapies are available. Cardiomy-

ocytes derived from induced pluripotent stem cells (iPSC-CMs) are powerful in-vitro models to study the mechanisms underlying cardiomyopathies. We combine traction force microscopy with fluorescence imaging of the actin structures in a time-resolved manner on a single cell level. The experiment is conducted by seeding iPSC-CMs on elastic substrates featuring fibronectin micropatterns, which regularize their geometry for imaging while simulating physiological conditions. Thus, we can quantify the altered contractility of iPSC-CMs with the R331Q *LMNA* mutation in comparison with wild-type cells.

BP 28.34   Thu 18:00   P2/EG

Cell migration on micropatterns - how regular is the motion of different cell types? — •Annika A. Vogler, Sebastian W. Krauss, Radhakrishnan A. Veettil, Florian Rehfeldt, and Matthias Weiss — Experimental Physics I, University of Bayreuth, Germany

During processes like embryonic development, wound healing, or cancer metastasis, cells are often migrating in complex and obstacle-rich environments. Microstructured surfaces offer a versatile opportunity to model such environments and study cell migration under controlled conditions. Recent studies on cells that migrate in fairly simple two-state micropatterns have revealed, for example, a rich and nonlinear migration dynamics [1]. Following up on this study, we have explored the migration dynamics of non-cancerous MCF-12A cells on simple dumbbell patterns in comparison to malignant MDA-MB-231 cells. As a result, we observed that MCF-12A cells exhibit a strikingly more regular migration pattern while trajectories of cancerous cells appeared more stochastic. In particular, the path of non-tumorigenic cells was mainly focused on the edges of the pattern whereas malignant cells explored the whole available adhesion area. These results suggest differences in how the external environment is perceived by the internal biochemical state of cells.

BP 28.35   Thu 18:00   P2/EG

Cell Shape and Tension alter Focal Adhesion Structure — Carolin Grandy[1], Fabian Port[1], •Jonas Pfeil[1], Mariana Azevedo Gonzalez Oliva[2], Massimo Vassalli[2], and Kay-Eberhard Gottschalk[1] — [1]Universität Ulm, Institut für experimentelle Physik, Ulm, Germany — [2]University of Glasgow, James Watt School of Engineering, Glasgow, United Kingdom

Cells are anchored to the extracellular matrix via the focal adhesion complex. It also serves as a sensor for force transduction. We analyse the effect of tension on the location of key focal adhesion proteins vinculin, paxillin and actin. We use micropatterning on gold surfaces to manipulate the cell shape, to create focal adhesions at specific cell areas, and to perform metal-induced energy transfer (MIET) measurements on the patterned cells. We use drugs influencing the cellular motor protein myosin or mechanosensitive ion channels to get deeper insight into focal adhesions at different tension states. We show here that in particular actin is affected by the rationally tuned force balance. Blocking mechanosensitive ion channels has a particularly high influence on the actin and focal adhesion architecture, resulting in larger focal adhesions with elevated paxillin and vinculin and strongly lowered actin stress fibres. Our results can be explained by a balance of adhesion tension with cellular tension together with ion channel-controlled focal adhesion homeostasis, where high cellular tension leads to an elevation of vinculin and actin, while high adhesion tension lowers these proteins.

BP 28.36   Thu 18:00   P2/EG

Interactions of cytoskeletal elements during phagocytosis in macrophages. — •Erbara Gjana[1] and Franziska Lautenschläger[1,2] — [1]Department of Physics, Saarland University, Saarbrücken, Germany — [2]Center for Physics, Saarland University, Saarbrücken, Germany

The structure of cells is realized via their cytoskeleton - a polymer network inside cells. It is the main component of structural integrity and it shapes cells. The cytoskeleton is involved in many active cellular activities that includes cell division, migration, and phagocytosis. In macrophages, we know that actin - one protein of the cytoskeleton * plays an important role during phagocytosis. In my project, I work on understanding how actin is involved in sensing the object which needs to be phagocytosed.

Particularly, I study the effect of the physical properties such as form, size and stiffness of the objects. Therefore, I am varying the stiffness of objects, e.g. I use gelatine beads, latex beads and polystyrene beads and investigate how these are phagocytosed with the help of actin. Through different microscopy methods (epi-fluorescence, confocal) I will be able to image the process of phagocytosis. Till now, we have established phagocytosis protocols with macrophages derived from the cell line HL60. For a better biological fit I am now shifting to THP1 derived macrophages. This will help me to understand questions such as how macrophages distinguish between dead cells (ei. Dead RBCs), cell debris, and healthy cells. Also, we collaborate with theoreticians be build general mathematical model of phagocytosis.

BP 28.37   Thu 18:00   P2/EG

Micromechanics of spherical cellular aggregates — •Antoine Girot[1,2], Marcin Makowski[2], Marco Rivetti[2], Christian Kreis[2], Alexandros Fragkopoulos[1,2], Matilda Backholm[3], and Oliver Bäumchen[1,2] — [1]University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — [2]Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Göttingen, Germany — [3]Aalto University School of Science, Department of Applied Physics, 02150 Espoo, Finland

Understanding the rich dynamics of biophysical processes, such as pathogenic tissue development and morphogenesis, requires a proper mechanical characterization of multicellular aggregates. Spherical aggregates often serve as model systems, yet, they cannot be readily characterized with conventional techniques that are optimized for single cells. In this presentation, we report on *Volvox globator*, a natural cellular aggregate that is composed of hundreds of bi-flagellated cells forming a spherical monolayer filled with mucilage. We employ *in vivo* micropipette force measurements combined with optical detection to simultaneously measure the force response and the deformation of this living aggregate. We show that the micromechanics of *Volvox* can be described by a model coupling elasticity and viscosity, which allows to extract the mechanical properties. We find that the viscous component exhibits a shear-thinning behavior, that can be properly described by implementing a power-law fluid model, while the elasticity of the aggregate depends on its size.

BP 28.38   Thu 18:00   P2/EG

The influence of calcium on the structure of the actin cortex in cell monolayers and single cells — •Christoph Anton[1], Lucina Kainka[1], Sandra Iden[2], and Franziska Lautenschläger[1,3] — [1]Department of Physics, Saarland University, Saarbrücken, Germany — [2]Center of Human and Molecular Biology (ZHMB), Saarland University, Homburg, Germany — [3]Center for Biophysics, Saarland University, Saarbrücken, Germany

We recently showed that adhesion to a substrate, mediated via integrins, causes significant changes to the structure, mechanics and dynamics of the cellular actin cortex. In tissues, however, cells additionally form cell-cell junctions. Therefore, we investigate how the structure of the actin cortex of healthy and cancerous epithelial cell lines is affected by the transition from single cells to cell monolayers. One important step during this transition is the formation of cell-cell junctions, such as the cadherin-based adherens junctions. These junctions are dependent on the presence of calcium ions. In our work, we varied the extracellular calcium concentration to investigate the effect of cadherin-mediated adhesion and other calcium-based cellular processes on the actin cortex. We used scanning electron microscopy (SEM) to visualize the actin cortex. We applied our filament network tracing algorithm to the SEM images to quantify the structural properties of the actin cortex, such as the mesh hole area. By comparing the cortex parameters of cells within a monolayer with the cortex parameters of isolated cells we plan to characterize the structural changes that are induced by cell-cell contacts and extracellular calcium concentrations.

BP 28.39   Thu 18:00   P2/EG

Motility of adherent cells on structured surfaces at elevated viscosities — •Radhakrishnan Adiyodi Veettil, Sebastian W Krauss, Annika A Vogler, Florian Rehfeldt, and Matthias Weiss — Experimental Physics I, University of Bayreuth, Germany

Cell motility is sensitive to the viscosity of the surrounding medium, suggesting that such external cues can trigger cells to switch gears. Indeed, it has been recently reported that elevated viscosities can induce significant changes in cell area, cell migration speed and focal adhesion turn over [1]. Here, we have followed up on these experiments by monitoring the viscosity-dependent migration of different cell types on microstructured surfaces, e.g. cell hopping of cancerous and non-cancerous cells in dumbbell patterns. Our data suggest that altering viscosity can markedly alter the migration dynamics of cells on microstructured surfaces.

BP 28.40   Thu 18:00   P2/EG

Coordination of information in *Physarum polycephalum* — •Kaspar Wachinger[1], Johnny Tong[1], Nico Schramma[2], Siyu Chen[1], and Karen Alim[1] — [1]School of Natural Sciences, Technical University of Munich, Germany — [2]Faculty of Science, University of Amsterdam, The Netherlands

Physarum polycephalum is a network-structured, single-cell organism with thousands of nuclei that can sense and adapt to its environment. To understand how *P. polyephalum* maintains efficient gene expression, it is necessary to understand the coordinated intracellular transport of nuclei within its structure. Microinjecting several fluorescent dsDNA markers into the tubes of *P. polyephalum* allows in-vivo imaging of nuclei and their dynamics: Nuclei can either be trapped in the more solid wall cortex or follow the oscillatory cytoplasmic streaming. We investigate the flow-driven behaviours of nuclei in functionally different regions of *P. polycephalum*'s network and motivate a hypothesis of inter-nuclei communication far past the degradation distance of mRNA.

BP 28.41   Thu 18:00   P2/EG

FilamentSensor 2.0: An open-source modular toolbox for 2D/3D cytoskeletal filament tracking — Lara Hauke[1], Andreas Primessnig[1], •Emese Zavodszky[1], and Florian Rehfeldt[2] — [1]Institute of Pharmacology and Toxicology, University Medical Center Göttingen, Germany — [2]Experimental Physics I, University of Bayreuth, Germany

Cytoskeletal pattern formation and structural dynamics are key to a variety of biological functions and a detailed and quantitative analysis yields insight into finely tuned and well-balanced homeostasis and potential pathological alterations. High content life cell imaging of fluorescently labeled cytoskeletal elements under physiological conditions is nowadays state-of-the-art and can record time lapse data for detailed experimental studies. However, systematic quantification of structures and in particular the dynamics (i.e. frame-to-frame tracking) are essential. Here, an unbiased, quantitative, and robust analysis workflow that can be highly automatized is needed. For this purpose we upgraded and expanded our fiber detection algorithm FilamentSensor [1] to the FilamentSensor 2.0 [2] toolbox, allowing for automatic detection and segmentation of fibrous structures and the extraction of relevant data (center of mass, length, width, orientation, curvature) in real-time as well as tracking of these objects over time and cell event monitoring. Furthermore, we offer the Focal Adhesion Filament Cross-correlation Kit (FAFCK) [3] for automated correlation with point-like structures. [1] B. Eltzner, et al., PLoS One, 2015 [2] L. Hauke, et al., PLoS One, under review [3] L. Hauke, et al., PLoS One, 2021

BP 28.42   Thu 18:00   P2/EG

Mechanically induced Bioluminescence - from single cells to glowing sea — •Nico Schramma[1], Hugo França[1,2], and Maziyar Jalaal[1] — [1]Van der Waals-Zeeman Institute, University of Amsterdam, Amsterdam, Netherlands — [2]Instituto de Ciências Matemáticas e Computação, Universidade de São Paulo, São Carlos, Brazil

The ability of single-celled organisms to sense mechanical cues is of high importance for their migration, navigation and survival in their ever-changing environment. However, studying single-cell mechano-sensing under dynamic mechanical conditions is complicated. For this reason, the bioluminescent marine algae Pyrocystis lunula is a particularly interesting organism: mechanical stimuli trigger them to release a flash of blue light, which is mostly known from the bioluminescent tide, turning the sea into a mysterious pale blue shimmering. Combining mechanical tests on single cells with dynamics of millions of bioluminescent algae in a wave impact experiment and computational fluid mechanics we find and test general relations describing macroscopic (fluid)mechanical cues with bioluminescence. Our research paves the way towards a better understanding of mechanosensation of algae and plants, but may also lead to applications of bioluminescent organisms as "living force sensors".

BP 28.43   Thu 18:00   P2/EG

Predicting optimal optogenetic control of cell migration with an active gel model — •Oliver M. Drozdowski, Falko Ziebert, and Ulrich S. Schwarz — Institute for Theoretical Physics and BioQuant, Heidelberg University, 69120 Heidelberg, Germany

Cell motility is one of the hallmarks of life and often results from flow in the actin cytoskeleton that is driven by actin polymerization at the front and myosin II motor contractility at the back. The standard model to describe such flows is active gel theory, in which myosin II contractility enters as active stress. Advancements in optogenetic tools have sparked interest in controlling these flows externally and consequently also motility.

Recently we have shown that bistability between motile and sessile states emerges in a one-dimensional active gel model if the myosin II motors are modeled as a supercritical van der Waals fluid [1]. We now incorporate optogenetic perturbations into this description and consider two experimentally accessible protocols for migration control - localized contractility perturbations and global upregulation of contraction. We find that the local protocol permits full external control. Global upregulation reliably leads to irreversible motility initiation, but does not allow for full control. Our results agree with recent experiments on cell migration in microchannels and reconcile experimental observations of local versus global regulatory mechanisms.

Nuclei trafficking dynamics in Physarum polycephalum — •Johnny Tong, Kaspar Wachinger, Nico Schramma, and Karen Alim — School of Natural Sciences, Technical University of Munich, Germany

Synthetical organism and organs house up to thousands of nuclei within a single envelope, often shaped into a complex network archi- tecture. How are nuclei able to efficiently exchange signals over long distances? To understand how synthetia coordinate gene expression, intracellular transport within these networks is key. Physarum poly- cephalum is an ideal syncytia model as its network-shaped body is a single multinucleated cell which can sense and adapt to its environ- ment in a short time scale and a long length scale. Here, nuclei are trapped in the tube walls or advected by the oscillatory cytoplasmic streaming.

We investigate its flow-driven dynamics and mechanochem- ical behaviors using image-based methods, including particle tracking and velocimetry, to analyze the nuclei trafficking. We also utilize the thousands of nuclei to propose a new technique akin to traction force microscopy. By analyzing the fluctuations of nuclei trapped in the ac- tomyosin cortex, we can probe the change of mechanical properties due to external stimuli, such as food, substrate stiffness, and light. Our techniques may be applied to other systems to unveil the mechanisms of long-range genetic communication within network-shaped organisms like fungi.

BP 28.45   Thu 18:00   P2/EG

Super-resolved Imaging of Cellular Traction Forces — •Armina Mortazavi, Jianfei Jian, and Benedikt Sabass — Ludwig Maximilian University of Munich, Munich, Germany

Traction force microscopy (TFM) is a well-established method that enables the measurement of forces that are exerted by adherent cells to an underlying substrate. We aim to enhance the spatial resolution of TFM by using stochastic optical reconstruction microscopy in total internal reflection mode. To measure the substrate deformations below adherent cells, we employ DNA-based FluoroCubes that each carries multiple, spontaneously blinking, fluorescent dye molecules. Grafting of these new fluorescent probes to the top surface of Polydimethylsiloxane gels and using RGD peptides as the smallest ligands representative of extracellular matrix allows us to measure the forces generated by individual focal adhesion sites. The proposed method in principle allows one to extend traction force microscopy to lengthscales below 100 micrometers and can therefore help to unravel the mechanobiology of highly localized cell-physiological processes.

Length distributions of microtubles with a multistep catastrophe mechanism — Felix Schwietert, •Lina Heydenreich, and Jan Kierfeld — TU Dortmund University, 44227 Dortmund, Germany

Regarding the experimental observation that microtubule catastrophe can be described as a multistep process, we extend the Dogterom-Leibler model for dynamic instability in order to discuss the effect that such a multistep catastrophe mechanism has on the distribution of microtubule lengths in the two regimes of bounded and unbounded growth. We show that in the former case the steady state length distribution is non-exponential and has a lighter tail if multiple steps are required to undergo a catastrophe. If rescue events are possible, we detect a maximum in the distribution, i.e., the microtubule has a most probable length greater than zero. In the regime of unbounded growth, the length distribution converges to a Gaussian distribution whose variance decreases with the number of catastrophe steps. All results are verified by stochastic simulations.

BP 28.47   Thu 18:00   P2/EG

Bridging the gap between surface flows and motility patterns of malaria parasites — •Leon Lettermann[1], Mirko Singer[2], Falko Ziebert[1], Friedrich Frischknecht[2], and Ulrich S. Schwarz[1] — [1]ITP & Bioquant, Heidelberg University — [2]CIID, Heidelberg University

Malaria is one of the most devasting infectious diseases and transmitted from mosquitos to humans by so-called Plasmodium sporozoites, which move by gliding motility. Myosin motors move actin filaments below the plasma membrane, which leads to surface flows of adhesins that are anchored into the plasma membrane. How this surface flow is converted into the complicated motility patterns observed in experiments is not clear. Here we introduce a theoretical model that bridges this gap. The coupling between surface flow and substrate is modeled by a system of reversible adhesion bonds. We numerically solve the resulting system of ordinary differential equations and find a rich variety of motility patterns, including the circular and helical paths observed in experiments. This allows us to estimate likely patterns of surface flows, which are hard to measure experimentally.

BP 28.48   Thu 18:00   P2/EG

Stem Cell Dynamics in Tissues — •Johannes C. Krämer, Gerhard Gompper, and Jens Elgeti — Theoretical Physics of Living Matter (IBI-5/IAS-2), Forschungszentrum Jülich, Jülich, Germany

The renewal of epidermal tissue relies on a few stem cells dividing asymmetrically, and a cascade of transient amplifying cells resulting in the necessary cell mass of terminally differentiated cells. We integrated this process in the two-particle growth model, and find that this simple process results in very interesting dynamic features: Stem cells repel each other in the tissue bulk and are thus found rather isolated in the tissue.

Simulating just two isolated stem cells, we construct the probability density function to find two stem cells in a given distance, and observe a reduced probability to find stem cells close to each other. To understand this repulsive mechanism better, we apply equilibrium methods to construct an effective interaction potential. Although a massive simplification it allows us describe the repulsive interaction in a simple fashion. Thermal colloid simulations, where particles interact via the effective interaction, are consistent with simulations of bulk tissues.

Our findings may contribute to better understand the cancer stem cell hypothesis. Here, cancerous growth is assumed to emerge from few stem cell like cancer cells, which might evade being targeted by therapy. However, the cancer stem cells are difficult to observe – maybe because they get separated by this mechanism.

BP 28.49　Thu 18:00　P2/EG

On multistability and constitutive relations of cell motion on Fibronectin lanes — •Johannes Clemens Julius Heyn[1], Behnam Amiri[2], Christoph Schreiber[1], Martin Falcke[2,3], and Joachim Oskar Rädler[1] — [1]Ludwig-Maximilians-Universität München — [2]Max Delbrück Center for Molecular Medicine in the Helmholtz Association — [3]Humboldt Universität zu Berlin

Migration of eukaryotic cells is a fundamental process for embryonic development, wound healing, immune responses, and tumour metastasis. Experiments on 2d migration show a broad spectrum of morphodynamic features for many cell types. Cells exhibit distinct motile states: They are spread or moving and either steady or oscillatory and they display spontaneous transition between those states. Here, we present a study of the motion of MDA-MB-231 cells on 1d Fibronectin (FN) microlanes and group the migratory behaviour into four discrete states. A high-throughput setup allows to quantitatively analyse state transitions for a broad range of FN densities. We develop a biophysical model based on the force balance at the protrusion edge, the noisy clutch of retrograde flow and a response function to integrin signalling. The model reproduces cell states, characteristics of oscillations and state probabilities in very good agreement with our experimental data. The statistics of trajectories and theory suggests an adhesion related mechanism that not only explains multistability but also the well-known biphasic adhesion-velocity relation and the universal correlation between speed and persistence (UCSP).

BP 28.50　Thu 18:00　P2/EG

Single-molecule tracking in dense images — •Jianfei Jiang[1,2], Armina Mortazavi[1,2], and Benedikt Sabass[1,2] — [1]Institute for Infectious Diseases and Zoonoses, Department of Veterinary Sciences, LMU München — [2]Department of Physics, LMU München

Traction force microscopy (TFM) quantifies cellular traction forces on a surface. The technique is based on measuring the deformations in the substrate. A standard implementation of TFM involves using first particle image velocimetry (PIV) to measure the two-dimensional deformations. Subsequently, a force reconstruction algorithm calculates the traction field based on PIV measurements. The spatial resolution of TFM can be improved by using smaller-sized fluorescent particles embedded in the substrate. To this end, we develop a new technique that combines TFM with Stochastic Optical Reconstruction Microscopy (STORM). Using STORM, we can record the positions of FluoroCubes (~ 6nm) that are densely distributed in the substrate. Here, we propose a new single-molecule tracking algorithm to acquire fine-grained displacement fields. We first use PIV with large-sized fluorescent beads (~ 40nm) to obtain coarse-grained displacement fields, which helps us to estimate the displacement of each FluoroCube. Then, the tracking process is formulated as a linear assignment problem, where we implement the Hungarian algorithm to minimize the overall deviation from PIV estimations. The particle tracking algorithm is parallelized by dividing the image into smaller subimages to reduce computation time. The tracking results enable us to build a high-resolution displacement field for force reconstruction.

Reconstituting a polymer hydrogel that mimics intracellular viscoelastic properties — •Dorian Marx, Bart Vos, and Timo Betz — 3. Institute of Physics, Faculty of Physics, Georg-August-University Göttingen

Throughout the years numerous models were developed that describe the mechanical response of cells to deformations. However, all models, both classic and modern, are phenomenological, that is, they lack a connection of their parameters to the real physical system, making them hard to interpret. Furthermore, the strongest argument for a particular model so far is how accurately it matches to measurements. While this is fine on a phenomenological level, a deeper understanding, e. g. why it fits, is missing. This also holds for the fractional Kelvin-Voigt model (fKVM) that is composed of two complex power-laws and was shown to fit a range of different cells very well.

To connect the fit parameters of the fKVM to the physical system we opt for a bottom-up approach by using a passive viscoelastic polymer with constituents that have analogs in cells. After confirming that the fKVM accurately fits this system, we focus on finding "the most cell-like" parameter set. Varying the composition of the gel (e. g. via the cross-linker concentration) allows us to directly connect properties of the physical system to model parameters. With this, we are now able to formulate hypotheses that can be checked in live cells, giving a quantitative handle for connecting the real world biophysics to rheological models.

BP 28.52　Thu 18:00　P2/EG

Does Size Matter? Actin filament length in cell migration — •Carsten Alexander Baltes[1], Divyendu Goud Thalla[1], and Franziska Lautenschläger[1,2] — [1]Experimental Physics, Saarland University, Saarbrücken, Germany — [2]Center for Biophysics, Saarbrücken, Germany

The ability to perform cellular locomotion is crucial for a large variety of tasks. This includes the search and chase of immunecells for pathogens as well as the search for food and the reorganisation of cells in tissue developement. The cytoskeleton protein actin is particularly important for migration of eucaryotic cells. It is involved in the formation of filopodia and creates a retrograde flow from the leading edge towards the back of the cell, both of which allow them to move forward. Alteration of the actin network therefore might have an impact of the migratory behavior of cells. Here I am going to present the effects of elongated actin filaments on migrating RPE-1 cells. I will show that cells, migrating either on 1D fibronectin lines or on a fibronectin coated surface, displayed a reduction of migration speed, while keeping their persistence. They also occupy a larger area when allowed to spread freely and expres a higher amount of focal adhesions. The change in migration speed vanishes when we put those cells under confinement in PDMS microchannels. Taking those facts together we propose that the length of actin filaments is important for cell migration. However further research is needed to fully understand the importance regarding the different migration modes cells can take depending on the surrounding environment.

BP 28.53　Thu 18:00　P2/EG

From Shape to Function of Sampling Resident Tissue Macrophages — •Miriam Schnitzerlein[1], Anja Wegner[2], Stefan Uderhardt[2], and Vasily Zaburdaev[1] — [1]Department of Biology, Friedrich-Alexander-Universität Erlangen-Nürnberg and Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — [2]Department of Internal Medicine 3 - Rheumatology and Immunology, Friedrich-Alexander-Universität Erlangen-Nürnberg und Universitätsklinikum Erlangen, Germany

Mammalian tissues are permanently subjected to various stresses - be it pathogens, dead cells and related waste products or injuries like micro-lesions - which have to be resolved properly to prevent inflam- mations and maintain tissue homeostasis. To detect such incidents, sessile resident-tissue macrophages (RTMs) persistently sample their surroundings by seemingly random extension and retraction of their protrusions. Quantifying these sampling dynamics over time and comparing RTM behaviour under different conditions can uncover certain patterns or strategies in RTM sampling, which will then help us to understand how RTMs ensure tissue homeostasis. In this project, we have employed a high-resolution intravital imaging protocol to generate movies of RTM sampling dynamics *in vivo*. Next we have built an image processing pipeline to assess cell dynamics via its shape, the curvature and displacement of the cell membrane as well as the movement of the cell protrusions over time. Such detailed measurements enable differentiating physiological states of RTMs, and will help to build a quantitative mathematical model for RTM protrusion dynamics.

BP 28.54　Thu 18:00　P2/EG

The energy cost of membrane-cortex deformation in phagocytosis of different sized pathogens — •Mehdi Ait Yahia and Rhoda Joy Hawkins — University of Sheffield

During their lifetime macrophages (a type of white blood cell) defend against infection in biological organisms by moving and interacting with micrometer sized pathogens. Interactions include phagocytosis which is the engulfment of pathogens by the cell deforming around the target. We model the physical description of the deformation of the membrane and cortex composition based on the energy of bending and stretching. For the bending energy we use the Helfrich energy for an elastic membrane in terms of its elastic moduli and curvature. The stretching energy is a function of the moduli and the extra surface needed to engulf the target object. We consider different methods to obtain the elastic moduli including the possibility of exocytosis modifying the surface area. The bending energy is expected to be smaller for larger objects since the curvature is inversely proportional to the radius. On the contrary the stretching energy is expected to increase for a larger object. We minimize the sum of these two energies with respect to the radius to find an optimum size for phagocytosis. We compare our theoretical predictions with data from simulations and experiments on macrophages engulfing beads of different sizes and the fungal pathogen Cryptococcus.

BP 28.55　Thu 18:00　P2/EG

We can see you think: Towards label-free imaging of action potentials — •Andrii Trelin[1], Heiko Lemcke[2], Sophie Kussauer[2], Christian Rimmbach[2], Robert David[2], and Friedemann Reinhard[1] — [1]Institute for Physics, University of Rostock — [2]Department of Cardiac Surgery, Rostock University Medical Center

The ability to directly observe neuronal communication like propagation of action potentials (AP) is crucial for the understanding of biological neural networks such as the mammalian brain. Existing methods either cannot access cells

deep inside tissue (microelectrode arrays) or are not suitable for observing cells over long time periods (fluorescence). We are developing a novel method of AP imaging, based on the fact that the propagation of an AP through a neural network is accompanied by tiny movements due to various processes, including an increase of cell volume, a change of membrane tension, and others. Although movements happen on a nm scale, i.e. beyond the resolution of classical microscopy, theoretical estimates show that detection of these movements is possible by performing high-speed video recording of the cell and combining information from multiple pixels. The sensitivity can be amplified by employing a suitable optical setup, e.g. interferometric microscope. In this poster, we present the design of the experimental setup and share some of the results obtained in the project. Additionally, we will discuss the development of algorithms, capable of extracting cell movement information from high-speed videos. These include simple statistical analysis of videos, decomposition methods such as PCA, as well as machine learning approaches.

BP 28.56   Thu 18:00   P2/EG
Classifying single cells by their motion — •Anton Klimek[1], Debasmita Mondal[2], Prerna Sharma[2], and Roland Netz[1] — [1]Freie Universität Berlin, Germany — [2]Indian Institute of Science, Bangalore, India
We present a method to differentiate cells solely by their trajectories based on the generalized Langevin equation and apply it to distinguish two differently swimming types of strongly confined microalgae Chlamydomonas reinhardtii cells with an accuracy of 100 %. The model we use is suggested by the data and succeeds to describe the motion on the single cell level. By a simple fit we can extract model parameters for individual cells and subsequently perform an unbiased cluster analysis to determine the number of different cell types in the population and obtain an assignment of every cell to one of the types. Additionally, the model suggested by the data includes information on the underlying processes leading to the observed patterns of motion, which in the case of our Chlamydomonas reinhardtii data could hint towards a harmonic coupling between the cell nucleus and the flagellar propulsion apparatus. As it still remains a challenge to classify cells on the single cell level, the presented method to distinguish cells with as little information as their trajectories might have important implications in biology and medicine.

BP 28.57   Thu 18:00   P2/EG
The role of vimentin in endothelial cells under flow — •Julia Kraxner[1,2], Wolfgang Giese[1,2], and Holger Gerhardt[1,2] — [1]Integrative Vascular Biology, Max Delbrück Center for Molecular Medicine in the Helmholtz Association (MDC) — [2]German Center for Cardiovascular Research (DZHK), partnersite Berlin
Vascular endothelial cells (VECs) compose the inner layer of blood vessels where they need to be able to constantly sense, withstand and adapt to varying mechanical stresses. For the sensing and adaptation to mechanical stress cytoskeletal proteins, i.e. actin, microtubules and intermediate filaments, play an important role. Here, we focus on vimentin which is the most abundant intermediate filament in VECs. These cells are constantly exposed to shear stress and they response to the flow by polarizing and aligning in direction of flow. We investigate the role of vimentin in this flow response by exposing VECs to shear stress in vitro. Furthermore, experiments under flow reveal an increase of specific phosphorylation sites in vimentin. We study the role of these specific phosphorylation sites on the mechanotransduction. Therefore, we want to combine traction force microscopy under flow with mutations in vimentin which inhibit phosphorylation of specific sites. Additionally, we plan on tuning the substrate stiffness to study the effect of tissue mechanics observed in aging of the vascular system and possible effects on mechanotransduction. These insights have the potential to improve our understanding of the complex mechanism of mechanotransduction in VECs.

BP 28.58   Thu 18:00   P2/EG
Optical Stretcher for Adherent Cells — •Alexander Janik, Tobias Neckernuss, and Othmar Marti — Institute of Experimental Physics, Ulm University
The characterization of cellular viscoelastic properties by utilizing the interface force arising from a laser beam shining through the cell has proven to be a valuable method for suspended cells, e.g. red blood cells.
   The work presented here is based on the same phenomenon. A laser locally pulls the membrane of an adherent cell upwards, while the displacement is detected by off-axis interferometry. In proof-of-concept measurements, it is shown, that this contact-free method is sensitive enough to determine the complex shear modulus of stiff adherent NIH-3T3 cells. Laser power and wavelength are chosen to minimize heating induced softening.

Evolutionary optimization of multicomponent phase separation — •David Zwicker[1] and Liedewij Laan[2] — [1]MPI-DS, Göttingen, Germany — [2]TU Delft, The Netherlands
Biological cells use passive phase separation to segregate different biomolecules into various condensates. Since the molecular interactions determine the number of distinct condensates and their composition, they have likely been optimized evolutionarily for robust segregation. To study this, I will present a numerical method that efficiently determines coexisting phases in multicomponent liquids and use it in evolutionary optimization experiments. I will demonstrate that the optimized interactions lead to a precise number of different condensates, even if the overall composition varies. Consequently, adjusting microscopic interactions leads to stable emergent behaviors in these complex systems.

BP 29.2   Fri 9:45   BAR Schö
Kinetics of droplet sizes in non-conserved emulsions — •Jacqueline Janssen[1], Frank Jülicher[1], and Christoph A. Weber[2] — [1]Max Planck Institute for the Physics of Complex Systems — [2]University of Augsburg
Droplets form via phase separation and coexist with a dilute phase that is composed of droplet material of lower concentration. Many droplets in an emulsion undergo coarsening to the thermal equilibrium state that corresponds to a single droplet in a finite system. In passive emulsions, where the total amount of droplet material is conserved, the average radius grows as a function $t^{1/3}$ in time, and the droplet size distribution function broadens. Here we consider emulsions for which the total droplet material is not conserved, e.g. material is supplied by a chemical reaction or external reservoirs. We calculate the kinetics of droplet sizes and show that there is a switch from coarsening to narrowing of the size distribution upon material supply. Regulation of droplet sizes by material supply could be relevant for biomolecular condensates in living cells.

BP 29.3   Fri 10:00   BAR Schö
Dynamics of vesicle clusters studied by passive x-ray microrheology — •Titus Czajka[1], Charlotte Neuhaus[1], Jette Alfken[1], Moritz Stammer[1], Yuriy Chushkin[2], Diego Pontoni[2], Christian Hoffmann[3], Dragomir Milovanovic[3], and Tim Salditt[1] — [1]Institut for X-ray Physics, Georg-August-Universität Göttingen, Germany — [2]ESRF, Grenoble, France — [3]Laboratory of Molecular Neuroscience, DZNE, Berlin, Germany
Inferring the viscoelastic properties of a complex fluid from the dynamics of suspended tracer particles is a common method to perform rheological measurements where a direct measurement of the constituents of the system is not possible or impractical. The previously observed pool formation of vesicles induced by divalent salts or the protein synapsin I is a case in point. One would like to know how the mobility of a single (tracer) particle changes in a dense pool as compared to a homogeneous vesicle suspension. Here we used x-ray correlation spectroscopy (XPCS) to measure silica nanoparticles immersed in a complex biomolecular fluid composed of small unilamellar vesicles and $CaCl_2$, or SUVs and Synapsin-Ia protein, both in buffer solution. While the former system leads to irregular clusters, the latter has been observed to form protein induced vesicle pools, suggesting a liquid-liquid phase separation. Analysis of the photon correlation functions reveals the presence of different timescales, which we attribute to the free diffusive motion of the tracer particles and the motion of the tracer particles that interact with the cluster.

BP 29.4   Fri 10:15   BAR Schö
A stereotypical sequence of condensation and dispersal of RNA polymerase II clusters during stem cell differentiation — •Tim Klingberg[1], Irina Wachter[2], Agnieszka Pancholi[2], Roshan Prizak[2], Priya Kumar[3], Yomna Gohar[3], Marcel Sobucki[2], Elisa Kämmer[2], Süheyla Eroğlu-Kayıkçı[2], Sylvia Erhardt[2], Carmelo Ferrai[3], Vasily Zaburdaev[1], and Lennart Hilbert[2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg — [2]Karlsruher Institut für Technologie — [3]Universitätsmedizin Göttingen
Most eukaryotic genes are transcribed by RNA polymerase II (Pol II). In stem cells, recruited Pol II forms prominent, long-lived clusters, which gradually disappear during differentiation, so that only smaller clusters remain. Here, we ask whether the loss of large Pol II clusters is a stereotypical transition that can be explained by changes in the Pol II transcriptional state during differentiation. We assess clusters by super-resolution microscopy in three different experimental models of differentiation. In all cases, Pol II clusters first become larger and rounder, then unfold, and finally split into small clusters. These shape changes are accompanied by changes of transcriptional activity of Pol II. Previous work suggests a surface-condensate model, where enhancer regions support Pol II cluster formation, and transcriptional activity disperses clusters. Using this theoretical model, we propose that the developmental changes in enhancer marks and transcriptional activity during differentiation are sufficient to define a stereotyped trajectory through a cluster shape space.

BP 29.5   Fri 10:30   BAR Schö

Anomalous dynamics of differentiated droplets — •Xi Chen[1], Frank Jülicher[2], Jens-Uwe Sommer[1], and Tyler Harmon[1] — [1]Leibniz-Institut für Polymerforschung Dresden, Institut Theory der Polymere 01069 Dsden — [2]Max-Planck-Institut für Physik komplexer Systeme, 01187 Dresden

Membraneless compartments formed by liquid-liquid phase separation in cells behave like droplets and take part in various biological processes. The function of these droplets are largely dependent on their components. We previously showed with a theoretical model that droplets can undergo a differentiation process where a homogeneous population of droplets converts into two coexisting types of droplets. We proposed this allows droplet specialization similar to cell differentiation.

These differentiated droplets exhibit new features and anomalous dynamics. Like a normal droplet system where droplets ripen and merge into one big droplet, this differentiation can significantly accelerate this Ostwald ripening. This happens with the caveat that instead of ripening into one droplet, it ripens into two droplets of different types with a competing reverse Ostwald ripening process. Unexpectedly, these differentiated droplets divide and repel each other over long distances.

Microrheology of red blood cell cytosol — •Thomas John and Christian Wagner — Universität des Saarlandes, Saarbrücken

Tracking of small particles undergoing a Brownian motion is a widespread method in passive microrheology. Washed human red blood cells (RBC) are destroyed by ultrasound treatment to extract the cytosol, the hemoglobin and protein solution inside the cells. We use microrheology with sub-micrometer-sized particles to determine the viscosity of the cytosol. Since the cytosol is always diluted with an unknown amount of water due to the treatment, this small dilution has a huge impact on the viscosity. To circumvent this problem, we measured very accurately the mass density of every sample. However, the resulting density-viscosity relation is a strong monotonic increasing relation. In a separate experiment we determined the mass density distribution of individual intact RBCs in a continuous density gradient by centrifugation. Finally, we can present the probability density distribution of the viscosity in naturally distributed human RBCs.

BP 29.7   Fri 11:15   BAR Schö

Clonal dynamics at tissue interfaces — •Ruslan Mukhamadiarov[1,2], Matteo Ciarchi[1,2], Fabrizio Olmeda[1,2], and Steffen Rulands[1,2] — [1]Ludwig Maximilian University of Munich, München, Germany — [2]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Tissue morphogenesis relies on the spatial separation of different cell types. Understanding how cells regulate the positions of such interfaces is key to understanding the processes that occur during dysregulation, such as in cancer. Genetic tracing has become an important experimental tool in studying the regulation of cell behaviour. However, its use in both homeostatic and growing tissues is limited by the emergence of universal size distributions. Here, we show that the mechanisms of tissues interface regulation is reflected in cell-fate specific size distributions of genetically labelled cells, termed clones. Specifically, we show how interface fluctuations affect the size distributions of labelled clones and derive theoretical predictions for a range of biologically relevant scenarios that can be tested experimentally. We test our theoretical framework by stochastic simulations and analysis of live imaging experiments. By relating interface fluctuations to clone size distributions our work paves the way for using genetic tracing experiments to understand the mechanisms underlying tissue compartmentalization.

Multivalent binding proteins can drive collapse and reswelling of chromatin in confinement — •Sougata Guha and Mithun K. Mitra — Department of Physics, IIT Bombay, India

Collapsed conformations of chromatin have been long suspected of being mediated by interactions with multivalent binding proteins, which can bring together distant sections of the chromatin fiber. In this study, we use Langevin dynamics simulation of a coarse grained chromatin polymer to show that the role of binding proteins can be more nuanced than previously suspected. In particular, for chromatin polymer in confinement, entropic forces can drive reswelling of collapsed chromatin with increasing binder concentrations, and this reswelling transition happens at physiologically relevant binder concentrations. Both the extent of collapse, and also of reswelling depends on the strength of confinement. We also study the kinetics of collapse and reswelling and show that both processes occur in similar timescales. We characterise this reswelling of chromatin in biologically relevant regimes and discuss the non-trivial role of multivalent binding proteins in mediating the spatial organisation of the genome.

A possible application of the Physics of topological defects to oncology — •Andy Manapany, Leïla Moueddenne, Sébastien Fumeron, Bertrand Berche, and Loriane Didier — Université de Lorraine

We propose a numerical study of the thermal diffusion process in non-Euclidian geometry applied to biological active matter. Thanks to the similarities displayed by both nematic and cells in biological tissue, we aim to apply results derived from the study of diffusion processes around topological defects found in liquid crystals, in order to highlight the thermal response in the vicinity of certain disclination defects found in epithelial tissues. This work is motivated by the fact that these types of disclination defects, mainly "comet" and "trefoil" systematically appear during metastatic phases in some forms of aggressive cancers. Thus, a study of the thermal footprint in such mediums may give us information on the most efficient ways to perform thermal ablation targeted towards aforementioned cells while preserving healthy surrounding tissue.

BP 30: Active Matter V (joint session BP/CPP/DY)

Time: Friday 9:30–12:00   Location: TOE 317

Invited Talk   BP 30.1   Fri 9:30   TOE 317

Experiments on Active Polymer-Like Worms — •Antoine Deblais[1], Daniel Bonn[1], and Sander Woutersen[2] — [1]Van der Waals-Zeeman Institute, Institute of Physics, University of Amsterdam, 1098XH Amsterdam, The Netherlands — [2]Van't Hoff Institute for Molecular Sciences, University of Amsterdam, Science Park 904, 1098XH Amsterdam, The Netherlands

We propose a new 'active particle' system in which the particles are in fact polymer-like: the Tubifex tubifex or 'sludge' worm. I will discuss three recent experiments that highlight the richness of this active system. In the first experiment, we perform classical rheology experiments on this entangled polymer-like system. We find that the rheology is qualitatively similar to that of usual polymers, but, quantitatively, the (tunable) activity of the particle changes the flow properties. In a second experiment, we disperse the worm in a quasi-2D aquarium and observe their spontaneous aggregation to compact, highly entangled blobs; a process similar to polymer phase separation, and for which we observe power-law growth kinetics. We find that the phase separation of active polymer-like worms occurs through active motion and coalescence of the phase domains. This leads to a fundamentally different phase-separation mechanism, that may be unique to active polymers. Finally, in the remaining time, I will briefly show that we can efficiently separate by size and activity these living polymers using hydrodynamic chromatography technics.

BP 30.2   Fri 10:00   TOE 317

Filamentous Cyanobacteria Aggregate at Light Boundaries — •Maximilian Kurjahn[1], Leila Abbaspour[1], Philip Bittihn[1], Ramin Golestanian[1,2], Benoît Mahault[1], and Stefan Karpitschka[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, OX1 3PU, Oxford, UK

Filamentous cyanobacteria are among the oldest, yet still most abundant phototrophic prokaryotes on Earth, fixing vast amounts of atmospheric carbon by photosynthesis. Gliding motility, coupled to photophobic responses (direction reversals in response to light intensity gradients), are believed to drive accumulation in suitable light conditions. Here, we demonstrate that photosensitivity goes beyond simple accumulation: Super-filamentous aggregates, capable of collective mechanical action, form at the boundaries of illuminated regions and may, for instance, contract and detach from the substrate, once grown to a critical mass. We explore how the light pattern, in particular its boundary curvature, impacts aggregation. A minimal model of active rods captures the behavior qualitatively. The ecological impact of such behavior is still unclear, but may enable colonies to escape from saturated habitats by switching to a planktonic state.

BP 30.3   Fri 10:15   TOE 317

Odd dynamics of living chiral crystals — •Tzer Han Tan[1,2,3,4], Alexander Mietke[4,5], Junang Li[4], Yuchao Chen[4], Hugh Higinbotham[4], Peter Foster[4], Shreyas Gokhale[4], Jorn Dunkel[4], and Nikta Fakhri[4] — [1]MPI-PKS, Dresden, Germany — [2]MPI-CBG, Dresden, Germany — [3]CSBD, Dresden, Germany — [4]MIT, Cambridge, USA — [5]University of Bristol, Bristol, UK

Active crystals are highly ordered structures that emerge from the self-organization of motile objects, and have been widely studied in synthetic and bacterial active matter. Whether persistent crystalline order can emerge in groups of autonomously developing multicellular organisms is currently unknown. Here we show that swimming starfish embryos spontaneously assemble into chiral crystals that span thousands of spinning organisms and persist for tens of hours. Combining experiments, theory and simulations, we demonstrate that the formation, dynamics and dissolution of these living crystals are controlled by the hydrodynamic properties and the natural development of embryos. Remarkably, living chiral crystals exhibit self-sustained chiral oscillations as well as various unconventional deformation response behaviours recently predicted for odd elastic materials. Our results provide direct experimental evidence for how non-reciprocal interactions between autonomous multicellular components may facilitate non-equilibrium phases of chiral active matter.

BP 30.4 Fri 10:30 TOE 317

Optimal collective durotaxis through active wetting — Macià-Esteve Pallarès[1], Irina Pi-Jaumà[2], Isabela Corina Fortunato[1], Valeria Grazu[3], Manuel Gómez-González[1], Pere Roca-Cusachs[1], Jesus de la Fuente[3], •Ricard Alert[4], Raimon Sunyer[1], Jaume Casademunt[2], and Xavier Trepat[1] — [1]Institute for Bioengineering of Catalonia — [2]University of Barcelona — [3]Instituto de Nanociencia y Materiales de Argón — [4]Max Planck Institute for the Physics of Complex Systems

The directed migration of cell clusters enables morphogenesis, wound healing and collective cancer invasion. Gradients of substrate stiffness are known to direct migration of cell clusters in a process called collective durotaxis, but underlying mechanisms remain unclear. Combining theory and experiments, we reveal a connection between collective durotaxis and the wetting properties of cell clusters. Our experiments show that durotaxis is non-monotonic with substrate stiffness, being optimal at intermediate stiffness. Modeling the cell clusters as active droplets, we explain this non-monotonic durotaxis in terms of a balance between active traction, tissue contractility, and surface tension. Finally, we show that the distribution of cluster displacements has a heavy tail, with infrequent but large cellular hops that contribute to durotactic migration. Our study demonstrates a physical mechanism of collective durotaxis based on the wetting properties of active droplets.

BP 30.5 Fri 11:00 TOE 317

Chlamydomonas axonemes twist during the beat — •Martin Striegler[1,2], Benjamin M. Friedrich[3], Stefan Diez[1,2,3], and Veikko F. Geyer[1] — [1]B CUBE - Center for Molecular Bioengineering, TU Dresden, Dresden, Germany — [2]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany — [3]Cluster of Excellence Physics of Life, TU Dresden, Dresden, Germany

Motile cilia are slender cell appendages that drive single cell locomotion and fluid transport across surfaces. The motility of cilia is generated by its inner core, the axoneme, which bends by the activity of dynein motor proteins. Generation of bending requires antagonistic dynein activity on opposing sides of the axoneme. How dyneins are activated antagonistically is unknown. Theoretical models propose dynein regulation by mechanical feedback, which entails structural deformations of the axoneme, but direct experimental evidence is missing. To study axonemal deformations during the beat, we purify and reactivate Chlamydomonas reinhardtii axonemes. Using defocused-high-speed-darkfield microscopy, we resolve the 3D waveforms with nanometer resolution on mil-

lisecond timescales. We find that asymmetric waveforms have a non-planar component, which is most pronounced during the recovery stroke. To generate non-planarity within the geometric constraints of the axoneme, twist is thought to be required. Using gold-nano-particles as probes attached to the outside of reactivated axonemes, we, for the first time, measure dynamic twisting deformations in reactivated axonemes. We hypothesize that these deformations are involved in controlling dynein motors generating the axonemal beat.

BP 30.6 Fri 11:15 TOE 317

Curvotaxis - the effect of curvature on cells and tissue — Lea Hppel, Jan Sischka, and •Axel Voigt — Institute of Scientific Computing, Technische Universität Dresden, Germany

How do cells respond to curvature? Does curvature has an influence on cell shape and movement? What are the consequences for collective behaviour of interacting cells in tissue? We address these questions using a multiphase field model on different curved surfaces and compare the results with experimental data on pillars, in tubes and other surfaces. The results show a significant influence of curvature and the possibility to effectively model the observed phenomena with classical models and additional curvature terms.

BP 30.7 Fri 11:30 TOE 317

Onset of Homochirality in Cell Monolayers — •Ludwig A. Hoffmann and Luca Giomi — Universiteit Leiden, Leiden, Netherlands

Chirality is a feature of many biological systems and much research has been focused on understanding the origin and implications of this property. Most famously, sugars and amino acids that are found in nature are homochiral, meaning that chiral symmetry is broken and only one of the two possible chiral states is ever observed. Perhaps less well-know, something similar is the case for certain types of cells too. They show chiral behavior and only one of the two possible chiral states is observed in nature. Understanding the origin of cellular chirality and what, if any, use or function it has in tissues and cellular dynamics is still an open problem and subject to much (recent) research. For example, cell chirality has already been shown to play an important role in drosophila morphogenesis.

BP 30.8 Fri 11:45 TOE 317

Dynamic instability of cytoplasmic compartments — •Melissa Rinaldin[1,2] and Jan Brugués[1,2] — [1]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany — [2]Cluster of Excellence Physics of Life, TU Dresden, Dresden, Germany

Early embryos are the epitome of self-organization. Following the cell cycle oscillator, their internal structure is continuously reorganized into precise patterns at remarkable speeds. For example, the mm-sized egg of the frog Xenopus Laevis divides every 30 minutes into equally-sized cells. Physical processes such as autocatalytic growth, active transport, and reaction-diffusion can allow these embryos to keep up with fast cell cycle times, however, their understanding in early development remains largely elusive. Here, we present recent data from experiments of in vitro cytoplasmic extract obtained from frog eggs and exhibiting cell-free division. We show that the properties of the cell cycle oscillator regulate the pattern of cytoplasmic compartments. Specifically, by perturbing the oscillator, we establish that the interface of cytoplasmic compartments is unstable. We demonstrate that such instability arises from competing waves of autocatalytic microtubule growth, and can generate compartment fusion, strongly affecting the early embryonic pattern formation. Altogether, our results propose that the cell cycle oscillator plays a critical role in partitioning the cytoplasm of early embryos, keeping the dynamic instability of cytoplasmic compartments at bay.

BP 31: Cell Mechanics III

Time: Friday 10:00–12:00 Location: BAR 0106

BP 31.1 Fri 10:00 BAR 0106

Viscoelastic properties of cells under influence of drugs — •Henrik Siboni[1,2], Ivana Ruseska[1], Leonhard Grill[2], and Andreas Zimmer[1] — [1]Pharmaceutical Technology & Biopharmacy, University of Graz, Austria — [2]Single Molecule Chemistry, University of Graz, Austria

Nanoscale Drug Delivery Systems are an increasingly popular type of pharmaceutical treatment with the recent vaccines against COVID-19 being prime example. Here, we present out latest results in characterising preadipocyte cells when treated with protamine-miRNA nanoparticles. We employ Atomic Force Microscopy to perform force-indentation experiments in order to spatially resolve the elastic properties before and after drug treatment. Going further, we use force clamping and creep-relaxation in order to map the viscous properties as well. We then discuss the potential conclusions that can be drawn from this study and the pharmaceutical implications.

BP 31.2 Fri 10:15 BAR 0106

A mechano-osmotic feedback couples cell volume to the rate of cell deformation — Larisa Venkova[1,2], •Amit Singh Vishen[3], Sergio Lembo[4], Nishit Srivastava[1,2], Baptiste Duchamp[1,2], Artur Ruppel[5], Alice Williart[1,2], Stéphane Vassilopoulos[6], Alexandre Deslys[1,2], J. M. Garcia Arcos[1,2], Alba Diz-Muñoz[4], Martial Balland[5], J.-F. Joanny[3], Damien Cuvelier[1,2,6], Pierre Sens[3], and Matthieu Piel[1,2] — [1]Institut Curie, PSL, CNRS, UMR 144, Paris, France — [2]IPGG, PSL Research University, Paris, France — [3]Institut Curie, PSL, CNRS, UMR 168, Paris, France — [4]Cell Biology and Biophysics Unit, EMBL, Heidelberg, Germany — [5]Laboratoire Interdisciplinaire de Physique, Grenoble, France — [6]Sorbonne Université, Paris, France

Mechanics has been a central focus of physical biology in the past decade. In comparison, how cells manage their size is less understood. Here, we show that a parameter central to both the physics and the physiology of the cell, its volume, depends on a mechano-osmotic coupling. We found that cells change their volume depending on the rate at which they change shape, when they sponta-

neously spread or when they are externally deformed. Cells undergo slow deformation at constant volume, while fast deformation leads to volume loss. We propose a mechanosensitive pump and leak model to explain this phenomenon. This mechano-osmotic coupling defines a membrane tension homeostasis module constantly at work in cells, causing volume fluctuations associated with fast cell shape changes, with potential consequences on cellular physiology.

BP 31.3   Fri 10:30   BAR 0106

Viscoelastic characterization of biological cells in hyperbolic microfluidic channels — •Felix Reichel[1,2] and Jochen Guck[1,2] — [1]Max Planck Institute for the Science of Light, Erlangen, Germany — [2]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany

Research over the last decades revealed that single-cell mechanical properties can serve as label-free markers of cell state and function and that mechanical changes are a sign of alterations in the cell's molecular composition. This led to the development of a number of microfluidics tools to rapidly measure the deformability and also the viscoelastic properties of cells. The quantification of the stresses, that cause the deformation of the cells in these channels, is often challenging and with that the derivation of a stress-strain relation for such a system becomes complex. Here, we used hyperbolic channels to create an extensional flow field where the acting stresses can be measured using calibration particles and yield a simple relationship between acting stress and resulting cell strain. We then used the setup to measure the Young's modulus and bulk viscosity of HL60 cells and blood cells over a wide range of time scales. Drug induced changes to the cell state could be measured by a change in cell mechanical properties. Our simple setup offers a straightforward measurement of the viscoelastic properties of cells and microscale soft particles.

BP 31.4   Fri 10:45   BAR 0106

Pancreatic cancer metastasis: mechanics and adhesion — •Shruti G. Kulkarni[1], Malgorzata Lekka[2], and Manfred Radmacher[1] — [1]Institute of Biophysics, University of Bremen, Otto-Hahn Allee 1, 28359 Bremen, Germany — [2]Institute of Nuclear Physics PAN, Radzikowskiego 152 , 31-342 Krakow, Poland

We use Atomic Force Microscopy (AFM) to characterise the mechanical properties of Pancreatic ductal adenocarcinoma (PDAC) cell lines from the primary tumour site (PANC1), and from liver (CFPAC1) and lymph node (Hs766T) metastases. AFM measures forces using the optical lever system. To measure their stiffness, cells were probed using a rectangular cantilever with a three-sided pyramidal tip. Apparent Young's modulus (E) and power-law exponent (α) can be calculated from the force curves. To probe the adhesive properties of the cells, a single cell was attached to functionalised triangular tipless cantilevers, and then pressed against a confluent layer of cells. When the cell-cantilever is retracted, the contact of the attached cell with the cell layer is broken. The detachment exerts force on the cantilever, and this signal is also recorded by and characterised from the retract curve. The adhesion of cancer cells was measured with self-cells (the same cell line) as well as with endothelial cells (EA.hy926). CFPAC1 cells soften in confluent layers, and have increased cell-cell interaction with endothelial cells as compared to self-cells. Hs766t have similar stiffness as both single cells and as a confluent layer, and have higher cell-cell interaction with self-cells than with endothelial cells.

15 min. break

BP 31.5   Fri 11:15   BAR 0106

Dynamics of confined cell migration in 3D micro-dumbbells — •Stefan Stöberl[1], Johannes Flommersfeld[2], Maximilian M. Kreft[1], Chase P. Broedersz[2], and Joachim O. Rädler[1] — [1]Faculty of Physics and Center for NanoScience, Ludwig-Maximilians-University, Munich, Germany — [2]Department of Physics and Astronomy, Vrije Universiteit Amsterdam, 1081 HV Amsterdam, The Netherlands

Cell migration plays a key role in physiological processes such as wound healing, cancer metastasis and immune response. In previous work we have studied the non-linear dynamics of single cells migrating between two surface-patterned adhesion sites guided by a bridging line. Here, we study the dynamics of MDA-MB-231 cells captured in three dimensional (3D) dumbbell-like micro cavities. The structures formed by photolithography of PEG-Norbornene hydrogels provide a soft and hence deformable frame, while cells attach and migrate on a fibronectin-coated bottom. We find that the dwell time of cells before transitioning is retarded when the width of the dumbbell constriction is narrowed below 10 um. In this limit, deformation of the nucleus determines the time course of the repeated stochastic transitions. We measure the forces exerted by the nucleus parallel and perpendicular to the dumbbell channel walls using the displacement field of beads embedded near the 3D constriction. At the same time, the nuclear deformation is followed by confocal 4D imaging revealing an elongation and temporary decrease in nuclear volume during migration through confinement.

BP 31.6   Fri 11:30   BAR 0106

Geometry sensing by active flows: how the cell cortex can feel its shape — •Jonas Neipel and Frank Jülicher — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Morphogenesis often involves chemical patterns, e.g. defined by the concentration of signalling molecules, that specify the shape of a cell or tissue. The robustness of such processes with respect to perturbations can be enhanced by feedbacks where the generated shape impacts back on the formation of the chemical pattern. Here, we show that such shape sensing can result from the same forces that drive shape changes. We consider sheets of active matter, such as the cell cortex or a developing tissue layer, that behave as active fluid surfaces on long time scales. In these systems, forces drive flows within the surface that inevitably depend on the surface geometry of the surface. When molecules are advected by this flow, a pattern arises, reflecting the symmetries of the geometry. In particular, we show that viscous shear forces result in an effective friction force being proportional to the Gaussian curvature, such that patches of contractile stresses are advected towards regions of minimal Gaussian curvature. On a surface with spherical topology but elongated shape, this implies that a contractile ring such as the cytokinetic ring aligns perpendicularly to the long axis of the surface. Hence, the actomyosin cortex can drive alignment of the division axis with the long axis of the cell by a rotation of the entire cell, consistent with recent experiments.

BP 31.7   Fri 11:45   BAR 0106

Large area automated structural and mechanical analysis of developing cells and tissues — •Joerg Barner, Tanja Neumann, André Körnig, Dimitar R. Stamov, and Heiko Haschke — JPK BioAFM Business, Bruker Nano GmbH, Am Studio 2D, 12489 Berlin, Germany

Active forces in biological systems define the interactions between single molecules, growing cells and developing tissues. Atomic force microscopy (AFM) can be successfully applied for comprehensive nano-mechanical characterization of such samples under near physiological conditions. Currently, the trend is to extend this by studying the mechanobiology of living cells while evaluating their structure and the interaction with their cell culture substrates.

We will demonstrate how cell spreading and migration in living KPG-7 fibroblasts and CHO cells, can be studied with high-speed AFM and associated with spatially resolved cytoskeletal reorganization events. We will further extend this with high-speed mechanical mapping of confluent cell layers, which in combination with optical tiling can be applied to automated analysis of large sample areas. As a tool for analyzing the complex cellular mechanobiology, we went beyond purely elastic models, and performed sine oscillations (up to 500 Hz, amplitude 5-60 nm) in Z while in contact with the surface to probe the frequency-dependent response of living fibroblasts.

BP 32: Closing Plenary Talk (joint session BP/CPP)

Time: Friday 12:15–13:00   Location: HSZ 03

Invited Talk   BP 32.1   Fri 12:15   HSZ 03

The physical regulation of brain development — •Kristian Franze — IMP, FAU Erlangen-Nürnberg — Max-Planck-Zentrum für Physik und Medizin, Erlangen — PDN, University of Cambridge

The brain is our most complex organ system. Billions of neurons form an intricate network that regulates all major body functions including thought and emotions. However, the brain is not always that complex. It originally starts off as a simple epithelium, i.e., a single layer of cuboid cells. Axons, which transmit information to other cells over large distances, are only formed during embryonic development. Their immense length - up to several meters in some large animals - comes with severe logistic challenges. For example, how is transport

of proteins and genetic information achieved from the nucleus, where the DNA is located, to the axon's distant end? And how does an axon growing through a crowded and dynamic environment know where to turn and where to connect? These questions have captured the imagination of neuroscientists for more than a century. However, despite tremendous progress in molecular biology and imaging technologies, many problems remain unresolved. Combining theory and experiments, we here identified how microtubules, which are polar polymers along which molecular motors transport cargo, orient uniformly along the axon to enable long-range transport, and how mechanical tissue properties regulate axon growth through the developing brain. Our results suggest that chemical and physical signals are integrated by neurons, and that their interaction is crucial for proper brain development and function.

Overview of Invited Talks and Sessions
(Lecture halls GÖR 226, MER 02, and ZEU 255; Poster P3 and P1A)

Invited Talks

CPP 1.1	Mon	9:30–10:00	GÖR 226	**Strategies for advancing the performance of organic photovoltaics** — •Thomas Anthopoulos
CPP 1.7	Mon	11:30–12:00	GÖR 226	**Lost in translation? Transport resistance in organic solar cells** — •Carsten Deibel
CPP 2.1	Mon	9:30–10:00	MER 02	**Molecular Theories meet Explainable Machine Learning – Novel Concepts for Advanced Drug Formulations** — •Jens Smiatek
CPP 11.1	Mon	15:00–15:30	GÖR 226	**Quantifying the potential of organic solar cells using luminescence measurements and modelling** — •Jenny Nelson
CPP 12.1	Mon	15:00–15:30	MER 02	**Adaptive Resolution Simulations: Past, Present and Open (Boundaries) Future** — Luis A. Baptista, Mauricio Sevilla, Kurt Kremer, •Robinson Cortes-Huerto
CPP 13.1	Mon	15:00–15:30	ZEU 255	**Nanocomposites and polymer thin films: from gas phase synthesis to functional applications** — •Franz Faupel, Stefan Schröder, Alexander Vahl, Salih Veziroglu, Cenk Aktas, Thomas Strunskus
CPP 19.1	Tue	9:30–10:00	MER 02	**Multiscale Model of Flow-Induced Crystallization in Polymers** — David Nicholson, Marat Andreev, Chenmay Gangal, •Gregory Rutledge
CPP 20.1	Tue	9:30–10:00	ZEU 255	**Granular Matter Rheology – fluid-/solid-like behavior and state-transitions** — •Stefan Luding
CPP 29.1	Wed	9:30–10:00	MER 02	**Imaging mineral-water interfaces with atomic force microscopy** — •Angelika Kühnle
CPP 53.1	Thu	15:00–15:30	ZEU 255	**Aqueous nanoclusters govern ionic transport in dense polymer membranes** — •Joachim Dzubiella
CPP 56.1	Fri	9:30–10:00	GÖR 226	**Self-assembled optical metamaterials** — •Ullrich Steiner
CPP 56.7	Fri	11:30–12:00	GÖR 226	**Simulating quantum systems with plasmonic waveguide arrays** — •Stefan Linden
CPP 56.8	Fri	12:00–12:30	GÖR 226	**single molecule detection on a smartphone microscope enabled by DNA origami biosensors** — •Philip Tinnefeld
CPP 57.1	Fri	9:30–10:00	MER 02	**Chiral transport of active and passive colloids** — •Anke Lindner, Andreas Zöttl, Olivia du Roure, Eric Clement, Francesca Tesser, Guangying Jing
CPP 58.1	Fri	9:30–10:00	ZEU 255	**Studies of polymer thermosets using scattering techniques** — •Mats Johansson

Invited Talks of the joint Symposium SKM Dissertation Prize 2023 (SYSD)
See SYSD for the full program of the symposium.

SYSD 1.1	Mon	9:30–10:00	HSZ 04	**Diffusion of antibodies in solution: from individual proteins to phase separation domains** — •Anita Girelli
SYSD 1.2	Mon	10:00–10:30	HSZ 04	**Intermediate Filament Mechanics Across Scales** — •Anna V. Schepers
SYSD 1.3	Mon	10:30–11:00	HSZ 04	**Ultrafast Probing and Coherent Vibrational Control of a Surface Structural Phase Transition** — •Jan Gerrit Horstmann
SYSD 1.4	Mon	11:00–11:30	HSZ 04	**Electro-active metasurfaces employing metal-to-insulator phase transitions** — •Julian Karst
SYSD 1.5	Mon	11:30–12:00	HSZ 04	**The role of unconventional symmetries in the dynamics of many-body systems** — •Pablo Sala

Invited Talks of the joint Symposium Physics of Fluctuating Paths (SYFP)

See SYFP for the full program of the symposium.

SYFP 1.1	Tue	9:30–10:00	HSZ 01	**Time at which a stochastic process achieves its maximum** — •Satya Majumdar
SYFP 1.2	Tue	10:00–10:30	HSZ 01	**Fluctuations and molecule-spanning dynamics of single Hsp90 proteins on timescales from nanoseconds to days** — •Thorsten Hugel
SYFP 1.3	Tue	10:30–11:00	HSZ 01	**Path reweighting for Langevin dynamics** — •Bettina Keller
SYFP 1.4	Tue	11:15–11:45	HSZ 01	**Out-of-equilibrium dynamics of trapped Brownian particles** — •Raul A. Rica
SYFP 1.5	Tue	11:45–12:15	HSZ 01	**Thermodynamics of Clocks** — •Patrick Pietzonka

Members' Assembly of the Chemical and Polymer Physics Division

Thursday 18:00-19:00 MER 02

- Report of the current speaker team
- Election of the second deputy speaker
- Award of the poster prize of the CPP Division
- Miscellaneous

Sessions
– Invited Talks, Contributed Talks, and Posters –

CPP 1: Focus: Organic Solar Cells Based on Non-fullerene Acceptors: Loss Mechanism and Options for Above 20 % Efficiencies I

Organized by Dieter Neher and Christoph J. Brabec

Time: Monday 9:30–13:00   Location: GÖR 226

Invited Talk   CPP 1.1   Mon 9:30   GÖR 226

Strategies for advancing the performance of organic photovoltaics — •Thomas Anthopoulos — King Abdullah University of Science and Technology (KAUST), Thuwal 23955-6900, Kingdom of Saudi Arabia

The dramatic advances in the power conversion efficiency (PCE) of organic photovoltaics (OPVs) witnessed in recent years have been primarily driven by the development of new materials and the minimisation of performance losses associated with conventional cell architectures. This talk will discuss our recent OPV work, focusing on practical strategies for boosting cell performance. I will first discuss using low-dimensional charge-extracting interlayers and the numerous advantages of these innovative materials for next-generation OPVs. I will then present recent progress in using molecular dopants to improve the PCE of OPVs and how their combination with innovative interlayers can improve the material utilisation and circularity of the ensuing OPV cells without compromising their performance.

CPP 1.2   Mon 10:00   GÖR 226

Can Organic Solar Cells Beat the Near-Equilibrium Thermodynamic Limit? — Tanvi Upreti[1], •Constantin Tormann[2], and Martijn Kemerink[1,2] — [1]Complex Materials and Devices, Department of Physics, Chemistry and Biology (IFM), Linköping University, Sweden — [2]Insitute for Molecular Systems Engineering and Advanced Materials, Heidelberg University, Germany

Switching to non-fullerene acceptors has led to an impressive increase in power conversion efficiencies (PCEs) of organic photovoltaic cells over the past decade. Despite this, the PCE of such devices is still below the near-equilibrium limit of the corresponding material, which is particularly evident from losses in the open-circuit voltage (Voc). A prominent yet incompletely understood loss channel affecting Voc is the thermalization of photogenerated charge carriers in the density of states, which is broadened by energetic disorder. In contrast to symmetric morphologies like classic bulk heterojunctions, morphologies with a gradient in the donor:acceptor ratio can mitigate this loss channel by rectifying the diffusive motion of the thermalizing photogenerated charge carriers. Here, we show by extensive numerical modelling how funnel-shaped donor and acceptor-rich domains in a phase-separated morphology promote directed transport of positive and negative charge carriers towards the anode and cathode, respectively. In such optimized funnel morphologies, this kinetic, nonequilibrium effect even allows one to surpass the near-equilibrium thermodynamic limit for the same active material in the absence of gradients.

CPP 1.3   Mon 10:15   GÖR 226

Transparent Conductive Electrodes: Figure of Merit Revisited for Photovoltaics — •Harald Hoppe — Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich Schiller University Jena, Philosophenweg 7a, 07743 Jena, Germany — Laboratory of Organic and Macromolecular Chemistry (IOMC), Friedrich Schiller University Jena, Humboldtstrasse 10, 07743 Jena, Germany

Figure of Merits (FOMs) are meant to provide a simple means for assessing the suitability of a certain material for or compartments within devices in general. In case of photovoltaic devices, the role of the transparent conductive electrode is to allow as much as possible light to enter into the device as well as to enable current flow out of the device. Over the last 5 decades a number of FOMs were introduced based on several approaches. Here we present a rather novel, yet implicit approach for an FOM, which is highly suitable for photovoltaics, allowing to assess the potential photovoltaic performance quantitatively.

CPP 1.4   Mon 10:30   GÖR 226

Reconnoitering the impact of fluorination on both donor and non-fullerene acceptor in bulk heterojunction organic photovoltaics — •Shahidul Alam[1], Jafar I. Khan[1], Vojtech Nádaždy[3], Tomáš Váry[3], Aurelien D. Sokeng[2], Md Moidul Islam[2], Christian Friebe[2], Wejdan Althobaiti[2], Martin Hager[2], Ulrich S. Schubert[2], Carsten Deibel[4], Denis Andrienko[5], Frédéric Laquai[1], and Harald Hoppe[2] — [1]KAUST Solar Center (KSC), Kingdom of Saudi Arabia — [2]FSU Jena, Germany — [3]Slovak Academy of Sciences, Bratislava — [4]TU Chemnitz, Germany — [5]MPIP, Mainz, Germany

Organic solar cells' performance can be often effectively improved through fluorination of the donor and/or non-fullerene acceptor (NFA). The end-group fluo-

rination of the well-known NFA ITIC yields further extension of the absorption spectrum to the near infrared, which results in an increment of the device's photocurrent as compared to the non-fluorinated version. Herein, ITIC and two fluorinated variants of ITIC (ITIC-2F* and ITIC-4F) were synthesized and systematically investigated the influence of end-group fluorination physicochemical properties, optical properties, and photovoltaic performance. Photovoltaic parameters are discussed in terms of exciton quenching, charge generation, charge dissociation, and recombination losses. Specifically, it is found that fluorinated acceptors control the devices' open circuit voltage. All the results shed light on the importance of the energy landscape and the quadrupole moment of acceptor beyond the underlying donor-acceptor interface.

CPP 1.5   Mon 10:45   GÖR 226

Synthesis and Characterization of Organic Heterojunction Model Interfaces — •Hanbo Yang[1], Jarvist Moore Frost[1], Jenny Nelson[1], and Hugo Bronstein[2] — [1]Imperial College London, London, UK — [2]Cambridge University, Cambridge, UK

Control of the molecular configuration at the interface of an organic heterojunction is key to the development of efficient optoelectronic devices. Due to the difficulty in characterizing these buried and (likely) disordered heterointerfaces the interfacial structure in most systems remains a mystery. Here, we demonstrate a novel synthetic strategy to design and control model interfaces, allowing for their detailed study in isolation from the bulk material. This is achieved by the synthesis of a donor polymer-non-fullerene acceptor 'through space' linked system, where the exact position and orientation of the moieties is completely controlled and we furthered showed that the kinetics of charge separation can be tuned using transient absorption spectroscopy and excited state calculations.

CPP 1.6   Mon 11:00   GÖR 226

Direct Determination of the Photogenerated Free Charge Carrier Luminescence in Organic Solar Cells via Transient Photoluminescence Measurements — •Jared Faisst, Mathias List, and Uli Würfel — Fraunhofer ISE, Freiburg, Deutschland

Photoluminescence (PL) measurements have shown to be a valuable tool characterizing the optoelectronic properties of semiconductors. In organic solar cells, the PL measurement of free charge carriers is hindered by the strong and spectrally broad luminescence of non-dissociated local exciton recombination. Therefore, the PL of free charge carriers under steady state condition is not directly detectable. To overcome this problem, we make use of the vastly different lifetimes of local excitons (ps-ns) and free charge carriers (μs). In this work, we present experimental time resolved PL data of a fullerene based D18:PC$_{71}$BM and two non-fullerene based D18:Y6 and PV-X plus organic solar cells and demonstrate the possibility to separate the luminescence of local excitons from the one of free charge carriers. We further show that the luminescence of the free charge carriers indeed correlates with the quasi-Fermi level splitting as expected. Hence, this novel measurement technique eventually allows to investigate free charge carriers in organic absorber layers directly. This is of great importance to further understand recombination mechanisms and degradation effects and to identify optimization potentials.

15 min. break

Invited Talk   CPP 1.7   Mon 11:30   GÖR 226

Lost in translation? Transport resistance in organic solar cells — •Carsten Deibel — Institut für Physik, Technische Universität Chemnitz, 09126 Chemnitz, Germany

With the advent of non-fullerene acceptors, breaking the 20 % power conversion efficiency limit is within close reach for organic solar cells. Understanding the efficiency-limiting processes remains important.

I will discuss how losses in the fill factor can be due to the transport resistance, a voltage loss because of a low conductivity in the active layer. Its relevance for organic solar cells was only shown a half dozen years ago [1]. I will present transport resistance limiting different organic solar cell types, and then focus on fresh and thermally degraded PM6:Y6 solar cells (heated to 85°C, in the dark, under nitrogen atmosphere), a state-of-the-art system based on the non-fullerene Y6.

The increasing fill factor losses on this degradation path are because of the transport resistance [2]. The reason seems to be trap formation in the tail states, which decrease the active layer conductivity.

CPP 1.8   Mon 12:00   GÖR 226

Thermal Degradation Mechanism in PM6: Y-series Acceptors Organic Solar Cells — •Si Chen, Julien Gorenflot, and Laquai Frederic — Abdullah University of Science and Technology Thuwal 23955-6900, Saudi Arabia

The stability issue is the core restriction for the application of organic solar cells (OSCs), and the study of the degradation mechanism of high-efficient PM6: Y-series systems is an urgent problem to be solved. We concluded one specific pathway of FF degradation for typical PM6:Y-series acceptors organic solar cells since FF changed most obviously after thermal aging. After developing several characterization measurements, including time-delayed collection field (TDCF), light intensity dependent measurements, etc. to study the photophysics of PM6:Y-series solar cells before and after thermal degradation, we can quantify FF degradation with field-dependent charge generation, non-geminate recombination, and transport resistance factors. The effect of transport resistance is quantified by the Suns-Voc method. The results show that the increase of charge transport resistance is the primary factor leading to FF degradation, which can be further explained by excessive phase separation with the information from GIWAXS and AFM. Our work can not only provide material design ideas for highly efficient and stable organic solar cells by figuring out the thermal degradation mechanism of PM6:Y-series organic solar cells but also come up with a new methodology to quantify the FF degradation of organic solar cells.

CPP 1.9   Mon 12:15   GÖR 226

Photophysics of Poly(3-hexylthiophene):Non-Fullerene Acceptor Based Organic Solar Cells — •Wejdan Althobaiti, Jafar Khan, Julien Gorenflot, Shahidul Alam, George Harrison, Stefaan De Wolf, and Frédéric Laquai — King Abdullah University of Science and Technology (KAUST), KAUST Solar Center (KSC), Physical Sciences and Engineering Division (PSE), Saudi Arabia

Charge generation can proceed through two different paths in Bulk Heterojunction based organic solar cells which are electron transfer from donor to acceptor and hole transfer from acceptor to donor. These processes can be controlled by Electron Affinity (EA) offsets and Ionization Energy (IE) offsets, respectively. Understanding the relationship between the IE offsets, EA offsets between donor and acceptor materials, and the performance of OSCs could improve the charge generation efficiency. We characterized the impact of large IE and EA offsets on device performances and more precisely on the internal quantum efficiency (IQE) using a wide bandgap polymer donor which has shallow IE such as P3HT and Non Fullerene Acceptor (NFA). This provides a wide range of diagonal bandgap (IE of the donor and EA of the acceptor). Thus, enables us to find the relation between small diagonal bandgap and the decrease of the IQE in energy gap law framework. Low IQE while high exciton quenching observed can be explained due to charge recombination as our results demonstrated by geminate and non-geminate recombination.

CPP 1.10   Mon 12:30   GÖR 226

Efficient Nanoscale Exciton Transport in Non-fullerene Organic Solar Cells Enables Reduced Bimolecular Recombination of Free Charges — •Drew B. Riley[1], Oskar J. Sandberg[1], Nasim Zarrabi[1], Ryun Kim[2], Paul Meredith[1], and Ardalan Armin[1] — [1]Swansea Univeristy, Swansea, Wales. — [2]Cambridge Univeristy, Cambridge, UK

The origins of reduced bimolecular recombination in high efficiency OPV-based solar cells are debated, and mechanisms related to the charge-transfer (CT) state and free-carrier encounter dynamics have been proposed as underlying factors.[1] Further, it is expected that the CT-state dynamics is strongly influenced by exciton dynamics in low off-set blends.[2]

In this presentation I will explore the role exciton dynamics play in the charge generation and recombination processes. Specifically, I will introduce a photoluminescence-based probe to quantify the acceptor domain size in OPV blends. It will be shown that NFA-based blends form larger domains than fullerene-based systems but that this increase is unable to account for the observed non-Langevin recombination. Further, I will show that the reduction of bimolecular recombination is correlated with enhanced exciton dynamics within the NFA domains. This indicates that the processes responsible for efficient exciton transport also enable strongly non-Langevin recombination in high efficiency NFA-based solar cells with low energy offsets.

CPP 1.11   Mon 12:45   GÖR 226

Power-law density of states in organic solar cells revealed by the open-circuit voltage dependence of the ideality factor — •Maria Saladina[1], Christopher Wöpke[1], Clemens Göhler[1], Ivan Ramirez[2], Olga Gerdes[2], Chao Liu[3,4], Ning Li[3,4,5], Thomas Heumüller[3,4], Christoph J. Brabec[3,4], Karsten Walzer[2], Martin Pfeiffer[2], and Carsten Deibel[1] — [1]Technische Universität Chemnitz, Germany — [2]Heliatek GmbH, Germany — [3]FAU Erlangen-Nürnberg, Germany — [4]Helmholtz Institute Erlangen-Nürnberg for Renewable Energy, Germany — [5]South China University of Technology, China

We determine the density of states (DOS) in disordered semiconductors via the diode ideality factor (n_{id}). We employ illumination intensity and temperature-dependent open-circuit voltage measurements. In amorphous silicon, we found that n_{id} only depends on the temperature, and can be explained by an exponential DOS distribution.

For the organic donor-acceptor solar cells, we find that n_{id} is not only temperature but also light intensity-dependent. The seemingly unsystematic dependence of n_{id} on the light intensity becomes systematic once the former is displayed in dependence of the open-circuit voltage, which is a means to sample the DOS distribution at a certain energetic depth. This evaluation approach leads to our central result: the DOS follows a power-law distribution over a broad range of energies. In particular, for the investigated organic solar cells under working conditions the DOS is best represented by the power-law, not a gaussian or exponential one.

CPP 2: Modeling and Simulation of Soft Matter I

Time: Monday 9:30–13:00   Location: MER 02

Invited Talk   CPP 2.1   Mon 9:30   MER 02
Molecular Theories meet Explainable Machine Learning – Novel Concepts for Advanced Drug Formulations — •Jens Smiatek — Institute for Computational Physics, University of Stuttgart, Germany — Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach (Riss), Germany

Pharmaceutical processes and drug formulations are based on a variety of molecular mechanisms and principles. Significant advances have been made in recent years in terms of basic understanding. Despite these advances, a large number of mechanisms are not yet fully understood, which would be of great advantage, especially for the optimization of development processes as well as the quality and stability of drugs. In this talk I will present fundamental molecular theories of electronic interactions in solutions. Due to the large number of components and the complexity of the interactions, these theories can only be used for a qualitative understanding. However, by combining it with explainable machine learning, the basic molecular mechanisms can be identified and the corresponding thermodynamic properties of the solutions can be predicted. I will present some examples and discuss the underlying benefits and additional challenges for future developments.

CPP 2.2   Mon 10:00   MER 02
Revealing the relation between structure and dynamics using unsupervised machine learning — •Moumita Maiti[1], Anand Narayanan Krishnamoorthy[2], Youssef Mabrouk[2], Diddo Diddens[2], and Andreas Heuer[1] — [1]Institute of Physical Chemistry, University of Münster, Corrensstrasse 28/30, 48149 Münster, Germany — [2]Forschungszentrum Jülich GmbH, Helmholtz-Institute Münster (IEK-12), Corrensstraße 46, 48149 Münster, Germany

Molecular dynamics trajectories of Li-ions in electrolytes with different anions are analysed using an unsupervised machine learning algorithm to understand the relation between structure and dynamics. The trajectories are generated using a polarizable force-field model instead of the standard OPLS force-field, thereby generating excellent agreement of structural and dynamical properties with experiment. The high-dimensional feature space is constructed from the distances and angles between Li-ions and its neighbours, reflecting the structural information of local environments. It can be reasonably reduced to 2 dimensions using the dimension reduction algorithm umap. This is performed for a large number of Li-ions. After the mapping distinct clusters can be identified. Although they are based on structural properites, they also reflect different dynamical properties with respect to diffusivity and ion-correlations. We finally show how the total ionic conductivity can be expressed in terms of the structural information of the first solvation shell.

CPP 2.3   Mon 10:15   MER 02

Data reweighting in metadynamics simulations — Timo Schäfer[1] and •Giovanni Settanni[1,2] — [1]Department of Physics, Johannes-Gutenberg University Mainz, Germany — [2]Faculty of Physics and Astronomy, Ruhr University Bochum, Germany

The data collected along a metadynamics simulation can be used to recover information about the underlying unbiased system by means of a reweighting procedure. We analyze the behavior of several reweighting techniques in terms of the quality of the reconstruction of the underlying unbiased free energy landscape in the early stages of the simulation and propose a simple reweighting scheme that we relate to the other techniques. We show[1] that the free energy landscape reconstructed from reweighted data can be more accurate than the negative bias potential depending on the reweighting technique, the stage of the simulation, and the adoption of well-tempered or standard metadynamics. While none of the tested reweighting techniques from the literature provides the most accurate results in all the analyzed situations, the one proposed here, in addition to helping simplifying the reweighting procedure, converges quickly and precisely to the underlying free energy surface in all the considered cases, thus allowing for an efficient use of limited simulation data.

[1]Schäfer TM, Settanni G. J Chem Theory Comput. 2020 Apr 14;16(4):2042-2052. doi: 10.1021/acs.jctc.9b0086

CPP 2.4   Mon 10:30   MER 02

findR: An automated workflow from molecular dynamic simulation to quantum chemical methods for reaction discovery — •Gunnar Schmitz[1], Özlem Yönder[2], Vanessa Angenent[3], Christof Hättig[2], and Rochus Schmid[3] — [1]Ruhr-Universität Bochum, Lehrstuhl für Theoretische Chemie II, Bochum, Germany, 44801 Bochum — [2]Ruhr-Universität Bochum, Lehrstuhl für Theoretische Chemie I, Bochum, Germany, 44801 Bochum — [3]Ruhr-Universität Bochum, Lehrstuhl für Anorganische Chemie II, Bochum, Germany, 44801 Bochum

Computer-guided reaction discovery is still an open issue, which will be vital for applications in science and industry. For this purpose, we present an automated workflow that, starting from molecular dynamics simulations (MD), identifies reaction events based on graph theory, filters them, and prepares them for accurate quantum chemical calculations using e.g. Density Functional Theory (DFT) or Coupled Cluster methods. The capabilities of the automatized workflow are demonstrated by the example of simulations for the combustion of polycyclic aromatic hydrocarbons. A limiting factor of the reaction sampling by means of MD simulations is the required simulation time to observe reactions. In order to enhance this process, we compare different acceleration techniques like metadynamics and a nano reactor setup, in which a spherical confinement is combined with periodically applied forces directed to the simulation box center. We demonstrate that our workflow can be used to identify reactions without prior chemical knowledge and can give new insights into the combustion process.

CPP 2.5   Mon 10:45   MER 02

Data-driven analysis and prediction of the performance of cleansing solutions — •takahiro yokoyama[1], hideki miwake[2], ryouichi nakatake[2], noriyoshi arai[1], and arash nikoubashman[1,3] — [1]Department of Mechanical Engineering, Keio University, Yokohama, Japan — [2]Research Institute, Fancl Corporation, Yokohama, Japan — [3]Institute of Physics, JGU Mainz, Germany

Cleansing solutions are complex multi-component liquids, which are commonly used to wash excess sebum, dirt, and make-up cosmetics directly from the skin. Their formulations typically contain a large variety of ingredients, including surfactants, viscosity modifiers, and polyols to meet the desired product requirements, such as high skin compatibility, moisture retention, and long shelf life. The large number of different components makes it, however, challenging to understand and predict the physical properties of such cleansing solutions, since the majority of established theories have been developed for pure systems. Machine learning (ML) methods are promising methods to solve these kinds of problems, as they can reveal non-trivial trends and interactions between the various components. In this work, we predict the cleansing performance of a large number of formulations using various ML methods, such as random forest regression and (recurrent) neural networks. Although this work focuses primarily on cleansing solutions, the applied methodology should be transferable to predict the physical properties of other multi-component liquids as well.

CPP 2.6   Mon 11:00   MER 02

Multiscale Simulation Framework for the electromechanical behavior of PEDOT:PSS — Steffen Kampmann[1], Alexander Croy[2], •Arezoo Dianat[1], and Gianaurelio Cuniberti[1] — [1]Chair of Materials Science and Nanotechnology, Faculty of Mechanical Science and Engineering, TU Dresden, Dresden , Germany — [2]Chair of Theoretical Chemistry, Faculty of Chemistry and Earth Sciences, Friedrich Schiller University Jena, Jena , Germany

Functional mechanically resilient polymer films, such as poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS), play an important role for strain gauges or organic light-emitting diode displays [1-3]. Typically, the respective material behavior results from an interplay of mechanisms across multiple scales. The modeling and simulation workflow presented here enables the generation of disordered polymers and the linking of their mechanical and their electronic properties from the atomistic to the microscopic scale. In particular, we focus on the relationship between deformation and conductivity by combining density functional tight binding calculations, molecular dynamics simulations, and finite element calculations. The in-situ processing, evaluation as well as the exchange of the generated data across the simulation methods is performed using a Python framework which provides a computationally efficient assessment of material properties at different scales. Exemplarily, we present results for a strain gauge based on PEDOT:PSS. [1] R. Luo, et al., Progress in Organic Coatings, 162, 106593 (2022) [2] M. Cinquino et al., JS: AMD, 7, 1,100394 (2022) [3] L. Liu, et al., Organic Electronics, 89, 106047 (2021)

15 min. break

CPP 2.7   Mon 11:30   MER 02

Differentiable simulation for Solar Power Plants and beyond — •Stefan Kesselheim[1], Max Pargmann[2], and Jan Ebert[1] — [1]Forschungszentrum Jülich — [2]German Aerospace Center (DLR)

In Solar Power Plants, temperatures sufficient for chemical processes or the generation of electrical power are created by reflecting sunlight with thousands of mirrors ("heliostats") to a surface ("the receiver"). In operation, the temperature distribution on the receiver is critical for the performance and must be optimized. The heliostats are never perfectly flat as due to budget constraints, the construction is not optimal. We have devised a method to infer the heliostat surface from the reflection of the sun. The technique is based on an implementation of a simulation in PyTorch, where the automatic differentiation engine is used to optimize the surface. The surface is modeled as by a Non-Uniform Rational B-Spline (NURBS) and the NURBS parameters are subject to optimization. Furthermore we employ a regularization technique to mitigate the appearing challenge of ambiguous solutions. Our approach makes efficient use of GPUs based on PyTorch's linear algebra engine. We believe our approach poses an interesting example of a fruitful interaction of techniques originating from Machine Learning and simulation, that can serve as an exciting example how to integrate simulation and experimental data, for example in biomolecular simulation.

CPP 2.8   Mon 11:45   MER 02

Simulation-based inference of single-molecule force-spectroscopy — •Roberto Covino[1,2], Lars Dingeldein[1], and Pilar Cossio[3] — [1]Frankfurt Institute for Advanced Studies, 60438 Frankfurt am Main, Germany — [2]International Max Planck Research School on Cellular Biophysics, 60438 Frankfurt am Main, Germany — [3]Center for Computational Mathematics and Biology, Flatiron Institute, 10010 New York, United States

Single-molecule force spectroscopy (smFS) is a powerful approach to studying molecular self-organization. However, the coupling of the molecule with the ever-present experimental device introduces artifacts, that complicates the interpretation of these experiments. Performing statistical inference to learn hidden molecular properties is challenging because these measurements produce non-Markovian time series, and even minimal models lead to intractable likelihoods. To overcome these challenges, we developed a computational framework built on novel statistical methods called simulation-based inference (SBI). SBI enabled us to directly estimate the Bayesian posterior, and extract reduced quantitative models from smFS, by encoding a mechanistic model into a simulator in combination with probabilistic deep learning. Using synthetic data, we could systematically disentangle the measurement of hidden molecular properties from experimental artifacts. The integration of physical models with machine-learning density estimation is general, transparent, easy to use, and broadly applicable to other types of biophysical experiments.

CPP 2.9   Mon 12:00   MER 02

Coarse-grained modelling of liquid-liquid and liquid-gas interfaces — •Jakob Filser[1], Harald Oberhofer[2], Christoph Scheurer[1], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]Chair for Theoretical Physics VII, University of Bayreuth

Modelling of dielectric interfaces remains a central challenge in computational chemistry. We present a new method to incorporate solvation effects into density-functional theory calculations of organic adsorbates at liquid-liquid and liquid-gas interfaces.

Simulating a large number of solvent molecules explicitly at first-principles level is generally not computationally tractable. We therefore resort to an implicit solvation approach, treating the solvent as a structureless dielectric continuum. Specifically, we advance the multipole-expansion method, in which we model the interface as the boundary of two semi-infinite media with different permittivity. Gauging the limiting behaviour for moving the solute from one bulk medium into the other is straightforward by referencing experimental transfer free energies. Complementary force-field level MD simulations with explicit solvent molecules are used as a reference for the behaviour at the interface. These calculations yield thermal distributions at atomic scale resolution, allowing for a fine assessment of the role of the solvent structure in the adsorption. In our im-

plicit method, we employ a model for the transition of free energy terms, such as the surface tension, between the two media, aimed at reproducing the above mentioned thermal distributions extracted from an atomistic solvent model.

CPP 2.10 Mon 12:15 MER 02

Geometrical frustration causes self-limiting assembly in systems of bipods — •Aswathy Muttathukattil and Michael Engel — Institute for Multiscale Simulation, IZNF, Friedrich-Alexander Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

Geometric frustration emerges in self-assembly if local interactions between building blocks are incompatible to form uniform (bulk) materials. Examples for geometrically frustrated assemblies with self-limiting size include protein filament bundles, twisted molecular crystals, bent core liquid-crystals and viral capsids. Despite of significant efforts to develop a general theory on geometrical frustration, it remains as a challenge to use it as a design principle to engineer finite-size equilibrium assemblies in soft matter. In this study, we control geometrical frustration deliberately and systematically in system of bipods to demonstrate self-limiting crystallization. Our minimal computational model consists of a central sphere that connect to two attractive rigid rods diametrically via a flexible hinge. Tuning the flexibility of the hinge and rod attraction, anisotropic fibrillar assemblies are observed. The fibrils do not grow wider than a fixed limit, which can be controlled by the misfit introduced by the radius of central sphere. Our model bipods can be realized in experiments as nanoparticles with tethered polymer bundles, partially unfolded polymer globules (including biopolymers like proteins) and organic molecules.

Pair-Reaction Dynamics in Water: Competition of Memory, Potential-Shape and Inertial Effects — •Florian Brünig, Jan Daldrop, and Roland Netz — Freie Universität Berlin, Department of Physics, 14195 Berlin, Germany

When described by a one-dimensional reaction coordinate, pair-reaction rates in a solvent depend, in addition to the potential barrier height and the friction coefficient, on the potential shape, the effective mass and the friction relaxation spectrum, but a rate theory that accurately accounts for all these effects does not exist. We show how to extract all parameters of the generalized Langevin equation (GLE) and in particular the friction memory function from molecular dynamics (MD) simulations of two prototypical pair reactions in water, the dissociation of NaCl and of two methane molecules. Simulations of the GLE by Markovian embedding techniques accurately reproduce the pair-reaction kinetics from MD simulations without any fitting parameters, which confirms the accuracy of the approximative form of the GLE and of the parameter extraction techniques. By modification of the GLE parameters, we investigate the relative importance of memory, mass and potential-shape effects. Neglect of memory slows down NaCl and methane dissociation by roughly a factor of 2, neglect of mass accelerates reactions by a similar factor, the harmonic approximation of the potential shape gives rise to slight acceleration. This error cancellation explains why Kramers' theory, which neglects memory effects and treats the potential shape harmonically, describes reaction rates better than more sophisticated theories.

The Crucial Role of Solvation Forces in the Steric Stabilization of Nanoplatelets — •Nanning Petersen, Martin Girard, Andreas Riedinger, and Omar Valsson — Max Planck Institute for Polymer Research, Ackermannweg 10, D-55128 Mainz

The precipitation of ligand coated cadmium selenide nanoplatelets is linked to the formation of nanoplatelet stacks. The exact nature of nanoplatelets' interaction is an open question, as the van der Waals attraction is too weak to be the cause of stack formation. CdSe nanoplatelets combine a large facet to particle size ratio, and a very dense ligand shell. Both features are in favor of interactions in the form of solvation forces.

We use coarse-grained molecular dynamics simulations of ligand coated nanoplatelets in different alkane solvents to investigate the role of solvation forces in nanoplatelet interactions [1]. We demonstrate that solvation forces resulting from solvent layering are sufficiently strong to stabilize nanoplatelet stacks. We examine the dependence of solvation forces on the nanoplatelets' ligand shell, size, and other parameters. In particular, we demonstrate that for sufficiently large nanoplatelets, solvation forces are proportional to the interacting facet area. We show that their strength is intrinsically tied to the softness of the ligand shell, depends on the isomer of the alkane solvent, and is increasing with the alkane molecule length.

Acousto-responsive poly(N-isopropylacrylamide) microgels — •Amin Rahimzadeh, Atieh Razavi, and Regine von Klitzing — Soft Matter at Interfaces, Department of Physics, Technical University of Darmstadt, Hochschulstraße 8, 64289 Darmstadt, Germany

In this work, we introduce a novel stimulus for Poly(N-isopropylacrylamide), known as PNIPAM, microgels. High-frequency ultrasonic waves provide the required energy for collapsing microgels while the solution temperature maintains below their volume phase transition temperature (VPTT). Ultrasound propagates through the liquid and its energy will be absorbed due to the liquid viscosity. A part of the energy will be absorbed due to the translational relaxation of the liquid molecules leading to the creation of a flow that is called acoustic streaming. Another part of the energy of the waves will be absorbed due to the rotational and vibrational relaxations of the liquid molecules. The former absorption is due to the dynamic viscosity and the latter is due to the bulk viscosity. We show that along with acoustic streaming, the absorbed energy due to the bulk viscosity provides the energy for breaking hydrogen bonds between the microgels and water molecules. The turbidity of the liquid is used as a way to visualize and quantify the energy absorption, by calculating the required energy for making the solution fully turbid. We use image processing to quantify the absorbed energy by the hydrogen bonds and investigate the effects of solution concentrations (0.2 wt.%, 1 wt.% and 5 wt.%), ultrasound amplitude and frequency.

Swelling and nanophase separation of amphiphilic star polymer conetworks — •Reinhard Scholz and Michael Lang — Leibniz Institut für Polymerforschung, Hohe Str. 6, 01069 Dresden, Germany

Polymer conetworks consisting of complementary four functional stars coupled via complementary end groups are simulated within the framework of a lattice-based Monte Carlo algorithm. A classification of different stars reveals that the conetworks are dominated by ideal star configurations surrounded by four different bonding partners. In a good solvent, the simulation reproduces analytical scaling relations for swelling, modulus and residual bond orientation [1]. A selective solvent induces a phase separation between a swollen polymer phase and embedded clusters consisting of insoluble polymer stars. Due to the com-plementary end groups, all elastically active chains cross the phase boundary, so that residual bond orientations correspond either to swollen conformations, collapsed stars, or bonds across the phase boundary with a particularly large component along the interface normal. Calculated pair distributions and scattering functions reveal that the length scale of phase separation depends only weakly on the concentration over a broad range of concentrations, $c^* < c < 6c^*$.

How topology impacts magnetic and rheological properties of a suspension of magnetic nanogels — •Ivan Novikau[1], Alla Dobroserdova[2], Ekaterina Novak[2], and Sofia Kantorovich[1,2] — [1]University of Vienna, Austria — [2]Ekaterinburg, Russia

Hydrogels are soft materials, that attracted solid interest over the last 6 decades and are widely used in chemical, biomedical, and even civil engineering applications. Today, at the front edge of gels' realm stand out nanogels, often additionally functionalization, for instance, by magnetic nanoparticles.

Given the magnetic nanogels (MNG's) size, typical time and velocity scales involved in their nanofluidics, experimental characterization of the systems is difficult. Here, we use molecular dynamics (MD) simulations in conjunction with the Lattice-Boltzmann (LB) scheme in order to describe how the MNG topology affects the rheological and magnetic properties of their suspensions.

We study in detail how the shape and magnetization of a single MNG are affected by the distribution of crosslinkers: uniform, with a displaced centre of mass, with Gaussian distribution from the centre to the periphery and reverse. The impact of a topology in a combination with an external magnetic field on MNG's viscoelastic and magnetic characteristics of the suspensions is also explored.

CPP 3.4 Mon 10:15 ZEU 255

Incorporation of Hydrophilic Microgels at Water in Oil Emulsion stabilized by Hydrophobic Nanospheres — •Sebastian Stock, Carina Schneider, Luca Mirau, Franziska Braun, and Regine von Klitzing — TU Darmstadt, Darmstadt, Germany

For particle-stabilized emulsions (Pickering emulsions, PEs), the affinity of the particular stabilizers to one or the other liquid decides about the resulting emulsion type - either oil in water (o/w) or water in oil (w/o). Besides specific exceptions, hydrophilic microgel particles (MGs) are only able to stabilize o/w emulsions. However, the w/o emulsion type is preferable in a multitude of applications ranging from the food industry over medicine towards interfacial catalysis. We solved this problem by using well-characterized, hydrophobic, positively charged, spherical silica particles (SNs) and hydrophilic, positively charged PNI-

PAM MGs to stabilize water in 1-dodecene emulsions simultaneously. Using these thoroughly characterized model particles allows deep insights into the interplay between soft and solid particles at the interface and the structure formation of the PEs. The interaction between different kinds of particles was studied on a Langmuir trough in combination with AFM measurements. The observable structure formation at the interface of the Langmuir Trough could explain the particle assembly at the droplet interfaces in PEs.

Spreading drops of volatile oil induce long range thickness gradients in swelling hydrophobic polymer brush layers — •Özlem Kap[1], Simon Hartmann[2], Harmen Hoek[1], Igor Siretanu[1], Sissi de Beer[3], Uwe Thiele[2], and Frider Mugele[1] — [1]University of Twente, Physics of Complex Fluids, PO Box 217, 7500 AE Enschede (NL) — [2]Westfälische-Wilhelms-Universität Münster, Wilhelm-Klemm-Str. 9, 48149 Münster (D) — [3]University of Twente, Sustainable Polymer Chem., PO Box 217, 7500 AE Enschede (NL)

Polymer brush layers are responsive materials that swell in contact with good solvents and their vapors. We combined optical experiments and numerical calculations based on gradient dynamics of a free energy density to study how fluid flow and solvent diffusion control the macroscopic spreading of (weakly) volatile oil drops and the swelling kinetics of an underlying hydrophobic polymer brush layer. The macroscopic spreading dynamics follow algebraic law with an exponent of 1/6, yet the spreading drops are found to be surrounded by halos of partially swollen polymer brushes. The width of the halos reaches values of hundreds of micrometers wide within hours to days, with thickness variations ranging from the dry thickness up to a maximum swelling ratio of ~4 close to the contact line. The halo profiles display long-living non-equilibrium steady state configurations that are controlled by the competition of two transport mechanisms, solvent diffusion through the polymer brush layer and through the vapor phase.

CPP 8.2   Mon 11:00   ZEU 255

Effect of architecture in thermoresponsive hydrogels from PEG-based tri- and tetrablock terpolymers — •Feifei Zheng[1], Wenqi Xu[1], Eirini Melampianaki[1], Anna P. Constantinou[2], Theoni K. Georgiou[2], and Christine M. Papadakis[1] — [1]TUM School of Natural Sciences, Technical University of Munich, Garching, Germany — [2]Department of Materials, Imperial College, London, UK

Thermogels are an exciting class of stimuli-responsive materials with many promising applications ranging from the medical field to additive manufacturing. The mechanical properties in the gel state strongly depending on the architecture of the polymer [1]. Here, we address an ABC triblock terpolymer and a BABC tetrablock terpolymer consisting of the hydrophilic oligo(ethylene gly-

col) methyl ether methacrylate (OEGMA, A), hydrophobic *n*-butyl methacrylate (BuMA, B), and thermoresponsive di(ethylene glycol) methyl ether methacrylate (DEGMA, C). The results from dynamic light scattering on dilute solutions show that the hydrodynamic radii of the micelles formed by both, ABC and of BABC, increase strongly above 25 °C, and the solutions feature a cloud point, i.e. aggregation of the micelles sets in. By synchrotron small-angle X-ray scattering, we found that, ABC and BABC form elongated and spherical micelles, respectively. Forward scattering attributed to large aggregates is observed at temperatures above the cloud point for both terpolymers.

Hydration Water Dynamics in a Thermoresponsive Polymer Solution Under Pressure — Bart-Jan Niebuur[1], Bahar Yazdanshenas[1], Feifei Zheng[1], Wiebke Lohstroh[2], Marcell Wolf[2], Marie-Sousai Appavou[3], Michaela Zamponi[3], Alfons Schulte[4], and •Christine M. Papadakis[1] — [1]Technical University of Munich, TUM School of Natural Sciences, Garching, Germany — [2]Technical University of Munich, Heinz Maier-Leibnitz Zentrum (MLZ), Garching, Germany — [3]Jülich Centre for Neutron Science (JCNS) at MLZ, Garching, Germany — [4]University of Central Florida, Department of Physics, Orlando FL, U.S.A.

The water dynamics is key to functionality and phase behavior of synthetic and biological polymers. We investigate the dynamic behavior of hydration water in a concentrated aqueous solution of the thermoresponsive polymer poly(*N*-isopropyl acrylamide) (PNIPAM) in dependence on temperature and pressure employing quasi-elastic neutron scattering (QENS) [1]. The susceptibility spectra reveal the relaxation peak of the hydration water in addition to the known dynamic processes of bulk water. We find that the dehydration process at the phase transition depends strongly on pressure. Using perdeuterated PNIPAM along with QENS allows us to suppress the signal of the chain segments and to identify and characterize the behavior of the different types of bound water at the phase transition.

CPP 8.4 Mon 11:45 ZEU 255

Topology Impact on nanoscale hydration of polymer brushes — •Apostolos Vagias[1], Andrew Nelson[2], Peixi Wang[3], Julija Reitenbach[3], Christina Geiger[3], Lucas Philipp Kreuzer[1,3], Thomas Saerbeck[4], Robert Cubitt[4], Edmondo Maria Benetti[5], and Peter Müller-Buschbaum[1,3] — [1]MLZ, TUM, Garching — [2]ANSTO, Sydney, Australia — [3]TUM School of Natural Sciences, Chair for Functional Materials, Garching — [4]ILL, Grenoble, France — [5]Polymer Surfaces Group, University of Padova, Padova, Italy

Polymer brushes have demonstrated growing interest during last years, in particular in combination with exposure to aqueous environment. By utilizing time-of-flight neutron reflectometry (ToF-NR), we correlate the swelling properties of hydrophilic cyclic grafted polymer brushes to their thermodynamics. Cyclic brushes exhibit more compact conformations with lower roughness compared to their linear analogues, due to the absence of dangling chain ends extending at the interface. In addition, due to increased interchain steric repulsions, cyclic brushes feature larger swelling ratios at the same composition and comparable molar mass. Moreover, the two topologies exhibit differences in ageing, upon repetitive swelling/drying cycles. We present a case where current Flory-like expressions breakdown in the explanation of the experimental observations.

Spiropyran/Merocyanine Amphiphile in Various Solvents: A Joint Experimental-Theoretical Approach to Photophysical Properties — Vladyslav Savchenko[1], Nino Lomadze[2], Svetlana Santer[2], and •Olga Guskova[1] — [1]IPF Dresden — [2]University of Potsdam

This joint experimental-theoretical work explains the negative photochromism of spiropyran-containing (SP) amphiphile aqueous solutions. Experiments demonstrate that the orange-red merocyanine (MC) form becomes thermodynamically more stable in water, and both UV and vis stimuli lead to the partial or complete photobleaching of the solution. The explanation of this phenomenon is given on the basis of DFT calculations and MD simulations. The latter reveal that stabilization of MC in water proceeds with the energy of ca. 70 kJ/mol, and that the Helmholtz free energy of hydration of MC form is 100 kJ/mol lower. The explanation of such a difference lies in the molecular properties of the MC. The presence of three charged groups on the periphery of a flat MC backbone stimulates its self-assembly in water ending up with the formation of elongated associates with stack-like building blocks. Our quantitative evaluation of the hydrophilicity switching in SP/MC containing surfactants may prompt the search for new systems, including colloidal and polymeric ones, aiming at remote tuning of their morphology, which could give new promising shapes and patterns for the needs of modern nanotechnology. This work is supported by DFG, grant GU1510/5-1. [1] Savchenko V., et al. Int. J. Mol. Sci. 2022, 23(19), 11535

CPP 8.6 Mon 12:15 ZEU 255

Mechanochemistry: a theoretical and experimental interplay — •Michael Walter, Wafa Maftuhin, and Pooja Bhat — Albert-Ludwigs-Universität Freiburg, Freiburg i. Br., Germany

Mechanochromic polymers are intriguing materials that allow to sense force of specimens under load. The connection between macroscopic stress and the forces acting on the molecular level is still elusive and covalently incorporated molecular mechanochromophors promise to shed light on this connection. Most mechanochromic systems rely on covalent bond scission with optically distinct *on* and *off* states. Bond rupture is induced by temperature fluctuations involving force dependent barriers. We show that these barriers are fully determined by the dissociation energy and the maximal force the potential can withstand, which allows for a re-interpretation of the Eyring-Zhurkov-Bell length

$\Delta x^{\ddagger}$ and the expressions going beyond.

We furthermore present and analyse the concept of mechanochromic donor-acceptor (DA) torsional springs that allows for a contineous mapping of molecular forces to photoluminescence wavelengths. The mechanically induced deflection from equilibrium geometry of the DA spring is theoretically predicted and reveals forces of 1 nN on the molecular level. Our theoretical analysis demonstrates a thiophene ring flip as the major part of the overall mechanochromic response within a related ansa-DAD spring at forces as low as 27 pN. Such micromechanical motion gives access to sensing of tiny forces and expands both sensitivity and the force range of conformational mechanochromophores.

Humidity & Electrochemical Switching of Mixed Conducting Polymer Films — •Sabine Ludwigs — IPOC - Functional Polymers, Institute of Polymer Chemistry, University of Stuttgart

Though electrochemistry of conducting polymers is a rather old topic(1), only recently conducting polymers have received renewed attention as inherently mixed-ionic-electronic conductors for a number of emerging switchable technologies including actuators, wetting on surfaces and electrically switchable metasurfaces. One of the work-horses of the community remains poly(ethylenedioxythiophene) :poly(styrenesulfonate) (PEDOT:PSS). While typically known as synthetic metal with application as transparent flexible electrodes, the material is a mixed conductor and shows ionic conductivity which is strongly affected by humidity.(2) The humidity dependence of the PSS polyelectrolyte phase together with the electroactive nature of the PEDOT can be used to create multifunctional and multiresponsive materials and films. A recent example from my group is the preparation of intelligent humidity-triggered bilayer actuators whose bending behavior (curvature) can be explained by the humidity-dependent mechanical behavior of the constituents.(3) In collaboration with the Giessen Group the electrochemical stimuli were further used to switch nanoantennas on and off between the metallic and the insulating state.(4)

CPP 8.8 Mon 12:45 ZEU 255

Stimuli-responsive high aspect ratio surfaces for wetting studies — •Gissela Constante[1], Indra Apsite[1], Paul Auerbach[2], Sebastian Aland[3], Dennis Schönfeld[3], Thorsten Pretsch[3], Pavel Milkin[1], and Leonid Ionov[1,4] — [1]Uni Bayreuth, Bayreuth, Germany — [2]HTW Dresden, Dresden, Germany — [3]Fraunhofer IAP, Postdam, Germany — [4]BPI, Bayreuth, Germany

The fabrication of switchable surfaces has been of interest in several fields such as biotechnology, industry, and others. The selection of materials and methods is crucial to provide proper control on the tunable surface. In this research, an exceptionally high aspect ratio lamellar surface topography was fabricated by melt-electrowriting of microfibers of a shape-memory thermo-responsive polyurethane. Two different types of stimuli: temperature and light exposition were applied to modify the mechanical properties and by it the deformation and recovery of the original surface. Wetting studies showed that the deformation of the high aspect ratio lamellar surface can be tunned not only manually, but as well by a liquid droplet. This behavior is controlled by variation of temperature conducted by direct heating/cooling or by exposure to light when the lamellae were stained with black ink. The liquid in combination with thermo-responsive topography presents a new type of wetting behavior. This feature opens the possibility to apply such topographies for the design of smart elements for microfluidic devices, for example, smart valves.

Quantifying the potential of organic solar cells using luminescence measurements and modelling — •Jenny Nelson — Department of Physics, Imperial College London, SW7 2AZ, UK

In a molecular photovoltaic device, charge separation and energy conversion result from the evolution of a photogenerated exciton into a charge separated state, in competition with recombination to ground. Recently, new molecular materials have increased power conversion efficiency to approach 20%. To make further advances, we need to understand and isolate the effects of chemical structure, molecular packing, energetics and disorder on the competition between charge separation and recombination and hence on device efficiency. Electro- and photoluminescence have proved to be valuable tools to probe the energy and dynamics of excited states involved in photoinduced charge separation, and indirectly of the structure of molecular interfaces. Combined with other spectroscopic techniques, electrical measurements and modelling, luminescence can help us to understand how chemical and physical structure control the basic mechanisms in photovoltaic conversion. We show how such an approach can be used to study the properties and role of charge transfer states, the impact of structural and energetic disorder and to infer structure-property relationships. We apply a computational model that integrates the molecular charge transfer process with a one-dimensional drift-diffusion simulation to interpret experimental measurements and explore the effects of parameters on device performance. We consider the ultimate limits placed on solar to electric conversion by the molecular nature of the materials.

CPP 11.2　Mon 15:30　GÖR 226

Increasing the ionization offset to increase the quantum efficiency in non-fullerene acceptor based organic solar cells: How far can we go? — •Julien Gorenflot, Wejdan Alsufyani, Maryam Alqurashi, Sri Harish Kumar Paleti, Anirudh Sharma, Derya Baran, and Frédéric Laquai — KAUST Solar Center, King Abdullah University of Science and Technology, Thuwal, Kingdom of Saudi Arabia

Molecular engineering offers a virtually unlimited number of unique semiconductors for organic photovoltaics applications, that can be tailored to adapt specific needs, but only a handful of combinations enables to reach state-of-the art efficiencies. Rules are thus strongly needed to guide the design of promising systems. A recently unraveled rule is that the electron acceptor molecule requires an ionization energy 0.5 eV deeper than that of the electron donor to overcome the bending of the energy levels at the donor acceptor heterojunction interface, maximizing the charge transfer, hence the cell's quantum efficiency. Here we study the energy losses associated to this Δ IE increase. Based on 30+ blends, we show that those losses remain minimal up to an offset of 0.7 eV. We then use electroluminescence spectroscopy to evaluate the charge transfer state energy (E_{CT}) and find that this low energy losses range is associated to E_{CT} remaining at most similar to the NFA's optical bandgap ($E_{g,NFA}$), while further ΔIE increase pulls E_{CT} below $E_{g,NFA}$, accordingly decreasing V_{OC}. We finally study the evolution of the fill factor (FF) within this maximum quantum efficiency – minimal energy losses Δ IE range.

CPP 11.3　Mon 15:45　GÖR 226

The excess energy optimum to minimize recombination losses in organic solar cells — •Clemens Göhler, Alexander Flamm, and Martijn Kemerink — Institute for Molecular Systems Engineering and Advanced Materials, Universität Heidelberg, Im Neuenheimer Feld 225, 69120 Heidelberg

Semiconductor blends that incorporate non-fullerene acceptors (NFA) have pushed organic solar cells to efficiency records based on an established principle: enhancing the generation yield of free charge carriers from tightly bound molecular excitations via interfacial charge transfer between donor and acceptor phases. Their success can in huge parts be attributed to an increase of the photocurrent; however, in comparison to less-effective systems, NFA blends possess a similar overall absorbance and lack the distinct low-energy absorption typically associated with charge transfer (CT) excitons.

The increased charge carrier densities are thus based on reduced recombination yields. As further improvements of the photocurrent are necessary to reach higher efficiencies, a thorough understanding of the mechanisms behind the cut in recombination losses compared to fullerene solar cells is invaluable. To contribute, we have investigated recombination signatures of both systems with respect to the available excess energy by combining field and excitation dependent electro-optical absorption spectroscopy in the steady state and close to solar cell working conditions with kinetic Monte-Carlo simulations. Our findings indicate towards an optimal excess energy which minimizes non-geminate recombination in CT processes.

CPP 11.4　Mon 16:00　GÖR 226

On the impact of the energy level offset on carrier recombination in organic non-fullerene acceptor-based solar cells — •Nurlan Tokmoldin[1], Bowen Sun[1], Floriana Moruzzi[2], Obaid Alqahtani[3], Brian Collins[3], Iain McCulloch[2], Dieter Neher[1], and Safa Shoaee[1] — [1]University of Potsdam, Potsdam-Golm, Germany — [2]University of Oxford, Oxford, UK — [3]Washington State University, Pullman, USA

The energetic offset between the highest occupied molecular orbital (HOMO) levels of the donor and acceptor components of the organic photovoltaic (OPV) blends is well-known to affect the efficiency of the singlet exciton (S1) dissociation into separated charges (CS) via the charge-transfer (CT) state, however the impact of this offset on bimolecular recombination of free charge carriers has not been explored. In this study, using three different non-fullerene acceptors Y6, ITIC and o-IDBTR, blended with the same donor polymer PM6, we demonstrate that, apart from reducing the driving force for charge generation, diminishing HOMO-HOMO energy offset also activates exciton reformation as a channel for bimolecular recombination of free charges. This is accompanied by the rise in the respective bimolecular recombination coefficient, which in turn influences the device fill-factor. Using the comparison between PM6:ITIC and PM6:o-IDBTR, we show that neither morphology, nor carrier mobilities can on their own explain the observed difference in performance, signaling the importance of the energy landscape in controlling the OPV device efficiency, both through generation and recombination of charge carriers.

CPP 11.5　Mon 16:30　GÖR 226

Relating free charge carrier generation and field induced photoluminescence quenching in a non-fullerene-based organic blend with a low energy offset — •Manasi Pranav[1], Thomas Hultzsch[1], Bowen Sun[1], Rong Wang[2], Safa Shoaee[1], Larry Lüer[2], Christoph Brabec[2], and Dieter Neher[1] — [1]Institute of Physics and Astronomy, University of Potsdam, 14476 Germany — [2]Institute of Materials for Electronics and Energy Technology (i-MEET), Friedrich-Alexander-Universität Erlangen-Nürnberg Martensstrasse 7, 91058 Erlangen, Germany

Many studies currently target the process of free charge carrier generation and recombination in relation to the energy level offset in organic blends based on non-fullerene acceptors (NFA). Here, we add to this discussion with a focus on the NFA Y5, characterized by a smaller highest occupied molecular orbital offset in PM6:Y5 compared to PM6:Y6, despite molecular similarity between Y5 and Y6. We find that the PM6:Y5 blend exhibits a pronounced field-dependence of free charge generation, as measured with the time-delayed collection field (TDCF) technique. We verify this with a new arbitrary-waveform TDCF technique that provides finer control over the time-delay parameters. In addition to this, we also observe a surprisingly pronounced effect of the electric field on both the steady state photoluminescence (PL) intensity and the transient PL lifetime. These results indicate that the field dependence of photo-current, free charge carrier generation and PL quenching in this low-offset system are governed by the same mechanism: likely field-induced exciton dissociation.

CPP 11.6　Mon 16:45　GÖR 226

Field Dependent Exciton Dissociation in Single-Component Organic Non-fullerene Acceptor Solar Cells — •Flurin Eisner, Mohammed Azzouzi, and Jenny Nelson — Blackett Laboratory, Imperial College London, South Kensington, SW7 2AZ, UK

Improvements in the molecular design of non-fullerene acceptors (NFAs) has almost doubled the power-conversion efficiency (PCE) of organic photovoltaics in the last 5 years, from 11 to 19%. However, the exact molecular reasons behind why some acceptors (e.g. Y-series) perform better than others (e.g. ITIC-series) remain unclear. Interestingly, recent studies have shown that some the most efficient non-fullerene acceptors can achieve relatively high charge-generation efficiency in the absence of a donor-acceptor interface, challenging the current understanding of how photogenerated excitons dissociate into free charges in organic solar cells.

Here, we study the charge-generation processes in a series of NFA molecules in single-component devices, including A-DA*D-A-type acceptors (e.g. Y6) and A-D-A type acceptors (e.g. ITIC) using optoelectronic and spectroscopy characterisation methods under strong applied fields and at different temperatures. By combining experimental results with molecular and device-level calculations, we link exciton and charge dissociation efficiency in NFA films to molecular pa-

rameters such as reorganisation energy and electronic coupling. We use this to suggest how to design materials with both higher single-component device performance and how to improve heterojunction device performance beyond 20% PCE.

CPP 11.7   Mon 17:00   GÖR 226

Triplet Excitons and associated Efficiency-Limiting Pathways in NFA-based Organic Solar Cell Blends — Jeannine Grüne[1,2], Giacomo Londi[3], Alexander J. Gillett[2], Yoann Olivier[3], Vladimir Dyakonov[1], and •Andreas Sperlich[1] — [1]Experimental Physics 6, Julius Maximilian University of Würzburg, Germany — [2]Cavendish Laboratory, University of Cambridge, UK — [3]Laboratory for Computational Modeling of Functional Materials, Université de Namur, Belgium

Organic solar cells (OSC) have made great progress in recent years, but are now reaching a performance plateau. Triplet states are known to adversely affect efficiency by opening a channel for non-radiative recombination pathways. Here, we use the complementary spin-sensitive methods of photoluminescence detected magnetic resonance (PLDMR) and transient electron paramagnetic resonance (trEPR) corroborated by transient absorption and quantum-chemical calculations to unravel exciton pathways in OSC blends employing the (non-) halogenated polymer donors PBDB-T, PM6 and PM7 together with NFAs Y6 and Y7. We reveal that all blends form triplet excitons on the NFA populated via non-geminate hole back transfer and, in blends with halogenated donors, also by spin-orbit coupling driven intersystem crossing. Identifying these triplet formation pathways in all tested solar cell absorber films highlights the untapped potential for improved charge generation to further increase efficiencies.

CPP 12: Modeling and Simulation of Soft Matter II

Time: Monday 15:00–17:15   Location: MER 02

Invited Talk   CPP 12.1   Mon 15:00   MER 02
Adaptive Resolution Simulations: Past, Present and Open (Boundaries) Future — Luis A. Baptista, Mauricio Sevilla, Kurt Kremer, and •Robinson Cortes-Huerto — Max-Planck-Institut für Polymerforschung, Mainz, Deutschland
Soft-matter systems challenge computational methods because interactions spanning a wide range of lengths and time scales require a multiscale approach capable of describing open systems and non-equilibrium conditions. Nonetheless, a high-resolution method is often only necessary to describe a relatively small portion of the system, embedded in a less detailed environment or even a particle reservoir. In this context, the adaptive resolution simulation (AdResS) method provides a seamless interpolation between high- and low-resolution descriptions: both concurrently present within the simulation box in a thermodynamically consistent framework.

In this talk, we introduce the AdResS method and present a few applications as a multiscale simulation protocol. By reducing the complexity of the low-resolution model and describing it as an ideal gas, it is practically possible to control the chemical potential of the system. In this context, we show extensions of AdResS as an efficient method to compute chemical potentials and solvation free energies in complex molecular systems. We also discuss its recent development into an open-boundary method to perform grand canonical and non-equilibrium molecular dynamics simulations. Finally, we examine possible extensions and challenges of developing the method into an open adaptive QM/MM approach.

CPP 12.2   Mon 15:30   MER 02
Chirality propagation across length scales: the case of knots in helical polymers — Yani Zhao[1], Jan Rothörl[2], Pol Besenius[3], Peter Virnau[2], and •Kostas Daoulas[1] — [1]Max Planck Institute for Polymer Research, Mainz, Germany — [2]Department of Physics, Johannes Gutenberg University, Mainz, Germany — [3]Department of Chemistry, Johannes Gutenberg University, Mainz, Germany
We use computer simulations to investigate the effect of helicity in isolated polymers on the topological chirality of their knots. Polymers are described by wormlike chains (WLC), where chiral coupling between segments promotes helical conformations. The sign and magnitude of the coupling coefficient u determine the sense and strength of helicity. The excluded volume is adjusted via the radius R of a hard sphere placed at each WLC segment. Open and compact helices are, respectively, obtained for R that is zero or smaller than the length of the WLC bond, and R that is a few times larger than the bond length. We perform Monte Carlo sampling of polymer conformations for u spanning a broad range of values, from achiral polymers to polymers with well-developed helices. First, we demonstrate that the coil-helix transition in our model is not a phase transition but a crossover. Next, we perform statistical analysis of knotted polymer conformations and demonstrate that the sense of polymer helicity, left- or right-handed, influences the handedness of molecular knots and identify a generic mechanism that underlies this effect.

CPP 12.3   Mon 15:45   MER 02
Dynamics of the Rouse-mode distribution of a Gaussian chain in an external field and connection to spinodal decomposition — •David Steffen[1], Jörg Rottler[2], and Marcus Müller[1] — [1]Institut für Theoretische Physik, Georg-August-Universität, 37077 Göttingen, Germany — [2]Department of Physics and Astronomy and Stewart Blusson Quantum Matter Institute, University of British Columbia, Vancouver, British Columbia V6T 1Z1, Canada
The current description of spinodal decomposition of a homopolymer blend via dynamic self-consistent field theory (D-SCFT) is based on the density of the monomers and uses a time-independent Onsager coefficient. This is sufficient for long wavevectors where the dynamics can be solely described by the diffu-

sion of the center of mass. On small timescales and for larger wavevectors the dynamic is influenced by subdiffusive processes inside the chain. Therefore, a more microscopic description is needed. In this work, we provide an analytical solution for the time-dependent Rouse-mode distribution of a single chain in a weak external field. The time-dependent monomer density can then be obtained via a projection from the Rouse-mode distribution. Although different Rouse-mode distributions yield the same monomer density, an accurate description of the dynamics of the density requires the more microscopic description via the Rouse-modes distribution. This technique can be extended to the spinodal decomposition of a binary homopolymer melt. We compare the analytical results for the density and the Rouse-mode distribution to Monte-Carlo simulations of Gaussian chains.

CPP 12.4   Mon 16:00   MER 02
Simulation of diblock-copolymer membrane fabrication — •Niklas Blagojevic und Marcus Müller — Universität Göttingen, Institut für Theoretische Physik
Diblock copolymers can be used to create integral asymmetric membranes used for ultrafiltration purposes – for example water purification. The combination of evaporation-induced self assembly (EISA) and non-solvent induced phase separation (NIPS) is a promising way for efficient membrane fabrication. The importance of different time- and length-scales makes it difficult to investigate the influence of processing parameters and molecular architecture in experiments. We use a coarse-grained particle based model in conjunction with the Single-Chain in Mean Field (SCMF) algorithm to simulate membrane fabrication with EISA and SNIPS to understand how the membrane structure is formed and how it can be tailored by different processing parameters and varying molecular architecture. For example, we find that nonsolvent macrovoids in the membrane substructure coarsen with an increasing distance into the membrane, while an increasing incompatiblity between nonsolvent and polymer leads to more narrow and straight macrovoids.

CPP 12.5   Mon 16:30   MER 02
Salt effects on N-isopropylacrylamide in aqueous solutions. Experimental measurements, Kirkwood-Buff theory and computer simulation — Jakub Polák, •Daniel Ondo, and Jan Heyda — Department of Physical Chemistry, University of Chemistry and Technology, Prague, Technická 5, 166 28 Prague 6, Czech Republic
In this work, we investigate salt-specific effects on N-isopropylacrylamide (NiPAM) by means of densimetry and vapor pressure osmometry, employing family of sodium and guanidinium salts from low NiPAM concentration up to the solubility limit. Employing Kirkwood-Buff (KB) theory, complete set of effective pair interactions, KB-integrals, at any composition are determined, serving as a bridge to well calibrated molecular dynamics (MD) simulation. All atom MD simulations were used in direct analogy to the experiments and volumetric properties determined. For the first time, in-silico vapor pressure osmometry experiment was performed and excess osmolality evaluated from ternary solution structure. Finally, we establish a strong correlation between salt effect on NiPAM hydration and the salting-out ability of studied salts.

CPP 12.6   Mon 16:45   MER 02
Evaporation-induced confinement assembly of functional terpolymer microparticles — •Elias M. Zirdehi[1], Manuel Trömer[2], André H. Gröschel[2], and Arash Nikoubashman[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz — [2]Institute of Physical Chemistry, University of Münster
Evaporation-induced confinement assembly of terpolymers is an effective technique for fabricating internally structured microparticles (MPs). The wide range

of usable building blocks allows for a large variety of MPs, but poses also an immense challenge due to the staggering amount of process parameters, which cannot be explored through experiments alone. Therefore, we performed dissipative particle dynamics simulations of a bead-spring model to study the directed assembly of triblock copolymers in evaporating droplets. We developed a semi-grand canonical simulation approach, where droplet particles in the vapor phase are periodically removed to drive evaporation at constant flux. In this model, the evaporation rate is controlled by the frequency and the number of particle removal. The resulting shrinking of the droplet was in excellent agreement with theory and experiments. We then implemented this procedure to investigate how the final morphology of terpolymer MPs is influenced by the evaporation rate as well as surfactant type. Finally, the possibility of altering the morphology tailored for specific applications by adding homopolymers will be discussed.

CPP 12.7   Mon 17:00   MER 02

Wavenumber dependent viscosity of a system of particles coupled dissipatively to a Lattice Boltzmann fluid — •Joydip Chaudhuri[1] and Burkhard Dünweg[1,2] — [1]Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany — [2]Department of Chemical and Biological Engineering, Monash Univer- sity, Clayton, Victoria 3800, Australia

We consider a particle based Molecular Dynamics (MD) system coupled dissipatively to a stochastic Lattice Boltzmann (LB) fluid. The employed force coupling method is dissipative which means that the velocity of an MD particle is damped with respect to the velocity of the LB fluid interpolated to the position of the particle. The present study explores the viscosity response of such a coupled LBMD system due to a sinusoidally varying external force. The analytic theory for that system is based upon a two-fluid model, whose predictions are well corroborated by numerical tests. Except for the respective viscosities of the two uncoupled fluids, the total viscosity of the coupled system depends on a hydrodynamic screening length associated with the Stokes coupling parameter, the mass density ratio, and the wavenumber of the applied external force. In the asymptotic long-wavelength limit, the total viscosity is just the sum of the two input viscosities. This behavior deviates significantly from the well known Einstein prediction for dilute colloidal dispersions, and this is due to the different type of particle-fluid coupling.

CPP 13: Composites and Functional Polymer Hybrids

Time: Monday 15:00–18:00   Location: ZEU 255

Invited Talk   CPP 13.1   Mon 15:00   ZEU 255
Nanocomposites and polymer thin films: from gas phase synthesis to functional applications — •Franz Faupel, Stefan Schröder, Alexander Vahl, Salih Veziroglu, Cenk Aktas, and Thomas Strunskus — Chair for Multicomponent Materials, Faculty of Engineering, Kiel University, Kiel, Germany
Highly filled particulate metal-dielectric nanocomposites films have unique functional properties with hosts of applications. To explore collective interactions between the particles, we control the particle separation on the nm scale by employing vapor phase deposition, which is a scalable approach permitting, inter alia, excellent control of the filling factor. For deposition of functional polymer thin films, we have recently used initiated chemical vapor deposition (iCVD) to avoid decomposition of the functional groups. Examples include highly stable electrets for electret microphones and magnetoelectric sensors, 3D superhydrophobic coatings, nanoscale gradient copolymers, and strain-invariant conductors for soft robotics. For the fabrication of the nanocomposites, the nanoparticles can form during gas phase co-deposition via self-organization or by means of high-rate gas aggregation cluster sources, which provide independent control of filling factor and size as well as in situ monitoring and control of composition. Recent examples of nanocomposites range from plasmonic meta-materials through photoswitchable molecular plasmonic systems to memristors and memsensors for neuromorphic electronics. We also explored nanoscale synergetic effects of plasmonics and photocatalysis, e.g. for photoinduced enhanced Raman spectroscopy (PIERS).

CPP 13.2   Mon 15:30   ZEU 255
Rheological optimization of filler packings using micro scale simulations — •Oliver Roser[1,2], Andreas Griesinger[3], and Othmar Marti[2] — [1]Center for Heat Management (ZFW), Stuttgart — [2]Institute of Experimental Physics, Ulm University — [3]Baden-Wuerttemberg Cooperative State University (DHBW) Stuttgart
In a wide range of applications, polymers are modified with granular fillers to improve thermal or electric conductivity. The higher the amount of filler, the higher the conductivity. However, the attainable conductivity is restricted by processing limitations as the amount of filler also affects the composites viscosity. Only a clever combination of filler with multimodal size distributions can shift this limit and allow for higher amounts of filler without significant viscosity increase. The effect of multimodal packing structures on viscosity has already been investigated in several experimental and numerical studies, however common calculation techniques are mainly restricted to spherical and equal-sized filler particles. We extended common approaches with new packing simulations, considering the actual size distribution and shape of different filler materials. We implemented numerical packing optimization to find the best filler compositions for highly filled polymers with up to 80 v%. In this talk we will introduce the new packing simulations and their use for packing optimizations and present the acquired results and experimental validations.

CPP 13.3   Mon 15:45   ZEU 255
Increasing the Electrical Conductivty of Polymer Thin Films for Thermoelectric Applications — •Marie Siegert[1], Markus Hönig[2], Michael Sommer[2], and Jens Pflaum[1,3] — [1]University of Würzburg — [2]Chemnitz University of Technology — [3]ZAE Bayern

Thermoelectric generators based on sustainable, low-cost organic materials harbor great potential for waste heat recovery. Polymer thin films in particular can be easily upscaled to meet industrial standards and display aptly low thermal conductivity κ, but lack high electrical conductivity σ. However, the augmentation of σ imposes a major challange as an increase in charge carrier concentration is usually accompanied by an unintentional decrease of the Seebeck coefficient S, which is detrimental for efficient thermoelectrics. Hence, we compare two possible strategies to enhance the charge carrier transport in such disordered systems. Firstly, doped polymer thin films utilizing the temperature activated n-type dopant TAM have been characterized regarding their thermoelectric properties. Secondly, composite films have been investigated, combining well studied polymers with metallic additives. Both approaches will be evaluated with respect to the enhancement in σ and the underlying transport mechanisms. First estimations of the resulting power factors indicate future strategies to further refine the electronic properties and thus, the thermoelectric figure of merit.
The Deutsche Bundesstiftung Umwelt (DBU) is acknowledged for financial support.

CPP 13.4   Mon 16:00   ZEU 255
Conductivity of filled diblock copolymer systems. — •Alexander Chervanyov — Institut für Theoretische Physik, Westfälische Wilhelms-Universität Münster, Münster, Germany
The reported work looks into the effect of stimuli-induced morphological changes in the composite consisting of insulating diblock copolymers (DBC) and conductive nanoparticles (NP) on the conductivity of this composite. The relation between the nano-structure of the described composite and its conductivity is studied by developing and making use of the multiscale computational approach. This approach relies on the consistent phase-field model of DBC, Monte-Carlo simulations of the filler distribution in DBC, and the resistor network model of the composite conductivity. The dependencies of the conductivity on the temperature of the composite, DBC morphology, and the affinities of fillers for copolymer blocks are studied in detail. In particular, the order-disorder transition in the host DBC system is found to be accompanied by the conductor-insulator transition in the filler network. The order-order transition between the lamella and cylindrical microphases of DBC proves to co-occur with a spike of the composite conductivity caused by restructuring of the conductive filler network.

CPP 13.5   Mon 16:30   ZEU 255
Modeling micro-structure evolution and its impact on moduli in magneto-active elastomers — •Mehran Roghani, Dirk Romeis, and Marina Saphiannikova — Leibniz-Institut für Polymerforschung Dresden, Germany
Magneto Active Elastomers (MAEs) are field-controllable composites made of micron-sized, magnetizable particles embedded into a soft elastomeric matrix. These materials show a strong coupling between their mechanical properties and an applied magnetic field. The coupling can be directly related to magnetic interactions between the particles, which lead to the evolution of microstructure under the field. In the case of initially isotropic MAEs, this micro-structure evolution results in chains forming from the magnetized particles. This in turn causes

a huge increase in the mechanical moduli along the field direction, leading to anisotropic behavior. We consider a transversely isotropic material model for the mechanics, and magnetic interactions are taken into account by the dipolar mean field approach. To couple the mechanical and magnetic effects, a restructuring parameter is introduced which is a function of material magnetization and moduli. This modeling approach improves our understanding of how microstructure evolution affects magnetically induced material deformation and stiffness. The first predictions are in good agreement with experimental results available in the literature. We thank the DFG for financial support through RTG-2430.

CPP 13.6   Mon 16:45   ZEU 255

Magneto-active elastomers: From composite structure to effective susceptibility — •Dirk Romeis and Marina Saphiannikova — Leibniz-Institute of Polymer Research Dresden e.V.

Embedding magnetizable particles into elastic polymer network yields a field-controllable material known as magneto-active elastomer (MAE). In order to describe macroscopic samples of such composite material it is useful to develop an effective macro-continuum model. Based on the dipole approximation, we derive analytic relations for the effective magnetization behavior in MAEs, spanning from linear to saturation regime, for isotropic and anisotropic particle arrangements. In the limiting case of linear magnetics and isotropic distributions we reproduce an expression known from previous works. Accordingly, we believe that the present homogenization scheme provides a general description of the effective magnetic behavior with high practical relevance also in case of anisotropic distributions and beyond the linear magnetization. For a given particle arrangement and magnetization model on microscale, the solutions are obtained with low computational effort. Furthermore, the present formulation can be directly implemented into a macroscopic material model for a composite sample of specified shape. It turns out, that an anisotropic particle distribution has an equivalent effect as an anisometric sample shape.

CPP 13.7   Mon 17:00   ZEU 255

Tuning the thermal conductivity of magnetic gels and elastomers — Gustav J. L. Jäger, •Lukas Fischer, Tyler Lutz, and Andreas M. Menzel — Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Magdeburg, Germany

When an external magnetic field is applied to magnetic gels or elastomers—composite materials consisting of magnetic or magnetizable particles inside an elastic matrix—these materials typically exhibit interesting deformational (magnetostrictive) responses or changes in rheological properties (magnetorheological effect).

We study how the induced magnetic interactions lead to an internal restructuring of the magnetic particles, mainly the formation of particle chains along the direction of the external magnetic field. This behavior is not only connected to the aforementioned effects, it can also change the thermal conductivity of the magnetic gels and elastomers, which we focus on here. We analyze this phenomenon numerically for 2D mesoscopic (particle-resolved) models of magnetic gels and elastomers [1], thus characterizing thin elastic films and membranes.

Our results indicate significant magnetically induced changes in the thermal conductivity. The influence of several parameters on this effect is investigated, such as the density and number of magnetizable particles, the amplitude of their magnetization, and the aspect ratio of the systems. Similar changes in the electric conductivity of magnetic gels and elastomers are expected.

CPP 13.8   Mon 17:15   ZEU 255

Morphology evolution and nanoparticle localization in printed hybrid nanoparticle-diblock copolymer thin films investigated by in situ GISAXS — •Christopher R. Everett[1], Guangjiu Pan[1], Manuel A. Reus[1], David Kosbahn[1], Frank Hartmann[2], Martin Bitsch[2], Matthias Opel[3], Markus Gallei[2], Matthias Schwartzkopf[4], and Peter Müller-Buschbaum[1,5] — [1]TUM, TUM School of Natural Sciences, Chair for Functional Materials, 85748

Garching — [2]Saarland University, LS Polymer Chemistry, 66123 Saarbrücken — [3]Walther-Meissner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching — [4]DESY, 22607 Hamburg — [5]MLZ, TUM, 85748 Garching

The diblock copolymer (DBC) PS-b-PMMA forms films with periodic ordered nanostructures that can act as scaffolds for inorganic magnetic nanoparticles. These films have application as magnetic sensors and in magnetic data storage devices. Film formation and the resulting magnetic properties both depend on the localization of the nanoparticles in the DBC domains. In this investigation, ultra-high molecular weight PS-b-PMMA films containing two types of nanoparticles, cobalt ferrite and nickel, are fabricated by a slot-die coating technique. Grazing incidence small-angle X-ray scattering (GISAXS) is used to monitor in situ the morphological evolution of the DBC films and nanoparticle segregation in the films during the deposition and drying process. The magnetic properties of the hybrid films are investigated with a SQUID magnetometer.

CPP 13.9   Mon 17:30   ZEU 255

Tunable mesoporous zinc titanate films via diblock copolymer-directed co-operative self-assembly and a sol-gel technique — •Yanan Li[1], Nian Li[1], Shanshan Yin[1], Constantin Harder[2], Yusuf Bulut[2], Apostolos Vagias[3], Stephan V. Roth[2,4], and Peter Müller-Buschbaum[1,3] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]DESY, 22607 Hamburg, Germany — [3]MLZ, TUM, 85748 Garching, Germany — [4]Department of Fiber and Polymer Technology, KTH, SE-100 44 Stockholm, Sweden

Mesoporous ordered films have broad applications ranging from sensors to supercapacitors and biodevices due to their large specific surface area and pore accessibility of their porous nanostructures. Here, we investigate the evolution and formation mechanisms of morphologies of mesoporous zinc titanate films obtained by changing the ratio of two inorganic precursors after calcining hybrid films consisting of organic-inorganic materials. The amphiphilic diblock copolymer self-assembles into micelles in a mixture of N,N-dimethylformamid/hydrogen chloride playing the role as structure directing template. The inorganic precursors are loaded in the micellar shell due to hydrogen bonds between PEO and precursors. We combine a sol-gel route with a spin coating to prepare hybrid films, and investigate the influence of the different weight fractions of precursors and polymer concentration on the film morphologies. The inner and surface morphologies of the hybrid films are characterized using grazing incidence small-angle X-ray scattering and scanning electronic microscopy, respectively.

CPP 13.10   Mon 17:45   ZEU 255

Gold Nanoparticle/Polymer Brushes Composites: Controlling the Structure via Ion-Specific Effects — •Philipp Ritzert and Regine v. Klitzing — Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstr. 8, 64289 Darmstadt, Germany

Nanocomposite materials based on inorganic gold nanoparticle (AuNP) inclusions inside an organic matrix (e.g. polymer brushes) are employed in various fields: medical technology, catalysis, materials engineering. Combining the properties of both material classes facilitates high versatility of mechanical, optical and chemical properties, while simultaneously covering obvious drawbacks, e.g. stability of one compound. To provide the wide range of applications, nanocomposite materials usually require a specific internal structure. Yet, the understanding of the formation of internal structure and control over formation process is still lacking. Therefore, we aim to provide an approach to manufacture nanocomposite materials with controlled structure. Our model system utilizes various sodium salts (anion: F, Cl, Br, I, SCN) as stimuli for the assembly of citrate-capped gold nanoparticles in a poly-(N-isopropylacrylamide) brush. In a first step, we characterize the effect of sodium salts on pure AuNP suspensions. In a second step, we investigate adsorption parameters of AuNPs from suspension to brush, e.g. adsorption time. The third step involves the structure control of the composite materials with the characterized stimuli. Optical measurements reveal distinct differences between the sodium ions and concentration dependent aging behaviour.

Plasmonic behaviour of surface modifications of γAlOOH nanoparticles and their effect on the particles Hamaker constant — •DOROTHEE SILBERNAGL[1], MATEUSZ DUDZIAK[1], ANNA MARIA MANZONI[1], and HEINZ STURM[1,2] — [1]Bundesanstalt für Materialforschung und -prüfung, Unter Den Eichen 87, 12205, Berlin, Germany — [2]Institute for Machine Tools and Factory Operations (IWF), TU Berlin, Pascalstr. 8-9, 10587 Berlin, Germany

Boehmite (γAlOOH) nanoparticles (BNP, particle size appr. 14nm) are known for their extremely low Hamaker constant A, which results in low interparticle van der Waals forces. However, surface modified nanoparticles (modifications are acidic acid BNPA, lactic acid BNPL and stearic acid BNPS) exhibit a gradually increased Hamaker constant A and therefore increased interparticle van der Waals forces. This was measured by atomic force microscopy force distance curves (AFM FDC). For this experiment an unmodified BNP agglomerate of approximately 50um diameter was attached to an AFM cantilever and measured against pressed BNPs without and with different surface modifications. This set-up provides a sphere/plane geometry, necessary to calculate the Hamaker constant A of each material pairing from the FDCs attractive regime. Electron energy loss spectroscopy (EELS) measurements in the low energy region (up to 80eV) of unmodified and surface modified BNPs were performed to understand the origin of the increased van der Waals forces. As a result, additional plasmon bands were found in the region below 10eV for surface modified BNPs, which contribute to the attractive forces between particles.

CPP 17.2   Mon 18:00   P3

Liquid phase (S)TEM of DNA origami gold nanoparticle hybrids — •A. ONG[1], D. POHL[1], T.K. JEONG[2,3], A. HEERWIG[2,3], M. MERTIG[2,3], and B. RELLINGHAUS[1] — [1]Dresden Center for Nanoanalysis (DCN), cfaed, TU Dresden, Germany. — [2]Physical Chemistry, TU Dresden, Germany — [3]Kurt-Schwabe-Institut für Mess- und Sensortechnik Meinsberg e.V., Germany

DNA origami pads with site-specific patterns of ssDNA are flexible molecular templates for gold nanoparticles to self-assemble into functional supracolloidal structures [1]. The structure-property relation of supracolloidal structures play a significant role in constructing novel materials with desired properties for application in devices [2]. However, this relation has not been adequately understood. The study focuses on investigating the self-assembly and kinetic processes in supracolloidal structures using (scanning) transmission electron microscopy [(S)TEM] both in vacuum and in the liquid phase. Images of gold nanoparticles attached to DNA origami were acquired under vacuum and in-situ in the liquid phase, highlighting the possibility of real-time visualizations at the nanometer scale in different environments. The measured distances between gold nanoparticles in liquid confirm the intended templating mechanism. Financial support by DFG through RTG 2767 and by the EU Horizon 2020 Research & Innovation Programme grant agreement no. 964248 is gratefully acknowledged.

CPP 17.3   Mon 18:00   P3

Probing photoluminescent polymers using plasmonic self-assembly — •ONIMA BISHT[1,3], SEZER SEÇKIN[1], and TOBIAS KÖNIG[1,2] — [1]Leibniz-Institut für Polymerforschung e.V., Hohe Straße 6, 01069 Dresden, Germany — [2]Center for Advancing Electronics Dresden (cfaed), Technische Universität Dresden, 01062 Dresden, Germany — [3]Department of Physics, Indian Institute of Technology Delhi, Hauz Khas, New Delhi, 110016, India

Surface Enhanced Raman Spectroscopy (SERS) is an advantageous and indispensable technique for detection and sensing applications. Although SERS substrates have been fabricated using several top-down approaches, these methods are limited by scalability, uniformity, and high instrumentation costs. Recent developments in template-assisted self-assembly (TASA) techniques have facilitated us to fabricate low-cost, scalable, and uniform gratings consisting of plasmonic nanoparticle chains.[König et al., Adv. Funct. Mater. 2021, 2105054] With the support of the finite-difference time-domain (FDTD) method, we have rationally designed the colloidal grating to benefit from the coherent interaction

between Rayleigh anomalies and various plasmon modes. We will combine these modes with the quantum emitter, which we used previously as an efficient gain component for optoelectronic devices. [König et al., Adv. Optical Mater. 2020, 2001280] Finally, we use this overlap of the plasmonic modes with the photoluminescence of the emitters for nonlinear effects such as lasing, strong coupling, and ultra-high SERS sensitivity.

CPP 17.4   Mon 18:00   P3

Influence of thermal effects on a combinatorial plasmonic nanostructure for bio-detection — •TIANFU GUAN[1], SUZHE LIANG[1], YUSUF BULUT[1,2], KRISTIAN RECK[3], MATTHIAS SCHWARTZKOPF[2], JONAS DREWES[3], THOMAS STRUNSKUS[3], FRANZ FAUPEL FAUPEL[3], STEPHAN V. ROTH[2,4], and PETER MÜLLER-BUSCHBAUM[1,5] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]DESY, 22607 Hamburg, Germany — [3]CAU, Chair for Multicomponent Materials, Faculty of Engineering, 24143 Kiel, Germany — [4]Department of Fiber and Polymer Technology, KTH, SE-100 44 Stockholm, Sweden — [5]MLZ, TUM, 85748 Garching, Germany

In recent decades, Au nanoparticles (NPs) have been utilized in a wide range of sensor applications, such as photodetection, bio-detection, and thermal-detection, because of their unique optical and chemical properties. Among the optical sensors, surface-enhanced Raman spectroscopy (SERS) has attracted extensive attention being used in the identification of unknown substances in analytical chemistry. In this work, we investigate in situ sputter deposition of Ag on highly ordered Au NPs substrates as probed by grazing incidence small angle X-ray scattering (GISAXS). In addition, we explore the effect of temperature on the silver growth kinetics on different sizes of Au NPs substrates. Furthermore, by correlating the growth steps of the composite Au/Ag nanostructures with their SERS performance, we obtain the plasmonic hot spot performance corresponding to the combined nanostructure.

CPP 17.5   Mon 18:00   P3

Understanding the Double Doping of Organic Semiconductors Via State Energy Renormalization upon Charging — •ROSS WARREN[1], EUNKYUNG CHO[2], HONG LI[2], JEAN-LUC BREDAS[2], and NORBERT KOCH[1,3] — [1]Institut für Physik & IRIS Adlershof, Humboldt-Universität zu Berlin, 12489 Berlin, Germany — [2]Department of Chemistry and Biochemistry, The University of Arizona, Tucson, Arizona 85721-0088, United States — [3]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, 12489 Berlin, Germany

The double ionisation of dopants is a recent experimental observation that allows the doping efficiency to rise above 100%. This is exciting because high conductivities can be achieved with fewer dopant molecules, meaning less disruption to the resulting film's microstructure. However, the current models of doped organic semiconductors based on Fermi-Dirac statistics fail to explain the double ionization of dopants and also the analogous situation of bipolaron formation on a host polymer. Here, we address this shortcoming by considering the renormalization of the state energies upon electron transfer between host and p-dopant. We vary the model parameters - the reorganization energy and evolutions of ionization energies and electron affinities upon charging - and plot the fractions of doubly ionized, singly ionized, and neutral species. We find good agreement with experiment. Finally, we suggest that the state energy renormalization upon charging is the key parameter to be minimized for double ionization of dopants or maximized to avoid formation of bipolarons on the host.

CPP 17.6   Mon 18:00   P3

Temperature Dependent Photoluminescence of β-Phase Zinc Phthalocyanine Single Crystals — •KILIAN STRAUSS[1], LISA SCHRAUT-MAY[1], SEBASTIAN HAMMER[1,2], KILIAN FRANK[3], BERT NICKEL[3], and JENS PFLAUM[1] — [1]Experimental Physics VI, Julius-Maximilians-Universität of Würzburg — [2]Department of Physics, Ludwig Maximilian University, Munich — [3]Departments of Physics and Chemistry, McGill University, Montreal, Canada

The photophysical properties of organic crystals are strongly dependent on the interactions between the comprising molecules. We chose zinc phthalocyanine (ZnPc) in its crystallographic β-phase as a model system to investigate the ex-

citonic coupling as a function of crystallographic direction. For this purpose, we performed polarization dependent photoluminescence (PL) measurements from 5 K to 300 K on needle-shaped single crystals grown by horizontal vapour deposition. A gradual optical transition from a J- to H-aggregate like behavior occurs on cooling down to 100 K. Upon further cooling, we find the emergence of superradiant luminescence typical for exciton delocalization in J-aggreagtes. This optical transition is induced by an anisotropic thermal compression of the crystal lattice.

We thank the Bavarian Research Network SolTech for financial support.

CPP 17.7   Mon 18:00   P3

On the Parametrization of Exciton-Phonon Coupling Matrix Elements by Ab Initio Methods — •Maximilian Franz Xaver Dorfner and Frank Ortmann — Department of Chemistry, Technische Universität München, 85748 Garching b. München, Germany

The accurate description of optical or transport properties of organic semiconductors, such as small molecules or polymers requires, besides the electronic degrees of freedom, also the incorporation of the nuclear motion into the theoretical treatment. This is because in these materials the electrons and the core movement are significantly coupled to each other.

This interaction co-determines macroscopic observables, like absorption cross-sections, charge carrier mobilities, or electronic relaxation time-scales. Close to the equilibrium configuration, the interplay of the electronic degrees of freedom and the nuclei can be cast into the form of a Holstein-Peierls model. In this representation, the interaction is characterized by a set of coupling constants, which are typical for a given molecule and dictate behavior in a range around the equilibrium configuration.

Here we present a novel scheme and an implementation for the computation of these effective coupling constants based on the CP2K software package. We benchmark our implementation for a number of molecules and study their non-radiative electronic relaxation behavior by the use of a matrix product state approach.

CPP 17.8   Mon 18:00   P3

Unraveling Structural Dynamics in Excimer Formation Using Ultrafast Electron Diffraction — •Sebastian Hammer[1], Laurenz Kremeyer[1], Tristan Britt[1], Maximilian Rödel[2], Syed Ali Hassan[1], Jens Pflaum[2,3], and Bradley Siwick[1] — [1]Departments for Physics and Chemistry, McGill University, Montreal, QC H3A 2K6, Canada — [2]Experimental Physics VI, University of Würzburg, 97074 Würzburg — [3]Bayerisches Zentrum für Angewandte Energieforschung (ZAE Bayern), 97074 Würzburg

Excimer formation, *i.e.* the formation of an excited dimer state which is accompanied by structural deformations in the local inter-molecular geometry, is a common phenomena in molecular solids and crucially determines the optoelectronic properties of the material. While the process is understood well on a theoretical level [1], direct observational evidence of the underlying structural dynamics are experimentally challenging.

In recent years, the technique of ultrafast electron diffraction (UED) has proven to be capable of unraveling the structural dynamics of molecular single crystals after photo-excitation [2]. Using the prototypical excimer system zinc-phthalocyanine in its crystallographic α-phase [3], we show that UED experiments on polycrystalline thins-films can disclose the structural dynamics accompanying excimer formation. We gratefully acknowledge funding from the DFG (Project 490894053).

CPP 17.9   Mon 18:00   P3

Influence of Ligands and Linker on the Optoelectronic Properties of Phenazine-based Iron Spin-Crossover Complexes — •Lydia Ploss[1], Florian Daumann[2], Konstantin Schötz[1], Gerald Hörner[2], Birgit Weber[2], and Anna Köhler[1,3] — [1]Experimental Physics II, University of Bayreuth — [2]Anorganische Chemie IV, University of Bayreuth — [3]Bayreuth Institute of Macromolecular Research, University of Bayreuth

Spin-crossover (SCO) complexes are a class of materials - typically organometallic complexes - whose electronic ground state can be switched between a high spin (HS) and a low spin (LS) state by external stimuli, e.g., by varying the temperature. This possibility renders them promising candidates for applications such as molecular switches or sensors.

An easy way to read out sensors is, e.g., by using photoluminescence (PL) spectroscopy. Recently, an iron-based SCO complex was found that shows PL in both spin states.[1] This is remarkable since most SCO complexes show PL in only one of the two spin states or are not luminescent at all. To understand what defines the optical properties of such compounds, we systematically vary ligands and linker molecules of the complexes and investigate their influence on the optical properties of the resulting complexes, using absorption and temperature-dependent PL spectroscopy.

CPP 17.10   Mon 18:00   P3

Multichromophore Macrocycles of Perylene Bisimide Dyes as Fluorescent OLED Emitters — •Theodor Kaiser[1], Björn Ewald[1], Ulrich Müller[1], Peter Spest[2], Matthias Stolte[2], Frank Würthner[2], and Jens Pflaum[1] — [1]Experimental Physics VI, University of Würzburg — [2]Institut für Organische Chemie and Center for Nanosystems Chemistry, University of Würzburg

While fluorescent organic emitters exhibit an efficient and bright singlet decay their efficiency in Organic Light Emitting Diodes (OLEDs) is limited by the lifetime and non-radiative loss pathway of triplet dark states. Therefore OLED applications are mainly based on phosphorescent emitters harvesting triplet excitons for light emission. In order to increase the efficiency of fluorescent OLEDs we present a novel approach for the chemical design of fluorescent emitters based on multichromophore macrocycles of perylene bisimide dyes (PBIs). By linking individual PBI chromophores in macrocyclic architectures, biexcitonic coupling can lead to an efficient transformation of triplet dark states by processes like triplet-triplet annihilation (TTA). This allows for an efficient bright electrical operation in OLED devices as the lifetime of dark states is drastically reduced. As recently reported by our groups trimeric perylene bisimides can even produce non-classical electrically driven single photon emission at room temperature [1], which has so far only been reported for phosphorescent emitters. Therefore these emitters offer new options for the application of strictly fluorescent materials in classical and non-classical OLED devices.

Investigation of Metal–Insulator Transitions in Organic Field-Effect Transistors of an n-Type Organic Semiconductor — •Paul Schlachter[1], Maximilian Frank[1], Matthias Stolte[2], Frank Würthner[2], and Jens Pflaum[1,3] — [1]Experimental Physics VI, University of Würzburg, 97074 Würzburg — [2]Institut für Organische Chemie and Center for Nanosystems Chemistry, University of Würzburg, 97074 Würzburg — [3]ZAE Bayern, 97074 Würzburg

Metal-insulator transitions in organic materials offer many exciting applications and are therefore gaining increasing scientific as well as technological interest. In this work, we aim to investigate electronic field-effect-induced phase transitions (semiconductor → conductor → insulator) in organic single crystals (especially Cl_2NDI [1]) of high electron mobility. The long-range order of their molecular entities in combination with a preferred (001) gliding plane geometry provides the pre-condition of a nearly defect-free interface for studying quasi-two-dimensional electron gas formations. For this purpose, we use an electrolyte as a top gate in addition to a dielectric conventional back gate. By simultaneously varying the bottom and top gate voltages, respectively, we aim to control the charge carrier density and thereby to gain deeper insights into Mott physics. First results on these efforts will be presented and evaluated with respect to the possible implementation in Mott field-effect transistors.

On the orientation mechanism of non-polar dyes in light-emitting guest-host systems — •Binh-Minh Nguyen, Markus Schmid, Johann Kirsch, and Wolfgang Brütting — Experimental Physics IV, Institute of Physics, University of Augsburg, 86159 Augsburg, Germany

After many years of development, OLEDs have continuously been optimized to reach higher efficiency, for which the horizontal orientation of the emitter molecules is one of the dominant factors [1]. For the purpose of studying intrinsic orientation without electrostatic interaction, our work considers non-polar dyes, namely TTPA, BSBCz, DIP and DBP. While the emitter orientation has been studied in neat film as a basic approach, their behavior in guest-host systems has not been studied widely. In this work we focus on the correlation between emitter concentration and its orientation. With the results from experimental and simulation study, we also discuss the possible orientation mechanism of emitter molecules on the substrate surface in terms of molecular structure, possibility to form crystallites and the effective glass transition temperature of the guest-host system. We observe that isotropic structure of the emitter as well as the crystallized and aggregated molecules are not favorable for horizontal orientation. However, molecules having a rod-like structure have the tendency to arrange horizontally to the substrate. These results contribute to a further understanding of orientation of non-polar emitter molecules.

Self-heating in OLED Lighting — •Anton Kirch[1,2], Axel Fischer[1], Matthias Liero[3], Jürgen Fuhrmann[3], Annegret Glitzky[3], Ludvig Edman[2], and Sebastian Reineke[1] — [1]Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP), TU Dresden, Germany — [2]Department of Physics, Umeå University, Sweden — [3]Weierstrass Institute Berlin, Germany

For bright area light sources, such as OLED lighting tiles, the electric resistivity of transparent electrodes induces a non-uniform current distribution within the device. At high driving currents, the interaction between conductivity, heat, and power dissipation results in a positive electrothermal feedback loop, which dras-

tically exacerbates inhomogeneities in local device temperature and luminance.

Such nonlinear behavior induces unprecedented electrothermal effects that compromise the performance of bright area light sources. In this contribution, we present how Joule self-heating squeezes temperature and current into a tiny device region, while the remainder of the active area decreases in luminance (Switch-back effect) [1]. We further introduce how the dimension of the active area governs the current-voltage characteristics of the OLED and how two and even three stable operating branches develop (tristability) that can promote destructive incidences [2].

Organic Photoconductors based on Rubrene Thin-Films — •Jonas Schroeder, Rishabh Rishabh, Johannes Benduhn, and Karl Leo — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden, Nöthnitzer Str. 61, 01187 Dresden, Germany

Thin films of organic semiconductors possess huge potential for large-scale industrial applications. However, the limited possibilities of crystal growth directly on the substrates often restrict device concepts but also achievable device performance. Here, we use vacuum-deposited rubrene in combination with a thermal post-treatment to fabricate different morphologies of polycrystalline thin films. To take advantage of the high in-plane mobility ($3 \, cm^2 \, V^{-1} \, s^{-1}$) of the well-known orthorhombic rubrene phase in light detection applications, we employ photoconductive detectors in which the contacts are placed laterally on the sides of the active material. This allows for decoupling of the filtering of the incident light from the channel geometry and a photocurrent gain due to the natural imbalance of electron and hole mobilities in organic semiconductors. We show performance benchmarks of prototypical photoconductive organic photodetectors and relate these to the optical and electrical properties of the used rubrene thin films.

CPP 17.15 Mon 18:00 P3

Optimizing narrowband OPDs for wavelength range from 700 nm to 1100 nm — •Fred Kretschmer, Louis Conrad Winkler, Jakob Wolansky, Johannes Benduhn, and Karl Leo — Technische Universität Dresden, Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute of Applied Physics (IAP), Dresden, Germany

In recent years, organic photodetectors have attracted particular interest, due to their advantageous properties, such as cheap manufacturing costs and high performance, compared to inorganic devices. Particularly important is the narrowband photo-response, which enables the detection of small wavelength ranges, making optical filters obsolete and allowing miniature detector compositions. Narrowband spectroscopic sensors are an integral part of modern society, for example, in food quality monitoring, signal communication, or medical imaging.

In this contribution, microcavity-enhanced organic photodetectors in the visible and near-infrared wavelength range are investigated. For these devices, the active and transport layer thickness are varied and analysed for the donor material Rubrene and Spiro-MeO-TPD. Therefore, performance parameters such as the external quantum efficiency, the specific detectivity, the dark current, the response speed, and parasitic side effects are investigated and examined, leading to concrete device guidelines which can increase the performance of narrowband organic photodetectors. In a next step, we are planning to complement these detectors with infrared light-emitting diodes for a fully organic, spectroscopic sensing system.

CPP 17.16 Mon 18:00 P3

Humidity Stable Thermoelectric Hybrid Materials for A Self-Powered Sensing System — •Suo Tu[1], Ting Tian[1], Tianxiao Xiao[1], Shanshan Yin[1], Julian Heger[1], Guangjiu Pan[1], Shujin Hou[2], Aliaksandr Bandarenka[2], Matthias Schwartzkopf[3], Stephan Roth[3], and Peter Müller-Buschbaum[1,4] — [1]Technical University of Munich, TUM School of Natural Sciences, Department of Physics, Chair for Functional Materials, 85748 Garching — [2]Technical University of Munich, TUM School of Natural Sciences, Department of Physics, Physik der Energiewandlung und -speicherung, 85748 Garching — [3]DESY, 22607 Hamburg — [4]MLZ, TUM, 85748 Garching

Highly sensitive and humidity-resistive detection of the most common physical stimuli is of primary importance for practical application in a real-time monitoring. Here, we report a simple yet effective strategy to achieve a highly humidity-stable hybrid composite that enables simultaneous and accurate pressure and temperature sensing in a single sensor. The improved electronic performance was due to the enhanced planarity of PEDOT and charge transfer between PEDOT:PSS and multi-walled carbon nanotubes (MWCNT) by strong π-π interaction. The preferred electronic pathway induced by robust morphology in the hybrid composite is responsible for the high humidity stability. These observations have been recognized by Grazing-incidence wide/small-angle X-ray scattering (GIWAXS/GISAXS), Raman, FTIR, and electrochemical impedance spectroscopy (EIS).

CPP 17.17 Mon 18:00 P3

New insights into the P3HT:PCBM bulk-heterojunction — •Shahidul Alam[1], Christopher E. Petoukhoff[1], Haya Aldosary[1], Xinyu Jiang[2], Tomáš Váry[3], Wejdan Althobaiti[1], Sandra P. Gonzalez Lopez[1], Wejdan Alsufyani[1], Peter Müller-Buschbaum[2], Vojtech Nádaždy[4], Harald Hoppe[5], and Frédéric Laquai[1] — [1]KAUST Solar Center (KSC), Kingdom of Saudi Arabia — [2]TU Munich, Germany — [3]STU Bratislava,Slovak Republic — [4]Slovak Academy of Sciences, Bratislava, Slovak Republic — [5]FSU Jena, Germany

Here, we studied the influence of thermal annealing on blends of well-known regio-random and regio-regular P3HT conjugated polymers and fullerene derivative [6,6]-phenyl-C60-butyric acid methyl ester (PC60BM). Several advanced microscopic and spectroscopic techniques were applied to investigate the thermal annealing effects on the structural, morphological, and energetic states, e.g., grazing-incidence wide-angle x-ray scattering, polarized light microscopy, hyperspectral photoluminescence spectroscopy, and photo-deflection spectroscopy. Furthermore, the blends' density of states (DOS) distribution was studied using energy resolved-electrochemical impedance spectroscopy. Coupled transfer matrix methods and drift-diffusion simulations were employed to see the impact of DOS on the solar cells' device parameters.

CPP 17.18 Mon 18:00 P3

Crystal Orientation and Surface Morphology in Thin Films of Poly-[3-(6-trifluorohexyl)thiophene] on Silicon and Graphene — •Alexander Much[1], Robert Kahl[1], Florian Meichsner[2], Mukundan Thelakkat[2], Thomas Thurn-Albrecht[1], and Oleksandr Dolynchuk[1] — [1]Experimental Polymer Physics, Martin Luther University Halle-Wittenberg — [2]Applied Functional Polymers, University of Bayreuth

Semiconducting polymers gained much interest for use in electronic devices due to their easy processing from solution and mechanical flexibility. To improve the efficiency of organic electronic devices, it is crucial to understand and control the crystal orientation in thin films.

As recently found in films of poly-(3-hexylthiophene) (P3HT) on graphene, the interfaces to vacuum and graphene induce edge-on and face-on orientation, respectively [1]. We propose to influence the crystal orientation in polythiophenes by increasing the polarity of the end group of the side chains. Thereby, melt-crystallized thin films of poly-[3-(6-trifluorohexyl)thiophene] (P3CF3HT) studied by GIWAXS showed an increased and thickness-dependent tendency to face-on orientation not only on graphene, but also on silicon, which is inactive for P3HT. Furthermore, the film surface morphology probed by AFM strongly depends on the crystal orientation and the substrate. Our results validate the approach and open a pathway to control molecular orientation in polythiophenes.

CPP 17.19 Mon 18:00 P3

Influence of amphiphilic additives on P3HT:PC60BM organic solar cells — •Jose Prince Madalaimuthu[1,2], Zhuo Xu[1,2], Ulrich S. Schubert[1,2], and Harald Hoppe[1,2] — [1]Laboratory of Organic and Macromolecular Chemistry (IOMC), Friedrich Schiller University Jena, Humboldtstr. 10, D-07743 Jena, Germany — [2]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich Schiller University Jena, Philosophenweg 7a, D-07743 Jena, Germany

The mechanical stability of the layer stack is a significant barrier to the continued functioning of flexible OPVs. Delamination processes have the potential to significantly reduce photovoltaic performance. High-crystallinity polymers retain blend morphologies for a long time but yield brittle thin films. Amorphous polymers produce more flexible films but have less morphological stability. Device performance is associated with high crystallinity and superior charge carrier mobility. Furthermore, the elasticity required for mechanical stability is often improved with more amorphous polymers. This seems to split the necessary material characteristics in two. The objectives of the investigations are to improve mechanical resilience by lowering the tensile modulus and reducing crystallization by introducing tiny amounts of amphiphilic plasticizers. The effect of amphiphilic small molecule additions in donor-acceptor blends was investigated for toluene sulfonic acid (TSA) and then with a series of perylenes with systematically varying amphiphilicity. Enhancing the device's performance and long-term stability illustrates that the active layer's morphology can be regulated by the presence of amphiphilic additives.

CPP 17.20 Mon 18:00 P3

Enhanced air stability of green-solvent polymer solar cells with green-fluorescent polymer EH-P — •Zerui Li[1], Sergei Vagin[2], Kun Sun[1], Morgan Le Dü[1], Manuel A. Reus[1], and Peter Müller-Buschbaum[1,3] — [1]Technical University of Munich, TUM School of Natural Sciences, Department of Physics, Chair for Functional Materials, James-Franck-Str. 1, 85748 Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Department of Chemistry, Chair of Macromolecular Chemistry, James- Franck-Str. 1, 85748 Garching, Germany — [3]Technical University of Munich, MLZ, Lichtenbergstr. 1, 85748 Garching, Germany

The rapid development of materials has promoted that the efficiency of polymer solar cells (PSCs) reached over 20%, which is highly close to the application requirement. While the relative poor stability of PSCs slows down their commercial progress. Nowadays the research of stability in nitrogen or vacuum recieved much attention, while the inevitable contact of air would also cause undesirable effect on the device performance. Here, we select a green-solvent based material system PBDB-TF-T1:BTP-4F-12 as research model. Firstly the degradation of solar cells in air was observed and the mechanism was investigated. Then a green fluorescent polymer additive could EH-P was explored and it*s found that it could improve the air-illumination stability of these solar cells. The doped solar cells shown obvious advantaged performance compared than reference ones after 24-hours-illumination in air. Such a material shows great potential in real application and provides guidance in exploring new additive.

CPP 17.21   Mon 18:00   P3

Calculation of intra-molecular transition rates depending on structural parameters with DFTB — •Fabian Teichert, Robin Silligmann, Florian Günther, and Angela Thränhardt — Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany

Organic semiconductors become increasingly important for electronic applications. The large number of organic materials and their combinations make it useful to investigate properties like current-voltage characteristics using simulations in order to find suitable material combinations for applications. We investigate the transition rates of electrons between two organic molecules, expecially between thiophene, zinc porphyrin and PCBM. For this, we calculate HOMO and LUMO states and energies, reorganisation energies and Hamiltonian coupling matrices with DFTB using the software dftb+. Based on these results, the transition rates are computed using Marcus theory for charge transfer. We present result for two systems: (1) two thiophene molecules and (2) zinc porphyrin and PCBM. We show reorganisation energies, Hamiltonian coupling constants and transition rates dependent on the structural configuration. E.g. the thiophene molecules are shifted and rotated against each other. The final goal of our work is to obtain the statistical distribution of all the results due to the statistical fluctuation of the structure. This is suitable as input for subsequent Monte-Carlo hopping simulations, which can be used to describe the large-scale transport of charges within organic materials for e.g. solar cell applications.

CPP 17.22   Mon 18:00   P3

Charge transfer characteristics of an optically-driven conjugated molecular system — Vladyslav Savchenko and •Olga Guskova — IPF Dresden, Dresden, Germany

Recently [1], we have simulated E/Z isomers of two azobenzene-bithiophene (azo-bt) molecular switches in-between an anchoring surface and a gold STM tip. One of these switches has been previously synthesized [2], another one represents a structural isomer of [2], where azo and bt blocks have been swapped along the molecule. Here, we focus on the intermolecular charge transfer within chemisorbed monolayer because this aspect is still unexplored. First, DFT method is applied to define the reorganization energies for electron and hole transfer and the transfer integrals for stacked molecules using energy splitting in dimer approach. Further, the charge carrier mobility is evaluated. The results show, that the position of azo and bt favors either hopping of electrons or holes. For example, both isomers of the molecule with swapped blocks [1] are prone to the electron transfer, whereas for switch [2] the UV light stimulus toggles the main charge carrier from electron to hole. Interestingly, that molecule [2] possesses a non-zero mobility for the hopping distances h<0.5 nm, which requires densely packed layers. On contrary, relatively high electron transfer is predicted for molecule [1] even for sparsely anchored switches (h ca. 1 nm); the UV light turns off the hole hopping at distances h>0.5 nm as well. This work is supported by DFG, grant GU1510/5-1. [1] Savchenko V., Guskova O. Herald of TvSU. Series: Chem. 3(45) 2021, 7. [2] Karpe S., et al. Chem. Commun. 46, 2010, 3657.

CPP 17.23   Mon 18:00   P3

Critical Conditions in Transfer Matrix Methods — •Reinhard Sigel — Independent Scientist, Markdorf, Germany

The propagation of light in a layered refractive index profile is well described by transfer matrix methods (TMMs) [1]. Critical conditions (CC) occur when the wave vector perpendicular to the layering becomes zero. This case can be encountered in a total reflection geometry. Conventional TMMS become singular for CC. We discuss the divergence of layer amplitudes when one approaches CC. It is furthermore elucidated, how this divergence shows up in different experiments. New types of basis functions for a TMM based on virtually linear functions to circumvent the singularity have been introduced recently [2].

CPP 17.24   Mon 18:00   P3

Surface doping of rubrene single crystals by molecular electron donors and acceptors — •Christos Gatsios[1], Andreas Opitz[1], Sebastian Hammer[3], Jens Pflaum[3], Yadong Zhang[4], Stephen Barlow[4], Seth R. Marder[5], and Norbert Koch[1,2] — [1]Institut für Physik & IRIS Adlershof, Humboldt-Universität zu Berlin, 12489 Berlin, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, 12489 Berlin, Germany — [3]Experimentelle Physik VI, Julius-Maximilians-Universität Würzburg, 97074 Würzburg, Germany — [4]Renewable and Sustainable Energy Institute (RASEI), University of Colorado, Boulder, CO 80309, USA — [5]Renewable and Sustainable Energy Institute (RASEI), Department of Chemical and Biological Engineering, Department of Chemistry, and Materials Science and Engineering Program, University of Colorado, Boulder, CO 80309, USA

Molecular doping can be used as a method to control the electronic energy levels and charge carrier densities of the organic semiconductor via charge transfer interactions with electron-donating or electron-accepting molecules. This work seeks to understand the mechanisms of interface engineering by focusing on the surface doping of rubrene single-crystals by molecular electron donors (CoCp2) and acceptors (Mo(tfd-CO2Me)3). Our angle-resolved photoemission results show that deposition of molecular dopants on rubrene shifts the valence band with respect to the Fermi level, thus changing the p- (n-) character of the surface, while the electronic band parameters remain essentially unaffected.

CPP 17.25   Mon 18:00   P3

Electronic structure of singlet fission donor-acceptor complexes — •Karin S. Thalmann[1], Pedro B. Coto[2], and Michael Thoss[1] — [1]Institute of Physics, University of Freiburg, Germany — [2]Spanish National Research Council (CSIC), Madrid, Spain

Singlet fission (SF) is a photophysical process in molecular materials describing the spin-allowed conversion of a singlet exciton to two triplet excitons [1]. Due to its ability to multiply charge carriers and its potential usage in solar cells to circumvent the Shockley-Queisser limit [2,3], SF has received significant attention recently. For future applications in energy conversion, the molecule exhibiting SF has to be combined with an electron acceptor to extract the energy of the two triplet excitons. As an example, we consider the complex of two covalently linked diazadiborine chromophore units as the SF exhibiting donor and tetracyanoquinodimethane as the acceptor molecule. Using multireference perturbation theory techniques, we analyze the electronic structure of the complex, in particular the electronically excited states, which include locally excited, charge transfer, and multiexcitonic states. Furthermore, we study the influence of the acceptor on the electronic structure of the donor molecule.

CPP 17.26   Mon 18:00   P3

Recyclable-refabricated efficient solar cells with cellulose-based materials — •Shuxian Xiong[1,2], Marie Betker[1,3], Benedikt Sochor[1], Constantin Harder[1,2], Yusuf Bulut[1,2], L. Daniel Söderberg[3], Peter Müller-Buschbaum[2,4], and Stephan V. Roth[1,3] — [1]DESY, 22607 Hamburg, Germany — [2]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [3]KTH Royal Institute of Technology, 10044 Stockholm, Sweden — [4]MLZ, TUM, Garching, Germany

Cellulose-based nanomaterials are used in a variety of potential applications, particularly in green electronics and optoelectronic devices, due to their sustainability, low cost and the ease of chemical functionalization. For recycling and prefabrications of cellulose-based solar cells, we propose the fabrication of green, fully sprayed solar cells based. The electrode material using conductive inks laminated with cellulose is easy to fabricate in large-area solutions. Preferably chlorine-free solvents are used in the active layer, and solvent engineering and post-treatment are used to control the morphology and aggregation to achieve high performance and environmental recyclability. The solar cells are planned to be recycled using the most environmentally friendly physical and chemical methods. The solar cell materials should be recycled to the maximum extent possible, and the recycled materials are then used to refabricate the solar cells and evaluate them in terms of morphology and efficiency.

CPP 17.27   Mon 18:00   P3

Towards needleless Electrospinning of a non-toxic, textile Dye-sensitized solar cell — •Marius Dotter — FH Bielefeld, University of Applied Sciences, Bielefeld, Deutschland

Photovoltaics can be used not only to feed energy into the power grid, but also to provide opportunities for applications on a smaller scale and for the autonomous supply of small electrical devices. In some cases, optimized efficiency can be dispensed with in favor of more cost-effective variants. Dye-sensitized solar cells (DSSC) offer a good option in this regard. They are also more effective indoors, because of a better conversion of stray light than semiconductor cells. Another idea is to make previously unused areas usable, with textiles such as tarpaulins, umbrellas and awnings being of particular interest. [2]This niche, which has hardly

been used so far, is to be filled by a textile DSSC, relying on needleless electrospinning for the textile haptics. This process, in which a polymer solution is formed into fine nanofibers using high voltage, which are then arranged in a disordered manner to form a nanofiber mat, enables simple and industrially scalable production of the DSSC components with a textile feel. In addition, simple production with non-toxic materials can also enable later reuse or simple recycling. In this context, this poster shows the general concept and progress of the work on the front electrode, which is based on a currently submitted paper.

CPP 17.28   Mon 18:00   P3

Exploring the kinetics of pseudo-bilayer architecture formation during sequential deposition via slot die coating — •Jinsheng Zhang[1] and Peter Müller-Buschbaum[1,2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching — [2]MLZ, TUM, Garching

Recently, organic solar cells have received increasing attention due to obvious advantages such as flexibility and being lightweight. Among the different types of structures of the active layer, typically planar and bulk heterojunction geometries are used, which introduces intrinsic shortcomings. The newly developed pseudo-bilayer structure can perfectly combine their strengths and circumvent the drawbacks. Unfortunately, most of the pseudo-bilayer are still prepared by spin coating and rarely by printing methods such as slot die coating. Besides these studies mainly focus on selecting solvents, adding third components and studying the vertical morphology. The kinetics of forming the pseudo-bilayer architecture with slot-die coating are still unknown. Here we select the donor acceptor system PM6 and Y6 and the solvents CB and CF. First, PM6 is printed on the substrate and then Y6 is printed on top of PM6. During the deposition, in situ GIWAXS, in situ GISAXS, and in situ UV-vis absorption is carried out to study the formation of the pseudo-bilayer.

CPP 17.29   Mon 18:00   P3

Flash-lamp processing of charge extraction layers for polymer solar cells — •Aurelien Sokeng Djoumessi[1,2], Jose Prince Madalaimuthu[1,2], Shahidul Alam[1,2,3], Aman Anand[1,2], Anastasia Sichwardt[1,2], Peter Fischer[4], Roland Rösch[1,2], Ulrich S. Schubert[1,2], and Harald Hoppe[1,2] — [1]Laboratory of Organic and Macromolecular Chemistry (IOMC), Friedrich Schiller University Jena, Humboldtstrasse 10, 07743 Jena, Germany — [2]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich Schiller University Jena, Philosophenweg 7a, 07743 Jena, Germany — [3]King Abdullah University of Science and Technology (KAUST), KAUST Solar Center (KSC), Physical Sciences and Engineering Division (PSE), Material Science and Engineering Program (MSE), Thuwal 23955-6900, Kingdom of Saudi Arabia — [4]Institute of Materials Engineering, Technical University of Ilmenau, Gustav-Kirchhoff-Str. 6, 98693 Ilmenau, Germany

Despite the benefits of thermal annealing (TA) in the fabrication of polymer solar cells, the high processing temperatures are not compatible with high throughput manufacturing techniques such as roll-to-roll, which commonly used flexible substrates. Therefore, techniques such as flash lamp annealing (FLA), which do not negatively affect the plastic substrate are needed. Herein, the FLA was successfully applied to PEDOT:PSS and SnO2 films used as interfacial layers in PM6:Y6-based solar cells, yielding device performances comparable to or even better than the devices treated with TA on a hotplate. Even at prototype size, the FLA is clearly more energy-efficient than the TA.

CPP 17.30   Mon 18:00   P3

Validating novel solar cells in space — •Lukas V. Spanier[1], Lennart K. Reb[1], Michael Böhmer[2], Christoph Dreissigacker[3], Zerui Li[1], Emanuel Anwander[1], Ahmed Krifa[2], and Peter Müller-Buschbaum[1,4] — [1]Technical University of Munich, TUM School of Natural Sciences, Department of Physics, Chair for Functional Materials, Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Department of Physics, Central Technology Laboratory, Garching, Germany — [3]Institut für Materialphysik im Weltraum, Deutsches Zentrum für Luft- und Raumfahrt (DLR), Köln, Germany — [4]Technical University of Munich, Heinz Maier-Leibnitz Zentrum (MLZ), Garching, Germany

The exploration of the outer solar system so far relied heavily on the use of scarce, highly radioactive plutonium stockpiles for power generation, as traditional solar cells have a too low power-to-mass ratio in low light environments to be suitable for those missions. Latest advances in organic and perovskite solar cells now open up the possibility of utilizing them on lightweight foils as photovoltaic solar sails for efficient power generation in low solar irradiation conditions.

We report the deployment of various organic and hybrid solar cell systems on a sounding rocket and their operation in outer space. We investigate the environmental influences during ascent, exposure to space, and reentry on the photovoltaic performance. We further study and compare the changes in morphology and optoelectronic behavior at various stages during the space mission, isolating different external impact factors.

CPP 17.31   Mon 18:00   P3

In situ study of superlattice self-assembly during slot-die coating of perovskite quantum dot films. — •David P. Kosbahn[1], Manuel A. Reus[1], Christopher R. Everett[1], Guangjiu Pan[1], Matthias Schwartzkopf[2], Stephan V. Roth[2,3], and Peter Müller-Buschbaum[1,4] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching — [2]DESY, 22607 Hamburg — [3]Department of Fibre and Polymer Technology, KTH, Stockholm, Sweden — [4]MLZ, TUM, Garching

Research into quantum dots (QDs) of metal halide perovskites has become increasingly popular due to their stability and tunable optoelectronic properties. Their controllable surface chemistry and simple preparation make them a promising alternative to bulk perovskite solar cells. The power conversion efficiency of $Cs_xFA_{1-x}PbI_3$ QD solar cells has been steadily rising, up to a recent record efficiency of more than 16%. However, the alignment and self-assembly of the colloidal precursor into a superstructure during film fabrication via slot-die coating is not yet well-understood. In this work, we study the formation of perovskite QD films using in situ grazing-incidence X-ray scattering on different substrates and at different temperatures, to achieve a better understanding of the kinetic processes during solvent evaporation.

CPP 17.32   Mon 18:00   P3

Steady-State Microwave Conductivity (SSMC) on ionic liquid doped lead halide perovskites — •Patrick Dörflinger[1], Yong Ding[2], Mohammad Khaja Nazeeruddin[2], and Vladimir Dyakonov[1] — [1]Experimental Physics VI, Julius Maximilian University of Würzburg, 97074 Würzburg — [2]Group for Molecular Engineering of Functional Materials, Institute of Chemical Sciences and Engineering, EPFL Valais, Sion 1950, Switzerland

Knowledge of the charge carrier lifetime and recombination behavior in perovskite solar cells is crucial, as non-radiative recombination processes still limit solar cell efficiencies. Here we present a technique to probe the charge carrier recombination. Of particular interest is the dominant charge carrier recombination pathway, which enables to quantify non-radiative recombination in the perovskite bulk. Furthermore, simultaneous photoluminescence measurements allow for estimating the doping density and determining the radiative efficiency at different charge carrier densities. As an example, the SSMC technique is applied to investigate the influence of ionic liquid additives, which are known to improve the stability of perovskite solar cells and the optoelectronic properties of perovskite absorbers.

CPP 17.33   Mon 18:00   P3

Giant Electrostriction in Lead Halide Perovskite MAPbI$_3$ Films as Measured with Double-Modulated Interferometry — •Philipp Ramming[1], Marvin Malchau[2], Emma Rauland[1], Anna Köhler[1], and Lothar Kador[2] — [1]Experimental Physics II, University of Bayreuth, Germany — [2]Institute of Physics and BIMF, University of Bayreuth, Germany

Hybrid lead halide perovskite semiconductor MAPbI$_3$ and similar materials have attracted much recent interest for photovoltaic devices. Upon application of moderate electrical fields, MAPbI$_3$ exhibits very large electrostriction effects. The thickness variation was measured with high precision using a double-modulation interferometer set-up. Phase modulation of the laser light and mechanical modulation of the interferometric path difference were employed. With field strengths on the order of 100 kV/cm, the relative thickness change of a polycrystalline film of 1 micron thickness can be as large as several per cent. The electrostriction varies with the square of the field strength; it is strongest at very low frequencies below one Hertz and decreases quickly at higher frequencies. The effect is compared to recently published data obtained on perovskite single crystals.

CPP 17.34   Mon 18:00   P3

First-principles study of the electronic and optical properties of perovskite solution precursors — •Freerk Schütt[1], Ana M. Valencia[1,2], and Caterina Cocchi[1,2] — [1]Carl von Ossietzky Universität, Institut für Physik, Oldenburg, Germany — [2]Humboldt-Universität zu Berlin und Iris Adlershof, Berlin, Germany

Metal halide perovskites have shown great promise for next-generation optoelectronic applications but the predominant employment of Pb poses a problem in terms of environmental sustainability of these compounds. Replacing Pb with Sn represents a viable solution, however, despite recent efforts in this direction [1], knowledge of Sn-based perovskites and precursors is to date still insufficient. In a first-principles work based on time-dependent density-functional theory coupled to the polarizable continuum model, we systematically investigate electronic and optical properties of SnI_2M_4 complexes, with M being common solvent molecules. We find that the structural, electronic, and optical properties are strongly affected by the choice of the solvent. By rationalising the behavior of 14 of such compounds even in comparison with lead-halide counterparts [2,3], we provide useful indications to complement experiments in the choice of the solvent molecules for SnI_2-based solution complexes and in their characterization towards the production of thin films [4].

CPP 17.35   Mon 18:00   P3

In situ Grazing-Incidence Small-Angle X-ray Scattering Observation of TiOx Sputter Deposition on SnO2 Layer for Perovskite Solar Cells Application — •Xiongzhuo Jiang[1], Zhuijun Xu[1], Yusuf Bulut[1,2], Stephan V. Roth[2,3], and Peter Müller-Buschbaum[1,4] — [1]TUM School of Natural Science, Chair for Functional Materials, 85748 Garching, Germany — [2]Deutsches Elektronen-Synchrotron (DESY), 22607 Hamburg, Germany — [3]Department of Fibre and Polymer Technology, KTH, Stockholm, Sweden — [4]MLZ, TUM, 85748 Garching, Germany

It is crucial for the efficiency perovskite solar cells to promote the charge transport and suppress the non-radiation recombination in the hole blocking layer (HBL) and at the interface between the HBL and the active layer. Here, TiOx layers are deposited onto a SnO2 layer via sputter deposition at room temperature, forming a bilayer HBL. The structure evolution of TiOx during sputter deposition is investigated via in situ grazing-incidence small-angle X-ray scattering. After sputter deposition of TiOx with suitable thickness on the SnO2 layer, the bilayer HBL shows a suitable transmittance, smoother surface roughness, fewer surface defects and more suitable energy arrangement with active layer, and thus resulting in a lower trap-assisted recombination at the interface between the HBL and the active layer. With this SnO2/TiOx functional bilayer, the perovskite solar cells exhibit higher power conversion efficiencies than the unmodified SnO2 monolayer devices.

CPP 17.36   Mon 18:00   P3

Interfacial engineering via modifications of the electron blocking layer in PbS quantum dot solar cells — •Timo Piecuch[1], Huaying Zhong[1], and Peter Müller-Buschbaum[1,2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]MLZ, TUM, Garching, Germany

Colloidal quantum dot solar cells (CQDSCs) have received tremendous attention as next generation solar cells. Best performances up to 15% power conversion efficiency (PCE) have been achieved using lead sulfide quantum dots in a heterojunction cell architecture. PbS is especially efficient in the infrared region, and thus particular interesting for future applications like space satellites. Research in the last years mainly has focused on improving the absorber layer and the hole blocking layer, but the potential by improving the electron blocking layer (EBL) has recently aroused increasing interest. In order to reduce interfacial charge carrier recombination and capture the large fraction of long wavelength photons at the EBL/active layer interface, the different interfacial energy-level offsets between EBL and absorber layer, tuned by the EBL-QDs size, are investigated using ultraviolet photoelectron spectroscopy (UPS) and absorption spectroscopy. Furthermore, the corresponding photovoltaic performances are characterized to demonstrate improved interfacial band alignment.

CPP 17.37   Mon 18:00   P3

PbS Quantum Dot Solar Cells for Space Applications — •Jasper Ebel[1], Huaying Zhong[1], and Peter Müller-Buschbaum[1,2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]MLZ, TUM, Garching, Germany

A key performance parameter for photovoltaics (PVs) on space missions is the power-to-weight ratio since launch costs increase drastically with the mass-to-orbit. During the last decades, several promising, light-weight and flexible alternatives to current silicon- and GaAs-based technology have emerged, such as perovskite, organic or colloidal quantum dot (CQD) based solar cells. Lead sulfide (PbS) CQD solar cells are especially interesting due to their easily size-tunable bandgap range in the infrared regime, allowing for the exploitation of previously unused parts of the solar spectrum. This in conjunction with ligand, solvent and interface-customizable opto-electronic properties makes QD solar cells a promising candidate for tandem solar cells reaching high efficiencies. Here, by mimicking heat and illumination cycles experienced in orbit, we analyse the performance and structural integrity of PbS CQD solar cells under lab conditions to explore the viability of their use for space applications. Repeating this experiment for various solvents, we test a range of devices to investigate their effects on the stability.

CPP 17.38   Mon 18:00   P3

Hybrid Energy Harvester Based on the Combination of Triboelectric Nanogenerator and PbS Quantum Dot Solar Cell — •Tianxiao Xiao[1], Wei Chen[1], Wei Cao[1], and Peter Müller-Buschbaum[1,2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]MLZ, TU München, 85748 Garching, Germany

Developing clean energy lies in the heart of sustainable development of human society. Triboelectric nanogenerator (TENG) originating from Maxwell's displacement current is a new type of energy harvester for harnessing ambient mechanical energy based on the coupling of triboelectrification and electrostatic induction effect. Compared with other counterparts, owing to the light-weight,

low-cost, and easy fabrication, TENG has become one of the most promising candidates in replacement of conventional fossil fuels and attracted worldwide attention in the past years. However, to further increase the energy harvesting efficiency and broaden application fields, integrating the TENG with other kinds of energy harvesters in one device is a possible way to meet these needs. In the present work, a TENG based hybrid energy harvester is designed and fabricated on the flexible polyethylene terephthalate (PET) substrate. This hybrid device consists of a single-electrode mode TENG component and a PbS quantum dot (QD) based solar cell component, which can harness both mechanical and solar energy from ambient environment to directly generate electricity.

CPP 17.39   Mon 18:00   P3

Improved surface passivation of AgBiS2 quantum dots for photovoltaic applications — •Petar Lovric[1], Huaying Zhong[1], and Peter Müller-Buschbaum[1,2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]Heinz Maier-Leibnitz-Zentrum (MLZ), TUM, Garching, Germany

AgBiS2 colloidal quantum dots (QDs) are a non-toxic alternative for the commonly used PbS QDs for photovoltaic applications. Similar to its PbS QDs, they show great promise due to a tunable bandgap and solution processing, but what makes them stand out is the abundance of materials as well as a high absorption coefficient, which enables to greatly reduce the thickness of the active layer to around 35 nm. Additionally, studies have shown that they are more stable in water and can effectively harvest photons in the near-infrared part of the solar spectrum. One of major issue that impedes the development of AgBiS2 based photovoltaics is QD surface defects induced recombination losses. Here, we aim to improve the surface passivation of individual QDs and improve the charge transport in the QD films using surface ligand treatment with ZnI, mercapto-carboxylic acid (MPA) and TBAI as surface ligands. The optical and electrical properties of corresponding QDs films are characterized utilizing FTIR, XPS and UPS techniques, and further the corresponding device performances are investigated.

CPP 17.40   Mon 18:00   P3

Effect of ground state charge transfer and photoinduced charge separation on the energy level alignment at metal halide perovskite / organic charge transport layer interfaces — •Lennart Frohloff[1], Fengshuo Zu[1], Dongguen Shin[1], and Norbert Koch[1,2] — [1]Institut für Physik & IRIS Adlershof, HU Berlin — [2]Helmholtz-Zentrum Berlin

A proper energy level alignment at semiconductor interfaces is of paramount importance for realising high performance in perovskite solar cells. Therefore, we investigated the interface between a modern triple cation perovskite and a prototypical electron acceptor molecule in great detail. Strong band bending on both sides of the junction as well as negatively charged species of the organic molecule were evidenced by the means of photoemission spectroscopy, indicating a ground-state charge rearrangement across the interface. The band bending leads to significantly altered charge extraction offsets as compared to a hypothetical vacuum level alignment and flat band conditions. Additionally, we present direct evidence of a reversible reduction of the electron extraction offset under white light illumination as compared to the dark condition. The energy levels of the organic semiconductor were observed to rigidly shift to lower binding energy by up to 0.26 eV whilst the perovskite energy levels remain essentially unchanged. Consequently, we emphasise the necessity to determine the energy level alignment at interfaces involving perovskites not only in the electronic ground state but also under device operating conditions to allow for a reliable correlation to the performance of the device.

CPP 17.41   Mon 18:00   P3

Active layer aging for the fabricating durable perovskite solar cells with improved reproducibility — •Yuqin Zou[1] and Peter Müller-Buschbaum[1,2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching — [2]MLZ, TUM, Garching

Solution processing of semiconductors is a highly promising approach for the fabrication of cost-effective electronic and optoelectronic devices. Although hybrid perovskites have potential in various device applications, challenges remain in the development of high-quality materials with simultaneously improved processing reproducibility and scalability. Here, we report a facile and practical aging treatment method to modulate crystal growth over the entire film to produces homogeneous films with high crystallinity, low defects and full-coverage. The resulting aged perovskite solar cells (PSCs) exhibits superior electronic properties: fast charge carrier transport, efficient charge extraction and low carrier recombination. The average power conversion efficiency (PCE) of MAPI-based PSCs greatly increase from 16.38% to 17.26% with high reproducibility. In addition, the aged PSCs maintain 80% of their initial PCE after 18 hours of operation under ambient and vacuum conditions, respectively, which illustrates their feasibility in scalable fabrication. Aging treatment effectively prevents the uneven performance and low reproducibility of PSCs arising from variations in the preparation environment (temperature, humidity). Thus, this method opens a new and effective avenue to improving the quality of perovskite films and photovoltaic devices in a scalable and reproducible manner.

CPP 17.42 Mon 18:00 P3

Investigating the Impact of Surfactants on Perovskite Film Formation Using In Situ Optical Spectroscopy — •Tobias Siegert, Simon Biberger, Konstantin Schötz, Anna Köhler, and Fabian Panzer — Soft Matter Optoelectronics (Experimental Physics II), University Bayreuth, Germany

Recent reports have shown that adding surfactants in the solution processing of halide perovskites, e.g. by blade-coating, can improve the morphology and optoelectronic properties of the resulting perovskite sample. In general, the crystallization processes of halide perovskites occuring during thin film formation largely determine the final film morphology. Thus, here we investigate the change in crystallization dynamics upon addition of surfactants to the precurser solution of halide perovskites. We monitor the film formation processes by multimodal optical in situ spectroscopy[1] to gain detailed insights about the film formation process of halide perovskites.[2-4] This finally allows us to elucidate the exact role and the impact of the presence of surfactants during solution processing on the crystallization behavior of the perovskite.

CPP 17.43 Mon 18:00 P3

Exploring the impact of nucleation seeds on the defect formation of printed hybrid perovskite films — •Altantulga Buyan-Arivjikh[1] and Peter Müller-Buschbaum[1,2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching — [2]MLZ, TUM, Garching

In the research of next-generation solar technologies, perovskite-based devices are prominent candidates due to their lucrative power conversion efficiencies and ease of fabrication. Such devices typically contain a polycrystalline perovskite layer grown via various coating methods. Due to the short timeframe of the growth process, the formation of defects is inevitable, leading to increased non-radiative recombination- and decreased extraction of photogenerated charge-carriers. One route to counteract the extensive formation of defects would be the addition of external seeds in the precursor solutions, leading to more controlled nucleation and improved crystallinity of the thin film. In this study, different nucleation seeds in the precursor solutions were used for the fabrication of polycrystalline perovskite thin films via slot-die coating. The effect of the seeds on the formation of defects in the film was explored via optical spectroscopical methods such as UV-vis & PL spectroscopy.

CPP 17.44 Mon 18:00 P3

In-situ observation of growth mechanisms during printing of 2D perovskite films — •Kun Sun[1], Renjun Guo[1], Linus F. Huber[1], Manuel A. Reus[1], Jungui Zhou[1], Matthias Schwartzkopf[2], Stephan V. Roth[2,3], and Peter Müller-Buschbaum[1,4] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]DESY, 22607 Hamburg, Germany — [3]Department of Fiber and Polymer Technology, KTH, SE-100 44 Stockholm, Sweden — [4]MLZ, TUM, 85748 Garching, Germany

Two-dimensional (2D) metal halide perovskites have emerged as a promising candidate for perovskite solar cells (PSCs) due to their remarkable stability compared with their 3D counterparts. However, solution-based spin-coating as fabrication method is not adequate in terms of upscaling. In this regard, the slot-die coating technique, having minimal expenditure and low costs, is a well suitable upscaling method to speed up the commercialization of PSCs. Nevertheless, a fundamental understanding of the film formation during printing is yet not well understood, which causes printed solar cells to stay behind in device efficiencies. Here, we investigate the nucleation and growth of 2D perovskite films during slot-die coating with in-situ grazing incidence wide angle X-ray scattering (GIWAXS) in combination with photoluminescence (PL) during printing. In addition, the crystallite orientation and phase distribution of 2D perovskite containing different dimensionality are well elucidated.

CPP 17.45 Mon 18:00 P3

Design, fabrication and application of PEO-based solid polymer electrolytes for all-solid-state lithium batteries — •Yingying Yan[1] and Peter Müller-Buschbaum[1,2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]Heinz Maier-Leibnitz-Zentrum (MLZ), TUM, Garching, Germany

All-solid-state lithium batteries (ASSLBs) have received extensive attention as one of the most promising power sources for flexible and wearable electronics, mainly because of their high flexibility, high energy density and reliable safety. However, the practical application of ASSLBs has been hindered by the poor interfacial stability and inferior ionic conductivity. Therefore, the exploration of advanced solid electrolytes with superior interfacial compatibility/ionic conductivity is an important research topic for all-solid-state batteries. Solid polymer electrolytes (SPEs) exhibit great potential in developing solid-state batteries, specifically for PEO and PEO-based derivatives, because of their superior interfacial compatibility, outstanding solubility against lithium salts, wide electrochemical windows and high ionic conductivity. At the same time, solid fillers,

as an important component in SPEs, play a crucial role in determining the overall electrochemical properties. As a consequence, we start from PEO-based materials and prepare SPEs by adding plastic additives and solid fillers with good structure. The electrochemical performance and structural stability of SPEs are elucidated by a combination of electrochemical characterization and morphological structural characterization.

CPP 17.46 Mon 18:00 P3

Study of PEO Composite Electrolyte in All-solid-state Lithium Batteries — •Yuxin Liang[1], Zhuijun Xu[1], Kun Sun[1], Tianfu Guan[1], Fabian A.C. Apfelbeck[1], Pan Ding[2], Ian Sharp[2], Matthias Schwartzkopf[3], Stephan V. Roth[3,4], and Peter Müller-Buschbaum[1,5] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]TUM Walter Schottky Institute, Experimental Semiconductor Physics, Garching, Germany — [3]DESY, 22607 Hamburg, Germany — [4]KTH Royal Institute of Technology, Stockholm Sweden — [5]MLZ, TUM, 85748 Garching

Lithium batteries (LBs) with composite electrolyte present good ionic conductivity, flexibility and intimate contact with electrodes. However, lithium dendrites will grow and the Coulombic efficiency (CE) will decrease with Li plating and stripping. Moreover, the poly(ethylene oxide) (PEO)-based electrolyte undergoes serious oxidation on the cathode side at high voltage and cause the battery collapse. Strategies have been applied to alleviate the abovementioned challenges, nevertheless, fundamental research on the degradation mechanism of the PEO electrolyte is still lacking. It is of great value to get a deeper understanding and therefore optimize the electrolyte for high voltage LBs. Herein, we select PEO/Al2O3 as composite electrode to understand the degradation process. The Li/cathode cells are assembled to observe the battery performance and grazing incidence wide-angle X-ray scattering (GIWAXS) is used to detect morphology changes of the electrolyte before and after cycling.

CPP 17.47 Mon 18:00 P3

Influence of Al2O3 concentration in poly(propylene carbonate) based solid polymer electrolyte — •Thien An Pham[1,2], Ralph Gilles[1], and Peter Müller-Buschbaum[1,2] — [1]MLZ, TUM, Garching, Germany — [2]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany

Solid polymer electrolytes (SPE) have emerged as promising electrolyte material group for all-solid-state batteries that allow the operation with Li metal anodes. Representing one of the main obstacles for Li metal anodes, Li dendrite growth can lead to short circuits which ultimately prevent the usage with liquid electrolytes. SPE offer higher mechanical stability compared to their liquid counterparts and thus, increase the general safety of Li metal batteries.

In this work, poly(propylene carbonate) based solid polymer electrolytes were synthesized with Lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) as Li salt and varying Al2O3 concentrations via solution casting. The addition of Al2O3 has shown to increase the ionic conductivity of SPEs while simultaneously improve the mechanical stability. Furthermore, small angle X-ray scattering and FTIR were used to study the influence of Al2O3 on the structure of the SPE.

CPP 17.48 Mon 18:00 P3

Investigating Thermoelectric Properties of a Sodium-based, Solid Polymer-Electrolyte — •Julian-Steven Schilling, Maximilian Frank, and Jens Pflaum — Experimental Physics VI, University of Würzburg, 97074 Würzburg

Motivated by the large amount of available waste heat and the need to use energy more efficiently, the development of thermoelectric generators is becoming increasingly important. Their efficiency is characterized by the thermoelectric figure-of-merit z which includes the electrical conductivity σ, the thermal conductivity κ and the Seebeck coefficient S, respectively, and, at a given temperature T, is given by $zT = \frac{S^2\sigma}{\kappa}T$. In contrast to electronic thermoelectric materials, ionic systems promise larger Seebeck coefficients due to lower mobility of the participating charge carriers . Therefore, ionic electrolytes based on organic polymers are of interest due to their expected good thermoelectric performance. In this work, first results on the thermoelectric properties of a methacrylate-based solid polymer electrolyte utilizing sodium as conducting salt are presented. By means of impedance spectroscopy in a frequency range from 100 mHz to 500 kHz we analyzed the mechanisms governing the electrical conductivity in the technologically relevant temperature range from 273K to 353K. Complementary, thermovoltage measurements as function of temperature enable the determination of the Seebeck coefficient and, together with impedance spectroscopy data, reveal strategies how the electronic and ionic transport properties can be modified by the respective salt concentration as well as by the ratio of different carbon-based additives.

CPP 17.49 Mon 18:00 P3

In-situ force measurements on a gold working electrode in lithium-ion electrolytes — •Sabrina Kerz, Thomas Tilger, and Regine von Klitzing — Department of Physics, Technische Universität Darmstadt, Germany

Batteries have gained a great importance in recent years. They play a vital role in our every-day lives e.g. in mobile-devices and are an important pillar in the transition to renewable energies.

For these applications the solid electrolyte interface (SEI) at electrodes is of great interest. The Gouy-Chapman-Stern (CGS) model describes the interactions of the electrolyte with the charged electrode surface as an interplay between direct adsorption (Stern Layer) and a diffuse double layer. DLVO theory describes the diffuse double layer at the electrode's surface.

In-situ colloidal probe atomic force microscopy (CP-AFM) measures the force between a silica particle and the SEI. The obtained force curves are analyzed using DLVO theory. In a three-electrode setup different potentials are applied between a gold surface (working electrode) and a reference electrode. Thus, changes in the structure of the SEI with varying potentials and salt concentrations are examined.

CPP 17.50   Mon 18:00   P3

High-concentration Lithium-ion Electrolyte Overcomes the Challenges of High-temperature Lithium Batteries — •Tianle Zheng[1,2], Ya-jun Cheng[2], and Peter Müller-Buschbaum[1,3] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Ningbo Institute of Materials Technology & Engineering, CAS, Ningbo, 315201, P. R. China — [3]TUM, MLZ, 85748 Garching, Germany

Conventional Li-ion batteries are severely constrained in high-temperature applications due to the low thermal stability of the electrolyte/electrode interface and electrolyte decomposition in the cell. Herein, we demonstrate a new electrolyte that achieves an excellent stable long-term cycling at 100 ˚C, well beyond the typical 60 ˚C limits of normal conventional Li-ion batteries. High concentrated lithium oxalyldifluoroborate (LiODFB) is selected as the lithium salt with a carefully designed high thermal stability solvent group. As a result, this unique high-concentration electrolyte can promote to form a stable and inorganic solid electrolyte interface layer on the electrode at elevated temperature, leading to improved performance in MCMB/Li and lithium iron phosphate (LFP)/Li half-cells, and achieve reversible capacities of 160 and 350 mA h/g, respectively, with Coulombic efficiencies > 99.3%. Subsequently, we further investigate the mechanism of high concentration LiODFB electrolytes by molecular dynamics simulations and XPS characterization techniques, exploring a new way for future high-temperature electrolytes.

CPP 17.51   Mon 18:00   P3

Morphology Control of Titanium Thin Films in a Low Temperature Process — •Guangjiu Pan[1], Shanshan Yin[1], Linus F. Huber[1], Caroline Ehgartner[2], Nicola Hüsing[2], Matthias Schwartzkopf[3], Stephan V. Roth[3,4], and Peter Müller-Buschbaum[1,5] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Universität Salzburg, 5020 Salzburg, Austria — [3]DESY, 22607 Hamburg, Germany — [4]KTH Royal Institute of Technology, SE 100 44 Stockholm, Sweden — [5]TUM, MLZ, 85748 Garching, Germany

A low-temperature routine to realize inorganic hole-blocking layers (HBLs) is important for the commercialization of perovskite solar cells. Fabricating HBLs at low temperature is energy-saving and compatible with flexible substrates. In this work, titania thin films are synthesized at low temperature (below 100 Celsius degree) with a polymer template sol-gel method based on the amphiphilic diblock copolymer polystyrene-b-polyethylene oxide (PS-b-PEO), in combination with selective incorporation of the titanium precursor ethylene glycol-modified titanate (EGMT). A joint process of UV treatment and water-vapor treatment is introduced to substitute the traditional high-temperature calcination. Morphology tailoring of titania thin films in the low-temperature process is achieved by managing phase separation of the polymer template. The surface morphologies of titania films are probed via scanning electron microscopy and GISAXS. The optical properties are examined with ultraviolet-visible spectroscopy and photoluminescence spectra.

Bilayer formation in liquid-processed mono-functionalized BTBT films — Tim Hawly, •Andreas Späth, Manuel Johnson, Marcus Halik, Mingjian Wu, Erdmann Spiecker, and Rainer H. Fink — FAU Erlangen-Nürnberg, Erlangen, Germany

Two-dimensionally (2D) extended thin films of the p-type organic semiconductor C13-BTBT were fabricated by self-controlled growth at the water-toluene interface. Depicting a compound class originally developed for further functionalization and subsequent realization of self-assembled monolayers (SAMs) or their implementation into SAM-based organic field-effect transistors, the potent BTBT core unit commonly excels in high-quality structure formation as well as charge-transport characteristics. Utilizing various spectromicroscopic tools, we observe extraordinarily crystalline C13-BTBT films with a close to upright standing configuration of the BTBT backbone accounting for superior intermolecular orbital overlap. The well-defined morphology and internal structure of the film are underpinned by superior charge-transport parameters in corresponding OFETs. The inherently favorable membrane-like bilayer molecular arrangement is confirmed by the unambiguous representation of the unit cell as derived from STEM tomography. This study has been funded by the DFG within GRK 1896, the BMBF (contract 05K19WE2) and the Bavarian SolTECH initiative. [1] T. Hawly et al., ACS Adv. Energy Mat.(2022)/doi:10.1021/acsaelm.2c01095

CPP 17.53   Mon 18:00   P3

Characterization of pure DbSeQ thin films and their multilayers with different semiconductor materials — •Anton Pylypenko, Elena Chulanova, Alexander Gerlach, and Frank Schreiber — Universität Tübingen, Auf der Morgenstelle 10, 72076 Tübingen, Germany

Organic semiconductor thin films are widely used in different areas of science and industry, especially for the manufacturing of organic optoelectronic devices. Bilayers of organic semiconductors are of high interest for research due to the possibility of increasing the advantages of blended materials [1]. Prospective candidates for these applications are derivatives of 2,1,3-benzothiadiazole, especially Dibenzoselenadiazoloquinoxoline (DbSeQ). The heavy atom has a strong impact on the spin-orbit coupling and thus the optical properties of the film. Understanding and investigating mechanisms of growth behavior is a key requirement for optimizing films.

We have investigated thin film growth and templating effects for various bilayers like DbSeQ:PIC or DbSeQ:DIP. The binary thin films are prepared by consistent evaporation of DbSeQ, DIP, and PIC on weakly interacting substrates under ultra-high vacuum conditions. Using ex-situ AFM, UV-VIS, and photoluminescence spectroscopies, X-ray reflectometry, and grazing-incidence wide-angle X-ray scattering, we have observed the morphology, structure, and crystallinity of bilayer films.

CPP 17.54   Mon 18:00   P3

Tunable morphologies in charged multiblock terpolymers in thin film geometry: effect of solvent vapor annealing — •Bahar Yazdanshenas[1], Florian A. Jung[1], Tim Bohnen[1], Sina Ariaee[2], Dorthe Posselt[2], Heinz Amenitsch[3], Constantinos Tsitsilianis[4], and Christine M. Papadakis[1] — [1]Technische Universität München, TUM School of Natural Sciences, Soft Matter Physics group, Garching, Germany — [2]Roskilde University, Department of Science and Environment, Roskilde, Denmark — [3]Graz University of Technology, Institute of Inorganic Chemistry, Graz, Austria — [4]University of Patras, Department of Chemical Engineering, Patras, Greece

Thin films of a pentablock terpolymer with an ABCBA architecture of two types of pH-responsive midblocks and short hydrophobic end blocks are investigated. As-prepared spin-coated films from different pH-values have previously shown highly tunable and non-monotonous behavior of the lateral structure sizes, based on the charge [1]. Here, we investigate further accessible morphologies by swelling the films in the vapors of solvents having different selectivity. Results from spectral reflectance, atomic force microscopy, and grazing-incidence small-angle X-ray scattering suggest that a solvent selective for the pH-responsive blocks leaves the nanostructures intact, while a nonselective solvent enables reorganization. Their vapor mixtures are also studied to potentially access further orientations and morphologies. In addition, an ABA triblock copolymer is investigated as a reference. [1] F. A. Jung, C. M. Papadakis et al., Adv. Funct. Mater. 2021, 31, 2102905.

CPP 17.55   Mon 18:00   P3

Computer simulations of liquids in extreme Confinement — •Luca Muigg[1], Gerhard Jung[2], Thomas Franosch[1], and Rolf Schilling[3] — [1]Institute for Theoretical physics, Universität Innsbruck, Innsbruck, Austria. — [2]Laboratoire Charles Coulomb (L2C), Université de Montpellier, CNRS, 34095 Montpellier, France. — [3]Institut für Physik, Johannes Gutenberg-Universität Mainz, Germany.

Computer simulations of a monodisperse hard-sphere liquid confined between two parallel hard walls of accessible width L are performed. By reducing the distance between the walls the two- dimensional limit $L \rightarrow 0$ is approached. An analysis of structural properties, such as the structure factor and the radial distribution function shows convergence to their two- dimensional counterparts, which is in agreement to the theoretical predictions. Furthermore an isobaric-like ensemble, with the slit width as an additional degree of freedom is introduced to study the behavior of the compressibility.

CPP 17.56   Mon 18:00   P3

Exploring the deposition conditions for formation of larger homogeneous colloidal arrays — •Joanne Neumann, Jan Rubeck, Andrei Chumakov, and Matthias Schwartzkopf — DESY, Photon Science, Notkestr. 85, D-22607 Hamburg

Installing regular arrays on mesoscopic length scales plays an important role in nanotechnology to create uniform templates for sputter deposition or plasma treatments. Different techniques of self-assembly via solvent evaporation out of dispersions have been used to obtain highly ordered colloidal structures. We used spin-coating, Langmuir-Blodgett (LB) technique and spray-deposition, representing the most attractive tools for the formation of larger homogeneous colloidal arrays on plain substrates. Due to their different deposition and boundary conditions, the assembly behaviour of polystyrene nanoparticles varies, resulting in two-dimensional layers with LB-technique and a large variety of pattern by spray deposition. We present our first results from atomic force microscopy and microbeam grazing incidence small-angle x-ray scattering (GISAXS).

CPP 17.57   Mon 18:00   P3

Incorporation of Nanomaterials to Form Electrically Conductive Multilayers with the Layer-by-Layer Technique — •Muhammad Khurram[1], Sven Neuber[2], Annekatrin Sill[3], and Christiane A. Helm[4] — [1]muhammad.khurram@uni-greifswald.de — [2]sven.neuber@uni-greifswald.de — [3]annekatrin.sill@uni-greifswald.de — [4]helm@uni-greifswald.de

Surface modification of an implant provides an adequate bio-interface and determines which promotes cell adhesion and proliferation. To promote healing, the coating should be electrically conductive. The Layer-by-Layer (LbL) method * sequential adsorption of oppositely charged macromolecules or nanoparticles - has become prominent in coating and functionalizing a surface. Polyelectrolytes show poor charge transfer capabilities; therefore, electrically conductive nanoparticles are essential. MXene nanoparticles are investigated. The MXene contains a high aspect ratio, functional groups, and good electrical conductivity. LbL films are built from polyanion MXene and polycation polydiallyldimethylammonium (PDADMA). In addition, the conductive and conjugated polymers poly(3,4-ethylene dioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) is used because of their promising electrical properties. PDADMA is again the polycation. With the Atomic Force Microscope (AFM) film morphology and roughness are determined. Layer growth is monitored by UV-Vis Spectroscopy and ellipsometry. The electrical conductivity is determined with the two-point method.

CPP 17.58   Mon 18:00   P3

Band Gap Modification of 2D Covalent-Organic Frameworks (COFs) with Electron Rich and Electron Deficient Molecules — •Laura Fuchs, Konrad Merkel, and Frank Ortmann — School of Natural Sciences, Technische Universität München

A new type of porous materials are covalent-organic frameworks (COFs), which are suitable candidates as active substances for solar cells due to their highly tunable physical and electronic properties. Introducing electron rich (donor) and electron deficient (acceptor) regions to the molecular structure of 2D-COFs has an significant influence on the energetic levels of the highest occupied (HOMOs) and lowest unoccupied molecular orbitals (LUMOs). We provide insights to construction principles for band gap modifications by comparing the nature of the effect of widely-known electron acceptor and donor molecules[1] on the frontier electronic levels, as well as their impact on the charge density distribution using ab initio calculations within the density functional theory (DFT).

[1]Chua, M. H., Zhu, Q., Tang, T., Shah, K. W., & Xu, J. (2019). Diversity of electron acceptor groups in donor-acceptor type electrochromic conjugated polymers. Solar Energy Materials and Solar Cells, 197, 32-75.

From a Completely Different Angle: Exploring Twistronics in Layered Materials with Atomic Force Microscopy — •Alexander Klasen[1] and James Kerfoot[2] — [1]Park Systems Europe GmbH Schildkroetstrasse 15,68199 Mannheim, Germany — [2]Park Systems UK Limited, MediCity Nottingham Thane Road NG90 8BH, Nottingham, UK

Single atomic layer-based systems emerged as a promising class of materials with unique optical, mechanical, and electronic properties that could provide a pathway to novel applications.1,2 Their two-dimensional nature gives rise to a wide range of tunability since their functional properties do not only depend on the type of atoms and bonds within one plane but also on the strain, local defects, and interplay between adjacent layers.3,4 Here, we present Atomic Force Microscopy (AFM) based approaches as an ideal toolbox to map various functional properties of 2D materials and heterostructures on a nanometer scale. More specifically, by deterministically breaking and re-stacking single flakes of layered materials, we form homostructures of both hexagonal boron nitride (hBN) and molybdenum disulfide (MoS2) Investigating ferroelectric superlattices on a hexagonal boron nitride bilayer on a graphene single layer, we can induce domain switching when applying a constant DC potential and study them via Piezoelectric Force Microscopy.5,6 We will show how conductive AFM (C-AFM) and Lateral Force Microscopy (LFM) allow imaging strain variations as distorted domains in both the current channel and the lateral force channel.

CPP 17.60   Mon 18:00   P3

Lieb lattice embedded in square polymer — •Yingying Zhang, Miroslav Položij, and Thomas Heine — Faculty of Chemistry and Food Chemistry, TU Dresden, Dresden, Germany

Dirac cone and flat band are exotic band features, which attracted much attention in these years, in which the movement of charge carriers is massless fermions, leading to ultra-high carrier mobility and various quantum Hall effects. Structure in lieb lattice owns these two intriguing bands simultaneously, characterized by one dispersive Dirac band inserted with a flat band, which may give rise to many exotic quantum phenomena such as ferromagnetism, topological states, or superconductivity.

The theoretical TB model predicted that the idea lieb band requires rigorous lattice symmetry and zero next-nearest neighbor (NNN) hopping, making the lieb band rarely found in real materials except widely studied via TB model or photonic and cold-atom. There are only two synthesized structures with lieb band were reported.

Therefore, I studied a systematic square phthalocyanine COF with a defined length of linkers, showing that the lieb band is embedded in square polymer. The Pc-xBz COFs show how the band evolution between square and lieb is based on a series of structures with extending linkers. The band structure and charge density distribution are analyzed to further study the electronic properties. We also show that, by charge doping and atom replacement, the fermi level can be tailored to the lieb band position, making the structure intriguing and potential.

Use of a multiple hydride donor to achieve an n-doped polymer with high solvent resistance — Farzaneh Saeedifard[1,2], Dominique Lungwitz[3], Zi-Di Yu[4], Sebastian Schneider[5], Ahmed E. Mansour[3,6], •Andreas Opitz[3], Stephen Barlow[1,2], Michael F. Toney[1], Jian Pei[4], Norbert Koch[3,6], and Seth R. Marder[1,2] — [1]University of Colorado Boulder, US — [2]Georgia Institute of Technology, Atlanta, US — [3]Humboldt-Universität zu Berlin, Germany — [4]Peking University, China — [5]Stanford University, US — [6]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Germany

Insolubilization of doped semiconducting polymer layers can help to fabricate efficient multilayer solution-processed electronic and opto-electronic devices. Here, we present a promising technique to simultaneously n-dope and largely insolubilize conjugated polymer films using tetrakis[4-(1,3-dimethyl-2,3-dihydro-1H-benzo[d]imidazol-2-yl)phenoxymethyl]methane (tetrakis-O-DMBI-H), which consists of four 2,3-dihydro-1H-benzoimidazole (DMBI-H) n-dopant moieties covalently linked to one another. [1] Doping a thiophene-fused benzodifurandione-based oligo(p-phenylenevinylene)-co-thiophene polymer (TBDOPV-T) with tetrakis-O-DMBI-H results in a highly n-doped film with bulk conductivity of 15 S/cm. Optical absorption spectra reveal a film retention of ~93% after immersion in o-dichlorobenzene for 5 min. This is caused by multiple electrostatic interactions the multiple electrostatic interactions between each dopant tetra-cation and up to four nearby anionic doped polymer segments.

Numerical Simulation of Crystallization Kinetics in Binary Mixtures for Organic Photovoltaic Applications — •Maxime Siber, Olivier Ronsin, and Jens Harting — Helmholtz-Institute Erlangen-Nürnberg for Renewable Energies (HI-ERN), Germany

With the aim to understand the formation process of organic photoactive layers, and identify process-structure relationships in order to optimize their fabrication, a computational framework relying on the phase-field modelling approach has recently been developed. It is now sought to quantitatively compare numerical simulations of drying organic photovoltaic (OPV) films with corresponding experimental realizations.

Since the fabrication process involves the interplay of multiple physical phenomena, which separate characterization already is a challenging task from the simulative, as well as from the experimental side, this first study focusses on crystallization behaviour in isothermal, non-evaporating, binary OPV blends. In particular, this talk addresses crystalline structures that arise from different crystallization processes such as solution-triggered crystallization, diffusion-limited crystallization, or spinodal decomposition-assisted crystallization. Furthermore, crystallization kinetics quantified for several blend ratios and material parameters are also analyzed and compared. Finally, perspectives regarding validation against in-situ experiments and derivation of design rules for OPV film fabrication are also provided.

CPP 18.3 Tue 10:00 GÖR 226

Optical properties of perfluorotetracene (PFT) crystal polymorphs — •Ana Maria Valencia[1,2] and Caterina Cocchi[1,2] — [1]Institut für Physik, Carl von Ossietzky Universität Oldenburg — [2]Physics Dept., Humboldt-Universität zu Berlin und IRIS Adlershof

The family of perfluorinated acenes is gaining popularity among organic materials for optoelectronics. Since the electronic and optical properties of molecular solids are crucially dependent on their packing motifs, it is crucial to consider crystalline phases in the simulations to understand the structure-property relationships of these materials, especially regarding electronic correlations and excitations. Here, we investigate from first principles by means of density functional theory and many-body perturbation theory the electronic structure and the optical excitations of two crystal polymorphs of perfluorotetracene, considering for comparison tetracene and the corresponding isolated molecules. This way, we can assess the effects of fluorination as well as of the crystal periodicity. We find that the absorption spectra are only mildly influenced by the packing motif. However, our analysis gives insight into the exciton binding energies as well as the spatial distribution of the excitons. We inspect not only the first excitations but also the higher-energy ones, thus providing an all-around understanding of the optical excitations in these materials.

CPP 18.4 Tue 10:15 GÖR 226

Controlling long-range order in dip coated piezo- and ferroelectric molecular materials — •Andrey Butkevich and Martijn Kemerink — Institute for Molecular Systems Engineering and Advanced Materials, Im Neuenheimer Feld 225, 69120 Heidelberg, Germany

Organic piezo- and ferroelectrics are of great interest due to their tunable properties. However, the extensive procedures that are often required to achieve saturation polarization limit their possible applications. A so far unexplored possible solution is to pre-align the molecules during the deposition from solution. Here, we analyzed the effect of dip coating parameters on the alignment of multiple supramolecular piezo- and ferroelectrics. Dip coated films were characterized for different material concentrations and dip coating velocities. The investigation revealed that morphologies with strong alignment along the dip coating direction are formed for both material types. For ferroelectrics, the changes in the ferroelectric switching behavior of the resulting thin films were investigated. The ferroelectric switching was investigated using the double wave method, revealing that dip coating perpendicular to the electrodes leads to an almost perfect in-plane alignment of the supramolecular polymers, which was confirmed by X-ray diffraction. The observed switching behavior was comparable to films that were aligned via conventional field-annealing. Hence, dip coating enhanced the ferroelectric switching in the investigated molecules, which we anticipate can be directly transferable to other molecular ferroelectrics.

CPP 18.5 Tue 10:30 GÖR 226

In search of novel organic ferroelectrics — •Heiko Mager — IMSEAM, Heidelberg University

The switchable polarization and concomitant pyroelectric and piezoelectric properties of ferroelectric materials enable a variety of applications, ranging from memory devices over thermal and mechanical sensors to energy harvesters. Although current applications are dominated by inorganic materials, organic ferroelectrics offer a flexible, cheap and possibly non-toxic and biodegradable alternative.

Here, we present experimental research on the ferroelectric-like behavior of the novel liquid crystalline molecule C6H6F5O-C3-Amide and its molecular derivatives. To screen for a possible para- to ferroelectric phase transitions, dielectric spectroscopy was employed. While the for ferroelectric materials characteristic Curie-Weiß behavior was not directly observed, features in the dielectric suggest a possible phase transition coinciding with a peak in differential scanning calorimetry traces.

Polarization hysteresis loops were obtained via double wave measurements and characteristic capacitance- voltage "butterfly" loops measured. Comparisons between the different molecular derivatives allow insights into the molecular groups relevant for the switching process.

CPP 18.6 Tue 10:45 GÖR 226

Implementation and simulation of drift-diffusion models for organic mixed conductor devices — •Andres David Peña Unigarro[1,2] and Florian Steffen Gunther[2,3] — [1]Institute of physics, TU Chemnitz, Chemnitz, Germany — [2]IFSC, University of São Paulo, Brazil — [3]UNESP, Rio Claro, Brazil

Organic electrochemical transistors (OECTs) have emerged as potential transducers in applications that require the conversion of ion fluxes to electronic current. For the understanding of the fundamental mechanism in OECTs and OECT-based applications, as well as for their rational optimization, however, it is essential to have theoretical models that agree with experimentally measured device responds. Most of the existing OECT models consider that the ion flux from the electrolyte into the organic, semiconducting layer takes place only due to an electrical field. These models are efficient to describe the steady state operations of OECTs, but are rather limited when compared to transient behaviors.

Recently, more refined models which take a diffusion term into account, have been developed. The simplifications needed to use an analytical solution of the governing equation, however, reduces its generality, limiting the results to specific cases. In our work, we use numerical methods to solve the drift-diffusion equation in one dimension to overcome these limitations of the analytical solution. This allows us to go beyond the standard boundary conditions and to analyze the impact of other alterations.

CPP 18.7 Tue 11:00 GÖR 226

Noise in Organics Semiconductors and Devices — •Priya Viji, Dorothea Scheunemann, Constantin Tormann, and Martijn Kemerink — Institute for Molecular Systems Engineering and Advanced Materials, Heidelberg University, Germany

Noise, typically considered an unwanted signal in measurements, can also contain information about the charge kinetics in organic semiconductors. Since the corresponding devices often show high resistances and capacitances, the measurement of -albeit very small- current fluctuations via voltage noise is most suitable. To quantify this noise and to eliminate noise from other devices in the measurement line, a cross-correlation technique is implemented and applied to P3HT doped with varying concentrations of F4TCNQ. The results compare quantitatively with kinetic Monte Carlo simulations in which noise calculations were implemented. To understand the effect of the electric field on the charge carriers, disentangling noise in directions parallel and perpendicular to the electric field is essential. The direction perpendicular to the electric field does show a gradual increase at high electric fields, which matches the concept of an Effective Temperature, as described by Marianer and Shklovskii, in which the effects of electric field and lattice temperature are combined. In the direction of the electric field, an additional contribution due to shot noise is observed. However, its magnitude deviates from the theoretical prediction of shot noise, which can be quantified as a non-unity Fano-factor.

Uniaxially Aligned Merocyanine Films by Graphene Nanoribbon Templated Growth — •Philipp Weitkamp, Lukas Böhner, Nora Gildemeister, Dirk Hertel, and Klaus Meerholz — Physikalische Chemie, Universität zu Köln, Deutschland

We herein report the unique and novel approach of achieving a polycrystalline thin film consisting of uniaxially aligned domains by using 7-armchair graphene nanoribbon (7-aGNR) monolayers as van-der-Waals template. For this purpose, a merocyanine dye was evaporated on 7-aGNRs, transferred on quartz glass substrates. The alignment of the formed molecular aggregate along the GNR alignment direction was proven by polarisation dependent absorbance spectroscopy. The J- and H-transition, formed by the dye aggregate, were correlated with distinct axes of the crystal structure. By combining this correlation with polarisation dependent absorbance measurements and X-ray diffraction experiments we elucidated the three-dimensional structure of the formed aggregate thin film. The growth mode of these films was investigated as a function of the applied layer thickness. Atomic force microscopy-based morphology analysis and X-ray diffraction experiments were used to reveal the anisotropic on-surface crystallisation along the 7-aGNR long axes direction. Furthermore, we found that the delocalisation length of the aggregate increases with increasing in-plane order. Finally, we demonstrated that the in-plane alignment leads to an anisotropic charge carrier transport by implementing the templated merocyanine thin film as active layer in a top-gated organic field effect transistor.

CPP 18.9 Tue 11:45 GÖR 226

Investigation on organic light-emitting diodes, fabricated by a self-developed and highly automated physical vapor deposition system — •Fabian Binder, Mona Löther, Pascal Schady, Vladimir Dyakonov, and Andreas Sperlich — Experimental Physics VI, Julius Maximilian University of Würzburg, 97074 Würzburg

Organic light emitting diodes (OLEDs) are most commonly produced in ultra-high vacuum by physical vapor deposition (PVD) of several organic and metallic layers on a carrier substrate. We developed an automated PVD system, mainly consisting of two vacuum chambers for organic and metal deposition, respectively. Stepper motors and sensor solutions ensure a smooth and precise positioning of the carrier substrate above the evaporation crucibles. The substrate is then rotated with a defined speed to achieve an even deposition of the material. In order to vapor-deposit material, a certain material-specific temperature range is required which is realized by a software-based temperature controller which manages the evaporation rate according to the user's specifications. A user interface facilitates planning of the desired OLED layer stack and provides information about the production progress. The capabilities of our new PVD system were tested by producing OLEDs based on multiple-resonance TADF emitters of the DABNA series. We performed electro-optical LJV-characterization and determined the devices'quantum efficiencies. The results of this investigation will enable us to optimize the production process with regard to evaporation rates and layer thicknesses.

CPP 18.10 Tue 12:00 GÖR 226

improvement of electrical transport in organic semiconductor thin films by charge transfer doping — •Hongwon Kim[1], Andreas Opitz[2], Florian Fenzl[1], and Wolfgang Brütting[1] — [1]Experimentalphysik IV, Institut für Physik, Universität Augsburg — [2]Institut für Physik, Supramolekulare Systeme, HU zu Berlin

Charge carrier transport in organic semiconductor is based on the hopping mechanism. We have used in-situ charge transfer doping during film-growth to improve the electrical conductivity by simultaneously increasing the carrier density and reducing their thermal activation energy. By doping planar organic semiconductors, such as DBTTF, a-6T, and DIP, with strong acceptors (F6-TCNNQ & HATCN), hybridization of pi-orbitals occurs while generating new interphases (charge transfer complex, CTC). On the other hand, DBP, a non-planar molecule, forms an amorphous thin film without any CTC generation. To measure the characteristics of CTC, we used near-infrared transmission spectroscopy, which can detect the absorption peaks of CTCs and the energy gap. In addition, the activation energy is obtained from temperature-dependent conductivity measurements. We observe a correlation between the magnitude of the electrical conductivity and its activation energy, which can be ascribed to the binding energy of CTCs. Depending on the specific system, conductivity maxima are observed between 10 and 30% molar doping ratios.

Electrical transport dynamics of conducting polymers in nanoconfinement — Sukanya Das and •K.S. Narayan — Chemistry and Physics of Materials Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Bengaluru-560064, India

Inherently disordered conducting polymers consist of different characteristic lengths, defect distribution over the polymer chains and their microstructural modifications can alter the transport properties significantly. The electrical transport of conducting polymers such as poly(3,4-ethylene dioxythiophene): poly(styrenesulfonate) PEDOT:PSS has shown conductivity enhancement when confined in an array of nanochannels in the form of alumina nanopillars. The transverse conductivity along the nanopillar axis, which is an otherwise suppressed quantity, increases nonlinearly by approximately three orders in magnitude as the diameter of the scaffold-channel is decreased to 20 nm, when measured at single nanochannel level as well as at bulk-macroscopic level. This suggests the major role of dimensions and geometry in eliciting efficient electrical transport. Similarly, more than 3 orders of conductivity increase have been shown by in-situ polymerized poly(3,4-ethylenedioxythiophene):tosylate within the nanochannels which has similar electronic backbone PEDOT but a different dopant environment. The microscopic insight into PEDOT:Tos has shown higher degree of crystallinity and ordering as compared to PEDOT:PSS nanochannels. We utilize this property of PEDOT:PSS to fabricate hybrid

organic-inorganic perovskite photodiode with efficient hole extraction and faster response times in the nanoconfined devices.

CPP 18.12 Tue 12:30 GÖR 226

In-situ spectro-electrochemistry of N-type conjugated organic systems for opto-electronic and electro-optic applications — •Meenal Kataria and Sabine Ludwigs — IPOC-Functional Polymers, Institute of Polymer Chemistry, University of Stuttgart, Pfaffenwaldring 55, 70569 Stuttgart, Germany

This talk will highlight our ongoing research on in-situ spectroelectrochemistry. We are developing functional organic conjugated materials and devices for opto-electronic and electro-optic applications. Here, one of our aims is to utilize an in-situ spectroelectrochemical approach to calculate the energy levels of blends of donor polymers (e.g. PM6) and non-fullerene acceptors (e.g. Y6) utilized for high performance organic solar cells. For relevant device information it is important to have precise values of energy levels of the same blend systems as used in devices. Thus, our absorption assisted electrochemistry technique proved be advantageous approach (1). In another research work discussing the effect of isomerism on conductivity of n-type polymers (e.g. P(NDI2OD-T2)), this above approach has been used to identify the redox states during electrochemical doping which helped to identify the charge transfer transport mechanism (2). In the last example, this technique has been utilized to calculate the frontier energy levels of push-pull D-π-A systems and to study the effect of acceptor strength on their energy levels (3).

CPP 18.13 Tue 12:45 GÖR 226

Delocalization Enhances Conductivity at High Doping Concentrations — •Dennis Derewjanko[1], Dorothea Scheunemann[1], Emmy Järsvall[2], Anna I. Hofmann[2], Christian Müller[2], and Martijn Kemerink[1] — [1]IMSEAM, Heidelberg University, Im Neuenheimer Feld 225, 69120 Heidelberg, Germany — [2]Department of Chemistry and Chemical Engineering, Chalmers University of Technology, 41296 Gothenburg, Sweden

Many p-type organic semiconductors are experimentally found to follow a universal power-law trend between conductivity and charge carrier concentration at practically relevant high doping levels. This behavior cannot consistently be explained by conventional charge transport models. Here, we develop a physically transparent model based on the combination of a tight binding model and a variable range hopping model to show that the observed power-law trend can be explained by consideration of an energy dependent localization length. The underlying cause is an energetic lifting of the charge carriers to partly delocalized states due to the rising Fermi energy level at high charge carrier concentration. At low charge carrier concentrations, the well-known Mott-Martens model is recovered.

Multiscale Model of Flow-Induced Crystallization in Polymers — David Nicholson, Marat Andreev, Chenmay Gangal, and •Gregory Rutledge — Massachusetts Institute of Technology, Cambridge, MA USA

The structure and properties of a semicrystalline polymer depends sensitively on both its chemico-physical nature and the way it is processed. Flow-induced crystallization (FIC) is one such coupled phenomenon. Models of FIC in polymers must account for the effect of flow on crystallization kinetics, but also the effect of evolving crystallinity on the rheology of the flowing polymer melt. For the first part, atomistic nonequilibrium molecular dynamics (NEMD) simulations are used to characterize the nucleation of a new crystal phase from the polymer melt under homogeneous flow conditions. The kinetics of nucleation are characterized using a mean first-passage time analysis, and a model based on the orientational ordering of Kuhn segments is proposed. For the second part, a variation of the discrete slip-link model (DSM) is used for the rheology of entangled polymer melts that accounts for partial crystallinity through the introduction of crosslinked *bridge* and/or *dangling* segments between developing crystallites, combined with a suspension model to reflect the stiffening associated with a growing crystal phase. This dual-network/suspension model describes well the evolution of both viscoelasticity and crystallinity for a number of linear low-density polyethylenes, and affords a deeper understanding of the essential physics that underlie the coupling between fluid mechanics and phase change.

CPP 19.2 Tue 10:00 MER 02

Polyethylene crystallization induced by a solution-prefolded nucleus — •Timur Shakirov and Wolfgang Paul — University of Halle, Halle, Germany
We present results of molecular dynamics simulations of an undercooled

polyethylene melt. We simulate a system of 2000 chains of 150 monomers each with the PYS force-field [1]. To initiate crystallization we insert in the melt a small two-chain nucleus (which we pre-fold in the vacuum) and cool down the system to 280 K. The crystalline lamella forms around the inserted nucleus during the cooling process and grows further at constant temperature. We characterize the growing crystallite by its average diameter (typical linear size in the cross-section perpendicular to the crystal director) and the height of the lamella (the averaged size along the crystal director). Both, diameter and height of lamella, grow during the entire simulation (~ 900 ns at the final temperature). A saturation of the growth is observed only as the crystallite reaches the surrounding spontaneously formed crystallites. Our analysis of the chain kinetics in the inner volume of the crystallite shows remaining chain mobility along the chain director. The distribution of short-time displacements of the inner-crystalline monomers has signatures of discrete jumps of a single bond length along the director of the crystal.

CPP 19.3 Tue 10:15 MER 02

How to grow semicrystalline lamellae in MD simulations — William Fall[1,2], Jörg Baschnagel[1], Olivier Lhost[3], and •Hendrik Meyer[1] — [1]Institut Charles Sadron, CNRS UPR22 and Université de Strasbourg, France — [2]LPS Université Paris-Saclay, Orsay, France — [3]TotalEnergies One Tech Belgium, Zone Industrielle C, 7181 Feluy, Belgium

To investigate the influence of short chain branches in the crystallization of high molecular weight polyethylene (PE) we adapted a united monomer model for molecular dynamics simulations. We showed recently that a small fraction of branches allows to control the lamellar thickness in the semicrystalline structures [Macromol **55** (2022) 8434]. This work is extended to bidisperse mixtures

of highly entangled C_{4000} and C_{400} with different branch distributions mimicking industrial PE morphologies. A self-seeding protocol is presented which allows to simulate the growth of well aligned lamella, and analyse morphological features. We thank TotalEnergies for funding and GENCI/IDRIS (Orsay) and CAIUS/HPC centre (Strasbourg).

CPP 19.4 Tue 10:30 MER 02

Crystallization precursors in polymer melt analyzed by machine learning — •Atmika Bhardwaj[1,2], Marco Werner[1], and Jens-Uwe Sommer[1,2] — [1]Leibniz-Institut für Polymerforschung Dresden e. V., Hohe Str. 6, D-01069 Dresden, Germany — [2]Institute for Theoretical Physics, Technische Universität Dresden, Zellescher Weg 17, D-01069 Dresden, Germany

Crystallization in polymers is a long-standing problem in both experimental and theoretical polymer science. The transition dynamics occurring in an undercooled polymer melt is a local environmental phenomenon rather than a property of individual particles (or monomers) and depends on subtle conformation patterns such as entanglements between the chains. We develop machine learning (ML) methods to study this non-equilibrium thermodynamic process. Upon recognizing the relevant parameter set to explore different phases during polymer crystallization, we investigate the spatial and temporal patterns of the precursor states that determine the nucleation sites. The objective is to recognize the precursors that stimulate crystal growth before the occurrence of such development.

CPP 19.5 Tue 10:45 MER 02

How entanglements determine the morphology of semicrystalline polymers — Zefan Wang, Mareen Schaller, Albrecht Petzold, Kay Saalwächter, and •Thomas Thurn-Albrecht — Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, 06099 Halle

Crystallization of polymers from entangled melts generally leads to the formation of semicrystalline materials with a nanoscopic lamellar morphology. Controlling this structure is key to the rational design of thermoplastic materials, but there is no consensus yet on the factors that control the thickness of the amorphous layers and therefore together with the crystal thickness the crystallinity. We here elucidate the effect of entanglements on the morphology in a series of model blends of high-molecular-weight polymers with unentangled oligomers leading to a reduced entanglement density in the melt as characterized by rheological measurements. Small-angle X-ray scattering experiments after isothermal crystallization reveal a reduced thickness of the amorphous layers, while the crystal thickness remains largely unaffected. A simple yet quantitative model without adjustable parameter is suggested, according to which the measured thickness of the amorphous layers adjusts itself in such a way that the entanglement concentration reaches a specific maximum value.

CPP 19.6 Tue 11:00 MER 02

Modelling Study of Reinforcement and Crack Formation in Strain-Crystallizing Elastomer Networks — •Lena Tarrach[1], Reinhard Hentschke[1], and Jan Weilert[2] — [1]Bergische Universität Wuppertal, Wuppertal, Germany — [2]Covestro Deutschland AG, Leverkusen, Germany

A coarse-grained model has been developed to simulate reinforcement and crack formation in strain-crystallizing elastomer networks. This work is based on the model for strain-induced crystallization (SIC) proposed by Plagge and Hentschke [1], which here is extended for the investigation of rupture.

Generally, strain-crystallizing elastomer networks possess a higher tensile strength than non-crystallizing networks. Therefore, the force on the links, i.e. the polymer chains in the model network, is analyzed to define a critical force for their rupture. It is examined how structural parameters and parameters for the free energy of semi-crystalline links affect the tensile strength of strain-crystallizing networks compared to non-crystallizing networks. The variation of these parameters does not improve the tensile strength in both the 2D- and the 3D-case.

Thus, a critical crystallinity, which makes certain links unbreakable, is introduced to model the alignment of the polymer backbones along the stretching direction. The tensile strength of 2D- and 3D-networks is enhanced.

[1] Plagge, J. & Hentschke, R. Microphase Separation in Strain-Crystallizing Rubber. *Macromolecules* **54**, 5629-5635. https://doi.org/10.1021/acs.macromol.1c00757 (2021).

CPP 19.7 Tue 11:30 MER 02

New experimental setup to analyze structure formation in thermoplastic polymer melts — •Anna Katharina Sambale[1], Eric Euchler[1], Regine Boldt[1], Kai Uhlig[1], Laura Neumann[1], Konrad Schneider[1], Matthias Schwartzkopf[2], Stephan Roth[2,3], and Markus Stommel[1,4] — [1]Leibniz-Institut fuer Polymerforschung, Dresden, Germany — [2]Deutsches Elektronen Synchrotron DESY, Hamburg, Germany — [3]KTH Royal Institute of Technology, Stockholm, Sweden — [4]Technical University Dresden, Dresden, Germany

The microstructure of semi-crystalline thermoplastics is significantly influenced by the processing procedure and its parameters. Inhomogeneous shear and ex-

tensional flow fields occurring during processing can cause constraints to the chain conformations, which in turn lead to altered crystallization behavior. Although the influence of crystallization kinetics on the properties of the most commonly used polymers is considered to be sufficiently known, (local) conditions and parameters in commercially used melt processing technologies are not fully understood. We recently started to develop a new experimental setup to study structure formation in polymers induced by melt processing. The first results on the crystallization processes in quiescent polymer melts under isothermal conditions investigated by X-ray scattering measurements will be presented. In particular, time- and temperature-dependent crystallization of polylactic acid (PLA) and isotactic polypropylene (iPP) with different crystallization rates were examined and proved the concept of the experimental setup.

CPP 19.8 Tue 11:45 MER 02

The missing billions in hard sphere nucleation — Sahana Kale, Nidhi Joshi, and •Hans Joachim Schöpe — Universität Tübingen, Institut für angewandte Physik, Auf der Morgenstelle 10, 72076 Tübingen

Crystal nucleation in colloidal hard spheres is a longstanding research topic in colloidal science. Light scattering experiments as well as simulations have been carried out to determine key parameters characterizing the nucleation process and to get a microscopic picture of the fluid to crystal transformation. In these studies, results both differ and agree with each other. It is still unclear whether the large disagreement in the nucleation rate densities between the experiments and simulations are of physical nature or result from different data analyses. Using laser-scanning confocal microscopy and polarization microscopy we study crystal nucleation in colloidal hard spheres. The used systems have been characterized with extreme care to allow for meaningful comparison with other experiments and simulations. We present high quality data of the nucleation rate density and key parameters describing crystal nucleation. Analyzing the nucleation process we conclude that classical nucleation theory fails.

CPP 19.9 Tue 12:00 MER 02

Non-metallic quasicrystals minimize sphere packing energy — •Martin Dulle[1], Vladislava Fokina[1], Thomas Gruhn[2], and Stephan Förster[1] — [1]Forschungszentrum Jülich, Jülich, Germany — [2]Universität Bayreuth, Bayreuth, Germany

Quasicrystals are a peculiar state of order, which is fundamentally different from classical ordered crystalline states. Discovered in 1982 for metal alloys, they have in recent years also been reported for an increasing number of non-metallic materials.

Using MD-simulations we calculate the phase diagram of soft repulsive core/shell particles and find stability regions for seven different octagonal, decagonal, dodecagonal and icosahedral quasicrystals. We compare the structure and stability region of the dodecaganol phase with experiments on different polymer and nanoparticle systems and find quantitative agreement. We identify a new high density dodecagonal phase in a large number of reported non-metallic quasicrystalline systems including polymers, mesoporous silica, surfactants, BaTiO3, TaTe and MnCrNiSi. All remaining reported non-metallic quasicrystals can be related to the other simulated quasicrystal types.

We geometrically derive all respective tilings and show how in-plane quasicrystalline order is combined with axial periodic order via the realization of certain gyro-elongated bipyramids. This geometrical arrangement minimizes sphere packing energy for certain length scale ratios and particle densities, irrespective of the absolute length scale, the type of interactions and chemical constituents.

CPP 19.10 Tue 12:15 MER 02

Controlling internal structure of colloidal supraparticles - crystalline to amorphous — •Yashraj Wani[1], Melis Yetkin[2], Michael Kappl[2], Hans-Jürgen Butt[2], and Arash Nikoubashman[1] — [1]Institute of Physics, JGU Mainz, Germany — [2]Max Planck Institute for Polymer Research, Mainz, Germany

Colloidal supraparticles made from smaller nanoparticles (NPs) are versatile materials whose properties can be tailored through the chemistry and ordering of their constituent NPs. Such supraparticles can be scalably fabricated using solvent-drying processes that assemble NPs inside liquid droplets. In charge stabilized dispersions, the interactions can be controlled by the salt concentration, which we systematically probed in experiments and simulations. In experiments at low salt concentrations, the dried supraparticles exhibited high crystalline order, whereas amorphous structures were found at high salinity. To understand this evaporation-induced structure formation, we first determined the interaction potentials between NPs via colloidal probe atomic force microscopy and dynamic light scattering experiments. Using these pair potentials, we carried out particle-based simulations to study the aggregation behavior in detail: At low salt concentrations, the effective NP-NP interactions remained purely repulsive until the end of drying, resulting in highly crystalline supraparticles. At higher salt concentrations, however, the electrostatic repulsion became screened, leading to the formation of small NP aggregates at early stages of drying, which then eventually merged into an amorphous supraparticles.

CPP 19.11 Tue 12:30 MER 02

Unravelling the synthesis of halide perovskite nanoplatelets by SAXS — •Kilian Frank[1], Carola Lampe[2], Alexander S. Urban[2], and Bert Nickel[1] — [1]Soft Condensed Matter Group and CeNS, Faculty of Physics, LMU Munich — [2]Nanospectroscopy Group and CeNS, Nano-Institute, Faculty of Physics, LMU Munich

Halide perovskite nanoplatelets (NPLs) are a promising material for optoelectronic applications, such as LEDs and single photon emitters. While highly scalable and reliable ligand-assisted synthesis routes exist, a detailed structural understanding of the underlying pathways is lacking. We elucidate the processes of nucleation, growth, and superstructure assembly of $CsPbBr_3$ NPLs using in situ small-angle X-ray scattering (SAXS), total scattering (TS) and photoluminescence (PL) spectroscopy during the synthesis. Thereby we enable even better control of the platelet thickness on the monolayer level, and therefore of the emission wavelength, due to quantum confinement. For this purpose we built and used a specialized reaction cell for in situ synthesis at the beamlines P07 and P62 (PETRAIII, DESY, Hamburg). By SAXS analysis we follow the assembly of the constituents into a regular superstructure. In addition, we investigated the effect of post-synthetic treatment of the NPLs using the same setup to further enhance their optoelectronic properties. With our results we contribute to the development of assembly-based synthesis routes for size-tunable nanomaterials. Such materials are of particular interest to the perovskite community as building blocks for hierarchical structures.

CPP 19.12 Tue 12:45 MER 02

From protein adsorption to crystallization: a simultaneous real-time QCM-D and microscopy study — •Hadra Banks, Furio Surfaro, Simon Storz, Anna Maischberger, Cara Buchholz, Kai-Florian Pastryk, Alexander Gerlach, and Frank Schreiber — University of Tübingen, Germany

Protein crystallization is widely investigated by employing a homogeneous nucleation approach; however, it is predicted that heterogeneous nucleation is energetically more favorable [1]. Nevertheless, only few experimental studies on the nucleation of protein crystals at surfaces are available, since this is a complex phenomenon and requires surface-sensitive techniques. Here, quartz crystal microbalance with dissipation monitoring (QCM-D), a real-time surface-sensitive technique, was employed simultaneously with optical microscopy to investigate protein adsorption and crystallization at a negatively charged surface. Human serum albumin (HSA) and β-lactoglobulin (BLG), in the presence of a trivalent salt, were used as model systems for the study of heterogeneous nucleation [2]. We found that their surface behavior during crystallization exhibit complex phenomena such as wetting transition, enhanced adsorption, and layer rearrangements. The results highlight the importance of the interaction between proteins and surfaces and how this can influence protein phase behavior.

CPP 20: Polymer and Molecular Dynamics, Friction and Rheology

Time: Tuesday 9:30–12:30 Location: ZEU 255

Invited Talk CPP 20.1 Tue 9:30 ZEU 255

Granular Matter Rheology – fluid-/solid-like behavior and state-transitions — •Stefan Luding — University of Twente, NL

The dynamic and static behavior of particulate and granular matter (like sand, powder, suspended particles, often with a wide distribution of particle sizes) is of considerable interest in a wide range of industries and research disciplines. Special is that they can behave both solid-like and fluid-like, which is a challenge for both academia and industry. The related mechanisms/processes in particle systems are active at multiple scales (from nano-meters to meters), and explaining their multiple states, and transitions, will lead to a better understanding of natural disasters like avalanches or industrial problems like silo-failure.

To understand the fundamental micro-mechanics and -physics, one can use particle simulation methods. However, large-scale applications (due to their enormous particle numbers) have to be addressed by coarse-grained models or by continuum theory. For this, to derive constitutive rheology relations, so-called micro-macro transition methods are necessary, which translate particle positions, velocities and forces into density-, stress-, and strain-fields, which must be compatible with the balance equations for mass, momentum, and energy of continuum theory. Additional non-classical fields describe the micro-structure (fabric, force-chains) or the statistical fluctuations,before an universal granular rheology can be defined, involving state-transitions between the states, the so-called jamming/un-jamming transitions.

CPP 20.2 Tue 10:00 ZEU 255

Phase-Sensitive, Active Microrheology via Probe-Free Application of Thermoviscous Flows — •Iliya Stoev, Elena Erben, Venkat Krishnaswamy, Antonio Minopoli, Susan Wagner, Benjamin Seelbinder, Nicola Maghelli, and Moritz Kreysing — Max Planck Institute of Molecular Cell Biology and Genetics, Pfotenhauerstraße 108, 01307, Dresden, Germany

We recently found how thermoviscous expansion phenomena give rise to a new, contactless particle trap that is characterised by a linear force-extension relationship and can therefore be employed in non-invasively measuring femtoNewton forces with thermally limited sensitivity. Our new force-measurement method is based on optically generated flows, thereby lifting prerequisites related to the probe material and resulting in only moderate heating at the position of the micromanipulated object. This methodology offers an appealing alternative to the use of optical tweezers in highly delicate samples and living systems. Next, we asked the question if our thermoviscous flows can be used to obtain more quantitative data and possibly demonstrate the equivalence between flow-driven and force-driven rheology in their ability to extract phase angles as a measure of relative mechanics. With our new flow-based and phase-sensitive microrheology, we provide access to the mechanics of highly viscous media, tenuous gels and even cellular cytoplasm. Further refinements of the method aim at multiplexing and removing the need for using fluorescent tags.

CPP 20.3 Tue 10:15 ZEU 255

Nanoscopic Friction on Monolayer MoS_2 in Presence of Water Investigated with Molecular Dynamics — •Miljan Dašić and Igor Stanković — Scientific Computing Laboratory, Center for the Study of Complex Systems, Institute of Physics Belgrade, University of Belgrade, Pregrevica 118, 11080 Belgrade, Serbia

We have implemented and applied a molecular dynamics (MD) simulation setup in order to study the nanoscopic friction on monolayer MoS_2 plate in the presence of different quantities of water. Our setup mimics a standard AFM experiment, including an amorphous SiO_2 probe, a monolayer crystalline MoS_2 plate, and water molecules in-between. Presence of water molecules matches experimental conditions of air humidity. We studied two different quantities of water: (1) *full water layer* - SiO_2 probe is fully immersed in water and surrounded by water molecules, and (2) *capillary water* - water forms a capillary around the SiO_2 probe, with lateral vacuum gaps. We conducted two modes of simulations: vertical approach of SiO_2 probe towards MoS_2 plate and lateral sliding of SiO_2 probe. There are always *trapped* water molecules in the gap between the probe and the plate; their number drops with the increase of temperature. We have obtained well-pronounced *stick-slip* friction loops; we found that an increase of the applied normal load leads to the more pronounced stick-slip behaviour, as seen in AFM experiments. The amount of water present in the studied nanoscopic tribosystem has a pronounced impact on the stick-slip frictional behaviour.

CPP 20.4 Tue 10:30 ZEU 255

Polymers of Intrinsic Microporosity - Molecular Mobility and Physical Aging Revisited by Dielectric Spectroscopy and X-Ray Scattering — •Farnaz Emamverdi, Glen Jacob Smales, Martin Böhning, and Andreas Schönhals — Bundesanstalt für Materialforschung und -prüfung (BAM), Unter den Eichen 87, 12205 Berlin, Germany

The applications of polymers of intrinsic microporosity (PIMs) membranes are restrained by their strong tendency to physical aging. Aging phenomenon involves a significant loss of their good performance in gas separation technology. The initial microporous structure approach a denser state via local rearrangements, leading to a reduction of the permeability. In this work, the dielectric behavior of PIM-1 films and their behavior upon hating (aging) were revisited by isothermal frequency scans during different heating/cooling cycles over a broad temperature range between 133 K and 523 K. In addition, the obtained results were compared with data of samples that were annealed at ambient temperatures over different time scales. Multiple dielectric processes were observed: several relaxation processes due to local fluctuations and a Maxwell-Wagner-Sillars polarization effect related to microporosity. The temperature dependence of the rates of all processes follows the Arrhenius law where the estimated activation energy depends on the nature of the process. SAXS/WAXS patterns were measured as a function of temperature during heating/cooling in a temperature range corresponding to that covered by dielectric spectroscopy. The influence of the aging on the processes is discussed in detail.

CPP 20.5 Tue 10:45 ZEU 255

Viscoplastic Modeling of Surface Relief Grating Growth on Isotropic and Pre-oriented Azopolymer Films — Tverdokhleb Nina[1], Loebner Sarah[2], Santer Svetlana[2], and •Marina Saphiannikova[1] — [1]Institute Theory of Polymers, Leibniz Institute of Polymer Research Dresden, 01069 Dresden, Germany — [2]Institute of Physics and Astronomy, University of Potsdam, 14476 Potsdam, Germany

We report on solving two intriguing issues concerning the inscription of surface relief gratings within azopolymer thin films under irradiation with SS, PP and RL interference patterns. For this, we utilize the orientation approach and viscoplastic modeling in combination with experimental results, where the change in surface topography is acquired in-situ during irradiation with modulated light. First, the initial orientation state of polymer backbones is proved to be responsible for the contradictory experimental reports about the efficiency of the SS interference pattern. Different orientation states can influence not only the phase of SS grating but also its height, which is confirmed experimentally using special pre-treatments. Second, faster growth of gratings inscribed by the RL interference pattern is shown to be promoted by a weak photo-softening effect. Overall, the modeled results are in good agreement with the order of relative growth efficiency: RL-PP-SS.

CPP 20.6 Tue 11:00 ZEU 255

Equilibration of free-standing films of highly entangled polymer melts — •Hsiao-Ping Hsu and Kurt Kremer — Max-Planck-Institut für Polymerforschung, Ackermannweg 10, 55128, Mainz, Germany

Equilibrating confined and free-standing films of highly entangled polymer melts is a challenge for computer simulations. We approach this problem by first studying polymer melts based on a soft-sphere coarse-grained model confined between two walls. The distance of the walls is compatible with the simulation box of bulk melts in equilibrium, while periodic boundary conditions in the directions parallel to the walls are kept. Then we successively insert more fine grained polymer representations until the underlying microscopic details of the bead-spring model are reached. Tuning the wall potential, the monomer density of confined polymer melts in equilibrium is kept at bulk melt density even near the walls. Switching to another recently developed variant of the bead-spring model we can study melts at zero pressure [1] and study free-standing polymer films [2]. Furthermore, this also allows us to study free-standing films under strain and analyze the influence of entanglements on the local film morphology. [1] H.-P. Hsu, K. Kremer, J. Chem. Phys. 150, 091101 (2019); 150, 159902 (2019). [2] H.-P. Hsu, K. Kremer, J. Chem. Phys. 153, 144902 (2020); 156, 019901 (2022).

CPP 20.7 Tue 11:30 ZEU 255

A nanofluidic system based on cylindrical polymer brushes: molecular dynamics simulation and scaling theory — •Cheng-Wu Li — Leibniz-Institut für Polymerforschung Dresden, Germany

Using molecular dynamics simulations and scaling theory, we present a systematic study of the function of cylindrical nanopores which are decorated with polymer brushes. Our focus is on the regimes in which these systems are able to function as controllable (switchable) gates for bulky nanoparticles. In a slightly poorer solvent, closed cylindrical brushes facilitate the self-organised formation of droplets from a continuous flow of incoming nanoparticles We analyze droplet formation and propagation by means of simple scaling arguments which are tested in the simulations. Polymer brushes in marginally poor solvents serve as a pressure feedback system, exhibit a collapse transition under the moderate pressure of the incident flow, without the need for additional external stimuli, and finally close spontaneously after droplet passage. Our results qualitatively demonstrate the control of polymer brushes over continuous fluids and droplet formation, and its effectiveness as a means of fluid control can be used to design nanofluidic rectification devices that operate reliably under moderate pressure.

CPP 20.8 Tue 11:45 ZEU 255

Polymer chain dynamics under shear studied by rheological NMR — •Ulrich Scheler — Leibniz-Institut für Polymerforschung Dresden e.V., Dresden, Germany

The NMR spin-lattice relaxation time T2 is particularly sensitive to slow chain-segment motion in polymers, at least two components in the signal decay are observed, a faster relaxing component from chain segments of motion restricted by crosslinks or entanglements and a slower component associated with parts moving more freely. Ordering of the polymer chains under shear would result in restrictions for the segment motion and thus a shortening of T2, a loss of entanglements due to the shear results in a prolongation of T2. Rheological NMR combined external shear with NMR experiments. In a polymer melt of poly(dimethylsiloxane) under shear longer relaxation times are observed. Together with a reduction of the fraction of shorter T2 this indicates the loss of entanglements is the dominating process for high molecular weight. In a new experimental setup both the amplitude and the frequency of the deformation are varied. It demonstrates that a minimum strain rate above 1000/s is required to observe the loss of entanglements. Combining pulsed-field-gradient (PFG) NMR with NMR imaging permits to measure flow pattern. After the turning point in oscillatory shear counterflow is observed when a fraction of the liquid at the static wall still is in initial flow direction while liquid in contact with the moving bob started in the new direction. At this time the velocity gradient drastically exceeds the velocity gradient at the point of maximum velocity representing a high shear rate.

CPP 20.9 Tue 12:00 ZEU 255

On the Relaxation Behavior of Linear Chains under Oscillatory Forces — •Ron Dockhorn[1] and Jens-Uwe Sommer[1,2] — [1]Leibniz-Institut für Polymerforschung Dresden e.V., D-01069 Dresden, Germany — [2]Technische Universität Dresden, Institut für Theoretische Physik, D-01069 Dresden, Germany

We are studying the relaxation spectra and the force-extension behavior of linear chains under externally driven oscillatory periodic forces f in means of theory and simulations. An oscillatory force $f = f_0 + f_a \cdot \sin(\omega t)$ is applied on the chain ends and the response of the end-to-end-distance R as well as the relaxation time τ_R on the oscillatory frequency ω is investigated. An analytical expression for the end-to-end-distance $R(f)$ is derived by using the Rouse model and compared to simulations. The dissipated energy is calculated by the hysteresis loop $A = \left| \oint df R(f) \right|$, which shows a characteristic maximum at $\omega \tau_R \simeq 1$ for ideal chains independent of the applied force. Contrary, excluded volume chains show a force dependence on the relaxation time $\tau_R \sim f^{-0.3}$ as well as a shift on the hysteresis in the Pincus regime. Extensive computer simulations are performed to investigate the scaling properties utilizing the Bond-Fluctuation-Model. Furthermore, the relaxation behavior of different polymer architectures (ring polymer, 3_1-trefoil knot, two concatenate rings) are compared to the linear chain behavior. The theory and simulations suggests implications for dynamic experiments of biopolymer subject to external forces.

Orientation Polarization Spectroscopy — •Friedrich Kremer, Wycliffe Kipnusu, and Markus Anton — Leipzig University, Peter Debye Institute for Soft Matter Physics, Linnéstr.5, 04103 Leipzig, Germany

The theory of orientation polarization and dielectric relaxation was developed by P. Debye more than 100 years ago. It is based on approximating a molecule by a sphere having one or more dipole moments. By that the detailed intra- and inter-molecular interactions are explicitly not taken into consideration. In this contribution the principal limitations of the Debye approximation are discussed and novel experiments based on Quantum Cascade IR-Lasers are presented [1] which enable to determine the orientation polarization of selected molecular moieties for the example of the glass forming liquid glycerol. Electronic and optical properties of thin film P3HT-based thermoelectrics — •Simon Schraad[1,2], Benedikt Sochor[1], Constantin Harder[1,3], Peter Müller-Buschbaum[3,4], Tim Laarmann[1,2], and Stephan Volkher Roth[1,5] — [1]Deutsches Elektronen Synchrotron DESY, Notkestraße 85, 22607 Hamburg, Germany — [2]University Hamburg, Mittelweg 177, 20148 Hamburg, Germany — [3]MLZ, TUM, 85747 Garching, Germany — [4]Research Neutron Source Heinz Maier-Leibnitz, Lichtenbergstraße 1, 85747 Garching, Germany — [5]KTH Royal Institute of Technology, Teknikringen 56-58, Stockholm, Sweden

The polymer Poly(3-hexylthiophen-2,5-diyl) (P3HT) is widely considered in research of organic electronics. If doped with metal chlorides or nanoparticles, P3HT shows thermoelectric properties. Deposition of small gold domains inside the polymer films optimizes the charge transport properties and thermoelectric Seebeck-coefficient and hence the so-called figure of merit zT. There is usually an AU, P3HT intermixing layer near the surface, but implanting the dopant deep inside the organic films results in higher thermoelectric coefficients. P3HT and Poly(3-hexylthiophen-2,5-diyl)-block-poly(methyl methacrylate) (P3HT-b-PMMA) diblock copolymer derivates were prepared by spray deposition and doped via chloroauric acid. Here, structural, optical and (thermo-)electrical properties were determined using AFM, ellipsometry as well as conductivity measurements. The results are a first step towards sprayed organic thermoelectric device, with great scalability potential in future industrial applications.

CPP 26.2 Tue 14:15 MER 02
On the way to sustainable photoluminescent tags — •Heidi Thomas, Shuaifei Zhu, Sebastian Schellhammer, and Sebastian Reineke — IAPP, TU Dresden

Recently, by using amorphous purely organic systems, we have been able to develop transparent programmable luminescent tags (PLTs) which can be used for labelling application or data storage [1,2]. So far the system consists of a phosphorescent organic emitter embedded in poly(methyl methacrylate) on quartz substrate or flexible foil. An oxygen-blocking layer allows for the spatial control of the phosphoresence of the system. The demand for sustainable solutions is high motivating the design of ecofriendly information storage. Here we present the investigation of suitable biocompatible and/or biodegradable polymers and emitters for their use in PLTs.

Programmed Assembly of Dipolar Precursors into Porous, Crystalline Molecular Thin Films — •Alexei Nefedov[1], Ritesh Haldar[1], Zhiyun Xu[1], Hannes Kühner[1], Dennis Hofmann[2], David Goll[2], Benedikt Sapotta[1], Stefan Hecht[3], Marjan Krstić[1], Carsten Rockstuhl[1], Wolfgang Wenzel[1], Stefan Bräse[1], Petra Tegerer[2], Egbert Zojer[4], and Christof Wöll[1] — [1]Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany — [2]Universität Heidelberg, Heidelberg, Germany — [3]RWTH Aachen University, Aachen, Germany — [4]Graz University of Technology, Graz, Austria

Liquid-phase, quasi-epitaxial growth has been used to stack asymmetric, dipolar organic compounds on inorganic substrates, permitting porous, crystalline molecular materials which lack inversion symmetry. This allows material fabrication with built-in electric fields. We describe a new programmed assembly strategy based on metal-organic frameworks (MOFs) that facilitates crystalline, non-centrosymmetric space groups for achiral compounds. Electric fields are integrated into crystalline, porous thin films with an orientation normal to the substrate. Changes in electrostatic potential are detected via core-level shifts of marker atoms on the MOF thin films and agree with theoretical results. The integration of built-in electric fields into molecular solids creates possibilities for band structure engineering to control the alignment of electronic levels in organic molecules and it may also be used to tune the transfer of charges from donors loaded via programmed assembly into MOF pores.

Strong Solvatochromism in a Two Metal Center Photocatalyst Molecule — •Miftahussurur Hamidi Putra[1] and Axel Gross[1,2] — [1]Universität Ulm Institut für Theoretische Chemie Mez-Starck-Haus Oberberghof 7 89081 Ulm Deutschland — [2]Helmholtz Institute Ulm (HIU) Electrochemical Energy Storage, 89069 Ulm, Deutschland

In the theoretical study presented here, we show that the electronic and optical properties of a molecular photocatalyst can strongly depend on the solvent it is dissolved in [1]. Ground-state density functional theory and linear response time dependent density functional theory calculations are applied in order to investigate the influence of implicit solvents on the structural, electronic and optical properties of a two metal center molecular photocatalyst $[(tbbpy)_2Ru(tpphz)PtI_2]^{2+}$ (RuPtI$_2$) [2]. These calculations predict a significant dependence of the HOMO-LUMO gap of the photocatalyst on the dielectric constant of the solvent. We elucidate the electronic origins of this strong solvatochromic effect and sketch the consequences of these insights for the use of

photocatalysts in different environments.

Dynamic Charge-Transport and Charge-Transfer Regimes for Electron-Phonon-Coupled Molecular Systems — •Michel Panhans, Sebastian Hutsch, and Frank Ortmann — Department of Chemistry, TU München

Different approaches for charge transport in organic solids exist but they differ significantly in the described physics of the electron-phonon coupling. In our recent work, we investigate the charge-transfer dynamics, the fading of transient localization (TL) and the formation of polarons for a large range of vibration frequencies and temperatures in the phase space of the two-site Holstein model. The combined numerical and analytical method is based on the time-domain Kubo formula of electrical conductivity to describe the highly correlated electron-phonon dynamics from femtoseconds to very large time scales, reaching nanoseconds. We identify three charge-transport regimes, which are TL, soft gating, and polaron transport. Of particular interest is the built up of correlations between the electronic motion and the nuclei manifesting in the crossover between TL and polaron transport. We find, that the transition between these two limiting cases is seamless at all temperatures and all adiabatic ratios even for the low-frequency vibrational modes that were often considered to be frozen.

CPP 28.3 Wed 10:00 GÖR 226

Multichromophore Macrocycles of Perylene Bisimide Dyes as Fluorescent OLED Emitters — •Björn Ewald[1], Ulrich Müller[1], Peter Spenst[2], Philipp Kagerer[1], Theodor Kaiser[1], Matthias Stolte[2], Frank Würthner[2], and Jens Pflaum[1] — [1]Experimental Physics VI, University of Würzburg, 97074 Würzburg — [2]Institut für Organische Chemie and Center for Nanosystems Chemistry, University of Würzburg, 97074 Würzburg

Highly efficient electroluminescence from Organic Light Emitting Diodes (OLEDs) is limited by the non-radiative character of triplet states for conventional fluorophores. While fluorescent emitters benefit from high radiative recombination rates on the order of 10^9 s^{-1}, they lack from dark triplet states with lifetimes up to several μs or ms. Here we elucidate the potential of perylene bisimide macrocycles as a novel class of fluorescent OLED emitters by applying photon-correlation studies. The correlation experiments unfold additional excitonic relaxation pathways shortening the dark state lifetime for the covalently linked perylene bisimide chromophores. A trimeric chemical design leads to efficient single-photon emission from optically excited thin film samples and even under electrical operation in OLEDs. To the best of our knowledge this is the first indication of electrically-driven single-photon emission from a fluorescent molecule [1]. Therefor we consider our work to constitute an important step towards the design of state-of-the art fluorescent OLED emitters that might also feature a high potential for application in non-calssical single-photon sources.

CPP 28.4 Wed 10:15 GÖR 226

A Tool Kit for Analyzing Emission Spectra of Multi-Molecular States — •Sebastian Hammer[1,4], Theresa Linderl[1], Kristofer Tvingstedt[1], Wolfgang Bruetting[2], and Jens Pflaum[1,3] — [1]Experimental Physics VI, University of Würzburg, 97074 Würzburg — [2]Institute of Physics, University of Augsburg, 86135 Augsburg, Germany — [3]Bayerisches Zentrum für Angewandte Energieforschung (ZAE Bayern), 97074 Würzburg — [4]Departments for Physics and Chemistry, McGill University, Montreal, Canada

The performance of opto-electronic devices is often crucially impacted by multi-molecular excited states such as charge-transfer (CT) states or excimers. Hence, the spectroscopic analysis of these states is a common tool in the characterization of such systems. Due to the many parameters at play full quantum mechanical interpretations are tedious and therefore the analysis is often performed on a phenomenological level only. Here we present a tool kit to analyze temperature dependent emission spectra using a Franck-Condon based approach with a single effective inter-molecular vibrational mode and discuss the implications of considering different potentials for the ground and excited state harmonic oscillators [1]. Finally, we show that fundamental parameters of the potential energy landscape can be extracted from temperature dependent steady state emission spectra using the example of a tetraphenyldibenzoperiflanthene:C$_{60}$ CT heterostructure [2]. Funding from the DFG (Project 490894053) is greatfully acknowledged.

CPP 28.5 Wed 10:30 GÖR 226

Singlet Fission search in polyacene molecules in gas-phase and on rare-gas clusters using ab initio methods — •Selmane Ferchane and Michael Walter — Institute of Physics, University of Freiburg, Germany

Singlet fission (SF), is a spontaneous photo-excited splitting phenomenon. Where an organic chromophore dimer, converts its singlet exciton into a pair of triplet excitons. A great promise for future photon-to-current conversion of solar energy using organic materials with high efficiency. To get more insight into these processes of SF, we employed different ab initio theories and approaches in our investigation, namely, density functional theory (DFT), TD-DFT, MCTDH, and CASPT2/CASSCF. Since the spatial orientation is crucial to whether the molecule will go SF and the rate of it due to the orbital coupling of both molecules, based on recent studies. We calculate the most favorable orientation of the chromophores with the binding energies in the gas phase and adsorbed on Argon and Neon surfaces. Then we calculate the lowest-lying excited states that contribute to the singlet and triple transition plus the search for the possible conical intersection that crosses the surface potential energies.

CPP 28.6 Wed 10:45 GÖR 226

Template-Designed Organic Electronics — •Klaus Meerholz — Chemistry Department, University of Cologne, Greinstr. 4-6, 50939 Cologne, Germany

Worldwide, organic electronic devices such as OLEDs and solar cells have revolutionized the field of electronics; however, technological progress has been largely made by empirical research and development, while fundamental knowledge is often still incomplete.

This presentation will report results from the DFG-funded Research Training Group Template-Designed Organic Electronics addressing the question, how structural order influences the optoelectronic properties of pi-conjugated materials, and how these properties can be improved via the use of templates for the optimization of devices. Our approach spans all the way from the design of appropriate pi-conjugated molecular building blocks and surface-active templates, investigation of surfaces and interfaces by different spectroscopies, fabrication of optoelectronic devices, and finally theoretically modelling.

CPP 28.7 Wed 11:00 GÖR 226

Optically detected magnetic resonance of TADF OLED emitters — •Pascal Schady, Mona Löther, Fabian Binder, Vladimir Dyakonov, and Andreas Sperlich — Experimental Physics VI, Julius Maximilian University of Würzburg, 97074 Würzburg

Thermally activated delayed fluorescence (TADF) is an efficient triplet harvesting mechanism for organic light-emitting diodes (OLED). Molecular TADF Donor-Acceptor type emitters are limited by low reverse intersystem crossing (rISC) rates and broad spectra, making them less suitable for potential OLED devices. In contrast, so-called multiple resonance (MR) effect emitters, are very promising as they show narrowband emission, even for deep blue wavelengths. MR-TADF emitters consist mostly of planar and rigidly bound benzyl groups with boron and nitrogen substituents for HOMO and LUMO pinning. As a result, the exchange integral is small, therefore the energy gap between singlet and triplet states is low enough to efficiently populate emissive singlet states by up-converting long-lived triplet states via thermal excitation, even at room temperature. However, many MR-TADF materials, like the DABNA-series behave differently in solution or as a solid. We therefore are investigating the spin system of those emitters by optically detected magnetic resonance (ODMR) in order to shed light on spin-dependent efficiency limiting pathways and how to address them to improve future OLED devices.

CPP 28.8 Wed 11:30 GÖR 226

Influence of Fluorination on the Temperature Dependent Optical Transition in β- Phase ZnPc Single Crystals — •Lisa Schraut-May[1], Kilian Strauss[1], Sebastian Hammer[2], Kilian Frank[3], Bert Nickel[3], and Jens Pflaum[1] — [1]Experimental Physics VI, University of Würzburg — [2]Departments of Physics and Chemistry, McGill University, Montreal, Canada — [3]Department of Physics, LMU Munich

The possibility of fluorination renders zinc phthalocyanine (ZnPc) an excellent model system to study the interplay between molecular packing and opto-electronic properties [1]. Here, we conduct temperature as well as polarisation dependent photoluminescence (PL) studies on β-phase ZnPc single crystals with different degrees of fluorination to modify the microscopic packing and, thus, the interaction between the molecules. For plain ZnPc an exceptionally sharp PL peak can be observed at temperatures below 100 K, which can be attributed to a superradiant enhancement [2]. Since this coherent coupling between several molecules strongly depends on the intermolecular spacing, we show, that this phenomenon can be steered by the fluorination of the molecules involved. We interpret the resulting PL signal and its temperature dependence in combination with X-ray studies by a model based on coupled excitons whose coupling is affected by the spatial anisotropy of the thermal contraction of the crystal lattice.

We thank the Bavarian research network SolTech for financial support. [1] Rödel et al., J. Phys. Chem. C (2022) [2] Hestand et al., Chem. Rev. (2018)

CPP 28.9 Wed 11:45 GÖR 226

Charge Delocalization and Vibronic Couplings in Quadrupolar Squaraine Dyes — Daniel Timmer[1], Fulu Zheng[2], Moritz Gittinger[1], Thomas Quenzel[1], •Daniel C. Lünemann[1], Katrin Winte[1], Yu Zhang[3], Mohamed E. Madjet[2], Jennifer Zablocki[4], Arne Lützen[4], Jin-Hui Zhong[1], Antonietta De Sio[1], Thomas Frauenheim[2], Sergei Tretiak[3], and Christoph Lienau[1] — [1]University of Oldenburg, Germany — [2]University of Bremen, Germany — [3]Los Alamos National Laboratory, USA — [4]University of Bonn, Germany

Squaraines are prototypical quadrupolar charge-transfer chromophores. Their optical properties are often rationalized using an essential state model, predicting that optical transitions to the lowest excited state (S1) are one-photon allowed and to the next higher state (S2) are only two-photon-allowed and that vibronic coupling to high-frequency modes is greatly reduced. Here, we combine time-resolved spectroscopy techniques and quantum-chemical simulations to test and rationalize these predictions. We find the one-photon-allowed S1 and two-photon-allowed S2 states to be energetically well-separated. Also, we find small Huang-Rhys factors, especially for the high-frequency modes. The resulting concentration of the oscillator strength in a narrow spectral region around the S1 transition makes squaraines almost perfect optical two-level. Thus, these molecules and their aggregates are exceptionally interesting for e.g. strong coupling applications. [1]: Timmer, Daniel, et al., J. Am. Chem. Soc., 144, 41, 19150-19162 (2022)

CPP 28.10 Wed 12:00 GÖR 226

In-operando observation of polaron formation in SAMFETs using NEXAFS spectroscopy — Manuel Johnson, •Andreas Späth, Baolin Zhao, Marcus Halik, and Rainer H. Fink — FAU Erlangen-Nürnberg, Erlangen, Germany

We present an in-operando near-edge x-ray absorption fine structure (NEXAFS) study on p-type BTBT-based self-assembled monolayer (BTBT-SAM) films. As a 2D-model system, the BTBT-SAM offers direct electron spectroscopic insight into the active organic semiconductor layer without interfering bulk contributions. This optimized geometry allows for the first time the observation of polaronic states caused by charged species at the dielectric/organic interface using a core-level spectroscopic tool. Linear NEXAFS dichroism is employed to derive the molecular orientation of the BTBT subunit. In addition to the conventional C K-edge NEXAFS resonances, we observe modifications in the density of unoccupied states. The spectral changes are affected by the strength and polarity of the applied gate voltage. Furthermore, the related energies match the energy levels of polaronic states. Thus, we have clear indications to interpret the data in the context of polaron formation due to charge accumulation induced by the applied electric field in ultrathin device.[1] The study has been funded by the DFG within GRK 1896 and the SolTECH initiative. CPP 28.11 Wed 12:15 GÖR 226

Machine learning for molecular design of organic molecules and reaction optimization — •Julia Westermayr[1], Reinhard J. Maurer[2], and Detlev Belder[3] — [1]Artificial Intelligence in Theoretical Chemistry Group, Leipzig University, Germany — [2]Computational Surface Chemistry Group, University of Warwick, UK — [3]Analytical Chemistry, Leipzig University, Germany

High-throughput screening of reaction conditions and electronic properties of molecules plays a crucial role in chemical industry and can be facilitated by automated workflows and machine learning. However, the high combinatorial complexity of the various parameters affecting molecular properties leaves unguided searches in chemical space highly inefficient and the optimization of reactions to synthesize these molecules often fails as theoretical protocols are usually decoupled from experiments. In this talk, we will show how predictive and generative deep learning models can be combined to theoretically design new molecules with potential relevance to organic electronics [1]. Further, we will present how these tools can be coupled with experiments to enable automated micro-laboratories [2] for targeted chemical synthesis. [1] JW et al. Nat. Comp. Sci, in press (2023). Imaging mineral-water interfaces with atomic force microscopy — •Angelika Kühnle — Bielefeld University, Bielefeld, Germany

Mineral-water interfaces are omnipresent in nature and technology. Consequently, mineral-water interfaces play a decisive role in many fields, ranging from geochemistry, environmental science and biomineralization to catalysis and electrochemistry. A comprehensive understanding of the interaction of minerals with their surroundings requires the knowledge of the atomic surface structure including the hydration at the interface. In this respect, atomic force microscopy allows for gaining real-space, molecular-level information of the interfacial structure. In this presentation, silver iodide will be discussed as a prototypical example for an ice nucleating material. Silver iodide is a polar material, calling for a stabilization mechanism. So far, however, the stabilization mechanism is unknown. Our atomically resolved atomic force microscopy images reveal no indication for a surface reconstruction at the atomic scale, indicating that another mechanism seems to be at play.

CPP 29.2 Wed 10:00 MER 02

Template-Induced Growth of Sputter-Deposited Gold Nanoparticles on Ordered Porous TiO2 Thin Films for SERS Sensors — •Suzhe Liang[1], Tianfu Guan[1], Shanshan Yin[1], Eva Krois[2], Wei Chen[1], Christopher R. Everett[1], Jonas Drewes[3], Thomas Strunskus[3], Marc Gensch[1,4], Jan Rubeck[4], Christoph Haisch[2], Matthias Schwartzkopf[4], Franz Faupel[3], Stephan V. Roth[4,5], Ya-Jun Cheng[6], and Peter Müller-Buschbaum[1,7] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching — [2]TUM School of Natural Sciences, Chair of Analytical Chemistry and Water Chemistry, Garching — [3]LS Materialverbunde, Institut für Materialwissenschaft, CAU, Kiel — [4]DESY, Hamburg — [5]Department of Fibre and Polymer Technology, KTH, Stockholm, Sweden — [6]Ningbo Institute of Materials Technology & Engineering, CAS, Ningbo, China — [7]MLZ, TUM, Garching

Ordered porous gold/titanium dioxide (Au/TiO2) hybrid nanostructured films are specifically interesting in large-scale applications using localized surface plasmon resonances (LSPRs) and surface-enhanced Raman scattering (SERS). We investigate the optical response of sputter-deposited Au/TiO2 nanohybrid thin films with a focus on the plasmonic response and application as molecular sensors. To elucidate the origin of this behavior, we apply in situ grazing-incidence small-angle X-ray scattering (GISAXS) to investigate the growth kinetics of Au on a TiO2 template during sputter deposition. The Raman intensity of deposited molecules, probed with rhodamine 6G (R6G), depends on the deposited gold thickness.

CPP 29.3 Wed 10:15 MER 02

Proteins as stabilizers for foam films: Untangling the different stabilizing effects — •Kevin Gräff, Sebsatian Stock, Luca Mirau, Sabine Bürger, and Regine von Klitzing — Soft Matter at Interfaces, Technische Universität Darmstadt, Darmstadt, Germany

Macroscopic foams consist of foam films, which separate the single air bubbles from each other. Investigation of foam films is crucial to understand macroscopic foam properties such as foam stability. In order to untangle electrostatic, steric and network stabilization effects, we study and compare two globular proteins (β-lactoglobulin and bovine serum albumin) and a disordered, flexible protein (whole casein) at low ionic strengths with varying solution pH. Image intensity measurement allows to record spatially resolved disjoining pressure isotherms in a Thin Film Pressure Balance (TFPB). This reveals insights into the structure formation in inhomogeneous protein films. We introduce inhomogeneity tracking (feature-tracking) as a novel method to enable the measurement of interfacial mobility and stiffness of foam films. Around the isoelectric point, Newton Black Films form which are stable for the globular proteins while they are unstable for the disordered flexible one. This difference in film stability is explained by different characteristics of the network structures which is supported by findings in the bulk and at the surface of the respective protein solutions.

CPP 29.4 Wed 10:30 MER 02

Anomalous underscreening in concentrated aqueous electrolytes: myth or reality? — Saravana Kumar[1], Peter Cats[2], Igor Siretanu[1], René van Roij[2], and •Frieder Mugele[1] — [1]Physics of Complex Fluids, Univ. Twente, Enschede, The Netherlands — [2]Institute for Theoretical Physics, Utrecht Univ., Utrecht, The Netherlands

Recent surface forces apparatus experiments that measured the forces between two mica surfaces and a series of subsequent theoretical studies suggest the occurrence of universal underscreening in highly concentrated electrolyte solutions. We performed a set of systematic Atomic Force Spectroscopy measurements for aqueous salt solutions in a concentration range from 1 mM to 5 M using chloride salts of various alkali metals. Experiments were carried out using flat substrates and submicrometer-sized colloidal probes made of smooth oxidized silicon immersed in salt solutions at pH values of 6 and 9 and temperatures of 25degC and 45 degC. While strong repulsive forces were observed for the smallest tip-sample separations, none of the conditions explored displayed any indication of anomalous long range electrostatic forces as reported for mica

surfaces. Instead, forces are universally dominated by attractive van der Waals interactions at tip-sample separations beyond approximately 2nm for salt concentrations of 1 M and higher. Complementary calculations based on classical density functional theory for the primitive model support these experimental observations and display a consistent decrease in screening length with increasing ion concentration.

CPP 29.5 Wed 10:45 MER 02

Layer-by-Layer Spray-deposition of Cellulose and Lignin — •Shouzheng Chen[1,2], Constantin Harder[1,3], Iuliana Ribca[4], Luciana Pluntke[1,5], Markus Oberthuer[5], Mats Johansson[4], Julien Navarro[2], and Stephan V. Roth[1,4] — [1]DESY, 22607 Hamburg, Germany — [2]University Hamburg, 20146 Hamburg, Germany — [3]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [4]KTH Royal Institute of Technology, 10044 Stockholm, Sweden — [5]HAW,Department Design, 22087 Hamburg, Germany

Cellulose and lignin are the main chemical components of wood and can be further processed and purified into more valuable chemical raw materials such as cellulose nanofibrils (CNF), Kraft lignin and lignosulfonate. Using the idea of a bottom-up approach, CNF-Lignin composite films were prepared by layer-by-layer (LbL) spray-deposition with CNF and different lignins. CNFs provide a three-dimensional porous network structure, and lignin molecules are attached to the structure of CNF to form a homogeneous structure. In addition, Kraft lignin and lignin derivatives contain a large number of phenolic hydroxyl groups, which might be preferential for thermoelectricity. Thus, CNF-Lignin composite film is an ideal template for composite functional materials.

CPP 29.6 Wed 11:00 MER 02

Growth Kinetics and Molecular Mobility of the adsorbed Layer of Poly(bisphenol-A Carbonate) (PBAC), Polysulfone (PSU), and Poly (2-Vinyl Pyridine) (P2VP) — •Hassan Omar, Paulina Szymoniak, Andreas Hertwig, and Andreas Schönhals — Bundesanstalt für Materialforschung und -prüfung (BAM), Berlin, Germany

Interactions between a polymer and a substrate interface play a vital role in understanding the improvement in thin film material properties as well as serving as a model for nanocomposites. For any non-repulsive polymer-substrate interactions, polymer segments form an irreversibly adsorbed layer and show a slowdown in the glassy dynamics and thus an increase in the thermal glass transition temperature compared to the bulk-like values. The growth kinetics of the adsorbed layer obey a two-step mechanism: formation of immobilized layer with flat segmental conformations and a loosely bound layer with stretched chains pinned to the surface. Here the adsorbed layer was studied for: poly (bisphenol-A carbonate) (PBAC) and polysulfone (PSU), two bulky polymers containing a functional group (phenyl ring) in the backbone and compared to poly (2-vinyl pyridine) (P2VP), where the backbone is a vinyl-derivative and the functional group (pyridine) is in the side chain. The growth kinetics for PBAC and PSU were found to deviate from the well-known mechanism, observed for polymers such as P2VP. Atomic force microscopy and ellipsometry were used for this investigation and was additionally supported by broadband dielectric spectroscopy.

CPP 29.7 Wed 11:30 MER 02

Influence of heavy chalcogen atoms on structural arrangement and spectroscopic properties in molecular donor/acceptor thin film heterostructures — •Elena Chulanova[1], Anton Pylypenko[1], Alexander Gerlach[1], Jannika Lauth[2], and Frank Schreiber[1] — [1]Institute for Applied Physics, University of Tübingen, 72076 Tübingen, Germany — [2]Institute for Physical and Theoretical Chemistry, University of Tübingen, 72076 Tübingen, Germany

Organic semiconductors are widely used in optoelectronics due to their tunable electronic and structural properties. For many applications, the active layers consist of heterostructures and the details of the interaction between an electron donating and accepting moieties are the key factors for enhancing devices' efficiency. The chalcogenadiazole ring is a common acceptor core for organic chromophores and a variety of its condensed derivatives is known and used in this context. The presence of heavy chalcogens in the latter can impact the spin-orbit coupling and affect the optical properties. Here, we present a study on organic binary mixtures in thin films prepared by vacuum deposition, namely of dibenzochalcogenadiazolopyrazines as acceptors and known donors; i.e. diindenoperylene, pentacene, α-sexithiophene. The bulk heterojunction geometry was used with two materials mixed on the molecular level. We discuss the correlation between the mixing behavior of the molecules, and their structural and optical properties to obtain a systematic understanding of the processes occurring in molecular D-A systems based on 1,2,5-chalcogenadiazoles.

CPP 29.8 Wed 11:45 MER 02

The influence of increased kinetic energy of gold deposition onto polymers — •Yusuf Bulut[1,2], Benedikt Sochor[1], Kristian Reck[3], Jonas Drewes[3], Suzhe Liang[2], Tianfu Guan[2], Thomas Strunskus[3], Franz Faupel[3], Peter Müller-Buschbaum[2,4], and Stephan V. Roth[1,5] — [1]DESY, 22607 Hamburg — [2]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [3]CAU Kiel, Chair for Multicomponent Materials, Faculty of Engineering, 24143 Kiel — [4]MLZ, TUM, 85748 Garching — [5]KTH Royal Institute of Technology, Department of Fibre and Polymer Technology, SE-100 44 Stockholm

High Power impulse magnetron sputtering (HIPIMS) is a novel industrial relevant deposition technique enabling thin metal layers being coated onto polymers with increased adhesion and density. Compared to conventional direct current magnetron sputtering, no pre- and post-treatment is required to achieve these properties. So far there is no report discussing the nucleation and growth process during HiPIMS deposition. In this study, the polymer templates polystyrene (PS), poly-4-vinylpyridin (P4VP) and polystyrene sulfonicacid (PSS) are studied. Even though the polymers are very similar in their structure, it is expected that the distinct different functional moiety influence the kinetics of the initial growth stages of the gold layer. Results of simultaneous in situ grazing-incidence small angle X-ray scattering (GISAXS) and grazing incidence wide angle X-ray scattering (GIWAXS) are presented.

CPP 29.9 Wed 12:00 MER 02

Analysis of non-equilibrium thin film growth using X-ray photon correlation spectroscopy — •Ingrid Dax[1], Ivan Zaluzhnyy[1], Michael Sprung[2], and Frank Schreiber[1] — [1]Universität Tübingen, Germany — [2]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

Thin film growth is a classic example of a non-equilibrium process in which a wide variety of functional properties can be obtained depending on the growth kinetics. Understanding the microscopic dynamics underlying the growth of molecular materials is an essential prerequisite for the rational design of complex structures and morphologies with controlled properties.

We perform in-situ X-ray experiments in grazing incidence geometry to follow the formation of thin film growth in real time, which reveals details of the dynamics during this process. This includes the adsorption of molecules on the substrate and the subsequent formation, realignment and diffusion of resulting molecular islands.

Specifically, we use modern coherent techniques based on X-ray photon correlation spectroscopy (XPCS). This resolves dynamics on the scale of 50-1000 nm, providing an unprecedented level of detail into the growth and diffusion of molecular islands during the growth process. We decompose our measurements into dynamic and kinetic time scales by comparing them to simulations, and interpret the results using established XPCS tools. This allows us to show that the time scales of a few 100 seconds are mainly due to kinetics, i.e., the growth of the islands.

CPP 29.10 Wed 12:15 MER 02

In situ GISAXS investigation of sputtering IZO thin film for optoelectronic applications — •Huaying Zhong[1], Lukas V Spanier[1], Christopher R. Everett[1], Xinyu Jiang[1], Shanshan Yin[1], Marlene Sophie Härtel[2], Jiahuan Zhang[2], Bertwin Bilgrim Otto Seibertz[3], Matthias Schwartzkopf[4], Stephan V. Roth[4,5], and Peter Müller-Buschbaum[1,6] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]HZB, Solar Energy, Berlin, Germany — [3]Department of technology for thin-film components, TU Berlin, Berlin, Germany — [4]DESY, Hamburg, Germany — [5]Department of Fibre and Polymer Technology, KTH, Stockholm, Sweden — [6]MLZ, TUM, Garching, Germany

Transparent conducting oxide (TCO) thin films have been studied intensively for optoelectronic devices, such as photodetectors, photovoltaics and light emitting diodes (LEDs). Among the several TCO thin films, zinc doped indium oxide (IZO) has received much attention as interface layer in optoelectronic devices due to its excellent electrical conductivity, optical transmittance, high thermal/chemical stability, low cost and low deposition temperature. Here, ITO glass and spin coated ZnO on ITO glass are used as the templates for IZO thin film deposition via DC magnetron sputtering technique. The growth dynamics of IZO film on these two templates are respectively investigated via grazing small angle x-ray scattering (GISAXS) characterization, and the morphology and optoelectrical properties of final films are further investigated.

CPP 29.11 Wed 12:30 MER 02

Investigation of Mg(0001) and Mg(1010) surfaces in Grignard electrolytes by reflection anisotropy spectroscopy — •Mario Löw[1], Holger Euchner[2], and Matthias M. May[1,2] — [1]Universität Ulm, Institute of Theoretical Chemistry, 89081 Ulm, Germany — [2]Universität Tübingen, Institute of Physical and Theoretical Chemistry, 72076 Tübingen, Germany

The high abundance and large volumetric capacity of the metal anode make rechargeable magnesium batteries potential candidates for future battery technologies. While understanding and controlling the electrode-electrolyte inter-

face is essential for battery performance, there is often little known about the underlying atomistic interface structure under operating conditions [1].

To address this issue for the case of Mg, we study single crystalline magnesium surfaces in contact with standard Grignard electrolytes and under applied potential [2]. We employ reflection anisotropy spectroscopy (RAS) as an optical, high-resolution technique for the operando investigation of the interfacial struc-

ture as a function of the applied electrode potential. The Mg-crystal surface is studied in various solvents and Grignard electrolytes during voltammetric cycling. Finally, we seek comparison to theoretical spectra obtained within the random phase approximation.

CPP 30: Biopolymers and Biomaterials I (joint session BP/CPP)

Time: Wednesday 9:30–13:00 Location: TOE 317

See BP 12 for details of this session.

CPP 31: Focus Session: From Inter-individual Variability to Heterogeneous Group Dynamics and Disorder in Active Matter (joint session DY/BP/CPP)

The study of active particle dynamics has developed into a vibrant field of multidisciplinary research, including such diverse systems as bacterial colonies, cellular self-organization, synthetic colloids and microrobots as well as macroscopic systems like locusts, flocks of birds, schools of fish or pedestrians. Whereas many studies in the past focused either on the random transport of individual particles or on the interplay of temporal fluctuations (noise) and interactions (velocity alignment or attraction/repulsion), there is now an increasing interest in the question how structural disorder and inter-individual variability, i.e., different motility characteristics of individuals, shape the active particle dynamics and emergent pattern formation of groups. The presence of structural or quenched disorder raises furthermore the immediate question how to bridge data and models based on (short time) tracking data, given the simultaneous presence of temporal fluctuations. With this focus session, we aim at bringing researchers from statistical physics and biophysics together to discuss this interdisciplinary topic and exchange ideas on common challenges arising in different application areas.

Organized by Robert Großmann (Potsdam)

CPP 35: Poster Session II

Topics: Biopolymers, Biomaterials and Bioinspired Functional Materials (1-5); Complex Fluids and Colloids, Micelles and Vesicles (6-13); Composites and Functional Polymer Hybrids (14-23); Crystallization, Nucleation and Self-Assembly (24-32); Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods (33-41); Hydrogels and Microgels (42-44); Modeling and Simulation of Soft Matter (45-50); Nanostructures, Nanostructuring and Nanosized Soft Matter (51-52); Polymer and Molecular Dynamics, Friction and Rheology (53-57); Responsive and Adaptive Systems (58-61); Wetting, Fluidics and Liquids at Interfaces and Surfaces (62-66).

Time: Wednesday 11:00–13:00 Location: P1

CPP 35.1 Wed 11:00 P1

Stability of biobased coatings on textiles — •Luciana Pluntke[1,2], Constantin Harder[1,3], Shouzheng Chen[1,4], Iuliana Ribca[5], Nadja Kölpin[1], Markus Oberthür[2], Peter Müller-Buschbaum[3], Mats Johansson[5], and Stephan V. Roth[1,5] — [1]DESY, 22607 Hamburg, Germany — [2]HAW, 20999 Hamburg, Germany — [3]TUM School of Natural Sciences, Department of Physics, Chair for Functional Materials, 85748 Garching, Germany — [4]University Hamburg, 20146 Hamburg, Germany — [5]KTH Royal Institute of Technology, 10044 Stockholm, Sweden

Functionalizing textiles by spray-coating is in wide-spread use. Here, we focus on functional multi-layer protective coatings on light woven textile materials. The functionalization is achieved by spray-coating with bio-based materials.

We investigate the mechanical stability of these novel coatings and changes in the coating under external stress and standard abrasion conditions. Our aim is to determine the degree of stress that the coating can withstand under different types of mechanical stress until it loses it functionality. The results are important for implementing sustainable materials in textile industry.

CPP 35.2   Wed 11:00   P1

In situ GISAXS printing of biotemplated titania nanostructures — •Linus F. Huber[1], Manuel E. Scheel[1], Stephan V. Roth[3], and Peter Müller-Buschbaum[1,2] — [1]Technical University of Munich,TUM School of Natural Sciences, Department of Physics, Chair for Functional Materials, James-Franck-Str. 1, 85748 Garching, Germany — [2]MLZ,TUM, 85748 Garching — [3]Deutsches Elektronen-Synchrotron (DESY), Notkestr. 85, 22607 Hamburg, Germany

Biotemplating is an effective method of nanostructuring hybrid inorganic-organic materials. This approach allows the tuning of material properties like porosity or domain sizes. Therefore, parameters like the electronic conductivity can be adjusted for different applications. In this work, differently structured Titania thin films are investigated for application in thermoelectric generators. Beta-lactoglobulin is a bovine whey protein that is used as a template during sol-gel synthesis. The Seebeck effect allows the conversion of waste heat into electrical energy. State of the art thermoelectric materials are rare, toxic and expensive. Biotemplated titania could provide a non-toxic and abundant alternative. To investigate the different titania morphologies, in situ GISAXS, GIWAXS and SEM are used. In situ GISAXS printing enables a time resolved investigation of the structure formation, domain sizes and domain distances. UV-Vis and Pl are used to analyze differences in the optical properties of the thin films. These structural and optical changes are then correlated with measurements of the Seebeck coefficient and the electrical conductivity.

CPP 35.3   Wed 11:00   P1

A two-state Gaussian loop under tension: negative extensibility and ensemble inequivalence — •Geunho Noh and Panayotis Benetatos — Department of Physics, Kyungpook National University, Republic of Korea

Loop formation is commonly observed in biopolymers and, in many cases, the loop structure is transient. Some examples of this structural rearrangement are the formation of denaturation bubbles in double-stranded DNA and the transient DNA looping associated with gene regulation. Here, we study the conformational statistics and the elastic behavior of a flexible polymer under tension with a two-state structure: looped or unlooped. We analyze two cases. In the first, the loop can zip to form a double-stranded chain. In the second, the dangling ends of a chain can bind to form a loop. In each case, we investigate the force-extension relation of the two-state loop in both the Helmholtz and the Gibbs ensembles. We also extend the two-level system to a three-level Gaussian loop by introducing a third (intermediate) state. In contrast to the single Gaussian chain, the two- or three-level systems show qualitatively different tensile response and ensemble inequivalence. Interestingly they can have negative extensibility in the Helmholtz ensemble, and we point out that this is one of the simplest polymer models which exhibits such metamaterial-like behavior.

CPP 35.4   Wed 11:00   P1

Determination of the roast-dependent pore size in coffee beans using positron lifetime spectroscopy — •Adrian Langrehr, Vassily Burwitz, Lucian Mathes, and Christoph Hugenschmidt — Forschungs-Neutronenquelle Heinz Maier-Leibnitz (MLZ), Technische Universität München, Lichtenbergstr. 1, 85748 Garching, Germany

Positron Annihilation Lifetime Spectroscopy (PALS) is an established method to determine the type and concentration of open volume defects in crystals as well as to investigate the free volume in polymers. Using ^{22}Na as β^+ emitting radioisotope in the so-called "sandwich" geometry we present the capabilities of our four-detector setup with digital readout and signal processing. The efficient readout of this PAL spectrometer produces 12 lifetime spectra simultaneously. Our study encompasses the comparison of three different methods to combine information contained in these 12 spectra. To demonstrate a use case of a biomaterial we measured the positron lifetimes in coffee beans as a function of the degree of roasting. The application of the so-called Tao-Eldrup model allows us to study the influence of the roasting parameters on the mean pore size on the nanometer scale.

CPP 35.5   Wed 11:00   P1

Microgels for Enhanced Adsorption of Endothelial Cells on Artificial Networks — •Souraj Mandal and Regine von Klitzing — Soft Matter at Interfaces, Department of Physics, Technical University of Darmstadt, Germany

Artificial 3-D supply networks can be applied as a transport system for oxygen and nutrients, which can promote vascularization for organ-like 3-D cell culture systems. In the human body, the inner surface of such networks (blood vessels) is lined with a layer of endothelial cells and they play a vital role in cell maturation and angiogenesis (formation of new blood vessels). So far, the attachment of endothelial cells on the surface of the artificial network system is not sufficient. Addressing this problem, this study focuses on designing a suitable mediator be-

tween the inner walls of the artificial network and endothelial cells, which should be mechanically stable to flows of nutrient solutions. Here we employ Poly(N-isopropylacrylamide) (PNIPAm) microgel (MG) as cell-culturing surface mediator. However, the main challenges are (i) ensuring the firm adhesion of MGs on the surface of the artificial polymeric network, and (ii) seeding endothelial cells on top of them. As a primary approach, we synthesized positively charged MGs to attach them on plasma-treated silicon (Si) and 3-D printed polymeric surfaces. MG particles are characterized by their Zeta potential and hydrodynamic radius. As a rapid fabrication technique, spin coating was used to deposit a thin polymeric layer of MG particles on the substrates. AFM analyses showed a stable adhesion of MG particles on the flat surfaces even upon water washing and mechanical stress.

CPP 35.6   Wed 11:00   P1

Depletion induced phase behavior and equilibrium clusters in charged BSA and HSA protein solutions — •Maximilian D. Senft, Fajun Zhang, and Frank Schreiber — Universität Tübingen, Germany

Understanding and predicting the phase behavior of proteins is an ongoing endeavor in many scientific research areas, including the pharmaceutical industry. In addition to crystallization, liquid-liquid phase separation and condensate formation, which includes equilibrium clusters, dense liquid droplets, fibrils, and gels, appear to be closely related to many pathological conditions. The formation of equilibrium protein clusters in solution requires an interaction potential with competing contributions, i.e., long-ranged repulsion and short ranged attraction. Bovine and human serum albumin (BSA and HSA) carry negative charges at neutral pH which provide a long-range electrostatic repulsion between proteins. The attractive potential can be generated via the depletion interactions introduced by the non-adsorbing polymer polyethylene glycol in protein solutions. By tuning the ionic strength, polymer size and concentration, the competing potential can be continuously adjusted, resulting in equilibrium protein clusters due to the subtle balance to the different contributions of the interaction potential. Having performed systematic small angle scattering measurements, on BSA and HSA, together with quantitative modeling combined with protein phase diagrams a better understanding of depletion induced protein phase behavior and cluster state can be provided.

CPP 35.7   Wed 11:00   P1

Purely elastic instability of semi-dilute polymer solutions in shear flow — Pegah Shakeri[1,2], •Michael Jung[1,2], and Ralf Seemann[1,2] — [1]Universität des Saarlandes, Saarbrücken, Germany — [2]Max Planck-Institute for Dynamics and Self-Organization, Göttingen, Germany

Polymer solutions in the semi-dilute regime are of considerable industrial importance. The complex rheological properties of such highly viscoelastic fluids and the complexity of their flow characteristics, especially in curved geometries, require a thorough experimental characterization of the dynamics of such fluid flows. We experimentally investigate the flow of highly elastic polymer solutions above their overlap concentrations in a microfluidic serpentine channel using pressure measurements and particle image velocimetry. Our results show that the flow resistance increases significantly at high Weissenberg numbers but vanishing Reynolds numbers, indicating the occurrence of a purely elastic instability. We show that the onset of instability can be scaled by including shear-dependent rheological properties of the polymer solutions in the nonlinear stability analysis. As a result, a universal criterion as a function of normalized polymer concentration is provided for scaling the onset of pure elastic instability in the semi-dilute regime independent of the type and molecular weight of the polymer.

CPP 35.8   Wed 11:00   P1

Improved displacement efficiency in porous media by invasion of viscoelastic fluids — •Michael Jung[1,2], Pegah Shakeri[1,2], and Ralf Seemann[1,2] — [1]Universität des Saarlandes, Saarbrücken, Germany — [2]Max Planck-Institute for Dynamics and Self-Organization, Göttingen, Germany

Improving the displacement efficiency of capillary entrapments in porous media by adding high molecular weight polymers to the invading phase has a variety of industrial applications. Apart from an increased viscosity contrast compared to water flooding, the flow of viscoelastic polymer solutions exhibits unstable flow behavior even at small Reynolds numbers, which can lead to an additional displacement mechanism of the capillary entrapments. We use a microfluidic approach to reveal the underlying mechanism of this enhanced displacement by first considering a random array of cylindrical posts to identify fundamental differences in displacement processes for elastic and non-elastic fluids. Then, to focus directly on displacement processes driven solely by elastic stresses and to exclude the effects of viscous stresses, we consider a single capillary entrapment connected to two symmetric serpentine channels. We show that the unique viscoelastic fluid features, such as the emergence of a significant first normal stress difference, combined with the curved flow geometry, lead to purely elastic instability and elastic secondary flow, which in turn generate the stresses required to overcome the capillary threshold and displace capillary entrapment.

CPP 35.9 Wed 11:00 P1

Supraparticles: Aggregation of colloids in evaporating dispersion drops — •Melis Yetkin[1], Yashraj Manish Wani[2], Arash Nikoubashman[2], Michael Kappl[1], and Hans-Jürgen Butt[1] — [1]Department of Physics at Interfaces, Max-Planck-Institute for Polymer Research, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz,Germany

Evaporating dispersion drops from superamphiphobic surfaces opens a way to fabricate supraparticles (SPs) with complex structures. The structure formation can be controlled by tailoring the interaction forces between particles and process conditions. In this study, the structure of the SPs was investigated by tuning the shape of the primary building blocks and the process conditions. Ellipsoidal polystyrene (PS) particles of different aspect ratios were obtained by stretching a polymeric film of spherical particles above the glass transition temperature. Aqueous dispersion drops of the ellipsodal particles were evaporated from silicone nanofilaments-based superamphiphobic surfaces under varying humidity conditions, during which the evaporation process was monitored by a camera. The interaction between the building blocks, and hence the final morphology of the SPs, were altered by the addition of surfactant sodium dodecyl sulfate (SDS). Control experiments with spherical PS building blocks were conducted in parallel. The study elucidated the effect of primary building block shape on the final morphology of supraparticles and the transition between a shape-dominated regime and an interaction-dominated regime.

CPP 35.10 Wed 11:00 P1

Temperature dependent measurments of the diffusion- and Soret-coefficient in a binary polystyrene/toluene mixture — •Jannik Kantelhardt and Werner Köhler — Physikalisches Institut Universität Bayreuth, Germany

In this work we investigate the dependence of the diffusion- and Soret-coefficient in respect to different ambient temperatures with a temperature range from 10°C to 50°C in steps of 5°C. The here investigated system, a solution of polystyrene (PS) in toluene with a weight fraction of c_{PS}=1%, has in a similar concentration also been used in the binary companion cell of the DCMIX4 microgravity campaign on ternary mixtures. Furthermore, binary and ternary polystyrene solutions are candidates for the forthcoming GIANT FLUCTATIONS project of ESA for the investigation of non-equilibrium fluctuations under microgravity conditions.

The measuements were performed with a Thermal-Diffusion-Forced-Rayleigh-Scattering (TDFRS) setup. Through a writing beam a holographic grating is created inside the mixture where a small amount of an inert dye is added. The grating heats the sample periodically which leads to temperature gradients. Through the Soret-effect concentration gradients appear and both lead to changes in the refractive index. The signal is measured with a readout beam under Bragg diffraction.

CPP 35.11 Wed 11:00 P1

Diffusion, Thermodiffusion and turbidity of thermoresponsive Poly(N-acryloylglycinamide) in water. — •Roman Reh[1], Nikola Majstorovic[2], Seema Agarwal[2], and Werner Köhler[1] — [1]Universität Bayreuth, Physikalisches Institut, Germany — [2]Universität Bayreuth, Macromolecular Chemistry II, Germany

We report about measurements on Poly(N-acryloylglycinamide) (PNAGA) in aqueous solution. Diffusion-, Thermodiffusion- and Soretcoefficients were measured with the polymer in linear form and as a crosslinked microgel. Furthermore, temperature dependent measurements on turbidity were done with the linear polymer. Experiments on diffusion were performed with the Optical-Beam-Deflection technique where a vertical temperature gradient is applied to the sample and information about the time dependent distribution of temperature and concentration in the sample is gathered by recording the position of a laser beam, which traverses the sample and gets deflected. This is because the refractive index changes with temperature and concentration, which on its part changes due to thermodiffusion. Turbidity measurments show a UCST-behavior and a hysteresis in the temperature of the cloud point, depending on the direction of the temperature ramp, which is in accordance with results from literature. Thermodiffiusion- and Soretcoefficients at different temperatures are described with an exponential Piazza function [S. Iacopini et al., Eur. Phys. J. E **19**, 59-67 (2006)] and are comparable for the linear polymer and the microgel, showing a systematical behaviour and a change in sign in the region of about 35 to 40 °C.

CPP 35.12 Wed 11:00 P1

Measurement of diffusion and thermodiffusion of polydisperse polymers by means of a compact optical beam deflection setup — •Mareike Hager, Roman Reh, and Werner Köhler — Universität Bayreuth, Physikalisches Institut, Germany

We have performed diffusion and thermodiffusion experiments on solutions of polydisperse polymers by means of a newly developed double-pass optical beam deflection (OBD) instrument. The aim is to develop a model for the description of the multimodal OBD signals and to develop the technique into a method for polydispersity analysis. The double-pass OBD instrument utilizes a laser beam that is reflected behind the Soret cell and passes the sample volume a second time. In the cell a vertical temperature gradient is applied that leads to thermodiffusion in the sample and, thus, to a concentration gradient and a gradient of the refractive index. The laser beam that traverses the cell twice is deflected and detected on a camera where the time dependent laser position is recorded. From the measured OBD signal the diffusion, thermodiffusion and Soret coefficients can be extracted. The multimodal time traces are evaluated with an adapted version of the CONTIN program for the solution of inverse problems. It is shown that diffusion coefficients extracted in this way agree with literature data. The results of the measurements of samples with two polymers of different sizes are in accordance with the results for the single components. Based on these results, polymers with a broad molar mass distribution can now be investigated.

CPP 35.13 Wed 11:00 P1

Mixture of magnetic and non-magnetic ellipsoids — •Elena Pyanzina[1], Anna Akisheva[1], Tatyana Belayeva[1], Marina Gupalo[1], and Sofia Kantorovich[2] — [1]Ekaterinburg, Russia — [2]University of Vienna, Vienna, Austria

In this contribution, mixtures of magnetic and non-magnetic ellipsoids were studied. We chose systems with the ratio of the semi-axes equal to 3 and 5 and different concentrations, as well as the direction of the magnetic moment along the main axis. The ratios of magnetic and non-magnetic particles considered were as follows: 30/70, 50/50 and 70/30. The initial susceptibility of such systems was calculated since the magnetic response of the system is very important for various applications. It turned out that with an increase in the magnitude of the magnetic moment, a structural transition occurs in the system: first, the initial susceptibility increases, and then it becomes almost zero. This is because the basic state of elongated ellipsoids is an antiparallel pair, which becomes stable with an increase in the magnitude of the magnetic moment. And its total magnetic moment is quite small, and the susceptibility of such an object is much lower than that of a pair of particles with a head to tail orientation. The behavior of mixtures of ellipsoids with similar systems of magnetic disks (like ellipsoids with a magnetic moment perpendicular to the main axis) was also compared. It turned out that at large values of the magnetic moment, the disks form "stacks" in which the magnetic moments are directed head to tail, and ellipsoids form flat structures with a thickness of one ellipsoid, with an antiparallel orientation of the moments.

CPP 35.14 Wed 11:00 P1

Mesoporous polymers as electrode material in hybrid organic-inorganic lithium-ion batteries — •Tom Wickenhäuser[1], Lucas Ueberricke[2], Angelina Jocic[2], Erik Misselwitz[2], Elisa Thauer[1], Yuquan Wu[1], Michael Mastalerz[2], Milan Kivala[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Institute of Organic Chemistry, Heidelberg University, Germany

We report on the characterisation of mesoporous polymers as electrode materials in hybrid organic-inorganic lithium-ion batteries. In particular, dendritic pyrene tetraone (D-PTO) and triphenylamine (TPA) is investigated as cathode material and non-planar covalent carbon networks are studied as anode material in lithium half-cells. Cyclic voltammetry as well as galvanostatic cycling measurements were done to investigate on ionic and electric transport mechanisms. For redox active dendritic pyrene tetraone, the mesoporous character of the amorphous polymer is confirmed and the specific surface areas range up to nearly 700 m^2g^{-1}. Galvanostatic cycling measurements show a specific capacity of 137 $mAhg^{-1}$ and a capacity retention of 86% after 50 cycles.

CPP 35.15 Wed 11:00 P1

Design, fabrication and nano-scale characterization of novel SEI layers — •Zhuijun Xu[1], Yajun Cheng[2], Yonggao Xia[2], and Peter Müller-Buschbaum[1,3] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Ningbo Institute of Materials Technology and Engineering, Chinese Academy of Sciences, 315201, Ningbo, China — [3]MLZ, TUM, 85748 Garching, Germany

Rechargeable lithium metal batteries have been recognized as one of the most promising energy storage devices due to their superior energy density. However, serious safety concerns and poor cyclability are challenges originating from an uncontrolled lithium dendrite growth and an unstable solid electrolyte interface (SEI) layer. SEI can be enhanced by synergetic additives in commercial electrolytes. Herein, amphiphilic block copolymers/inorganic materials–PS-b-PEO/LiNO3 as additives, which bear some clear advantages including absorbing mechanical stress, conducting lithium ion and controlling the lithium dendrite growth, are mixed with commercial electrolytes and applied in the lithium metal battery. Remarkably, Li symmetric cells have a long-term cycling life over 300 h with a capacity of 3 mAh cm-2. Moreover, full battery with lithium metal anode and LiFePO4 exhibits a stable and high capacity of 138 mAh g-1 at 1 C. With ex-situ scattering techniques or in-situ scattering studies, the structures of the surface modified lithium metal anodes and structure formation processes are studied.

CPP 35.16 Wed 11:00 P1

Less is more: tiny amounts of insoluble multi-functional microporous additive plays a big role in lithium secondary batteries — •Ruoxuan Qi[1], Peter Müller-Buschbaum[1,2], and Ya-Jun Cheng[3] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]MLZ, TUM, Garching, Germany — [3]NIMTE, CAS, Zhejiang Province, P. R. China

Binders play an important role in multi-component electrodes for rechargeable batteries, which suffer from poor electronic and ionic conductivity. Binder-free electrodes provide another way to resolve problems, where sophisticated structure construction is required. A new concept of electrode processing alternative to binder-containing and binder-free electrodes was established. A multifunctional PIM-1 (a polymer with intrinsic microporosity) additive was used instead of PVDF to form mechanically processable Li secondary battery cathodes. Due to its unique nanoporous structure built by the spiro-containing rigid aromatic polymer chain, only a tiny amount of PIM-1 in the LiNi0.8Co0.1Mn0.1O2 cathode is needed to retain good performance, far below the typical composition for PVDF. Homogeneous dispersion of carbon black is achieved by PIM-1, which stabilizes the electrode and increases the electronic conductivity. Different from PVDF, mechanical buffering by stiff PIM-1 yields crack-free electrodes after cycles. Moreover, an inorganic rich cathode-electrolyte interface layer is formed via a desolvation process promoted by PIM-1, because of its strong binding ability with lithium ions, which is beneficial for cyclic stability and rate capability.

CPP 35.17 Wed 11:00 P1

Positrons probe advanced and functionalized porous materials — •Ahmed Gamal Attallah, Eric Hirschmann, Maik Butterling, Maciej Oskar Liedke, and Andreas Wagner — Institute of Radiation Physics, Helmholtz-Zentrum Dresden-Rossendorf

Positron annihilation lifetime spectroscopy (PALS) is an effective porosimetry technique complementing standard gas intrusion methods. PALS is able to detect open and closed pores, and resolve depth-dependent porosity. It can operate under variable pressures, temperatures, and atmospheres to monitor structural changes during in situ conditions. In this contribution, PALS results of various functionalized porous materials including polymer grating, structural changes in metal-organic-frameworks (MOFs), effect of additives in food ingredients (maltodextrin) on water uptake, and impact of modification of low-k dielectrics on stiffness will be presented. In polymer grafting, the mechanism of polymer grafting on MCM-48-type mesoporous silica nanoparticles forming core-shell composite structure is understood from PALS. Uniquely in MOFs, PALS was able to prove that the temperature-driven transformed metal-organic framework DUT-8(Ni) is still porous possessing closed porosity that is not accessible by other techniques. Sucrose in maltodextrin is the third topic where in situ humidity experiment during PALS revealed that adding 10 % sucrose to maltodextrins has a negligible effect on hygrocapacity at relative humidity > 50 %. Finally, the improved mechanical stability of low-k materials by adding methyl terminal groups that cause less interconnected pores has been verified by positron annihilation.

CPP 35.18 Wed 11:00 P1

Insights into the morphology-structure-property relationship of mesoporous ZnO films during humidity sensing — •Ting Tian[1], Shanshan Yin[1], Suo Tu[1], Apostolos Vagias[2], Anna-Lena Oechsle[1], Tianxiao Xiao[1], Sigrid Bernstorff[3], and Peter Müller-Buschbaum[1,2] — [1]Technical University of Munich, TUM School of Natural Sciences, Department of Physics, Chair for Functional Materials, 85748 Garching — [2]MLZ, TU München, 85748 Garching — [3]Elettra-Sincrotrone Trieste S.C.p.A., Strada Statale 14 km 163.5, AREA Science Park, Basovizza, 34149 Trieste, Italy

Moisture can strongly influence the conductivity of ZnO semiconductors via the physisorption and chemisorption of water molecules on the ZnO surface. Mesoporous ZnO structures can facilitate the absorption process by providing a large surface area and active sites. However, little effort has been devoted yet to gain an in-depth understanding of the effect of water on the morphology and electrical property In the present work, different mesoporous ZnO thin films were synthesized by exploiting different diblock copolymers. Benefiting from the different inorganic frameworks, these thin films show significantly different structural properties and defects density. To explore the morphology-structure-property relationship, in situ Fourier-transform infrared spectroscopy (FTIR) was used to confirm the water absorption. Simutalenouesly, in situ grazing-incidence small-angle X-ray scattering (GISAXS) measurements were performed to investigate the morphology evolution, and in situ electrochemical impedance spectroscopy (EIS) was used to monitor the conductivity changes.

CPP 35.19 Wed 11:00 P1

Morphology transformation pathway of block copolymer- directed cooperative self-assembly of ZnO hybrid films monitored in situ during slot-die coating — •Ting Tian[1], Shanshan Yin[1], Suo Tu[1], Christian L. Weindl[1], Kerstin S. Wienhold[1], Suzhe Liang[1], Matthias Schwartzkopf[2], Stephan Volkher Roth[2], and Peter Müller-Buschbaum[1,3] — [1]Technical University

of Munich, TUM School of Natural Sciences, Department of Physics, Chair for Functional Materials, 85748 Garching — [2]James-Franck-Str. 1 — [3]MLZ, TUM, 85748 Garching

Co-assembly of diblock copolymers (DBCs) and inorganic precursors that takes inspiration from the rich phase separation behavior of DBCs can enable the realization of a broad spectrum of functional nanostructures with the desired sizes. In a DBC assisted sol*gel chemistry approach with polystyrene-block-poly(ethylene oxide) and ZnO, hybrid films are formed with slot-die coating. Pure DBC films are printed as control. In situ grazing-incidence small-angle X-ray scattering (GISAXS) measurements are performed to investigate the self-assembly and co-assembly process during the film formation. Combining complementary ex situ characterizations, several distinct regimes are differentiated to describe the morphological transformations from the initially solvent-dispersed to the ultimately solidified films. The precursor reduces the degree of order, prevents crystallization of the poly(ethylene oxide) block, and introduces additional length scales in the hybrid films.

CPP 35.20 Wed 11:00 P1

Evaluation of different textile mount designs for printing on textiles in commercial SLA 3D printers for scientific investigation — •Timo Grothe[1], Elise Diestelhorst[1], Jan Lukas Storck[1], Daniel Koske[1], Natalie Frese[2], and Martin Wortmann[2] — [1]Faculty of Engineering and Mathematics, Bielefeld University of Applied Sciences, Interaktion 1,33619 Bielefeld, Germany — [2]Faculty of Physics, Bielefeld University, Universitätsstraße 25, 33615 Bielefeld, Germany

The technology of 3D printing has already reached the commercial sector. But it is not only the industry that is interested in 3D printing; the scientific world is also investigating the possibilities of this multifaceted technology. Here, in addition to the fused deposition modeling (FDM) process, the cornerstone stereolithographic (SLA) process in particular has become the focus of scientific attention. Especially in combination with textiles, some unique composites with outstanding properties can be produced. In order to be able to print these in commercially available printers, some textile mounts were developed and their applicability as well as usability were investigated. Not only the printing result and the adhesion between resin and different textiles were investigated by abrasion tests, but also the application of the individual holders was evaluated. Finally, the produced composites were examined with a scanning helium ion microscope to show, in combination with the other examination methods, that both the textile-resin composites have exceptional abrasion resistance and that the textile holders make it much easier to produce them.

CPP 35.21 Wed 11:00 P1

Polymer Composite Films with Induced Structural Anisotropy for Thermoelectric Application — •Christian Gradl[1], Marie Siegert[1], and Jens Pflaum[1,2] — [1]Experimental Physics VI, University of Würzburg, 97074 Würzburg — [2]ZAE Bayern, 97074 Würzburg

Thermoelectric generators offer a prospective opportunity to handle the increasing energy demand by utilizing waste heat. Organic thin films represent a promising candidate because of benefits like non-toxicity, cost-effectivity or versatile implementation. For an efficient thermoelectric device, the thermoelectric figure of merit $zT = \sigma S^2 T/\kappa$ needs to be high. So the Seebeck coefficient S and the electrical conductivity σ should achieve high values, whereas the thermal conductivity κ has to be low. Taking advantage of the intrinsically low κ, we combine the polymer PEDOT:PSS with additives like silver nanowires, the crystalline organic TTT_2I_3 or VO_2 needles, by which a higher σ is aspired without pronounced detriment of the Seebeck coefficient. TTT_2I_3 and VO_2 are fabricated via microspacing in-air sublimation. Controlled orientation of the additives induced by the substrate is a main topic of our research. Further we investigate the alignment of additives embedded in polymer thin films prepared via doctor-blading to improve the efficiency for thermoelectric application. The results on characterizing the electrical and thermal properties of the organic-metallic composites with respect to their anisotropy will be presented.

CPP 35.22 Wed 11:00 P1

Morphological studies in semicrystalline polymers and polymer nanocomposites using spin diffusion — •Dorit Hartmann, Anna Nitsche, Yury Golitsyn, Horst Schneider, and Kay Saalwächter — Department of Physics / NMR Group, University of Halle, Betty-Heimann-Str. 7, 06120 Halle, Germany

ABSTRACT: The properties of synthetic polymers can be selectively modified by adding nanoparticles, which is why polymer nanocomposites have a wide range of applications. The interaction of the polymer chains with the surface of silica particles leads to the formation of a multiphase structure, characterized by a gradient of molecular dynamics. [1] Studies of polymer nanocomposites using spin diffusion (SD) experiments in conjunction with the numerical simulations have shown that the interphases exhibit complex morphology with dynamic heterogeneities. [2] In this work, we investigate the effect of magnetic field strength on spin diffusion in semicrystalline poly(ϵ-caprolactone) and a poly(2-vinyl pyridine)-silica nanocomposite. The experiments were performed at two

different field strengths of 0.47 T and 4.7 T (proton Larmor frequency of 20 MHz and 200 MHz, respectively) and were supported by spin diffusion calculations. In addition, this paper aims to provide an overview of the different data acquisition and analysis strategies for high- and low-field instruments. Two-step electrochemical Au nanoparticle formation in polyaniline — •Bin Zhao and Sebastian Gutsch — institut für mikrosystemtechnik, freiburg, germany

In this study, we report on an electrochemical insertion of Au nanoparticles in polyaniline (PANI) using a two-step process. In the first step, tetrachloroaurate anions (AuCl4-) are attached on the protonated imine sites of PANI while holding the potential at +0.8 V. The applied electrochemical potential prevents any reduction of the PANI/AuCl4- complex. After rinsing of excess AuCl4-, a controlled reduction is carried out via cyclic voltammetry. Therefore, we investigate the introduction of Au species into PANI via precise electrochemical control in a flow cell system. The PANI/Au composites are characterized using scanning electron microscopy (SEM) and Rutherford backscattering spectrometry (RBS) to quantify the amount of introduced Au. It is demonstrated that the PANI/AuCl4- complex is not aggregating prior to the electrochemical reduction process. However, the controlled reduction of these PANI/Au complexes leads to the subsequent formation of Au nanoparticles, whose density and size dispersion depend on the Au loading in PANI. Furthermore, additional Au deposition cycles increase both the Au nanoparticle density and size. We propose a two-step growth model based on our experimental results. The results are discussed with respect to the formation of atomic Au clusters reported in previous works.

CPP 35.24 **Wed 11:00** **P1**

Accelerating self-assembly of colloidal particles at air-water interface by laser induced heating of upconverting particle — •Lokesh Chinnakanna Muruga, Gokul Nalupurackal, Sresta Roy, Snigdhadev Chakraborty, Jayesh Goswami, and Basudev Roy — Indian Institute of Technology Madras, Chennai, India - 600036

Particles can be assembled at the air-water interface due to optically induced local heating. This induces convection currents in the water which brings particles to the surface. We improve the technique by employing an upconverting particle (UCP), which, when illuminated with 975 nm light, not only emits visible emission but also generates heat owing to the poor efficiency of the upconversion process. This induces strong convection currents which makes particles dispersed in the suspension assemble at the interface and immediately under the UCP. We show assembly of polystyrene particles of 1 μm diameter and diamonds of 500 nm diameter bearing Nitrogen-Vacancy (NV) centers around the UCP. We also show, for the first time, that the microdiamonds are assembled within about 30 nm at the bottom of the UCP by utilizing non-radiative energy transfer that reduces the lifetime of the 550 nm emission from about 90 μs to about 50 μs.

CPP 35.25 **Wed 11:00** **P1**

Following the directed self-assembly of crystallizable block co oligomers via in situ AFM — •Alexander Meinhardt[1], Peng Qi[2], Ivan Maximov[3], and Thomas F. Keller[1] — [1]Centre for X-ray and Nano Science (CXNS), Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]Paul Scherrer Institut, Villigen, Switzerland — [3]Solid State Physics and NanoLund, Lund University, Lund, Sweden

Bottom up nanofabrication utilizing the molecular self-assembly of block co-oligomers with sub-10 nm domain sizes is widely discussed as a promising route for next generation photolithography. Double crystalline co-oligomers can be used to create well defined, high-fidelity nanostructures by controlling the competing driving forces microphase separation and crystallization. We report on the surface nanostructure formation and the temporal evolution during annealing of thin films of an amphiphilic double crystalline polyethylene-block-poly(ethylene oxide) co-oligomer (PE-b-PEO) on planar and patterned surfaces. On a planar Si surface we observed the self-assembly of PE-b-PEO into locally ordered lamellar surface structures extending over several micrometers. Directed self-assembly (DSA) of this PE-b-PEO system by physical guiding patterns can enable the formation of large scale nano-templates interesting for future applications. First DSA experiments indicate that the formed PE-b-PEO based surface nanostructures depend on the pitch of the guiding pattern. We furthermore aim to use in situ AFM to shed light on the pitch-dependent structural evolution during dedicated temperature-controlled annealing procedures.

CPP 35.26 **Wed 11:00** **P1**

Intracrystalline dynamics of polybutylene succinate and poly(3-Hydroxybutyrate) — •Mohd Afiq Bin Anuar, Yu Qiang, Thomas Thurn-Albrecht, and Kay Saalwächter — Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, 06099 Halle, Germany

The dynamics behavior of polymers chain in crystal lamellae plays a critical role for its semicrystalline morphology [1, 2]. It is influenced by this intracrys-

talline dynamics (ICD) explaining the factors that limit its crystal thickness during isothermal crystallization. In this work, two different behaviours of semicrystalline polyesters, namely polybutylene succinate (PBS) and poly(3-Hydroxybutyrate) (P3HB), are discussed. A combination of nuclear magnetic resonance (NMR) techniques shows that isothermally crystallized PBS exhibit slow ICD longer than 1s which is similar to the reported crystal-fixed polymer, polycaprolactone [1]. Meanwhile, in P3HB crystal chain, the ICD with correlation jump motion around 0.5s/monomer at 120˚C was detected. This is in contrast to previous reported [3] demonstrating a crystal-mobile behavior. Small-angle X-ray scattering measurement reveal that the P3HB crystal lamellae are significantly thicker than in PBS, confirming that P3HB and PBS can be classified as crystal-mobile and crystal-fixed, respectively. Details regarding morphology are shown in the poster.

Non-linear mechanical properties of polycaprolactone polymer/oligomer blends with defined entanglement density and crystalline thickness — •Tonghua Liu, Albrecht Petzold, and Thomas Thurn-Albrecht — Von-Danckelmann-Platz 3, 06120, Halle(Saale)

The mechanical properties of semi-crystalline polymers are determined by the semi-crystalline morphology and the entanglements in the amorphous regions. Here we use polymer/oligomer blends to control the entanglement density independently of the crystallinity. This system is also used as a model to study effects on the non-linear mechanical properties. The aim of the project is to develop a quantitative method for the determination of the entanglement density in the amorphous region as well as to investigate its relation to yielding, modulus and strain hardening. The commonly used method is tensile testing, but cavitation and necking cannot be avoided. Instead, we use plane-strain compression tests, which allow the direct determination of the true stress and avoids problems like cavitation. A separation of viscous and elastic contributions can be achieved by inserting relaxation measurements during the deformation. Our preliminary results indicate a strong effect of the crystallinity on the modulus and yield stress. The relation between strain hardening and entanglement density will be discussed.

CPP 35.28 **Wed 11:00** **P1**

New experimental methods for structure analysis of soft matter — •Eric Euchler[1], Anna Katharina Sambale[1], Regine Boldt[1], Kai Uhlig[1], Laura Neumann[1], Konrad Schneider[1], Matthias Schwartzkopf[2], Stephan Roth[2,3], and Markus Stommel[1,4] — [1]Leibniz-Institut fuer Polymerforschung, Dresden, Germany — [2]Deutsches Elektronen Synchrotron DESY, Hamburg, Germany — [3]KTH Royal Institute of Technology, Stockholm, Sweden — [4]Technical University Dresden, Dresden, Germany

Recently developed stretching devices for synchrotron measurements are available to investigate deformation-induced phenomena, such as strain-induced crystallization in natural rubber or void formation in biological tissues, at quasi-static and impact loading. In addition to measurements in transmission, novel studies of thin layers on flexible substrates can be realized by performing in situ grazing-incidence (GI) experiments.

Beside structure analysis in solid parts, the flow-induced structure formation in polymer melts is of particular interest to better understand the impact of melt processing parameters on macroscopic material properties, such as Young's modulus and tensile strength. For this purpose, a new experimental setup has been designed and built to study time- and temperature-dependent structure evolution events in thermoplastics. Within a temperature-controlled flow channel, polymer melts can be monitored with a microfocus X-ray synchrotron beam and first results obtained for two different thermoplastic materials proofed the experimental concept under quiescent melt conditions.

CPP 35.29 **Wed 11:00** **P1**

Towards experimental detection of crystallization in individualized polymer chains — •Wing Kit Or, Alaa Hassan, and Martin Tress — Peter Debye Institute for Soft Matter Physics, Leipzig University, Leipzig, Germany

Although crystallization of polymers has been investigated since decades, it is not yet fully understood. One way to gain more insight is to study the difference between bulk polymer and confined polymer chains with focus on how crystallization characteristics change depending on the size and type of confinement. Until now, most studies have used confinement in thin films or nanopores but the approach to study crystallization and aggregation in individual chains was accessible only to computer simulations. Since detection of phase transitions in individual polymer chains poses a severe challenge to most experimental methods, the measurement of ensembles of individual chains is desirable. However, maintaining the individual character requires a sophisticated method to separate them. Here, we use block copolymer micelle lithography (BCML) to deposit a regular pattern of well-separated gold nanodots on a silicon substrate in order to chemically graft end-functionalized polymer chains on these nanodots to in-

dividualize them. Instead of common thermodynamic methods (which require considerably more sample material), we employ dielectric spectroscopy using a nanostructured electrode arrangement since it is much more sensitive. Albeit being typically considered a dynamics method, it also allows to examine density changes and thus phase transitions of polymers.

CPP 35.30   Wed 11:00   P1

Uniaxially Aligned Merocyanine Films by Graphene Nanoribbon Templated Growth — •Philipp Weitkamp, Nora Gildemeister, Lukas Böhner, Dirk Hertel, and Klaus Meerholz — Physikalische Chemie, Universität zu Köln, Deutschland

We herein report the unique and novel approach of achieving a polycrystalline thin film consisting of uniaxially aligned domains by using 7-armchair graphene nanoribbon (7-aGNR) monolayers as van-der-Waals template. For this purpose, a merocyanine dye was evaporated on 7-aGNRs, transferred on quartz glass substrates. The alignment of the formed molecular aggregate along the GNR alignment direction was proven by polarisation dependent absorbance spectroscopy. The J- and H-transition, formed by the dye aggregate, were correlated with distinct axes of the crystal structure. By combining this correlation with polarisation dependent absorbance measurements and X-ray diffraction experiments we elucidated the three-dimensional structure of the formed aggregate thin film. The growth mode of these films was investigated as a function of the applied layer thickness. Atomic force microscopy-based morphology analysis and X-ray diffraction experiments were used to reveal the anisotropic on-surface crystallisation along the 7-aGNR long axes direction. Furthermore, we found that the delocalisation length of the aggregate increases with increasing in-plane order. Finally, we demonstrated that the in-plane alignment leads to an anisotropic charge carrier transport by implementing the templated merocyanine thin film as active layer in a top-gated organic field effect transistor.

CPP 35.31   Wed 11:00   P1

Long chain Polyamides: Influence of methylene sequence length and external forces on structural features — •Rene Sattler[1,2], Varun Danke[3], and Mario Beiner[1,2] — [1]Fraunhofer IMWS, Walter-Hülse-Str. 1, D-06120 Halle (Saale), — [2]Martin-Luther-Universität Halle-Wittenberg, Naturwissenschaftliche Fakultät II, D-06099 Halle (Saale) — [3]Evonik Operations GmbH, Research Development & Innovation, Paul-Baumann-Str. 1, D-45722 Marl

Crystallographic studies towards the influence of methylene sequence length on a series of even-even polyamides PA 10.n (with n = 12, 14, 16 and 18) are performed. Temperature-dependent X-ray diffraction measurements show that the triclinic α phase is the preferred phase at room temperature after slow cooling from melt. In PA 10.12 and PA 10.14 a reversible Brill transition to the (pseudo)hexagonal high temperature γ phase is observed. However, the Brill transition temperature is strongly dependent on n and shifting to higher temperatures with increasing methylene sequence length. For the two higher members a Brill transition is absent. The analysis of annealed, uniaxial oriented fibers reveals that the crystalline state achieved under ambient conditions is influenced by external forces. This is due to relatively small energetic differences between the α and β polymorphs. All the uniaxial oriented PA 10.n samples show a β polymorph which is most prominent for PA 10.12 and PA 10.14. The higher members show a mixture of the β polymorph superimposed with a certain franction of the α polymorph.

CPP 35.32   Wed 11:00   P1

Bond order parameters in crystallization of short polymer chains in thin films: SAMC simulation — •Evgeniia Filimonova, Timur Shakirov, and Viktor Ivanov — Martin Luther University of Halle-Wittenberg, Institute of Physics, 06120, Halle (Saale), Germany

We study the crystallization of polymer melts in thin films using a coarse-grained model and stochastic approximation Monte Carlo (SAMC) simulation. Our goal is to reveal physical factors which are responsible for one of two possible scenarios of surface-induced polymer crystallization: heterogeneous nucleation or prefreezing. We have developed an approach that allows us to identify the translational and orientational local ordering by means of comparing our system configurations with reference crystalline structures of different symmetries. In addition to calculating the usual order parameters (Steinhardt parameters, common neighbors analysis, nematic order parameter, etc.), we suggested new order parameters based on scalar products of bonds between nearest neighbors. We observe a coexistence of an isotopic structure in the center of the film with ordered structures at the walls at intermediate values of energies (in microcanonical analysis). A change in the crystal structure accompanying a change in density at different energies is also shown. Financial support of the International Graduate School AGRIPOLY supported by the European Social Fund (ESF) and the Federal State Saxony-Anhalt is acknowledged.

CPP 35.33   Wed 11:00   P1

Investigating the thermodynamics and kinetics of catechin pyrolysis for environmentally friendly binders — •Jakob Kraus and Jens Kortus — Institute of Theoretical Physics, TU Bergakademie Freiberg, Leipziger Str. 23, D-09599 Freiberg, Germany

The thermodynamics and kinetics of the pyrolysis of (+)-catechin, a building block of the condensed tannins found in recipes for sustainable binders, are evaluated at the CCSD(T) level and compared to other methods from quantum chemistry. Using the climbing image nudged elastic band method coupled with transition state optimization, minimum energy paths and highest-energy transition states are identified for the first two pyrolysis steps, a catechol splitoff with subsequent dehydrogenation. While the catechol splitoff path was very smooth, the dehydrogenation featured an additional transition state in the form of an OH group rotation. The combined reaction was judged endothermic in the range of 0 K to 1250 K, and exergonic at 1000 K and above. It is shown that the catechol splitoff is the rate-determining step of the pyrolysis of catechin, which is equivalent to kinetic inhibition at all investigated temperatures.

CPP 35.34   Wed 11:00   P1

Pyrolysis of ellagic acid - a thermodynamic and kinetic study by means of quantum chemistry — •Philip Schöne, Jakob Kraus, and Jens Kortus — TU Bergakademie Freiberg (Institut für Theoretische Physik) Leipziger Str. 23, 09599 Freiberg, Deutschland

By performing ab-initio calculations, thermodynamic and kinetic data on the pyrolysis of ellagic acid were computed. The reaction path consists of two decarboxylations and two hydrolyses. The pyrolysis of ellagic acid can take place via the formation of either hexahydroxydiphenic acid or urolithin m5. Using select DFT functionals and quantum chemical methods, data for each reaction were calculated between 0 K and 1200 K. The occurring decarboxylations were found to be very similar to each other, being exothermic and exergonic reactions that become increasingly so with rising temperature. The hydrolyses show the opposite behavior, being slightly endothermic and endergonic reactions that become increasingly so with rising temperature. With the help of the climbing image nudged elastic band method, mechanisms for all reactions could be proposed and highest energy transition states could be identified. For the decarboxylations, these represent H transfers from the carboxylic group to the neighboring C atom. For the hydrolyses, the highest energy transition states correspond to H transfers from water to the nascent carboxylic group. Moreover, the rate-determining steps in the pyrolysis of ellagic acid were determined, which are the hydrolyses of urolithin m5 and luteic acid.

CPP 35.35   Wed 11:00   P1

Transversal piezo-force-microscopy with the use of interdigitated electrodes — •Maximilian Litterst, Andrey Butkevich, and Martijn Kemerink — Institute for molecular systems engineering and advanced materials, Heidelberg, Germany

Piezoresponse force microscopy (PFM) is a simple method to measure the piezoelectric effect of many materials with an atomic force microscope (AFM). Usually, a voltage is applied between the tip and the substrate to trigger a vertical displacement of the material via the converse, longitudinal, piezoelectric effect, which results in a vertical displacement of the tip. The transversal piezoelectricity can result in a torsion of the tip, it is however often very difficult to find a direct connection between the two.

Here, we present how interdigitated electrodes (IDEs) can be used to apply an electric field in the film-plane, resulting in a vertical displacement of the film due to the converse, transversal, piezoelectric effect. In addition, the longitudinal component can be measured via the torsional tip motion. This does not only provide a direct way to measure the transverse piezoelectricity, but also opens new possibilities for the device preparation.

CPP 35.36   Wed 11:00   P1

Ca substituion instead of Sr in La$_{0.58}$Sr$_{0.4}$Co$_{0.2}$Fe$_{0.8}$O$_{3-\delta}$ as a cathode electrode for IT-SOFCs — •Majid Jafari[1], Fatemeh Yadollahi Farsani[2], Norbert Menzler[3], Christian Lenser[4], and Fabian Grimm[5] — [1]Plön, Germany — [2]Isfahan university of technology, Isfahan, Iran — [3]Forschungszentrum Jülich, Jülich, Germany — [4]Forschungszentrum Jülich, Jülich, Germany — [5]Forschungszentrum Jülich, Jülich, Germany

La$_{0.58}$Ca$_{0.4}$Co$_{0.2}$Fe$_{0.8}$O$_{3-\delta}$ (L58CCF) was synthesized and evaluated as a cathode electrode for intermediate temperature solid oxide fuel cells (IT-SOFC) based on the Y$_2$O$_3$-stabilized ZrO$_2$ (YSZ) electrolyte. The effect of sintering temperature on the L58CCF performance was investigated. The best Area specific resistances (ASRs) for the L58CCF sintered at 950 °C were 1.218, 0.447, 0.228, 0.156, 0.099 $\Omega.cm^2$ at 600, 650, 700, 750, 800 °C, respectively.

CPP 35.37   Wed 11:00   P1

Antiperovskites (Li$_2$Fe)ChO as cathode material for lithium-ion batteries and investigation of the reaction mechanism — •Bowen Dong[1], Lennart Singer[1], Mohamed Abdullah Abdullah Mohamed[2], Silke Hampel[2], Nico Grässler[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Leibniz Institute for Solid State and Materials Research (IFW) Dresden e.V., Germany

Due to it unique structure, antiperovskite (Li$_2$Fe)ChO (Ch = S, Se) have emerged as a promising Li-ion battery (LIB) cathode material with excellent rate capability and a good discharge capacity. We report synthesis of antiperovskites by a

direct ball-milling process and evaluate the phase stability, cycling performance, and rate performance. The effect of post-synthesis heat treatment on the resulting materials as well as on its battery performance is studied. Cyclic voltammetry studies reveal a high-voltage decomposition process which progressively yields the formation of Fe_xCh_y. Galvanostatic measurements exhibit outstanding electrochemical cycling performance of antiperovskite-based cathodes of 250 mAh/g at 0.1 C. Further, we suggest a route to avoid the progressing conversion of $(Li_2Fe)ChO$ (Ch=S, Se) to Fe_xCh_y which effectively improves the cell performance of antiperovskites.

CPP 35.38 **Wed 11:00** **P1**

Rational Design of Novel Photoswitches with Generative Models — •Robert Strothmann, Christian Kunkel, Johannes Margraf, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin, Germany

The sheer vastness of chemical spaces poses a daunting challenge to molecular discovery through high-throughput screening based on exhaustive sampling. Generative models (GMs) are an emerging machine learning (ML) approach that enables a more guided discovery. Implicitly learning chemical design rules from large reference data sets and suitable descriptors of a targeted functionality, GMs directly propose promising, yet diverse candidates.

Here we explore the use of GMs for the design of novel molecular photoswitches. In a first step, large general molecular databases are used to train a GM to generate chemically valid photoswitches. In a second step, the creation process needs to be conditioned towards performant switching capabilities. In the absence of sufficient corresponding experimental reference data, this conditioning is based on synthetic first-principles data. For that purpose computationally efficient descriptors are used in a multi-objective fashion to account for the desired key aspects of the switching process.

Correlating molecular properties to nonlinear optical activity: Prerequisites for white light generation. — •Ferdinand Ziese, Lena Albohn, Kevin Eberheim, and Simone Sanna — Institut für Theoretische Physik Heinrich-Buff-Ring 16, 35392 Gießen, Germany

Recent studies have demonstrated white light generation from molecular clusters with adamantane-like cores and different ligands [1,2]. To understand the origin of this behavior, we have investigated structural, electronic, and (nonlinear) optical properties from first principles for isolated molecules and dimer structures [3]. In this contribution, we focus on the comparison between isolated molecules and molecular dimers. We correlate the structural and electronic properties with the optical response and investigate the effect of symmetry and heterogeneous composition.

Effect of electron and laser irradiation on the structure of halogen substituted adamantane clusters — •Lena Albohn, Simone Sanna, Kevin Eberheim, and Ferdinand Ziese — Institu für Theoretische Physik Heinrich-Buff-Ring 16, 35392 Gießen, Germany

Functionalized adamantane molecular clusters are highly nonlinear optical materials which are able to convert infrared radiation into a directed emission supercontinuum. While the origin of the optical nonlinearity is still under debate, the amorph habitus of the materials seems to be a prerequisite for the white-light generation.

Unfortunately, many adamantane-based or organotetrel clusters crystallize in an ordered structure characterized by intense second-harmonic generation instead of white-light emission. In order to render the molecular crystals amorph, electron or laser irradiation has been suggested. In order to explain the mechanisms leading to the structural modification, we model electron or laser irradiation from first principles. Thereby, we employ halogen substituted adamantane clusters as a model system. Our calculations reveal that laser and electron irradiation have a similar effect on the compounds. Depending on the irradiation dose, intermolecular rearrangements as well as intramolecular deformations (photochemical rearrangement) may occur, thus facilitating the white-light emission.

CPP 35.41 **Wed 11:00** **P1**

Structural properties of a semi-dilute suspensions of magnetic multi-core nanoparticles — •Ekaterina Novak[1], Andrey Kuznetsov[2], Elena Pyanzina[1], Marina Gupalo[1], Tatyna Belyaeva[1], and Sofia Kantorovich[2] — [1]Ekaterinburg, Russia — [2]University of Vienna, Vienna, Austria

During the last thirty years, magnetic soft matter systems have become highly promising candidates for medical applications such as magnetic hyperthermia and magnetic drug targeting. The subject of this work, magnetic multicore nanoparticles (MMNPs), are rigid clusters of single-domain magnetic nanocrys-

tals (cores or grains) embedded in a polymer or other non-magnetic matrix. While the grains typically have a characteristic linear size of the order of 10 nm, the size of MMNPs can range from tens to a few hundred nanometers. Here, using Langevin dynamics computer simulations, we investigated diluted suspensions of MMNPs composed by grains, whose positions are fixed within the particle body, but their magnetic moments are free to rotate, corresponding to the grains with negligibly low magnetic anisotropy.

We calculated cluster size distributions and compared them to their counterparts in a system of single-domain magnetic nanoparticles. A drastic difference was found: for two MMNPs to aggregate they need to form a bridge a stable array of grains from both multicores that are connected via dipolar interactions. The more bridges the two MMNPs form, the more stable is their aggregate.

CPP 35.42 **Wed 11:00** **P1**

Characterisation and transport within tetra-PEG*tetra-PCL amphiphilic end-linked polymer model networks — •Lucas Löser[1], Carolin Bunk[2], Frank Böhme[2], and Kay Saalwächter[1] — [1]Inst. F. Physik * NMR, Martin-Luther-Universität Halle-Wittenberg, Halle/D — [2]Leibnitz-Institut für Polymerforschung Dresden e.V., Hohe Str. 6, Dresden/D

A new approach for the synthesis of model-like amphiphilic co-networks is introduced, and their structure is analyzed by static 1H time-domain nuclear magnetic resonance (NMR) methods [1]. The hetero-complementary end-linking reaction of two well-defined star precursors [2] is implemented to obtain amphiphilic gels. We link PEG stars with hydrophobic poly-*-caprolectone stars (tetra-PCL), resulting in the formation of an amphiphilic network. NMR is shown to be capable of distinguishing different chain species in the swollen PEG-PCL networks, allowing quantification of network connectivity defects arising from the end-linking reaction, as well as accurate quantification of inelastic material. The mesh size of the networks is studied by Pulsed-Field Gradient (PFG) NMR, using dextrans as hydrophilic probe molecules for the network swollen in selective solvents. Furthermore, we performed measurements using small-angle x-ray scattering and 1H MAS recoupling NMR for information on the properties of the selectively swollen networks, e.g., estimates for the correlation length of PCL domains, and chem. shift-specific information about the chain dynamics.

CPP 35.43 **Wed 11:00** **P1**

Hybrid hydrogel films for scalable H2 production — •Morgan Le Dû[1], Julija Reitenbach[1], Manuel A. Reus[1], Kun Sun[1], Zerui Li[1], Sigrid Bernstorff[2], Cristiane Henschel[3], André Laschwesky[3], Christine M. Papadakis[4], and Peter Müller-Buschbaum[1,5] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]Elettra-Sincrotrone Trieste, Basovizza, Italy — [3]Fraunhofer-Institut für Angewandte Polymerforschung, Potsdam-Golm, Germany — [4]TUM School of Natural Sciences, Soft Matter Physics group, Garching, Germany — [5]Heinz Maier-Leibnitz-Zentrum (MLZ), TUM, Garching, Germany

The water splitting reaction can produce hydrogen-based energy from solar radiation. A promising photocatalyst for this reaction is Pt loaded graphitic carbon nitride (g-CN). It shows a high H2 evolution efficiency in aqueous solution. Previous works proposed to introduce hydrogels as host matrix and water storage to facilitate homogeneous spreading. This work aims to develop this system industrially scalable in a polymer thin film configuration. Poly(N-isopropylacrylamide) thin films exhibit good swelling capacity in water vapor atmosphere and appear suitable for a hybrid thin film system. A new isomer poly(N-vinylisobutyramide) seems also promising due to its higher lower critical solution temperature in aqueous solution. Therefore, a comparison of both polymers is based on in situ spectral reflectance and FT-IR measurements. The films have been spray coated to proceed grazing incident small angle x-ray scattering where g-CN/Pt blended polymer films microstructure was analysed under light irradiation.

CPP 35.44 **Wed 11:00** **P1**

Effect of type of initiator and purification on the properties of thermo-responsive PNIPAM microgels — •Joanne Zimmer, Sebastian Stock, Souraj Mandal, Carina Schneider, Luca Mirau, and Regine von Klitzing — Soft Matter at Interfaces, Institute for Condensed Matter Physics, TU Darmstadt, Germany

Microgels (MG) are polymeric networks in the size range of micrometers boasting properties of both colloids and polymers. Depending on their composition MG can respond to external stimuli such as temperature or pH. An example of a thermo-responsive polymer is Poly(N-isopropylacrylamide) (PNIPAM). PNIPAM MG can be synthesized by surfactant-free precipitation polymerization comprising NIPAM monomers, the crosslinker N,N'-methylenebisacrylamide (BIS) and a radical initiator. Depending on the radical initiator, either negatively or positively charged MG are generated. The subject of this work is the evaluation of the MG charge on the thermo-responsive swelling behavior and elastic properties using Dynamic Light Scattering and Atomic Force Microscopy. In addition, the type of MG purification and its effect on the resulting MG proper-

ties is investigated. It was shown, that the presence of undesired low-molecular weight products strongly impacts the MG interfacial adsorption behavior what we wish to understand. In this regard, sufficient removal was only achieved if, apart from the standard purification via dialysis, subsequent centrifugation steps were carried-out. The MG bulk properties (hydrodynamic radius, Zeta-potential) remained unchanged before and after centrifugation.

CPP 35.45   Wed 11:00   P1

Diketopyrrolopyrroles on graphite: Carpets self-assembled via hydrogen bonding — Moufdi Hadjab[1,2], Vladyslav Savchenko[2], Nina Tverdokhleb[2], and •Olga Guskova[2] — [1]Mohamed Boudiaf University of M'sila, Algeria — [2]IPF Dresden, Germany

We investigate the initial stages of the adsorption and thin-film formation of N-unsubstituted difuryl-diketopyrrolopyrroles (DPP) on graphite. Molecules in a particular conformational state (cis-cis, cis-trans or trans-trans) build the adsorption layers during in-silico self-assembly on surface through intermolecular hydrogen bonding. Here, the vacuum deposition of the molecules is reproduced in the all-atom MD setup [1]. We found out the formation of stable carpets made of molecular stripes. These carpets can be characterized as monomolecular layers in contrast to the sructures, formed using droplet deposition [2]. The most stable stripes are made of cis-cis conformers, which is explained by stronger intermolecular hydrogen bonding. The stripe growth is accompanied by the reduction of the Eg gap. At the same time, the binding energy of the molecules does not show a clear dependence on the stripe length, which is a signature of the isodesmic self-assembly. Additionally, we quantify the intermolecular and the molecule/graphite energies for the hydrogen-bonded DPP molecules and compare the results with known experimental data. This work is supported by DFG, grant GU1510/5-1. [1] Guskova O.A., et al. J. Phys. Chem. C 2013, 117, 33, 17285. [2] Hadjab M., Guskova O. Herald of TvSU. Ser. Chem. 2021, 4, 46, 118.

CPP 35.46   Wed 11:00   P1

Ground- and excited-state properties of tetraphenyl compounds from first-principles calculations — •Kevin Eberheim, Lena Albohn, Ferdinand Ziese, Christof Dues, and Simone Sanna — Institut für Theoretische Physik and Center for Materials Research, Justus-Liebig-Universität Gießen, 35392 Gießen, Germany

Tetraphenyl compounds with formula $X(C_6H_5)_4$ (X being a tetrava- lent atom of the 14th group such as C, Si, Ge, Sn, Pb), crystallize either in a tetragonal crystalline structure or in an amorph phase [1]. Depending on their habitus, the compounds are characterized by very different optical properties. The molecular crystals are known for their second harmonic generation (SHG) properties, while the amorph phase is a white light emitter. Tetraphenyl molecules feature indeed the de- localized π-orbitals, which have been proposed as a prerequisite for the white-light generation [2]. In an attempt to understand the mechanisms related to the white light emission, we model the structural, electronic and vibrational properties of different $X(C_6H_5)_4$ structures within density functional theory. The calculated structural parameters closely reproduce the measured values, however vdW corrections are crucial for a correct description of the structural properties. This con- firms that dispersion forces are responsible for the intermolecular bonds in the compound. Different implementations of the vdW forces lead to very similar results. Calculated vibrational properties are in agree- ment with measured Raman spectra. [1] A Kitaigorodsky, Molecular crystals and Molecules, Acad. Press (1973). [2] Nils W. Rosemann et al., J. Am. Chem. Soc. 138, 16224 (2016), Science 352, 1301 (2016).

CPP 35.47   Wed 11:00   P1

Scaling Properties of Tree-like Self-Similar Polymers — •Ron Dockhorn[1] and Jens-Uwe Sommer[1,2] — [1]Leibniz-Institut für Polymerforschung Dresden e.V., D-01069 Dresden, Germany — [2]Technische Universität Dresden, Institut für Theoretische Physik, D-01069 Dresden, Germany

In this study, regular polymeric Vicsek- and T-fractals are compared to dendrimers in means of theory and simulations. Albeit all structures exhibit exponential growth both for the number of monomers inside the structures and also for the terminal groups their structural properties differ significantly. Computer simulations are performed to investigate the scaling properties of the tree-like self-similar polymers utilizing the Bond-Fluctuation-Model with the Metropolis method as well as with the Wang-Landau algorithm. The radius of gyration, the heat capacity and the θ-point of those systems is investigated to examine the coil-globule transition of the polymeric fractals. A mean field theory for the scaling exponent in different solvent regimes is applied and found in fair agreement to the simulation data. A cross-over from almost linear chain behavior to spherical shape is observed, which can be tuned by the intrinsic functionality of the building blocks. The polymeric fractals can be an alternative to dendrimers in the class of hyperbranched polymers.

CPP 35.48   Wed 11:00   P1

Statistical Analysis of the Dimerization of Polyglutamine Chains — •Christian Lauer and Wolfgang Paul — Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany

We are presenting a numerical investigation of the dimerization of polyglutamine homo-peptides of varying length. We use the intermediate resolution protein model PRIME20 and study it with a flat-histogram type Monte Carlo simulation. This gives us access to the thermodynamic equilibrium of this model over the complete control parameter range, which for our simulations is the temperature. For densities comparable to typical in vitro experimental conditions we find that the aggregation and folding of the polyglutamine chains occur concurrently. However, as a function of chain length the sequence of establishment of intra- and intermolecular hydrogen bonding contacts changes. Chains longer than about $N = 24$ polyglutamine repeat units fold first and then aggregate. This agrees well with the experimental finding, that beyond $N = 24$ the single polyglutamine chain is the critical nucleus for the aggregation of amyloid fibrils. A finite size scaling of the ordering temperatures reveals that for this chain length (and longer chains) folding occurs at physiological (respectively larger) temperatures whereas shorter chains are disordered at physiological conditions.

CPP 35.49   Wed 11:00   P1

Construction of a polarizable force field for molecular dynamics simulation of a NaOTF Water-in-Salt electrolyte — •Majid Rezaei, Sung Sakong, and Axel Gross — Institute of Theoretical Chemistry, Ulm University, 89069 Ulm, Germany

A NaOTF Water-in-Salt (WiS) electrolyte is modeled using classical molecular dynamics (MD) simulations. For this, four different force fields are employed to account for atomic polarization at different levels: a non-polarizable all-atom force field where the polarization effect is only implicitly included in the Van der Waals interaction parameters; the same force field with uniformly scaled ionic charges which, in a mean-field approximation, mimics electron polarization; a partially polarizable force field where ion polarization is explicitly accounted for via Drude oscillators while water is modeled by the non-polarizable SPC/E model; and a fully polarizable force field where the Drude oscillator model is used to account for both water and ion polarization. The primary goal of this study is to evaluate the simulation stability when using the above force fields and to investigate how the electrolyte properties are sensitive to the force field parameters. The results are then used to construct a force field that best reproduces the electrolyte properties obtained from ab initio molecular dynamics (AIMD) calculations. For this purpose, we use the partially polarizable model, which we believe is accurate enough to reproduce various properties of the studied electrolyte while the computational effort is affordable. The optimized force field will then be used to study the structure and dynamic properties of a NaOTF WiS solution under different conditions.

CPP 35.50   Wed 11:00   P1

Kirkwood-Buff theory approach towards cosolvent effects on single polymer chain collapse transition — •Martin Melčák, Jakub Smutek, and Jan Heyda — Department of Physical Chemistry, University of Chemistry and Technology, Prague, Technická 5, CZ-16628 Praha 6, Czech Republic

The so-called smart materials are unique for their ability to rapidly and fully reversibly change physical or chemical properties upon exposure to external stimuli, such as temperature, light, pH, or solvent quality. In this contribution, we have taken under focus the prominent example of thermoresponsive polymer, which conformation can be near critical temperature modulated by the addition of small doses of cosolvents. To reveal the microscopic origin of the thermodynamic effect, we employed coarse-grained molecular dynamics simulations of a single polymer chain in mixed solution. The studied model can effectively describe changes in polymer chain conformation as well as the responses of the local solution composition in polymer proximity. Utilizing this fact, we have described and analyzed system thermodynamics in the framework of Kirkwood-Buff theory, which combines the polymer and environmental perspective of cosolvent effect on the polymer transition. Within a single unifying concept, our model is thus capable to quantitatively describe cosolvent effects in three interaction regimes, namely: depleted, weakly binding, and bridging regime.

CPP 35.51   Wed 11:00   P1

Fabrication of Plasmonic Au Nanostructures for Electrocatalysis — •Gina Ross and Björn Braunschweig — Institut für Physikalische Chemie, WWU Münster, 48149 Münster, Germany

Nanosphere lithography (NSL) is a classical technique to fabricate reproducible 2D masks. These masks can be used to structure surfaces in a well-defined fashion. We have used spherical polystyrene (PS) particles to generate closed-packed hexagonal layers on a substrate surface that serves as a quasi 2D mask. The latter is subsequently coated with Au to fabricate Au nanopyramids which are received by dissolution of the PS particles. Their deposition as a mask was done with the Langmuir-Blodgett transfer at the air-water interface. For that a suspension of polystyrene particles was spread on the water subphase containing no additional salt or surfactant. The fraction of PS particles sinking into the bulk subphase was drastically reduced by a 1:1 suspension of water and ethanol, and by dispensing the PS suspension onto the air-water interface with a glass slide at an angle of 45° relative to the interface. Au deposition and mask removal with an ultrasonic bath led to the formation of Au nanopyramids. We expect the interaction of

these nanostructures with electromagnetic radiation to result in a local field enhancement which promises to improve chemical reactions sensitive to electric field gradients. For that reason we have investigated the ability of Au plasmonic structures to promote CO_2 electrocatalysis.

CPP 35.52   Wed 11:00   P1

Luminescence properties of Nd complexes and processing of photonic crystal structures — •Miriam Gerstel[1], Ingo Köhne[2], Paul Mertin[3], Bernd Witzigmann[3], Johann Peter Reithmaier[1], Rudolf Pietschnig[2], and Mohamed Benyoucef[1] — [1]Institute of Nanostructure Technologies and Analytics — [2]Institute of Chemistry, CINSaT, University of Kassel, Germany — [3]EEI Department, Friedrich-Alexander University of Erlangen-Nürnberg, Germany

Lanthanide ion luminescence exhibits characteristic narrow emission bands along with relatively long emission lifetimes which makes them attractive for applications in lighting, sensing, and display technologies. We investigate the optical characteristics of phosphonate ester-supported nitrite and chloride neodymium(III) complexes as solid bulk material and in solution. Optical properties of Nd complexes are determined by photoluminescence (PL) spectroscopy, which reveals emission bands of Nd(III) ions in the NIR region. PL measurements of equimolar solutions reveal information about the emission strength of the complexes with different ligand types. Temperature-dependent PL spectra enable the assignment of the emission lines observed around 880 nm. For light enhancement, molecules are immobilized on photonic crystal cavities (PhCs). The fabrication of PhCs by electron-beam lithography, inductively coupled plasma reactive ion etching and selective wet etching techniques is discussed. This work is supported by the state of Hesse in the frame of LOEWE priority project SMolBits and the DFG grant-BE 5778/4-1.

CPP 35.53   Wed 11:00   P1

Insights into structure and dynamics of polycaprolactone-based star-shaped polymer electrolytes from molecular dynamics simulations — •Mirko Fischer[1], Diddo Diddens[2], and Andreas Heuer[1] — [1]Institute of Physical Chemistry, Westfälische Wilhelms-Universität Münster, Münster 48149, Germany — [2]Forschungszentrum Jülich GmbH, Helmholtz Institute Münster, Münster 48149, Germany

Solid polymer electrolytes (SPEs) are promising candidates to substitute classical organic electrolytes in lithium-ion batteries, as they are chemically and mechanically more stable and have improved safety. However, they exhibit low ionic conductivity, which can be generally improved by developing novel polymer architectures. Experiments have shown that the biodegradable Grafted Cyclodextrin-Polycaprolactone (GCD-PCL) has higher transfer numbers than classical poly(ethylene oxide). In this work, we present results of molecular dynamics (MD) simulations to understand the ion transport in GCD-PCL. In order to directly compare our simulations with experiments, we used the time-temperature superposition of mean residence times and mean squared displacements of lithium ions to calculate the ionic conductivity at low temperatures, which would otherwise require larger time scales than are accessible through MD simulations.

CPP 35.54   Wed 11:00   P1

Organisation of Nanoparticles with Polymer Brushes: Computer Simulation Studies — •Bhuwan Poudel, Hsiao-Ping Hsu, and Kurt Kremer — Max Planck Institute for Polymer Research, Mainz, Germany

For polymer brushes containing nanaoparticles, the interplay between concentration of nanoparticles and interaction between monomers and nanoparticles affects the ordering of nanoparticles and the structural and dynamical properties of the respective polymer brushes. We perform molecular dynamics simulations of polymer brushes based on the bead-spring model and treat nanoparticles as hard spheres with a diameter six times larger than the monomer size. Initially, nanoparticles are randomly distributed inside or above the polymer brushes. By tuning the attractive interaction between monomers and nanoparticles, we study the assembly of nanoparticles within the polymer brushes as a function of nanoparticle concentration. The appropriate choice of monomer-nanoparticle interaction and concentration of nanoparticles gives rise to a single (ordered) layers of nanoparticles whose equilibrium positions fluctuate within their diameters.

CPP 35.55   Wed 11:00   P1

Tribological Properties of Selected Vanadium Oxides Investigated with *ReaxFF* molecular dynamics — •Miljan Dašić[1,2], Ilia Ponomarev[1], Tomáš Polcar[1], and Paolo Nicolini[1] — [1]Department of Control Engineering, Faculty of Electrical Engineering, Czech Technical University in Prague, Technicka 2, Prague 6, 16627, Czech Republic — [2]Scientific Computing Laboratory, Center for the Study of Complex Systems, Institute of Physics Belgrade, University of Belgrade, Pregrevica 118, 11080 Belgrade, Serbia

Providing effective lubrication at high temperatures/pressures and in oxidative environments is relevant for various industrial applications, such as turbomachinery and cutting tools. Promising solutions are oxidation-resistant hard coatings consisting of binary or ternary films (e.g., $Cr-N$, $Ti-N$, $Cr-Al-N$,

$Ti-Al-N$) doped with vanadium. The amount of oxygen present in an oxidative environment can be varied, leading to different vanadium oxide stoichiometries. We investigated tribological performance of under-oxidized vanadium lubricants, selected based on available experiments. We conducted a *ReaxFF* molecular dynamics study on selected stoichiometries $\{V_2O_3, V_3O_5, V_8O_{15}, V_9O_{17}, VO_2\}$ at elevated temperatures $\{600, 800, 1000\}$ [K] and pressures $\{1, 2, 3, 4\}$ [GPa]. Our tribosystem consists of two rigid V_2O_5 layers, and a vanadium oxide in-between. At a fixed temperature, we did not notice significant changes of the friction coefficient with stoichiometry. All considered stoichiometries provide effective lubrication. Our study is relevant and interesting for the design of vanadium doped oxidation-resistant hard coatings.

CPP 35.56   Wed 11:00   P1

interfacial rheology of PNIPAM aqueous solutions at air-water interface: effect of cross-linking and oscillation frequency — •Atieh Razavi, Regine von Klitzing, and Amin Rahimzadeh — Hochschulstraße 8, 64289 Darmstadt, Germany

PNIPAM microgels are swollen and dispersible in water at temperatures below their VPTT .Microgels tend to adsorb at the liquid-air interface, thus reducing the surface tension. The degree of crosslinking influences the required time to reach the steady state. Higher cross-linker content results in a longer transient time in the order of several minutes (depending on the solution concentration). Upon the formation of a new interface, this transient time together with the mechanical properties of microgels play key roles in the interfacial elasticity of the air-water interface. The dynamic surface elasticity of aqueous solutions of PNIPAM has been measured by the oscillating barrier method as a function of time and concentration in different surface elongation frequencies. Results shows the apparent dilational elastic and loss moduli deduced from the pendant drop shape analysis at the air*water interface, as a function of pressure for the three cross-linking densities: 1, 5 and 10 mol%. In all cases, the apparent elastic modulus is much larger than the apparent loss modulus. The magnitude of the different elastic moduli goes through a maximum of elasticity for pressure values of about 15 mN/m. This behavior is a direct consequence of the particular structure of microgels, i.e. a dense and rigid core surrounded by a deformable shell made of dangling chains.The effect of oscillation frequency is still challenging and open question.

CPP 35.57   Wed 11:00   P1

Diffusion controlled pairwise associations of telechelic polymer chains — •Michael Lang and Ron Dockhorn — Leibniz-Institut für Polymerforschung Dresden, Institut Theorie der Polymere, Hohe Straße 6, 01069 Dresden, Germany

We study the pairwise association of telechelic chains in polymer melts. We derive the life time distributions of open stickers that return to the same partner as before (return walks) and the life time distribution of open stickers that exchange their binding partners (exchange walks) for both entangled and non-entangled chains. These distributions contain the full information of the bond association dynamics and allow to develop a generalization of the law of mass action in the diffusion controlled limit. The model predictions are tested by Monte-Carlo simulations and compared with preceding work on associations in networks.

CPP 35.58   Wed 11:00   P1

Architecture effect on the behavior of gradient and triblock terpolymer OEGMA-BuMA-DEGMA — •Wenqi Xu[1], Eirini Melampianaki[1], Feifei Zheng[1], Anna P. Constantinou[2], Theoni K. Georgiou[2], and Christine M. Papadakis[1] — [1]TUM School of Natural Sciences, Technical University of Munich, Garching, Germany — [2]Department of Materials, Imperial College, London, England

Triblock terpolymers with hydrophilic, hydrophobic, and thermoresponsive blocks feature micellization, aggregation, and gelation in response to temperature changes and are therefore promising in various biomedical applications [1]. Gradient terpolymers can serve as a cost-effective alternative. Here, we investigate a triblock and a gradient terpolymer composed of hydrophilic oligo(ethylene glycol) methyl ether methacrylate (OEGMA), hydrophobic *n*-butyl methacrylate (BuMA), and thermoresponsive di(ethylene glycol) methyl ether methacrylate (DEGMA). Dynamic light scattering and synchrotron small-angle X-ray scattering revealed that the gradient terpolymer forms spherical micelles, whereas the triblock terpolymer is apt to form elongated micelles. With increasing temperature, the former grow in radius and the latter in length, which may be due to the increasing hydrophobicity of the DEGMA block.

CPP 35.59   Wed 11:00   P1

Adaptive Air-Water Interfaces with Spiropyran and Arylazopyrazole Photoswitches — •Michael Hardt and Björn Braunschweig — University Münster, Center for Soft Nanoscience, 48149 Münster, Germany

Interfaces that respond to stimuli such as light or temperature are of great interest for new intelligent materials. Using molecular switches that respond to orthog-

onal triggers, the properties of fluid interfaces can be preconditioned and a low level of adaptivity can be integrated that extents the possibilities of soft matter interfaces beyond responsive functions.

In this contribution, we report on the adaptive behavior of air-water interfaces that are decorated by spiropyran (SP) and arylazopyrazole (AAP) photoresponsive surfactants. The SP surfactants increase their surface activity when irradiated with UV light that causes a ring-closure reaction. *E/Z* photoisomerization of the AAP surfactants drives a substantial decrease in surface activity and thus desorption from the interface when the AAP surfactants are switched from their *E* to the *Z* state. In addition, at low pH the short thermal lifetime of the *Z* state as well as of the SP form offers the use of thermal relaxation as an alternative trigger, while also irradiation with green light can partially recover the initial properties. Interfacial properties and molecular kinetics were studied in detail using surface tensiometry and vibrational sum-frequency generation (SFG).

CPP 35.60 Wed 11:00 P1

A thermo- and photoresponsive polymer for schizophrenic switching of amphiphilic self-assembled micelles — •Peiran Zhang[1], René Steinbrecher[2], André Laschewsky[2,3], Peter Müller-Buschbaum[4], and Christine M. Papadakis[1] — [1]Soft Matter Physics Group, TUM School of Natural Sciences, Technical University of Munich — [2]Institute of Chemistry, University of Potsdam — [3]Fraunhofer IAP, Potsdam-Golm — [4]Chair for Functional Materials, TUM School of Natural Sciences, Technical University of Munich

Schizophrenic switching, namely the exchanging of hydrophilic and hydrophobic segment of an amphiphilic diblock copolymer, leads to self-assembly of micelles and inverse micelles, which can be used in the drug delivery application [1]. We aim to achieve such behavior by means of diblock copolymers composed of a thermo-responsive block with a fixed LCST (lower critical solution temperature) and a photo-responsive block with a tunable LCST, which is accomplished by cis-trans isomerization of the incorporated azobenzene group. As a first step, we use turbidimetry and dynamic light scattering (DLS) to investigate a homopolymer precursor with respect to the cloud point and the chain size in the cis- and trans-form of the azobenzene group, which is realized by 365 nm UV light and 470 nm blue light, respectively.

CPP 35.61 Wed 11:00 P1

Effect of pressure on the micellar structure of PMMA-*b*-PNIPAM in aqueous solution — •Pablo A. Alvarez Herrera[1], Geethu P. Meledam[1], Cristiane Henschel[2], Leonardo Chiappisi[3], André Laschewsky[2], and Christine M. Papadakis[1] — [1]TU München, School of Natural Sciences, Garching Germany — [2]Universität Potsdam, Institut für Chemie, Potsdam-Golm, Germany — [3]Institut Laue- Langevin, Grenoble, France

In aqueous solution, amphiphilic diblock copolymers consisting of a permanently hydrophobic and a thermo-responsive block self-assemble into core-shell micelles. In particular, poly(methyl methacrylate)-*b*-poly(*N*-isopropylacrylamide) (PMMA-*b*-PNIPAM) forms micelles featuring a hydrophobic PMMA core and a thermo-responsive PNIPAM shell. This phase transition can be also induced by changing the pressure. Here, we study the effect of pressure on the micellar structure of PMMA-*b*-PNIPAM in aqueous solution by small-angle neutron scattering (SANS). In temperature-resolved experiments, we find that the micellar shell strongly dehydrates after crossing the co-existence line at 0.1 MPa. At 75 MPa, on the contrary, it remains hydrated and the micelles are highly-correlated within the aggregates. We also characterized the micellar structure in a pressure-resolved experiment at 31.8 ˚C. In this case, we find that, after crossing the co-existence line, the micellar shell appreciably shrinks, even though it remains partially hydrated. We conclude that the micellar structure in the two-phase region strongly depends on pressure.

CPP 35.62 Wed 11:00 P1

Synthesis of diblock copolymer brush surfaces to control the adaptation time to water — •Benjamin Leibauer[1], Andres de los Santos Pereira[2], Ognen Pop-Georgievski[2], Hans-Jürgen Butt[1], and Rüdiger Berger[1] — [1]Max-Planck institute for polymer research, Ackermannweg 10, 55128 Mainz — [2]Institute of macromolecular chemistry cas, Heyrovskeho nam. 1888, 162 00, Praha 6

The Young's model describes the wetting behavior of an ideal surface. Recently, Butt et al. presented a model, which connects adaptation processes of the surface to dynamic contact angles. We developed an experimental setup, which allows measuring adaptation processes. The adaptation model was experimentally verified by Li et al. using surfaces coated with films of statistical copolymers. We synthesize polymer brush surfaces with the aim to control the adaptation time scale upon wetting and dewetting systematically. We used the surface-initiated atom transfer radical polymerization / ATRP to selectively synthesize diblock copolymer brushes. We prepared poly(2-hydroxyethyl methacrylate) (PHEMA) as a hydrophilic block from the surface and we grafted polystyrene (PS)) as hydrophobic block on top of the PHEMA block. By regulating the architecture and thickness of the polymer brush we can tune surface adaption to wetting.

CPP 35.63 Wed 11:00 P1

Droplets sliding on compressed soft surfaces — •Youchuang Chao, Hansol Jeon, and Stefan Karpitschka — Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany

The motion of droplets on rigid substrates is mainly slowed up by the viscous dissipation inside the liquid phase. However, this does not hold for droplets sliding on soft substrates: viscoelastic dissipation inside solid phase now dominates the motion, leading to 'viscoelastic breaking". A recent study revealed that droplets move anisotropically on soft, pre-stretched solids, which is incompatible with the classical visco-elastocapillary wetting theory. Here, we impose a compression rather than a stretch on the soft solid, and explore how pre-compression influences the droplet speed. Intriguingly, we observe a non-monotonic dependence of the sliding speed on the pre-strain: a minimal speed exists as the solid is consecutively compressed. This may enrich our current understanding of elastocapillarity, for instance, in tissue engineering where soft materials are frequently squeezed.

CPP 35.64 Wed 11:00 P1

Understanding wetting and drying of nanoporous media through optical and dilatometry experiments — •Laura Gallardo[1,2,3], Juan Sánchez[1,2,3], Yannick Tetzner[1,2,3], and Patrick Huber[1,2,3] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology, Germany — [2]Photon Sciences, Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [3]Center for Hybrid Nanostructures CHyN, Hamburg University

While imbibition kinetics is well-understood in nanoporous materials [1], their drying dynamics is still under investigation [2]. In this study, we present time-dependent macroscopic dilatometry experiments on the deformation of nanoporous monoliths upon spontaneous, capillary-driven infiltration of water as well as drying. During both processes, we find characteristic dynamical regimes that can be quantitatively described in terms of Laplace pressure effects and changes in the surface stress at the inner pore walls [3]. In the particular case of transparent nanoporous Vycor glass, additional imaging experiments are conducted, allowing direct optical access to the filling front. The observed wetting-drying dynamics are consistent with our analysis of the strain regimes. Our study demonstrates that it is possible to monitor the interplay of imbibition and drying dynamics by simple dilatometry measurements, provided proper humidity control. CPP 35.65 Wed 11:00 P1

Studying Solid-liquid Contact Charge Separation Dynamics using Mirror Charge — •Pravash Bista[1], Hans-Jürgen Butt[1], and Stefan A.L Weber[1,2] — [1]Max-Planck-Institut for Polymer research Mainz — [2]Johannes Gutenberg University of Mainz

Charge separation as water drops slide over a hydrophobic solid surface is a well known phenomenon (Slide electrification). Nevertheless, a macroscopic understanding of dynamics in solid-liquid contact charge separation is still incomplete. To address that, we introduce a method based on "*mirror charge*" detection to locally measure the change in surface charge density ($\Delta\sigma$). Here, we placed a grounded metal electrode parallel beneath the substrate. As a spontaneously charged drops move over a surface, they attract opposite charge in the metal electrode causing a flow of capacitive current. Analysing this current, we studied $\Delta\sigma$ dynamics with increasing slide length and drop number as multiple deionized water drops slid down the inclined hydrophobic surface (trichloro(1H,1H,2H,2H-perfluorooctyl)silane, PFOTS-functionalized glass). Using the results, we estimated a set of parameters to describe the $\Delta\sigma$ dynamics in slide electrification. Further, we used these parameters in a numerical simulation where we numerically reproduced the experimental results.

CPP 35.66 Wed 11:00 P1

Towards wetting on switchable and adaptive conducting polymer surfaces — •Junqi Lu[1], Aldilene Santos Franca[1], Nikolaos Karadimitriou[2], Holger Steeb[2], and Sabine Ludwigs[1] — [1]IPOC-Functional Polymers, Institute of Polymer Chemistry, University of Stuttgart, Germany — [2]Institute of Mechanics (MIB) & SC SimTech, University of Stuttgart, Germany

Conducting polymers (CPs) are discussed in a huge variety of electronic devices including electrochromic windows, batteries, actuators and chemical-biology sensors, mainly because of switchable electronic and optical properties. Compared to other conducting materials, CPs have advantages of light-weight, low cost, non-toxicity, flexibility, easy processing, and low voltage operation. In our group, poly(3-hexylthiophene) (P3HT) and poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) are mostly studied. In the case of P3HT, the doping states can be precisely controlled by electrochemical or chemical doping, which results e.g. in an increase of conductivity over 6 orders of magnitude with a maximum of 224 S/cm. [1] On the other hand, PEDOT: PSS can be controlled by electrochemical means, but also by humidity, as used e.g. for actuators. [2] In this contribution, we will show our preliminary data on the wetting behavior on such switchable and adaptive CP surfaces.

CPP 36.1 Wed 15:00 GÖR 226

Charge-carrier dynamics across seven orders of magnitude in double-cable polymer-based single-component organic solar cells — •YAKUN HE[1,2], BINGZHE WANG[1], LARRY LUEER[1], DIRK GULDI[1], NING LI[1], and CHRISTOPH BRABEC[1] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Martensstrasse 7, 91058 Erlangen, Germany — [2]KAUST Solar Center, King Abdullah University of Science and Technology, Thuwal 23955, Saudi Arabia

Single-component organic solar cells (SCOSCs) with intrinsically high stability have witnessed efficiencies from 2-3% to 6-11%. For boosting higher efficiencies of SCOSCs, essential information of charge-carrier dynamics as a function of microstructure is highly demanded, requesting systematical investigation on photophysics. In this work, for the first time, the charge-carrier dynamics of a representative double-cable polymer, which achieves efficiencies of over 6% as an active layer in SCOSCs, is investigated across seven orders of magnitude in time scale, from fs-ps TAS and ps-ns TRPL for probing charge generation to ns-us TAS for charge recombination. Specific emphasis is placed on understanding the impact of thermal post-treatment on the charge dissociation, transport, and recombination dynamics. By increasing the thermal annealing temperature, geminate recombination is reduced accompanied by more efficient charge dissociation and suppressed bimolecular recombination. Annealing the photoactive layer at 230 oC results in the highest photovoltaic performance correlating well with the findings from transient studies. This work intends to present a complete picture of the charge-carrier dynamics in SCOSCs.

CPP 36.2 Wed 15:15 GÖR 226

What determines the Recombination Order in Organic Solar Cells? — •KATHRIN BROCKER, JANA SEILER, DOROTHEA SCHEUNEMANN, CLEMENS GÖHLER, and MARTIJN KEMERINK — Institute for Molecular Systems Engineering and Advanced Materials, Heidelberg University

Organic Solar Cells provide an interesting and low-cost alternative to conventional inorganic photovoltaics. Upon illumination, excitons are created that separate into free electrons and holes at the donor-acceptor-interface and can be extracted to deliver electricity. The opposing loss mechanism is the recombination of charge carriers, which happens in the bulk both prior to and after charge separation. To understand these processes, the recombination order is crucially important. Experimentally, orders around or above 2 are typically found. Surprisingly, kinetic Monte Carlo (kMC) simulations that otherwise accurately reproduce experimental observations, yield values closer to 1. Here, we investigate the factors that might lead to higher recombination orders. Apart from the influence of morphology and contacts, special focus is laid on the effect of charge carrier delocalisation, which is shown to facilitate charge carrier separation and increase the fraction of bimolecular recombination. Simulation results are compared to experimental data obtained via the Steady State Bias Assisted Charge Extraction (BACE) method on P3HT:PCBM and PM6:Y6 solar cells.

CPP 36.3 Wed 15:30 GÖR 226

Modeling of the photoluminescence of geminate pairs using a hopping based Monte Carlo simulation — •MAIK SCHWUCHOW, ANGELA THRÄNHARDT, CARSTEN DEIBEL, and SIBYLLE GEMMING — TU Chemnitz, Institut für Physik, 09126 Chemnitz, Deutschland

The investigation of the transport and recombination characteristics of optically excited charge carriers in organic materials is an on-going research topic. Studying the underlying effects is crucial for understanding and improving practical applications, e.g. organic solar cells (OSCs). A main step in the process of free charge carrier generation in OSCs is the formation of geminate pairs, so called charge transfer complexes, consisting of spatially separated, Coulomb-bound charges. The radiative recombination of geminate pairs yields a photoluminescence (PL) decay $\propto t^{-3/2}$ (t is time) on long time scales which arises due to a combination of thermally activated diffusion and attractive Coulomb interaction. While a continuous drift-diffusion model is able to theoretically explain this experimentally observed decay, weak molecular interaction and disorder are known to cause charge carrier localization. Therefore, a hopping model, based on tunneling between localized states, is usually more appropriate to describe charge transport in organic materials. We simulate the diffusion and recombination of hopping charge carriers using the Monte Carlo method and investigate the influence of different parameters, e.g. temperature and energetic disorder, on the PL data and the asymptotic slope.

CPP 36.4 Wed 15:45 GÖR 226

Time-consistent hopping, transient localization, and polarons - new insights and approaches for carrier transport in organic crystals — SEBASTIAN HUTSCH, MICHEL PANHANS, and •FRANK ORTMANN — Technische Universität München, Germany

Charge transport in organic semiconductors is affected by the complex interplay of electronic degrees of freedom and molecular vibrations. This is further complicated due to the rich vibrational spectrum of these materials with mode energies covering two orders of magnitude. If the electronic coupling between molecules is small, hopping approaches are a popular choice to model charge transport for which we have recently derived a time-consistent hopping theory. [1]

Similarly, for high-mobility materials a recent improvement has been realized based on a mode-specific treatment of molecular vibrations. This leads to an unprecedented level of accuracy for the prediction of the carrier mobility for a large number of systems. [2] I will finally discuss physically motivated predictors with a very good correlation to the mobility and low computational costs.

CPP 36.5 Wed 16:00 GÖR 226

Analysis of industrial viability for single-component organic solar cells — •YAKUN HE[1,2], NING LI[1], THOMAS HEUMÜLLER[1], JONAS WORTMANN[1], and CHRISTOPH BRABEC[1] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Martensstrasse 7, 91058 Erlangen, Germany — [2]KAUST Solar Center, King Abdullah University of Science and Technology, Thuwal 23955, Saudi Arabia

Despite approaching 20% efficiency, organic solar cells still lag behind for industrial application. The industrial figure of merit (i-FOM) of OSCs is analyzed, including PCE, photostability, and synthetic complexity (SC) index. Single-component organic solar cells (SCOSCs) employing materials with donor and acceptor moieties chemically bonded within one molecule or polymer exhibit intrinsically high morphological stability. SCOSCs exhibit overall much higher i-FOM values than the corresponding bulk heterojunction OSCs, and the highest value reaches 0.3, which is even higher than the famous PM6:Y6, even though the PCE (8%) is only half of PM6:Y6. Synthetic complexity of SCOSCs is slightly higher than that of the corresponding BHJ OSCs due to extra synthetic step for connecting donor and acceptor moieties. This feature however overcomes the large-scale phase separation and stability issue. SCOSCs based on dyad 1 exhibit surprisingly high photostability under concentrated light (7.5 suns and 30 suns), corresponding to almost unchanged device stability up to 10,000 hours under 1-sun illumination. For realizing industrial application, SCOSCs have to achieve higher efficiencies, while BHJ should be developed with less complicated synthesis.

15 min. break

CPP 36.6 Wed 16:30 GÖR 226

Temperature-induced morphology changes at the organic-metal interface: effects on the structure, electronic and thermoelectric performance — •BENEDIKT SOCHOR[1], YUSUF BULUT[1,2], MARIE BETKER[1,3], ANNA LENA OECHSLE[2], SIMON SCHRAAD[1,4], CHRISTOPHER R. EVERETT[2], CONSTANTIN HARDER[1,2], TZU-YEN HUANG[5,6], ANTON LE BRUN[5], TIM LAARMANN[1,4], PETER MÜLLER-BUSCHBAUM[2,7], and STEPHAN V. ROTH[1,3] — [1]Deutsches Elektronen-Synchrotron DESY, Notkestr. 85, 22607 Hamburg, Germany — [2]TUM School of Natural Sciences, Chair for Functional Materials, James-Franck-Str. 1, 85748 Garching, Germany — [3]KTH Royal Institute of Technology, Teknikringen 56-58, 100 44 Stockholm, Sweden — [4]University Hamburg, Department of Physics, Notkestr. 85, 22607 Hamburg, Germany — [5]ANSTO, New Illawarra Road, Lucas Heights, NSW 2234, Australia — [6]NSRRC, 101 Hsin-Ann Road, Hsinchu Science Park, Hsinchu 30076, Taiwan — [7]MLZ, TUM, Lichtenbergstr. 1, 85748 Garching, Germany

Flexible organic electronics are one of the most sought-after devices in the field of photovoltaics, sensors, or smart wearables. Here, the structure of the organic-metal interface and its modification potential are of utmost interest for future large-scale production. This study focuses on two semiconducting Poly(3-hexylthiophene-2,5-diyl) diblock variants, whose sprayed and doped thin films show excellent potential as thermoelectric generators. Using AFM, ellipsometry, *in situ* GISAXS/GIWAXS, and NR measurements, the structural changes of the polymer-gold interfaces were tracked during thermal annealing.

CPP 36.7 Wed 16:45 GÖR 226

Compatible solution-processed interface materials for improving the efficiency of organic solar cells — •ZHUO XU[1,2], JOSE PRINCE MADALAIMUTHU[1,2], JOSEF BERND SLOWIK[1,2], RICO MEITZNER[1,2], AMAN ANAND[1,2], SHAHIDUL ALAM[1,2,4], HÉCTOR CORTE[5], STEFFI STUMPF[1,3], ULRICH S. SCHUBERT[1,2,3], and HARALD HOPPE[1,2] — [1]Laboratory of Organic and Macromolecular Chemistry, Friedrich Schiller University Jena, Germany. — [2]Center for Energy and Environmental Chemistry Jena, Friedrich Schiller University Jena, Germany. — [3]Jena Center for Soft Matter, Friedrich Schiller University Jena, Germany. — [4]King Abdullah University of Science and Technology, KAUST Solar Center, Physical Sciences and Engineering Division, Material Science and Engineering Program, Thuwal, Kingdom of Saudi Arabia. — [5]Nanosurf AG, Liestal, Switzerland.

The electron transport layer (ETL) is a key components for better performance and stability in OSCs. Herein, conjugated PDINO, sol-gel derivatized under stoichiometric TiOx, and the same combination as the ETL was used to fabricate solution-processed PBDTTT-C-T:PC71BM-based OSCs. A hybrid of organic-inorganic ETL revealed less bimolecular and trap-assisted recombination than a single ETL of either material. Furthermore, the efficiency of devices using blend ETLs showed better performance in comparison to single ETLs in both fullerene and non-fullerene systems. This blending strategy have demonstrated beneficial consequences in device stability and efficiency, which will play key role for future commercialization of OSCs.

CPP 36.8   Wed 17:00   GÖR 226
Influence of dye-doping on the nanostructure of the highly efficient PM6:Y6 solar cells — •Elisabeth Erbes[1,2], Constantin Harder[1,3], Benedikt Sochor[1], Susann Frenzke[1], Naireeta Biswas[1,2], Jan Rubek[1], Matthias Schwartzkopf[1], Volker Körstgens[3], Peter Müller-Buschbaum[3,5], Stephan V. Roth[1,4] und Simone Techert[1,2] — [1]DESY, Hamburg, DE — [2]Institute for X-ray Physics, Goettingen University, Goettingen, DE — [3]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [4]KTH Royal Institute of Technology, Stockholm, SWE. — [5]MLZ, TUM, Garching, DE
Organic solar cells based on the donor polymer PM6 and the acceptor Y6 give power conversion efficiencies (PCE) of 13-16% without any additives. The current study aims to investigate systematically the effect of doping PM6:Y6 with optical-light absorbing, electron transfer (ET) dyes. These pyrene-based dyes (PyxDMA) have inter- and intra-molecular charge transfer properties and a very high quantum yield. Also the absorption in the UV regime extends the absorption range of the PM6:Y6 system. The structural and morphological integrity of the dopants within the active layer were studied with grazing incidence X-ray scattering experiments. The analysis showed the intercalation and distribution of the dyes within the PM6:Y6 matrix. The sprayed solar cell architecture Cu/PM6:Y6:PyxDMA/PEDOT:PSS/Au/ITO/Glass was used to measure the PCEs. Correlating these efficiencies with the molecular and nanostructural results allows explaining the changing PCE due to different doping levels of PyxDMA.

CPP 36.9   Wed 17:15   GÖR 226
Hydrogenated nanodiamonds as efficient electron extraction layers in organic solar cells — •Aurelien Sokeng Djoumessi[1,2], Anastasia Sichwardt[1,2], Daria Miliaieva[3], Jan Čermák[3], Maximilian Schaal[4], Felix Otto[4], Štěpán Stehlík[3], Vojtech Nádaždy[6], Torsten Fritz[4], Bohuslav Rezek[5], Ulrich S. Schubert[1,2], and Harald Hoppe[1,2] — [1]Laboratory of Organic and Macromolecular Chemistry, Friedrich Schiller University Jena (IOMC), Jena, Germany — [2]Center for Energy and Environmental Chemistry (CEEC), Friedrich Schiller University Jena, Jena, Germany — [3]Institute of Physics, Czech Academy of Sciences, Prague 6, Czech Republic — [4]Institute of Solid State Physics, Friedrich Schiller University Jena, Jena, Germany — [5]Faculty of Electrical Engineering, Czech Technical University, Prague, Czech Republic — [6]Institute of Physics, Slovak Academy of Sciences, Bratislava, Slovak Republic
Surface tunability is one property of nanodiamonds (NDs), which enables to attachment of a range of functional groups on their surfaces. This may have a significant impact on NDs' electrical and optical characteristics and be helpful for charge extraction in solar cell devices. Herein, the surface chemistries of HPHT NDs modified by hydrogenation in a hydrogen atmosphere exhibit sp2-phases, which may help in improving the material's electrical conductivity and electron extraction when employed as an electron transport layer in PBDB-T:ITIC-based solar cells. The device performance was 7%, which differs only marginally from the outcomes of the state-of-the-art ETLs (ZnO, SnO2).

CPP 37: Nanostructures, Nanostructuring and Nanosized Soft Matter

Time: Wednesday 15:00–16:15   Location: MER 02

CPP 37.1   Wed 15:00   MER 02
Structure and dynamics of a 1,4-polybutadiene melt in an alumina nanopore: A molecular dynamics study — •Lama Tannoury[1], Mathieu Solar[2], and Wolfgang Paul[1] — [1]Martin-Luther-Universität Halle-Wittenberg — [2]Université de Strasbourg
The study of the structure and dynamics of polymer melts confined by solid surfaces enhances our knowledge about the glass transition temperature as well as that of composite materials. It has been shown that conformations and dynamics of polymer melts confined to thin films and flat surfaces as well as cylindrical pores are altered in comparison with the bulk. The change in properties depends on several factors including but not limited to the geometry of confinement. In this research, we study the effects of both nanoscopic confinement and curvature on the dynamics and properties of a chemically realistic 1,4-polybutadiene (PBD) melt using Molecular Dynamics (MD) simulations. We investigate the density layering across the nanopore as well as the orientational ordering in the melt on both the segmental and chain scales. As for the dynamics, we show that the confinement creates an adsorbed layer that not only slows down the relaxation but also creates a third step not present in the bulk. The system has also been investigated by different experimental techniques, allowing for a comparison of our simulations to the experimental data.

CPP 37.2   Wed 15:15   MER 02
Toluene-mediated morphology transition of amphiphilic diblock copolymer templated Si/Ge/C thin films — •Christian L. Weindl[1], Kexin Wu[1], Christian E. Fajman[2], Constantin Harder[3], Benedikt Sochor[3], Matthias Schwartzkopf[3], Stephan V. Roth[3,4], Thomas F. Fässler[2], and Peter Müller-Buschbaum[1,5] — [1]TUM School of Natural Sciences, Chair of Functional Materials, 85748 Garching — [2]TUM School of Natural Sciences, Chair of Inorganic Chemistry with Focus on Novel Materials, 85748 Garching — [3]DESY, 22607 Hamburg — [4]Royal Institute of Technology KTH, 100 44 Stockholm — [5]MLZ, TUM, 85748 Garching
The latest research has revealed promising results for silicon (Si) and germanium (Ge) as anode materials for lithium-ion batteries. These two group 14 semiconductors are considered auspicious additives in graphite anodes due to their high specific capacity (Si) and electron mobility (Ge). This study aims to synthesize a mesoporous Si/Ge/C structure over a wet chemical sol-gel approach with the structure-directing amphiphilic diblock copolymer PS-b-PEO and the Zintl cluster $K_{12}Si_xGe_{17-x}$. Furthermore, we added toluene as an additive to further induce the microphase separation. Real-space data as SEM will be discussed with the reciprocal-space analysis methods as grazing-incidence small/wide-angle x-ray scattering (GISAXS/GIWAXS). Finally, as an application, we will show the performance of these novel films as Li-ion battery anodes.

CPP 37.3   Wed 15:30   MER 02
Ultracompact Beam Deflector using Electrically Switchable Metallic Polymer Nanogratings — •Yohan Lee, Julian Karst, Monika Ubl, Mario Hentschel, and Harald Giessen — 4th Physics Institute and Research Center SCoPE, University of Stuttgart, Pfaffenwaldring 57, 70569, Stuttgart, Germany
We introduce nanogratings from metallic polymers which show an electrochemically-driven optical metal-to-insulator transition. A key feature of the design is separately addressable electrodes to vary the superlattice period of the grating via the applied voltages. Thus, the proposed ultracompact beam deflectors can generate various angles.

CPP 37.4   Wed 15:45   MER 02
Molecular dynamics of superglassy polymers for gas separation by neutron scattering, dielectric spectroscopy, and calorimetry — •Paulina Szymoniak[1], Mohamed Aejaz Kolmangadi[1], Reiner Zorn[2], and Andreas Schönhals[1] — [1]Bundesanstalt für Materialforschung und -prüfung, Berlin, Germany — [2]Forschungszentrum Jülich, Jülich Centre for Neutron Science, Jülich, Germany
Janus polytricyclononenes (PTCN) with rigid backbones and flexible n-alkyl (n=propyl-decyl) are innovative materials that show potential in separating hydrocarbons. These superglassy polymers were designed to show an enhanced, controllable gas permeability via flexible alkyl side chains. PTCNs show nanophase separation between the alkyl side chains and the backbones with a distinct α-relaxation of the alkyl-rich nanophase found by broadband dielectric spectroscopy and temperature modulated DSC. Further, Janus PTCNs were studied by quasielastic neutron scattering (QENS) employing backscattering and time of flight instruments. For an overview of dynamic processes inelastic fixed window scans were performed showing segmental motions of alkyl-rich nanodomains and an additional low temperature relaxation, assigned to methyl group rotations. The molecular mobility was extracted from a combined analysis of backscattering and time of flight QENS data. The glass transition of the backbone-rich domains, which is beyond or near to the degradation of the materials, was evidenced by fast scanning calorimetry by decoupling it from decomposition, employing high heating rates.

CPP 37.5   Wed 16:00   MER 02
Size matters: Size Effects on Surface Chemistry and Raman Spectra of Sub-5 nm Oxidized High-Pressure High-Temperature and Detonation Nanodiamonds — •Bernhard Schummer[1] and Stepan Stehlik[2] — [1]Fraunhofer Development Center X-ray Technology, 90768 F*urth, Germany — [2]Institute of Physics of the Czech Academy of Sciences, 162 00 Prague 6, Czechia
Materials with very small dimensions of a few nanometers is of major importance for fundamental science as well as innovative applications. Those nanomaterials show different effects like quantum size effects, structural transformation or

phonon-confinement effects. It has been predicted theoretically that nanodiamonds (NDs) have a structural transformation and phonon-confinement effect below 3 nm in size. Here, we investigate how size effects the surface chemistry, microscopic structure, and Raman scattering of high-pressure high-temperature (HPHT) and detonation nanodiamonds (DNDs) between 2 to 3 nm. The particle size and particle size distribution (PSD) of those different fractions was analyzed with dynamic light scattering, analytical ultracentrifugation, small-angle X-ray scattering, X-ray diffraction, and transmission electron microscopy as complementary techniques. Comprehensive comparison of detonation and pure monocrystalline HPHT NDs reveals effects of diamond core size and defects, chemical and temperature (in)stability, and limitations of current phonon confinement models.

CPP 38: Microswimmers and Fluid Physics of Life (joint session DY/CPP)

Time: Wednesday 15:00–18:15 Location: MOL 213

See DY 31 for details of this session.

CPP 39: Focus Session: Physics of Fluctuating Paths (joint session DY/CPP)

State-of-the-art experiments probe physical observables, such as heat, work or entropy production, empirical densities and currents, on the level of individual, stochastic paths. Such experiments are typically analysed by averaging along a limited number of individual realisations, which leads to substantial uncertainties in estimates. The systematic sample-to-sample fluctuations of such path-observables encode important information about the underlying, microscopic dynamical processes and are therefore a frontier of experimental, theoretical, and computational physics. Recently there has been a surge in the development and applications of path-based concepts across many fields of physics. This focus session complements a symposium and contains contributed talks.

Organized by Aljaz Godec, Udo Seifert, and Peter Sollich

Time: Wednesday 15:00–18:15 Location: ZEU 160

See DY 32 for details of this session.

CPP 40: 2D Materials V: Growth, Structure and Substrate Interaction (joint session O/CPP)

Time: Wednesday 15:00–17:30 Location: GER 37

CPP 41: Biopolymers, Biomaterials and Bioinspired Functional Materials II (joint session CPP/BP)

Time: Wednesday 16:30–18:00 Location: MER 02

CPP 41.1 Wed 16:30 MER 02

Low-Temperature and Water-Based Biotemplating of Nanostructured Foam-Like Titania Films using ß-Lactoglobulin — •Julian E. Heger[1], Wei Chen[1], Shanshan Yin[1], Nian Li[1], Volker Körstgens[1], Calvin J. Brett[2,3], Wiebke Ohm[2], Stephan V. Roth[2,3], and Peter Müller-Buschbaum[1,4] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]DESY, Hamburg, Germany — [3]Royal Institute of Technology KTH, Stockholm, Sweden — [4]MLZ, TUM, Garching, Germany

Energy-related applications such as solar cells, batteries, and the photocatalytic production of hydrogen are broadly built up on titania nanostructures. A tailored titania morphology is necessary to match the required charge diffusion lengths and the crystallinity beneficial for efficient performance. In the context of large-scale fabrication, the aspect of sustainability becomes essential. Biopolymer templating based on ß-Lactogobulin (ß-lg) and spray deposition promotes low-temperature and water-based synthesis of nanostructured, crystalline, foam-like titania films. During spray deposition, the ß-lg biopolymer matrix sterically directs the titania morphology. Afterwards, the biotemplate is removed by UV-light exposure. To understand the kinetics of film formation during the spray deposition on the nano and crystalline length scale, we simultaneously perform in situ grazing-incidence small-angle and wide-angle X-ray scattering (GISAXS/GIWAXS). Together with scanning electron microscopy (SEM), the results explain the role of ß-lg as a biotemplate.

CPP 41.2 Wed 16:45 MER 02

Structural changes in cellulose nanofibril-colloid hybrid films during humidity cycling — •Stephan V. Roth[1,2], Calvin J. Brett[1,2], Alexandros Alexakis[2], Lucas P. Kreuzer[3], Martin Mansson[2], Sarah Rogers[4], Eva Malmström[2], Peter Müller-Buschbaum[3,5], and L. Daniel Söderberg[2] — [1]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]KTH Royal Institute of Technology, Stockholm, Sweden — [3]TUM School of Natural Sciences, Chair for Functional Materials, Garching — [4]ISIS-STFC, Rutherford Appleton Laboratory, Chilton, Oxon OX11 0QX, UK — [5]MLZ, TUM, Garching, Germany

Biocompatible cellulose nanofibrils (CNFs) are an ideal material for sustainable biomaterial templates. Combined with latex colloids, the resulting hybrid colloid-CNF functional materials are excellent candidates for bio-inspired structural colors. Due to the hydrophilic nature of CNFs, we investigate the stability against humidity cycling in terms of reversible/irreversible structural rearrangements. We applied depth sensitive grazing incidence small-angle neutron scattering to evaluate the humidity-induced rearrangements in hybrid latex colloid:CNF templates in situ during cyclic humidification. After the first humidity cycle, a change in morphology on the scale of several 10 nm was observed, which is attributed to latex particles which diffused in the network and enlarged the pores of the network. The measured kinetics resolve the time- and depth-dependence of the differently sized colloids' penetration into the porous CNF network.

CPP 41.3 Wed 17:00 MER 02

Fluorescence correlation spectroscopy for studying the aggregation of nanoplastics in model biofilm substances — •Tobias Guckeisen, Rozalia Orghici, and Silke Rathgeber — Universität Koblenz, Deutschland

Nanoplastics in the environment are a growing problem. Pollutants can adhere to their surfaces and therefore be easily transported into the natural systems. Biofilms are found everywhere in the environment; they are formed by microbial communities that produce a matrix of extracellular polymeric substances. The interaction between nanoplastics and biofilms can lead to aggregation and sedimentation of nanoparticles and determines the transport and fate of nanoplastics. A better understanding of the transport and fate of nanoplastics is important to improve our ability to predict risks associated with these ubiquitous contaminants. In this project, we use fluorescence correlation spectroscopy (FCS) to study the aggregation and interactions of nanoplastics with model biofilm substances. Protein-polysaccharide mixing ratio and pH-dependent aggregation studies show that it is crucial to consider correlative effects between multiple biofilm components to better understand the impact biofilms have on nanoplastic aggregation. Biofilm model systems with only one component, as commonly considered, may lead to an incorrect assessment of the tendency to aggregation.

CPP 41.4 Wed 17:15 MER 02

Ensemble inequivalence and negative extensibility in a wormlike chain with fluctuating bending stiffness — •Panayotis Benetatos — Department of Physics, Kyungpook National University, Republic of Korea

Many semiflexible polymers exhibit fluctuations in the local bending stiffness along their contour. This may be due to intrinsic conformational changes (e.g., denaturation bubble formation in double stranded DNA or helix-coil transition in polypeptides) or to the reversible adsorption and desorption of molecules from the polymer's environment. In this presentation, we analyse the tensile elasticity of a strongly stretched wormlike chain which consists of N concatenated segments, where each segment can be in one of two states, A and B, which differ in bending stiffness. We call this model the reversible wormlike chain (rWLC) model. In the Gibbs (fixed-force, isotensional) ensemble, we obtain analytic expressions for the force-expression relation and the mean fraction of B segments. We show that, under certain conditions, there is a tension-induced crossover from a mostly A to a mostly B rWLC. In the Helmholtz (fixed-extension, isometric) ensemble, we obtain analytic expressions up to a summation. We show that, for finite N, there is marked ensemble inequivalence. Remarkably, in the Helmhlotz ensemble, the rWLC can exhibit negative extensibility and multiple peaks.

CPP 41.5 Wed 17:30 MER 02

Aging and compressed exponential stress relaxation in mechanoresponsive hydrogels — •Geonho Song[1,2], Wouter Ellenbroek[3], and Kerstin Blank[1,2] — [1]Johannes Kepler University Linz, Linz, Austria — [2]Max Planck Institute of Colloids and Interfaces, Potsdam, Germany — [3]Eindhoven University of Technology, Eindhoven, The Netherlands

Biological materials, such as the extracellular matrix (ECM), are viscoelastic and exhibit stress relaxation. Stress relaxation in the ECM is linked to cellular behav-ior and needs to be considered as a design parameter when developing bioinspired materials for cell culture and tissue engineering. Here, we introduce a collagen-inspired hydrogel with tunable crosslink kinetics. We utilize collagen-mimetic peptides with controlled association and dissociation rates to crosslink star-shaped polyethylene glycol. We show that ultraslow crosslink dissociation rates cause a distinctive relaxation behavior that is reminiscent of soft glassy materials, showing out-of-equilibrium properties. In particular, subjecting the networks to a sequence of pre-stress and aging causes uncommon compressed exponential relaxation. This unique phenomenon has previously only been reported for a small number of soft glassy systems where compressed exponential relaxation was related to ultraslow dynamics that prohibited the release of internal stresses. In such systems, slow crosslink dissociation delays network relaxation until an external trigger is applied. In future work, we aim to investigate the interplay between locally generated stresses, such as cellular traction forces, and network relaxation properties.

CPP 41.6 Wed 17:45 MER 02

Nonaffinity controls critical slowing down and rheology near the onset of rigidity — •Abhinav Sharma[1], Jordan Shivers[2], and Fred MacKintosh[2] — [1]Leibniz institute for polymer research, Dresden — [2]Rice University, Houston, Texas

Fluid-immersed networks and dense suspensions often reside near a boundary between soft (or fluid-like) and rigid (or solid-like) mechanical regimes. This boundary can be crossed either by varying the concentration or by deformation. Near the onset of rigidity, dissipation-limiting nonaffine rearrangements dominate the macroscopic viscoelastic response, giving rise to diverging relaxation times and power-law rheology. Here, we derive a simple relationship between nonaffinity and excess viscosity in fluid-immersed amorphous materials. We then demonstrate this relationship and its rheological consequences in simulations of stress relaxation in strained filament networks and dense suspensions.

CPP 42: Battery Materials (joint session KFM/CPP)

Chair: Prof. Dr. Anna Grünebohm (Ruhr-University Bochum)

CPP 43.1 Thu 9:30 GÖR 226

Determining exciton diffusion lengths in organic non-fullerene acceptors with Kinetic Monte Carlo Simulation — •Wenchao Yang, Safakath Karuthedath, Catherine Castro, Julien Gorenflot, and Frederic Laquai — KAUST Solar Center, King Abdullah University of Science and Technology, Thuwal, Saudi Arabia

Optimal exciton diffusion length (L_D) is a key parameter for reducing losses during exciton to charge carrier conversion in organic solar cells (OSC). However, different research groups report contradicting numbers for the same non-fullerene acceptors (NFA) using different lifetimes to calculate L_D. In this work, in order to verify the measured L_D's in NFAs (ITIC, IT4F, ITM and IT2Cl) using transient absorption (TA) spectroscopy, we employed the Kinetic Monte Carlo (KMC) method to simulate the exciton dynamics and calculate the corresponding L_D. With the assumption of Förster resonant energy transfer type exciton hopping rate in a cubic lattice, the TA decay kinetics under different fluences are reproduced by the KMC simulation, and the only free parameter: the energetic disorder σ is extracted. The use of the lifetime τ measured by time-resolved photoluminescence in neat NFA enables to reproduce the transients using more realistic σ values. The L_D's in the NFAs are further calculated with the τ's and found to be consistent with the experimental values. This work provides microscopic descriptions of exciton diffusion and more insight into the determination of L_D in organic semiconductors.

CPP 43.2 Thu 9:45 GÖR 226

A thorough analysis of conformational locking and related electrical properties in fluorinated thieno-quinoxalines — •Md Moidul Islam[1,2], Arthur Markus Anton[1,2,5], Shahidul Alam[6], Rico Meitzner[1,2], Christos L. Chochos[3,4], Ulrich S. Schubert[1,2], and Harald Hoppe[1,2] — [1]Laboratory of Organic and Macromolecular Chemistry (IOMC),Friedrich Schiller University Jena, Jena, Germany — [2]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich Schiller University Jena, Jena, Germany — [3]Institute of Chemical Biology, National Hellenic Research Foundation, Athens 11635, Greece — [4]Advent Technologies SA, Patra, Greece — [5]Peter Debye Institute for Soft Matter Physics, Universität Leipzig, Leipzig, Germany — [6]King Abdullah University of Science and Technology (KAUST), KAUST Solar Center (KSC), Physical Sciences and Engineering Division (PSE), Material Science and Engineering Program (MSE), Kingdom of Saudi Arabia

Thieno-quinoxaline derivatives with low band gaps are promising donor materials for organic solar cells. Therefore, investigations have been conducted on thieno-quinoxaline polymers with systematically varied fluorination sites. Cyclic voltammetry revealed that fluorination lowers both the HOMO as well as LUMO energy levels, whereas the size of photochromic units is affected through the particular kind of fluorination demonstrated by UV-Vis absorption spectra. Furthermore, excitation-emission mapping exposed excitation-independent and excitation-selective PL pathways.

CPP 43.3 Thu 10:00 GÖR 226

Orientation and Order of Molecular Subunits and Excited State Dynamics in a P3HT Bottlebrush Copolymer — •Arthur Markus Anton[1,2], Friedrich Kremer[1], Jenny Clark[2], and Frank Cichos[1] — [1]Leipzig University, Peter Debye Institute for Soft Matter Physics, Linnéstr. 5, 04103 Leipzig, Germany — [2]The University of Sheffield, Department of Physics and Astronomy, Hounsfield Rd, Sheffield S37RH, United Kingdom

Orientation and order at different length scales are believed to play a crucial role for the performance of organic semiconductor devices. Taking advantage of the material properties of *bottlebrush copolymers* and gain control of structure formation, a poly-(3-hexylthiophene) grafted copolymer has been studied [1]. In order to investigate the structure on the molecular scale the technique of *Infrared Transition Moment Orientational Analysis* (IR-TMOA) has been employed [2,3]. The absorbance of structure-related bands is evaluated depending on the inclination of the sample film (ϑ) and polarization of the IR light (φ). This combination then allows to determine the tensor of absorption separately for the respective molecular moieties and to deduce their orientation (Θ,Φ) relative to a sample-fixed coordinate system. In addition *transient absorption* measurements have been conducted. The dynamics of exciton and polaron formation and decay has been investigated and the derived results on the basis of the bottlebrush copoly-

mer are compared with results from linear P3HT. [1] Heinrich and Thelakkat, *J. Mater. Chem. C* **4** (2016) 5370 [2] Anton et al, *J. Am. Chem .Soc.* **137** (2015), 6434 [3] Anton et al, *Macromolecules* **49** (2016) 1798

CPP 43.4   Thu 10:15   GÖR 226

Utilizing High Gain and Spectral Narrowing for Near-Infrared Organic Photodetectors — •Louis Conrad Winkler[1], Jonas Kublitski[2], Johannes Benduhn[1], and Karl Leo[1] — [1]TU Dresden, Germany — [2]Federal University of Technology Paraná UTFPR, Curitiba, Brazil

There is a multitude of applications for infrared photodetectors that demand high-volume fabrication, including blood oxygen determination, continued monitoring of food quality, control of industrial processes, and many more. Organic photodetectors (OPDs) have great potential to enrich today*s photodetector marked with their low-cost fabrication, flexible devices and tunable response. However, most studied organic semiconducting materials have neglectable absorption above 1000 nm. This contribution presents a donor-acceptor blend with a low-energy and broad charge-transfer (CT) feature. To overcome the inherent increase of charge carrier recombination of such low-energy systems, we introduce two photocurrent multiplication (PM) mechanisms. By embedding this OPD into an optical micro-cavity, a spectral response (SR) of 15 AW-1 at 1095 nm is achieved. Furthermore, a very narrow response of only 18 nm makes this architecture ideal for spectroscopic resolved measurements that could be easily integrated into CMOS readout circuitry due to the optimization for operation under reverse bias.

CPP 43.5   Thu 10:30   GÖR 226

Realizing a high-performance, fully thermal-evaporated, blue narrowband organic photodetector — •Tianyi Zhang, Johannes Benduhn, and Karl Leo — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden, Dresden, Germany

Organic photodetector (OPD) boasts of its tunable absorption window, mechanical flexibility, transparency, non-toxicity, facile processing, and cheaper cost. Recent development of high-performing polymers and small molecules further reveals its potential in numerous communication and biomedical applications. To realize visible light communication, commercially available inorganic photodetector usually incorporates additional optical filters, which further increases the complexity and cost of the sensing system. Therein, we demonstrate a blue absorbing organic photodetector with ultrahigh specific detectivity (D^*) approaching 10^{14} Jones. By employing a wide bandgap hole transporting layer BF-DPB with Rubrene:C_{60} active layer, the absorption peaks at 450nm with an external quantum efficiency (EQE) of 50% at zero bias. The parasitic absorption renders the narrowband characteristic of the blends to span merely over the blue wavelength region. Upon BF-DPB incorporation, ultrafast responses are also observed at sub-microseconds. We conclude that the judicious choice of transporting layer is critical for achieving application-tailored properties, namely high speed or high D^*. To date, those values are among the best-reported blue OPDs.

CPP 43.6   Thu 10:45   GÖR 226

Investigation of high performance organic photodetectors based on single component photoactive layer — •Jakob Wolansky[1], Cedric Hoffmann[2], Felix Talnack[3], Michel Panhans[4], Donato Spoltore[5], Stefan C.B. Mannsfeld[3], Frank Ortmann[4], Natalie Banerji[2], Johannes Benduhn[1], and Karl Leo[1] — [1]IAPP, TU Dresden — [2]University of Bern — [3]Cfaed, TU Dresden — [4]TU Munich — [5]University of Parma

In organic semiconductor applications such as organic photovoltaics and photodetectors, an intermolecular interface with an energetic gradient between electron donating and accepting materials is usually required for efficiently generating charges. This driving force facilitates the dissociation of the photogenerated excitons. At the same time, this energy offset reduces the maximum possible open-circuit voltage, and the additional interface can act as a recombination site and increases the dark current. Therefore, single-component devices are extensively researched to overcome these drawbacks.

Here, we report on single-component devices that perform very well as organic photodetectors. By utilizing different device processing parameters and employing different interface layers, we optimized the device characteristics such as external quantum efficiency, dark current, and specific detectivities of more than 1e13 Jones. Investigations of the morphology, combined with ultrafast transient absorption measurements, give insight into the charge generation mechanism in our material system.

CPP 43.7   Thu 11:00   GÖR 226

Reduced defect density in crystalline halide perovskite films via methylamine treatment for the application in photodetectors — •Emilia Rosa Schütz[1], Azhar Fakharuddin[1], Yenal Yalcinkaya[2,3], Efrain Ochoa-Martinez[4], Shanti Bijani[5], Abd. Rashid bin Mohd Yusoff[6], Maria Vasilopoulou[7], Tobias Seewald[1], Ullrich Steiner[4], Stefan Weber[2,3], and Lukas Schmidt-Mende[1] — [1]University of Konstanz, Konstanz, Germany — [2]Max Planck Institute for Polymer Research, Mainz, Germany — [3]Johannes Gutenberg University Mainz, Mainz, Germany — [4]Adolphe Merkle Institute, University of Fribourg,

Fribourg, Switzerland — [5]Unidad de Nanotecnología, Centro de Supercomputador y Bioinnovación SCBI, Universidad de Málaga, Málaga, Spain — [6]Pohang University of Science and Technology, Pohang, Republic of Korea — [7]National Center for Scientific Research Demokritos, Attica, Greece

The quality of a perovskite layer strongly depends on the processing conditions. Consequently, the fabrication process is often complex, and reproducibility is a challenge. Our methylamine gas-based method is able to recrystallize perovskite layers of any given quality in a controlled way, leading to millimeter-sized domains. Crystallinity significantly increases upon methylamine treatment, and crystal growth follows a preferred orientation. Photoluminescence- and space-charge limited current measurements imply that the trap density decreases after recrystallization. When applied in photodetectors, the improved film quality of the recrystallized films leads to increased detectivities and shorter response times.

CPP 43.8   Thu 11:30   GÖR 226

Reducing Dark Current in Highly Ordered Rubrene:C_{60} Heterojunctions for Organic Photodetectors — •Anna-Lena Hofmann[1], Jakob Wolansky[1], Lucy Winkler[1], Max Herzog[1], Felix Talnack[2], Eva Bittrich[3], Johannes Benduhn[1], and Karl Leo[1] — [1]IAPP, TU Dresden, Dresden, Germany — [2]Cfaed, Dresden, Germany — [3]Leibniz-Institut für Polymerforschung Dresden e.V., Dresden, Germany

Vacuum-deposited rubrene can form highly ordered phases, demonstrating an exceptionally high charge carrier mobility for holes ($> 10\,cm^2\,V^{-1}\,s^{-1}$) even in thin films. Depending on the post-treatment of our films, we can control different crystalline phases. For fast-response OPDs, the triclinic phase is very promising since it exhibits high hole mobility in the vertical direction. However, the high surface roughness is a key reason why these devices fall short in specific detectivity. In this work, we employ different strategies to reduce the impact of Ohmic shunts within the device to minimize the noise current of our devices. We characterize the morphology of our films and investigate the performance parameters of fully working devices. Finally, these characteristics are compared to rubrene's other two crystalline phases.

CPP 43.9   Thu 11:45   GÖR 226

Utilizing charge-transfer states for narrowband and highly sensitive photodetection — •Johannes Benduhn, Louis Conrad Winkler, Awais Sawar, Jonas Kublitski, and Karl Leo — IAPP, TU Dresden, Germany

Near-infrared (NIR) spectroscopic material sensing has the potential to revolutionize many aspects of life, ranging from food control to material determination. However, currently available products are either too bulky or too expensive to be used in mobile customer applications. In this regard, organic photodetectors (ODPs) can open new perspectives due their cheap and versatile processing techniques. Nevertheless, the external quantum efficiency (EQE) as well as the specific detectivity of those devices in the NIR wavelength range are still lacking behind. In this contribution, we explore photomultiplication (PM) in fully vacuum deposited OPDs. Broadband devices achieve a maximum EQE of almost 2000 % at -10 V. Employing very sensitive measurement techniques as well as optical modelling of our devices, we are able to proof that the photomultiplication can take place even if weakly absorbing charge-transfer states are responsible for the photon harvesting. Employing a suitable donor-acceptor system as well as an optimized device architecture for photomultiplication and constructive interference in the NIR wavelength range, we achieve narrowband OPDs with the spectral response of more than $10\,A\,W^{-1}$ at a wavelength of 1100 nm with full width at half maximum even below 20 nm. These results demonstrate the versatility of OPDs and their potential for spectroscopic material sensing.

CPP 43.10   Thu 12:00   GÖR 226

Design of Integrated All-Organic Oxygen Sensors — •Toni Bärschneider and Sebastian Reineke — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP), Technische Universität Dresden

Organic electronic devices, such as light-emitting diodes (OLEDs) and photodetectors (OPDs), are ideal for sensor applications because of their versatility and flexibility. Additionally, they can be easily fabricated on any substrate, making integrated sensor applications possible. This allows for easy miniaturization and cheap fabrication. Organic room temperature phosphorescence (RTP) materials are well suited for optical oxygen sensing because of their strong oxygen dependency.

In this work, we developed a monolithic all-organic oxygen sensor composed of a RTP sensing layer, an ultraviolet OLED as an excitation source, and a narrow bandwidth OPD for detection. The RTP sensing layer simultaneously shows fluorescence and phosphorescence at room temperature, which enables self-referencing to avoid photodegradation-caused distortion. Due to the long phosphorescence lifetime, sensing within the ultra-trace range is possible.

The presented sensors overcome drawbacks of current optical oxygen sensors, such as complexity, expensive read-out electronics, and a lack of possible miniaturization.

CPP 43.11 Thu 12:15 GÖR 226

Atomistic insights on the electrode material CuDEPP — •Christoph Jung[1,2] and Timo Jacob[1,2] — [1]Universität Ulm, Institut für Elektrochemie, Ulm, Germany — [2]HIU, Ulm, Germany

Devices for electrical energy storage need to provide high energy yields as well as output power while at the same time guaranteeing safety, low costs and long operation times. The porphyrin CuDEPP [5,15-bis(ethynyl)-10,20-diphenylporphinato]copper(II) is a promising electrode material for various battery systems both as anode or cathode. CuDEPP combines the positive properties of lithium ion batteries (high energy density) with those of a supercapacitor (fast electron release and absorption). While its functionality has been demon-

strated experimentally, there had been no atomistic information as to why CuDEPP expresses these interesting properties or how the incorporation of ions affects its structure. Starting with the smallest possible unit (i.e. a single molecule) we successively increased the spatial dimensionality of the structure by studying: a) di- and trimers, b) molecular stacking in a 1D chain, c) extending these chains to planar CuDEPP sheets and finally c) a three-dimensional extended polymer structure. Combining the individual results of the molecule, the chain, the plane and the extended polymer lead to a comprehensive and consecutive understanding of the CuDEPP system. Afterwards the insertion (or intercalation) of different ions (including Li, Mg and Na) has been studied. Based on the optimal ion intercalation structure, discharge voltage curves have been calculated and compared to experimental measurements.

Dynamic wetting of concentrated granular suspensions — •Reza Azizmalayeri, Peyman Rostami, and Günter K. Auernhammer — Leibniz-Institut für Polymerforschung Dresden e.V., Dresden, Germany

Concentrated granular suspensions are employed in a variety of processes where the contact line dynamics and internal structure of the suspension interact. The process can be characterized using individual particle analysis and average suspension descriptions. Along the contact line, particles interact with each other and the substrate, and the shear rate influence the suspension's non-Newtonian rheological behavior. In this study, we use fluorescently-labeled tracer particles in a refractive index-matched silica suspension. We track the motion of the tracer particles in the concentrated suspension with astigmatism particle tracking velocimetry (APTV). Averaging over single tracks gives the flow profile in a droplet near the advancing contact line. In addition, side-view allows characterizing the drop shape. The behavior of high-concentration suspensions near contact lines differs significantly from that of simple liquids. Near the advancing contact line, we observe the fast-moving layering of suspensions close to the substrate, which is controlled by the suspension's rheology. Near the receding contact line, the suspension adheres to its previous layer and moves on top of it. Initially, there is an unsteady motion, which becomes stationary with time.

CPP 44.2 Thu 9:45 MER 02

Sliding drops: towards a universal law of friction — Xiaomei Li[1], Francisco Bodziony[2], Mariana Yin[2], Holger Marshall[2], Rüdiger Berger[1], and •Hans-Jürgen Butt[1] — [1]Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz — [2]Computational Multiphase Flows, Technische Universität Darmstadt, Alarich-Weiss-Straße 10, 64287 Darmstadt

Liquid drops moving on tilted surfaces are an everyday phenomenon and are important for many industrial applications. Still, it is not possible to predict their velocity. To make a step forward in quantitative understanding, we measured the velocity U, width w, length, advancing Θ_a, and receding contact angle Θ_r of liquid drops sliding down inclined flat surfaces. By solving the equation of motion, we determined the friction force versus slide velocity for different hydrophobic surfaces. The friction force acting on moving drops of polar and non-polar liquids with viscosities ranging from 10^{-3} to 1 Pa s can empirically be described by $F_f(U) = F_0 + \mu w Ca^\alpha$ for the whole relevant velocity range. Here, $Ca = U\eta/\gamma$ is the capillary number, in which η is the viscosity and γ the surface tension of the liquid. The friction coefficient μ is in the range of 1 - 3 N/m for all liquid/surface combinations. For viscosities above 0.006 Pa s, we find $\alpha = 1.0$. Bulk and wedge viscous dissipation can fully account for the velocity-dependent friction force. These results were confirmed by direct numerical diffuse-interface simulations of the flow pattern inside sliding drops. We demonstrate that the Furmidge-Kawasaki equation, is also valid in the dynamic case.

CPP 44.3 Thu 10:00 MER 02

Spreading of soft elasto-viscoplastic droplets — •Maziyar Jalaal[1], Cassio Oishi[1], and Hugo França[1,2] — [1]Institute of Physics, University of Amsterdam, Amsterdam, The Netherlands — [2]Sao Paulo State University, Sao Paulo, Brazil

The spreading under surface tension of a droplet of complex fluid with elastic and plastic properties is studied. Unlike Newtonian fluids, the droplet converges to a final equilibrium shape once the driving stresses inside the droplet fall below the critical yield stress. Scaling laws are presented for the final radius and complemented with an asymptotic analysis for shallow droplets. Moreover, numerical simulations using the volume-of-fluid method and an elastoviscoplastic (EVP) constitutive law, and experiments with an aqueous solution of Carbopol, are presented.

CPP 44.4 Thu 10:15 MER 02

Stick-slip Contact Line Dynamics in Forced Wetting of Polymer Brushes — •Daniel Greve[1], Simon Hartmann[1], and Uwe Thiele[1,2] — [1]Institut für Theoretische Physik, WWU Münster — [2]Center for Nonlinear Science (CeNoS), WWU Münster

We study the wetting of adaptive substrates using a mesoscopic hydrodynamic model for a liquid droplet on a polymer brush, refining the model in [1]. First, we show that Young's law still holds for the macroscopic equilibrium contact angle and that on the mesoscale a Neumann-type law governs the shape of the wetting ridge (comparable to the case of elastic substrates [2]). Further, we numerically examine the wetting ridge dynamics for a moving meniscus, i.e., we consider an "inverse Landau-Levich geometry" where a brush-covered plate is introduced into a bath. We find stick-slip motion in good qualitative agreement with experimental observations [3,4] and discuss criteria for the onset of the corresponding instability.

CPP 44.5 Thu 10:30 MER 02

Demixing of liquid PDMS during dewetting into the equilibrium state — •Khalil Remini[1], Leonie Schmeller[2], Dirk Peschka[2], Barbara Wagner[2], and Ralf Seemann[1] — [1]Experimental Physics, Saarland University, Saarbrücken, Germany — [2]Weierstrass-Institute, Berlin University, Berlin, Germany

The study of micrometer-sized equilibrium droplets on elastic substrates is of great interest because, due to negligible gravity, other interactions such as elastic or capillary forces and their mutual influence can easily be investigated, so deviations from the expected behaviour at larger scales becomes visible. This applies in particular to soft solids like PDMS that are typically considered as ideal rubbers on the macro scale. Our experimental system is composed of liquid polystyrene (PS) droplets on a viscoelastic substrate consisting of cross-linked polydimethylsiloxane (PDMS) of different elasticities. Using atomic force microscopy (AFM), we analyse the topography of the materials and thus their contact angles with high precision, we also use AFM to demonstrate the existence of non-cross-linked liquid PDMS that migrates from the elastic PDMS toward the three-phase contact line TPCL to form a demixed liquid ring around the dewetted PS droplet. In that situation, on the nanometer distance around the TPCL, liquid PS meets liquid PDMS instead of being in direct contact with the soft solid PDMS. Further analysis allows us to say that this phenomenon also exists during the dewetting of liquid polystyrene in the same type of elastic solids.

CPP 44.6 Thu 10:45 MER 02

How droplets dry on stretched soft substrates — •Binyu Zhao, Yixuan Du, and Günter K. Auernhammer — Leibniz Institute of Polymer Research Dresden, Dresden 01069, Germany

Droplets evaporation on solid substrates is a ubiquitous phenomenon and relevant in many natural and industrial processes. Well known are the coffee-ring. Many studies have succeeded in promoting, suppressing or even reversing the formation of coffee-ring by using non-spherical particles, surfactants, patterned substrates, and so on.

Here, we show that a uniaxial stretching of soft substrates strongly controls the dynamics of droplet evaporation and particle deposition through controlling the contact line motion. Water droplet evaporates with an elongated non-circular contact line on the stretched substrates and switches the elongation direction during evaporation. The contact line evolution depends on the orientation of the contact line relative to the stretching direction. When nanoparticles are added into the liquid, the circular deposition pattern, i.e., the so-called coffee-ring, becomes elongated along the direction perpendicular to the stretching direction.

Particularly, such non-circular deposition pattern exhibits periodic height gradients along its rim. The finer structure of the pattern can be controlled by applying different stretching ratios to the soft substrate and thus are correlated to the anisotropic surface stresses near the contact line. The findings broaden our understanding of droplet wetting and evaporation on soft and anisotropic substrates, and open the way to reshaping the coffee-ring to allow anisotropic, non-circular patterning.

CPP 44.7   Thu 11:00   MER 02

Gradient dynamics model for sessile drop evaporation in a gap: from simple to applied scenarios — •Simon Hartmann[1], Uwe Thiele[1], Christian Diddens[2], and Maziyar Jalaal[3] — [1]Institut für Theoretische Physik and Center for Nonlinear Science, Universität Münster — [2]Physics of Fluids group, Max Planck Center Twente for Complex Fluid Dynamics, and J. M. Burgers Center for Fluid Dynamics, University of Twente — [3]Van der Waals-Zeeman Institute, Institute of Physics, University of Amsterdam

We consider an evaporating drop of volatile partially wetting liquid on a rigid solid substrate. In addition, the setup is covered with a plate, forming a narrow gap with the substrate. First, we develop an efficient mesoscopic description of the liquid and vapor dynamics in a gradient dynamics form. It couples the diffusive dynamics of the vertically averaged vapour density in the narrow gap to an evolution equation for the drop profile. The dynamics is purely driven by a free energy functional that incorporates wetting, bulk and interface energies of the liquid as well as vapour entropy.

Subsequently, we employ numerical simulations to validate the model against both experiments and simulations based on Stokes equation. Finally, we show that the gradient dynamics approach allows for extensions of our model to cover more intricate scenarios, e.g., spreading drops of volatile liquid on polymer brushes or on porous media.

CPP 44.8   Thu 11:30   MER 02

Modeling the temporal evolution and stability of thin evaporating films for wafer surface processing — •Max Huber[1,2,3], Xiao Hu[1,2,3], Andreas Zienert[1,2,3], and Jörg Schuster[1,2,3] — [1]Fraunhofer Institute for Electronic Nano Systems ENAS, Technologie-Campus 3, 09126 Chemnitz, Germany — [2]Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, Rosenbergstr. 6, 09126 Chemnitz, Germany — [3]Center for Microtechnologies, Chemnitz University of Technology, Reichenhainer Str. 70, 09126 Chemnitz, Germany

Thin liquid films play a crucial role for many applications, e.g., coating, particle deposition, wafer bonding, and the cooling of electronic devices. As an example, we investigate the evaporation of thin water films on $LiTaO_3$. *Ab initio* density functional theory is used to calculate the Gibbs free energy of adsorption. These results are fitted to an expression of the Gibbs free energy which is derived from the disjoining pressure, consisting of molecular and structural components. In this way, the parameters for the disjoining pressure can be determined. A combination of literature-known models for spin drying and evaporation is used to analyze the temporal evolution of the water layer. The vapor above the water layer is modeled by diffusion and a mass balance is applied at the water-air interface. The results can be used to optimize the process time needed to reach the equilibrium thickness of the water layer. In addition, computational fluid dynamics simulations are utilized to investigate the evaporation in a wafer bond chamber during pump-down.

CPP 44.9   Thu 11:45   MER 02

Electrokinetic, electrochemical and electrostatic surface potentials of the pristine water liquid-vapor interface — •Maximilian R Becker and Roland R Netz — Freie Universität Berlin, Berlin, Germany

Although conceptually simple, the interface between liquid water and vapor displays rich behavior and is subject to intense experimental and theoretical investigations. Different definitions of the electrostatic surface potential as well as different calculation methods, each relevant for distinct experimental scenarios, lead to widely varying potential magnitudes. Here, based on density-functional-theory (DFT) molecular dynamics (MD) simulations, different surface potentials are evaluated and compared to force-field (FF) MD simulations. The laterally averaged electrostatic surface potential, accessible to electron holography, is dominated by the trace of the water molecular quadrupole moment and therefore differs strongly between DFT and FF MD. Thus, when predicting electrostatic potentials within water molecules DFT simulation methods need to be used. The electrochemical surface potential inside a neutral atom, relevant for ion transfer reactions and ion surface adsorption, is much smaller and depends specifically on the atom radius. Charge transfer between interfacial water molecules leads to a sizable surface potential as well. However, when probing electrokinetics by explicitly applying a lateral electric field in DFT-MD simulations, the electrokinetic zeta-potential turns out to be negligible. Thus, interfacial polarization charges from charge transfer between water molecules do not lead to a significant electrokinetic mobility.

CPP 44.10   Thu 12:00   MER 02

How Charges Separate at Moving Contact Lines — •Aaron D. Ratschow[1], Lisa S. Bauer[1], Pravash Bista[2], Stefan A. L. Weber[2,3], Hans-Jürgen Butt[2], and Steffen Hardt[1] — [1]Technische Universität Darmstadt, Darmstadt, Germany — [2]Max Planck Institute for Polymer Research, Mainz, Germany — [3]Johannes Gutenberg Universtität, Mainz, Germany

Spontaneous charge accumulation in sliding drops is ubiquitous in nature and has been the subject of research activities for over two decades. Despite the growing number of experimental investigations in recent years, the physical mechanism behind the charging remains poorly understood. We identify the origin of charge separation as the dewetting of the immobilized part of the electric double layer (EDL) by the moving contact line. This layer of physically or chemically bound surface charges depends strongly on the local EDL structure, which is disturbed by the vicinity of the gas-liquid interface and the flow in the liquid. We summarize the physics of charge separation in an analytical model that predicts parametric dependencies on surface chemistry, wetting, and liquid properties. The results agree well with our experiments and numerical simulations and uncover decreasing charge separation with decreasing dynamic contact angle and increasing contact line velocity. Our findings reveal the universal mechanism of charge separation at moving contact lines, not limited to drops, with broad implications for the field of wetting.

CPP 44.11   Thu 12:15   MER 02

Beyond the plate capacitor: Calculating the full dielectric tensor for arbitrary system geometries — •David Egger, Christoph Scheurer, and Karsten Reuter — Fritz Haber Institute of the Max Planck Society, Berlin, Germany

Realistic models for catalytic reactions at aqueous interfaces require a profound understanding of the electrostatic properties in the vicinity of the solvated catalytic complex, in particular for (photo-)electrochemical reactions with charged intermediates. However, explicit quantum mechanical simulations of these systems on the required length- and time-scales remain oftentimes out of reach. Coarse-graining the electrostatic response of the molecular solvent into a continuum dielectric, described by the dielectric permittivity tensor ε, can hence be a necessity. Existing coarse-graining protocols for ε typically assume a separation of the dielectric response parallel and perpendicular to the active interface. This approximation is equivalent to two decoupled sets of in-series plate capacitors and ignores potential non-zero off-diagonal elements in the ε tensor.

In this contribution, we present a comprehensive and general formalism to coarse-grain molecular solvents into a truly anisotropic ε beyond this approximation. We obtain the full, spatially resolved dielectric tensor for arbitrary system geometries with no prior assumptions on boundary conditions. Common bulk and slab formulas are obtained as special cases. The approach is applied exemplarily to bulk water, water-dichloroethane liquid-liquid interfaces, and solvated platinum nanoparticles following from Wulff constructions.

CPP 44.12   Thu 12:30   MER 02

Asymmetric Sessile Compound Drops — •Jan Diekmann and Uwe Thiele — Westfälische Wilhelms-Universität, Münster, Germany

We consider compound drops of two immiscible liquids on a rigid solid substrate. Having established a mesoscopic model (amending [1]) consistent with the macroscopic description of [2,3], we show for one-dimensional (1D) substrates that asymmetric compound drops can be energetically favoured using continuation techniques. Furthermore, we investigate selected dewetting and coarsening processes and discuss emerging steady compound drops for two-dimensional (2D) substrates, thereby discussing the relation of 1D and 2D results.

Steering droplets on substrates with plane-wave wettability patterns and deformations — •Josua Grawitter and Holger Stark — Technische Universität Berlin, Institut für Theoretische Physik, Straße des 17. Juni 135, 10623 Berlin

Droplets are set in motion on substrates with a spatio-temporal wettability pattern as generated, for example, on light-switchable surfaces. To study such cases, we implement the boundary-element method to solve the governing Stokes equations for the fluid flow field inside and on the surface of a droplet and supplement it by Cox–Voinov friction for the dynamics of the contact line. One objective of our research is targeted microfluidic transport of such droplets. In earlier work we investigated how a droplet can be steered by imposing a wettability pattern on the substrate [Grawitter and Stark, Soft Matter **17**, 2454 (2021)]. As a next step, we have recently extended our method to include substrates the height profile of which varies temporally in a prescribed manner.

We compare two cases: First, we investigate a droplet on substrates with planar-wave wettability pattern by varying the speed and wave length of the pattern. Second, we investigate a droplet on substrates with a planar-wave height profile. In both scenarios, for small wave velocities the droplet moves steadily forward. In contrast, above a wave velocity the droplet performs steady oscillations. These speed oscillations correlate with oscillations in the shape of the droplet which decay linearly as a function of pattern speed.

CPP 45: Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods

Structural effects of many-body van der Waals interactions: from small molecules to polymers — •Raul Ian Sosa, Mario Galante, and Alexandre Tkatchenko — Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg City, Luxembourg.

Van der Waals (vdW) dispersion interactions are among the key determinants of structure, stability, and dynamics in a wide range of systems such as supramolecules, complex interfaces and low-dimensional nanostructures. Most commonly used approaches for incorporating vdW interactions in extended systems rely on pairwise approximations, neglecting the quantum many-body nature of molecular interactions [Quantum Chem. 114, 1157 (2014), Science. 350, 6257 (2015)]. Recent simulations which incorporate Many-Body Dispersion (MBD) show that a many-body description of van der Waals can be essential for properly describing extended molecules and molecular solids [Physical Review Letters. 108, 23 (2012)]. These effects often manifest themselves as increased ranges of interaction and collective dynamics in a way that is highly dependent on the molecular structure [Nat Comm. 11, 1651 (2020)]. Here we will present a systematic analysis on the impact that many-body interactions have on the range of van der Waals forces in polymers, one dimensional nanostructures and small molecules, making a particular emphasis on the structural dependence of such interactions.

CPP 45.2　Thu 9:45　ZEU 255
Bulk magneto-mechanical response of magnetic filaments in applied magnetic fields — •Deniz Mostarac and Sofia Kantorovich — Univesity of Vienna,Vienna,Austria

Incorporating magnetic nanoparticles within permanently cross-linked structures, opens up the possibility for synthesis of complex, highly magneto-responsive systems. Magnetic filaments (MFs) are polymer-like chains of magnetic, nano-sized colloids, and are a promising platform for engineering novel, magnetically controlled filtering and flow control elements in micro-fluidic devices. The interplay between central attraction forces, and anisotropic, dipolar interactions is the key factor when tuning the macroscopic response of MFs. In this contribution, we show that taking in to account nonlinear contributions to the magnetisation of super-paramagnetic colloids is essential to capture the bulk, magneto-mechanical response of MFs consisting of magnetisable colloids. In the presence of central attraction forces, we report substantial differences in the equilibrium structure of filament clusters, and the mechanical and magnetic response of filament suspensions, to static and time dependant magnetic fields. While on the level of a single filament, magneto-mechanical properties are in general more dependant on the crosslinking approach than on the magnetic nature of colloids, in bulk, the long-range nature of dipolar interactions in quasi-infinite systems makes up for a tremendous difference, and underlines the necessity of a sophisticated model of magnetic colloids that can be magnetised by the presence of magnetic and dipole fields.

CPP 45.3　Thu 10:00　ZEU 255
Improving the Electrochemically Assisted Surfactant Assembly of Vertically Aligned Mesoporous Silica Films — •Gilles Möhl[1,2], Samuel Fitch[2], Li Shao[2], Jonathan Rawle[3], Ralph Gilles[1], Guy Denuault[2], Tauqir Nasir[2], Yisong Han[4], Richard Beanland[4], Ruomeng Huang[2], Yasir Noori[2], Philip Bartlett[2], and Andrew Hector[2] — [1]FRM II/TUM, München, Deutschland — [2]UOS, Southampton, United Kingdom — [3]Diamond Light Source, Harwell, United Kingdom — [4]Warwick University, Coventry, United Kingdom

Mesoporous silica films are typically produced by evaporation-induced self-assembly (EISA), but vertical alignment of the pores to the substrate remains difficult. Hexagonal arrays of vertically aligned mesopores can be made by electrochemically assisted surfactant assembly (EASA). The self-assembly of a cationic surfactant (cetyltrimethylammonium bromide), which relies on the production of hydroxide species close to the substrate, also leads to the formation of spheroidal surface aggregates, limiting the obtainable film thickness to a few hundreds of nm. In this work, we show the results obtained from operando Grazing incidence small angle X-ray scattering (GISAXS) experiments done during the EASA of silica, following the evolution of the structure formation in real time with sub-second time resolution. We include the findings from operando pH measurements using an electrochemical microsensor, revealing the temporal evolution of the hydroxide concentration close to the electrode. This enabled us to adapt the EASA protocol to reduce aggregate formation and increase film thickness.

CPP 45.4　Thu 10:15　ZEU 255
Pair-wise dependences of morphological descriptors provide fingerprint of pore structure in cellulose-based materials — •Karin Zojer[1], Matthias Neumann[2], Phillip Gräfensteiner[2], Eduardo Machado Charry[1], Andre Hilger[3], Ingo Manke[3], Ulrich Hirn[4], and Volker Schmidt[2] — [1]Institute of Solid State Physics,Graz University of Technology, Petersgasse 16, 8010 Graz, Austria — [2]Institute of Stochastics, Ulm University, Helmholtzstrasse 18, 89069 Ulm, Germany — [3]Institute of Applied Materials, Helmholtz-Zentrum Berlin für Materialien und Energie, Hahn-Meitner-Platz 1, 14109 Berlin, Germany — [4]Institute of Bioproducts and Paper Technology, Graz University of Technology, Inffeldgasse 23, 8010 Graz, Austria

Predicting the macroscopic behavior of heterogeneous porous materials from their microscopic structure is formidably challenging, because local morphological microstructure descriptors markedly and erratically vary across a sample. We demonstrate how to quantify cross relationships between pore space-related descriptors and to use these relations to distinguish complex pore spaces at a glance, alike using fingerprints. The key idea is to map the actual microstructure on a multivariate probability distribution. The latter contains strongly compressed information to reproduce the spatial variations of selected properties and their pair-wise interdependencies. Using R-vine copulas, we will exemplarily construct such a distribution of the local morphological descriptors porosity, thickness, surface area per volume and pathway tortuosity for the measured microstructure of paper sheets.

CPP 45.5　Thu 10:30　ZEU 255
Ab initio **cavity QED - modifying chemistry with strong light-matter interaction** — •Christian Schäfer[1,2], Enrico Ronca[3], Johannes Flick[4,5], Prineha Narang[5], and Angel Rubio[2,4] — [1]Department of Microtechnology and Nanoscience, MC2, Chalmers University of Technology, 412 96 Göteborg, Sweden — [2]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [3]Istituto per i Processi Chimico Fisici del CNR (IPCF-CNR), Via G. Moruzzi, 1, 56124, Pisa, Italy — [4]Center for Computational Quantum Physics (CCQ), The Flatiron Institute, 162 Fifth Avenue, New York NY 10010, USA — [5]John A. Paulson School of Engineering and Applied Sciences, Harvard University, Cambridge, Massachusetts 02138, USA

The alchemical dream of altering a given material on demand into something desirable is at the very heart of chemistry. Optical-Cavity environments provide a novel handle to non-intrusively control materials and chemistry. The self-consistent interaction between complex electromagnetic environments and realistic materials gave birth to a new discipline, sometimes referred to as '*ab initio* QED', on the interface of condensed matter, chemistry and quantum optics.

I will provide a brief introduction into this newly emerged field and illustrate how chemical reactions can be controlled [1] with optical cavities.

[1] Schäfer, C., Flick, J., Ronca, E., Narang, P., and Rubio, A., arXiv:2104.12429 (2021).

CPP 45.6　Thu 10:45　ZEU 255
Structural Descriptors for Constructing High-Dimensional Neural Network Potentials — •Moritz R. Schäfer[1,2], Jonas A. Finkler[3], Stefan Goedecker[3], and Jörg Behler[1,2] — [1]Lehrstuhl für Theoretische Chemie II, Ruhr-Universität Bochum, 44780Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research AllianceRuhr, 44780 Bochum, Germany — [3]Basel University, Department of Physics, Klingelbergstrasse 82, 4056 Basel, Switzerland

High-dimensional neural network potentials (HDNNPs) are a well established method to efficiently compute close-to ab initio-quality energies and forces for performing large-scale molecular dynamics simulations of complex systems. In this method, the total energy is constructed as a sum of environment-dependent atomic energy contributions. Also electrostatic interactions based on flexible atomic charges can be included. Both components crucially depend on the quality of the structural descriptors employed to characterize the local atomic environments. Here we investigate the combination of atom-centered symmetry functions with the recently proposed overlap matrix descriptor. Moreover, the advantages and disadvantages of both descriptors are discussed and illustrated for benchmark systems.

CPP 45.7 Thu 11:00 ZEU 255
Solving inverse transport problems across irregular interfaces of sorptive porous media via physics-informed neural networks — •Alexandra Serebrennikova and Karin Zojer — Institute of Solid State Physics, TU Graz, Petersgasse 16, 8010, Graz, Austria

We show how state of the art extended physics-informed neural networks serve us to solve inverse transport problems with jump conditions across irregular interfaces. This approach reveals the material constants which govern reactive diffusion of organic volatiles migrating across an interface between porous sorptive packaging and food media if we provide experimental data and a transport model.

In such scenarios, associated differential equations (PDE) imply jumps not only in the solution, but also in the solution gradient across interfaces. The idea is to use multiple NN to construct the solution; each NN approximates the solution function of the PDE associated to a domain within the defined interfaces. The networks are coupled across interfaces such that the boundary conditions are satisfied.

As NNs are required to fit underlying physics by minimizing PDE residuals, they are inherently suited to solve inverse problems for the parameters involved in the equations. As further benefit, the discretized experimental data can be represented with a continuous function which offers a meshfree and compact surrogate model for the solution function.

CPP 45.8 Thu 11:30 ZEU 255
Aging-driven compositional changes in Li-ion batteries — •Dominik Petz[1,2], Peter Müller-Buschbaum[1,2], and Anatoliy Senyshyn[1] — [1]MLZ, TUM, Garching — [2]TUM School of Natural Sciences, Chair of Functional Materials, Garching

Electrochemical cycling of lithium-ion batteries is supplemented by the active transport of lithium ions and electrons, which are exchanged between the cathode and anode material. Besides material properties, such exchange is facilitated by the parameters of electrochemical cell like electrode dimensions and geometry, current density, temperature, etc. Such parameters are neither uniformly distributed nor static in general and, therefore, serve as a factor stabilizing heterogeneous states in Li-ion batteries typically reflected in the lithium concentration profiles in the electrodes. Thus, cell aging directly affects the distribution of the lithium-ions in the graphite anode of 18650-type lithium-ion batteries. Lithium heterogeneities (often reflected in loss of lithium inventory) are directly related to the electrolyte filling level. In order to quantify and correlate them simultaneously, a set of cells at different state-of-health was studied non-destructively using spatially resolved neutron powder diffraction. Experimental results unambiguously revealed changes of the lithium and electrolyte distribution versus cell state-of-health in a series of commercial 18650-type lithium-ion battery.

CPP 45.9 Thu 11:45 ZEU 255
Dedoping of PEDOT:PSS using amines to shift the threshold voltage in OECTs — •Laura Teuerle, Rakesh Nair, Hans Kleemann, and Karl Leo — IAPP Dresden

With an increasing importance of organic semiconductors, due to their flexibility, transparency and possible biocompatibility, more applications and device classes emerge.

One of them - the organic electochemical transistor (OECT) can be utilized in neuromorphic computing and printed digital logic. The most commonly used - PEDOT:PSS is a p-type semiconductor, which leads to normally-on type transistors. However, normally-off type devices are needed for a successful application in logic circuits.

We show that a chemical dedoping method involving amines leads to a shift in threshold voltage to zero and even negative in the corresponding devices.

Different processing methods for the dedoping process and device building are studied, which involve photolithography, inkjet printing and spraycoating.

Furthermore, IV measurements for device characterization were taken.

The results show that the studied chemical dedoping of -PEDOT:PSS can be a viable method to create normally-off type transistors for an application in logic circuits.

Analysis of glass transition for polymer melts using data-driven methods — •Atreyee Banerjee, Hsiao-Ping Hsu, Kurt Kremer, and Oleksandra Kukharenko — Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany

Upon cooling, the dynamical properties of most polymer melt slow down exponentially leading to a glassy state without any drastic change in structure. While determining glass transition temperature and understanding the glass transition are important topics of current physical research, the properties in the glassy state are crucial for their general applicability. The conventional ways to calculate glass transition temperature from simulation data of polymer melts rely on the fitting of high- vs. low-temperature branches of macroscopic properties such as volume or density and are sensitive to the choice of parameters. We propose a new data-driven approach based on the information about structural fluctuations in the chains to identify the glass transition temperature. Our data-driven approach utilizes high-resolution details accessible through molecular dynamics simulations and considers the structural information of individual chains. The method was tested for coarse-grained weakly semi-flexible polymer model sim-

ulations [1]. It is also applied to the all-atom acrylic polymer simulations with different lengths of side-chain residues.

Roughness Induced Rotational Slowdown near the Colloidal Glass Transition — Beybin Ilhan, Michel Duits, and •Frieder Mugele — University of Twente, Physics of Complex Fluids group

Rotational diffusion of colloidal spheres has been studied rarely, in spite of its importance in the kinetics of many processes involving friction. While for smooth hard spheres, rotational diffusion gets impeded only weakly with increasing volume fraction, the picture changes drastically when surface roughness is introduced. We show this for a system of undeformable all-silica colloidal raspberries, studied with time-resolved 3D Confocal Scanning Laser Microscopy (CSLM).

We find that the strong surface roughness leads to a significantly lower maximum volume fraction, preceded by a broad concentration range in which the rotational Brownian motion changes signature from high-amplitude diffusive to low-amplitude rattling. This strong rotational slowdown occurs at significantly higher concentrations than for the translations, thus presenting a second glass transition.

In the regime where the Mean Squared Angular Displacement (MSAD) is sub-diffusive, significant correlations are found between the translational and rotational motions. The drastic rotational slowdown occurs when the particle inter-surface distance becomes comparable to the surface roughness amplitude. Concurrently, the number of contacts exceeds a critical value. This picture is supported by observations in a densely packed layer of raspberries at a smooth wall: here significant rotational motions are found while the translations are almost completely frozen.

CPP 50.3   Thu 12:45   ZEU 255

When molecular heterogeneities matter: thermal expansion and relaxation time in polyalcohols — •Martin Tress[1], Jan Gabriel[2], and Friedrich Kremer[1] — [1]Universität Leipzig, Leipzig, Germany — [2]Roskilde University, Roskilde, Denmark

Structural relaxation in liquids is considered to depend directly on the available free volume. Many theoretical concepts of liquid dynamics and the glass transition approximate this molecular quantity using macroscopic density. However, particularly hydrogen (H-) bonding liquids defy proper description by these approaches (e.g. the failure of density-scaling in such materials). To study densification on molecular scale, we use infrared spectroscopy on a series of polyalcohols. By analyzing specific molecular vibrations and correlating them with interatomic bond lengths, the thermal expansion of several types of intramolecular covalent bonds and intermolecular H-bridges is quantified. Pronounced differences between intra- and intermolecular expansion verify the dominance of the latter. Surprisingly, the overall thermal expansion (i.e. cube root of inverse density) is even bigger than that of the strong H-bridges. This suggests that weak H-bridges dominate thermal expansion while strong ones must control structural relaxaztion, i.e. the glass transition. The method is validated by successfully describing the density of water based on extracted H-bridge lengths. Consequently, inhomogeneities on intra- and intermolecular scale can play distinct roles in densification and orientational relaxation and require a careful consideration in a comprehensive theoretical description. [Gabriel, Tress et al. J Chem Phys 154 (2021) 024503]

CPP 51: Hybrid and Perovskite Photovoltaics III

Time: Thursday 15:00–17:15   Location: GÖR 226

CPP 51.1   Thu 15:00   GÖR 226

Slot-die coating of nanocrystal and bulk perovskite thin films for photovoltaics — •Manuel A. Reus[1], Ahmed Krifa[1], David P. Kosbahn[1], Quinten A. Akkerman[2], Alexander Biewald[3], Lennart K. Reb[1], Matthias Schwartzkopf[4], Andrei Chumakov[4], Stephan V. Roth[4], Achim Hartschuh[3], Jochen Feldmann[2], and Peter Müller-Buschbaum[1,5] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching — [2]Nano-Institut München und Fakultät für Physik, LMU München — [3]Department Chemie und CeNS, LMU München — [4]DESY, 22607 Hamburg — [5]MLZ, TUM, Garching

Thin-film solar cells might offer large-scale and cheap production with highly tunable properties, e.g., semi-transparency, color, thickness, or flexibility. Slot-die coated nanocrystal and bulk hybrid perovskite thin films are significant for high-efficiency next-generation solar cell absorber materials. In this work, we show the feasibility of creating high-quality thin films of this material class by the easily scalable and roll-to-roll compatible deposition method of meniscus-guided slot-die coating. We use time-resolved grazing-incidence X-ray scattering to investigate the crystal structure, texture, and morphology of the printed thin films. We track the printing process in real-time and extract parameters describing the quality and kinetics of the printing process. We also present solar cell data with perovskite absorber layers printed from colloidal hybrid perovskite nanocrystal solution.

CPP 51.2   Thu 15:15   GÖR 226

Time-resolved structural changes in hybrid perovskites under illumination — •Ivan Zaluzhnyy[1], Linus Pithan[1], Alexander Hinderhofer[1], Rustam Rysov[2], Fabian Paulus[3], and Frank Schreiber[1] — [1]Institute of applied physics, University of Tübingen, Tübingen, Germany — [2]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [3]Center for advancing electronics Dresden, Technical University of Dresden, Dresden, Germany

Hybrid perovskites with mixed halides are known to undergo phase segregation when illuminated by visible light. We used coherent X-ray diffraction at synchrotron sources to reveal the structural changes in the series of $MAPbBr_{(3-x)}I_x$ perovskites illuminated with a white and blue light (broad spectrum and $\lambda \approx$ 450 nm, respectively). The experimental data allow us to characterize the initial structure of the perovskite films, observe the changes during the illumination, and estimate the time scales over which these changes take place. Moreover, using x-ray photon correlation spectroscopy (XPCS), we can observe the movement of the domain walls and characterize the mobility of the halide ions. The obtained results allow us to better understand the microscopic mechanisms leading to the halide segregation.

CPP 51.3   Thu 15:30   GÖR 226

Investigation of defects inside of mixed halide perovsike solar cells — •Pascal Rohrbeck[1], Yenal Yalcinkaya[1,2], and Stefan A. L. Weber[1,2] — [1]Max Planck Institute for polymer research, department physics at interfaces, Ackermannweg 10, 55128 Mainz, Germany — [2]Johannes Gutenberg University, Department of Physics, Staudingerweg 10, 55128 Mainz, Germany

Understanding the electron and ion dynamics is an important task for improving the lead halide perovskites and related devices. For this task, macroscopic measurement techniques are not sufficient. Therefore, nanoscale characterization methods can play an important role in studying perovskite solar cells. In this study, we investigate the spatial defect distribution in the vicinity of grain boundaries. We introduce local photovoltage, photovoltage decay, and defect mapping via time-resolved Kelvin probe force microscopy (tr-KPFM) methods. We are able to detect and localize areas of increased charge carrier recombination, ion migration, and defects. This will help to understand recombination losses and improve perovskite solar cells on the long run.

CPP 51.4   Thu 15:45   GÖR 226

Post-Flight Analysis of Space-Probed Perovskite and Organic Solar Cells by Means of Grazing-Incidence X-Ray-Scattering — •Lennart Klaus Reb[1], Michael Böhmer[1], Benjamin Predeschly[1], Sebastian Grott[1], Christian Ludwig Weindl[1], Goran Ivkovic Ivandekic[1], Renjun Guo[1], Lukas Viktor Spanier[1], Christoph Dreissigacker[2], Jörg Drescher[2], Roman Gernhäuser[1], Andreas Meyer[2], and Peter Müller-Buschbaum[1,3] — [1]TU München, Garching, DE — [2]Deutsches Zentrum für Luft- und Raumfahrt (DLR), Köln, DE — [3]Heinz Maier-Leibnitz-Zentrum, Garching, DE

Thin-film perovskite and organic solar cells exhibit an exceptional power per mass that makes them particularly interesting for space applications. Recently, we launched perovskite and organic solar cells into space on a suborbital rocket flight for the first time [1, 2]. The rocket experiment enables post-flight characterization of the space-probed solar cells, based on Grazing-Incidence Small-Angle and Wide-Angle X-ray Scattering (GISAXS/GIWAXS) to investigate morphological and structural changes in the active layers. The morphology is altered slightly by the space flight and environmental conditions before and after the rocket launch; interestingly, the sole solar cell transport in nitrogen environment modified their active layers compared to the reference solar cells. The crystalline phase, however, does not reveal changes in any solar cell type. [1] L. Reb et al., Joule 4,1880-1892 (2020), doi.org/10.1016/j.joule.2020.07.004. [2] L. Reb et al., Rev. Sci. Instrum. 92 (2021), doi.org/10.1063/5.0047346.

CPP 51.5 Thu 16:00 GÖR 226

Simulation of the impact of processing conditions on the perovskite film morphology — •Martin Majewski, Olivier Ronsin, and Jens Harting — Forschungszentrum Jülich GmbH, Helmholtz Institute Erlangen-Nürnberg (IEK-11), Dynamics of Complex Fluids and Interfaces, Cauerstraße 1, 91058 Erlangen, Germany

The solution-processed perovskite layer forms complex structures during drying. This morphology of the dry film heavily influences the efficiency of the final solar cell. The impact of the physical mechanisms on the morphology, like for example nucleation and evaporation rate, in a drying, crystallizing wet film is not really understood yet. Therefore a better understanding of the interplay of these phenomena is needed. We will present phase field simulations which are capable to describe the main physical processes like: evaporation, diffusion, spontaneous nucleation, crystal growth and advection, to investigate the impact of processing conditions on the final morphology of the perovskite film. Comparisons of the simulation to the theory will be presented. First simulations of drying solutions, including all physical phenomena, will be shown and compared to experiments.

15 min. break

CPP 51.6 Thu 16:30 GÖR 226

Influence of mesoporous-TiO_2 on mobile ion migration and charge extraction of perovskite solar cells — •Patrick Dörflinger[1], Valentin Schmid[1], Yong Ding[2], Mohammad Khaja Nazeeruddin[2], and Vladimir Dyakonov[1] — [1]Experimental Physics VI, Julius Maximilian University of Würzburg, 97074 Würzburg — [2]Group for Molecular Engineering of Functional Materials, Institute of Chemical Sciences and Engineering, EPFL Valais, Sion 1950, Switzerland

Hybrid lead halide perovskite solar cells have reached over 25% power conversion efficiency in the past years but still suffer from poor long term stability. Therefore, increasing attention is given to interfacial engineering. Especially the interplay of the transport layer with the perovskite layer is essential, determining various key properties like the ability of charge extraction or surface recombination. In this study, the potential of different mesoporous TiO_2 electron transport layers (ETL) with focus on the mobile ions is investigated. Therfore, concentration and diffusion of mobile ions, often linked to device degradation, is analyzed by measuring open-circuit voltage decay (OCVD). Furthermore, measuring the photoluminescence quenching efficiencies (PLQE) between open-circuit and short-circuit conditions of complete devices allows to study charge extraction and link the obtained results to device performance. These studies prove the advantage of using a mesoporous-TiO_2 layer made of single-crystalline nanoparticles as an ETL.

CPP 51.7 Thu 16:45 GÖR 226

Interferometric Bulk Access in Pump-Probe Microspectroscopy of MAPbBr$_3$ Crystals — •Tobias Seewald[1], Ulrich J. Bahnmüller[2], Sebastian Polarz[2], and Lukas Schmidt-Mende[1] — [1]Department of Physics, University of Konstanz, Germany — [2]Institute of Inorganic Chemistry, Leibnitz University Hannover, Germany

We present a microspectroscopic study on individual facets of MAPbBr$_3$ crystals synthesized via an aerosol method controlling the exposed lattice planes. Transient reflection and photoluminescence spectra collected from single few μm facets allow to correlate the findings to micromorphology and lattice termination. Internal reflection of the probe pulse is found to form Fabry-Pérot resonances in the sub-band gap spectral region, which sensitively respond to the modified refractive index upon photoexcitation. Comparing one- and two-photon pump absorption, the dynamics of bulk and surface states can be distinguished on ps timescales.

CPP 51.8 Thu 17:00 GÖR 226

An alternative non-invasive technique for studying hybrid perovskite solar cells' in-situ degradation — •Chikezie Williams Ugokwe[1,2], Zekarias Teklu Gebremichael[1,2], Kehinde Ogunmoye[1,2], Ulrich S. Schubert[1,2], and Harald Hoppe[1,2] — [1]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich Schiller University Jena, Philosophenweg 7a, 07743 Jena, Germany — [2]Laboratory of Organic and Macromolecular Chemistry (IOMC), Friedrich Schiller University Jena, Humboldtstrasse 10, 07743 Jena, Germany

The main obstacle to the commercialization of hybrid organic-inorganic perovskite (HOIP) solar cells is stability. Hence understanding degradation routes within the solar cell is essential. Traditional characterization methods have so far either monitored global properties, which precludes a better knowledge of local degradation processes, or induced some type of degradation, which conflates results in in-situ degradation studies of perovskite solar cells. In this paper, we describe a non-invasive technique for the in-situ analysis of the degradation of the active layer of an inverted HOIP solar cell. Utilizing the phenomenon of coherent light propagation in thin film layer stacks, we were able to see lead (II)iodide formation over time in a fully functional perovskite solar cell, which is an undeniable by-product of degradation. We were able to quantify the vertical distribution of the degradation product along the thickness of the active layer by using the measured reflectance of the entire solar cell as the input data for the optical modeling.

CPP 52: Wetting, Fluidics and Liquids at Interfaces and Surfaces III (joint session CPP/DY)

Time: Thursday 15:00–16:15 Location: MER 02

CPP 52.1 Thu 15:00 MER 02

Hierarchical superhydrophobic composite membrane for enhanced distillation with excellent fouling resistance — •Prexa Shah[1], Youmin Hou[2], Michael Kappl[1], and Hans Jürgen Butt[1] — [1]Max-Planck-Institute for Polymer Research, Physics at Interfaces group, Ackermannweg 10, 55128 Mainz, Germany. — [2]School of Power and Mechanical Engineering, Wuhan University, 430072, Wuhan, China.

In arid areas near the coast, seawater desalination has become an essential supply of clean water. As a result, energy-efficient desalination systems must be developed to avoid overburdening the restricted energy supply. Membrane distillation (MD) is gaining popularity as a hybrid thermal/membrane-based desalination approach that may use waste heat for small-scale desalination as well as treating high-salinity brines. The objective is now to maximize the distillation rate while avoiding membrane wetting and fouling. In this work, composite membranes with multiscale pore sizes are formed by depositing a thin layer of nano-porous nanofilaments over microporous membranes. Distillation performance and fouling resistance are explored utilizing low surface tension impurities, which might enhance the chance of membrane wetting. The resistance of protein adsorption to organic fouling is also examined. Our unique multiscale porous membranes outperform traditional hydrophobic membranes in terms of fouling resistance while achieving better distillation flow. This research shows how to optimize MD procedures for wastewater and saltwater treatment.

CPP 52.2 Thu 15:15 MER 02

Surface tension of cavitation bubbles — •Marine Bossert[1], Panayotis Spathis[2], Pierre-Étienne Wolf[2], Laurent Cagnon[2], Isabelle Trimaille[3], and Étienne Rolley[4] — [1]Institut of Materials Physics and Technology, Hamburg University of Technology, Germany — [2]Institut Néel, Grenoble, France — [3]Institut des NanoSciences de Paris, Paris, France — [4]Laboratoire de Physique de l'Ècole Normale Supérieure, Paris, France

The evaporation of a fluid contained in a porous material occurs by cavitation when the pores are connected to the outer gas reservoir through small constrictions. Using monolithic transparent porous samples, we have measured the cavitation rate J as a function of the departure from equilibrium for hexane at room temperature [1] and nitrogen over a wide temperature range.

When the radius of the critical nucleus R* is large, our measurements are in agreement with the prediction of the Classical Nucleation Theory. However, when the thickness of the interface is not negligible compared to R*, we find that J is much larger than predicted. We show that this shift can be accounted for if the liquid-vapor surface tension is allowed to depend on the interface curvature. This dependence is in reasonable agreement with Density Functional calculations for Lennard-Jones fluid, including the correction to second order in curvature.

[1] V. Doebele, et al, Phys. Rev. Lett. 125 (2020) 255701.

CPP 52.3 Thu 15:30 MER 02

Simulations for Wetting of Biomembranes — •Marcel Mokbel and Sebastian Aland — TU Bergakademie Freiberg, Freiberg, Germany

The dynamics of membranes, shells, and capsules in fluid flow has become an active research area in computational physics and computational biology. The small thickness of these elastic materials enables their efficient approximation as a hypersurface, which exhibits an elastic response to in-plane bending and out-of-plane stretching deformations. If such a closed thin shell is filled with (and/or surrounded by) multiple fluids, capillary forces on the contact line between the fluids and the shell may arise and force the shell to deform.

In this work, we present a novel Arbitrary Lagrangian-Eulerian (ALE) method to simulate such elastic surfaces immersed in Navier-Stokes fluids, which is combined with a phase field approach to model droplets inside and/or outside the surface. This method combines high accuracy with computational efficiency, since the grid is matched to the elastic surface and can therefore be resolved with relatively few grid points near the surface. We formulate elastic surface forces

and propose an evolving finite-element discretization. Several wetting test cases demonstrate the versatility of the proposed method. Examples are simulations of single or multiple droplets deforming a vesicle-like shell.

CPP 52.4 Thu 15:45 MER 02

Dilute suspensions of chemically active particles in thin liquid films — •Tilman Richter, Paolo Malgeretti, and Jens Harting — Helmholtz-Institut Erlangen-Nürnberg für erneuerbare Energien, Erlangen, Germany

Thin liquid films are important for many microfluidic applications such as printing or coating of e.g. printable electronics or photovoltaic cells as well as so called lab-on-a-chip devices. Also in catalysis at liquid interfaces thin film dynamics are important. It is well known that a thin film on a solid substrate can be unstable and droplet formation may arise.

The dynamics of thin liquid films and their instability has been the subject of intensive experimental, analytical, and numerical studies, the latter often based on the thin film equation. We propose a set of newly developed equations for the influence of chemical active colloids suspended in a thin liquid film based on the lubrication and Fick-Jackobs approximation. For this novel set of equations we perform a linear stability analysis (LSA) that reveals surprisingly interesting dynamics. We identify the subset of parameters for which the thin film becomes stable i.e. is not rupturing, as well as a variety of different dominating wave-modes. This allows us to control not only the stability but also the droplet size distribution after film rupture, as well as the time it takes for an initially flat film to rupture.

In order to assess the asymptotic state of the thin film, the LSA results are compared against numerical simulations using the Lattice Boltzmann method.

CPP 52.5 Thu 16:00 MER 02

Light properties and water resistant of combined sobrerol methacrylate cellulose thin films. — •Constantin Harder[1,2], Alexandros E. Alexakis[3], Marie Betker[1,3], Yusuf Bulut[1,2], Benedikt Sochor[1], Huaying Zhong[2], Guangjiu Pan[2], Manuel Reus[2], Korneliya Goordeyeva[3], Apostolos Vagias[2,4], Daniel Söderberg[3], Eva Malmström[3], Peter Müller-Buschbaum[2,4], and Stephan V. Roth[1,3] — [1]DESY, 22607 Hamburg, Germany — [2]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [3]KTH Royal Institute of Technology, 10044 Stockholm, Sweden — [4]MLZ, TUM, 85748 Garching, Germany

Functionalization of porous materials in terms of optical, chemical and mechanical properties is achieved by applying fully wood-based layers materials. In this project, the refraction index, extinction coefficient and water adhesion properties of cellulose thin films combined with sobrerol methacrylate colloids are investigated together with their topography and morphology. Cellulose nanofibrils (CNF) are a hydrophilic material, and form networks during the drying with specific refraction index, extinction coefficient. Applying additional colloids, their optical properties and water-contact angle can be tuned. Hence, in order to produce water-resistant thin film, a combination of CNF and colloids is a perfect candidate.

CPP 53: Charged Soft Matter, Polyelectrolytes and Ionic Liquid

Location: ZEU 255

Invited Talk CPP 53.1 Thu 15:00 ZEU 255

Aqueous nanoclusters govern ionic transport in dense polymer membranes — •Joachim Dzubiella — Physikalisches Institut, Universität Freiburg

Hydrated polymer materials with low water uptake exhibit a highly heterogeneous interior characterized by water clusters in the form of nanodroplets and nanochannels. Here, based on our recent insights from computer simulations, we argue that the water cluster structure has large implications for ionic transport and selective permeability in polymer membranes. Importantly, we demonstrate that the two key quantities for transport, the ion diffusion and the solvation free energy inside the polymer, are extremely sensitive to molecular details of the water clusters. In particular, we highlight the significance of water droplet interface potentials and the nature of hopping diffusion through transient water channels. These mechanisms can be harvested and fine-tuned and may optimize selectivity in ionic transport in a wide range of applications.

CPP 53.2 Thu 15:30 ZEU 255

Why weakly hydrated anions bind to polymers but not to monomers? — Bradley A. Rogers[1], Halil I. Okur[1,4], Chuanyu Yan[1], Tinglu Yang[1], •Jan Heyda[2], and Paul S. Cremer[1,3] — [1]Department of Chemistry, The Pennsylvania State University, University Park, PA, USA. — [2]Department of Physical Chemistry, University of Chemistry and Technology, Prague, Dejvice, Czech Republic. — [3]Department of Biochemistry and Molecular Biology, The Pennsylvania State University, University Park, PA, USA. — [4]Present address: Department of Chemistry and National Nanotechnology Research Center (UNAM), Bilkent University, Ankara, Turkey.

Weakly hydrated anions help to solubilize hydrophobic macromolecules in aqueous solutions, but small molecules comprising the same chemical constituents precipitate out when exposed to these ions. Here, this apparent contradiction is resolved by systematically investigating the interactions of NaSCN with polyethylene oxide oligomers and polymers of varying molecular weight. A combination of spectroscopic and computational results reveals that SCN- accumulates near the surface of polymers, but is excluded from monomers. This occurs because SCN- preferentially binds to the centre of macromolecular chains, where the local water hydrogen-bonding network is disrupted. These findings suggest a link between ion-specific effects and theories addressing how hydrophobic hydration is modulated by the size and shape of a hydrophobic entity.

CPP 53.3 Thu 15:45 ZEU 255

Constrained Conductivity in Smallest Polymer Aggregates — •Alaa Hassan, Wing Kit Or, and Martin Tress — Peter Debye Institute, Leipzig university

Detailed insight into material properties at the nanometric level is highly desired in advancing nanotechnology. In the past, Broadband Dielectric Spectroscopy (BDS) revealed altered dynamics of polymers confined to thin films or nanometric channels. However, little is known about the properties of individual polymer chains because of the extreme experimental challenge. We aim to investigate individualized polymer chains using nano-BDS by refining a nanostructured electrode setup and combining it with chemical surface modification. The latter involves depositing a very regular pattern of gold nanoparticles (AuNPs)

of well-controllable size and separation at the nanometer scale. These AuNPs act as anchors for chemical grafting-to of thiol-terminated polyethylene oxide (PEO). AFM is used to determine the volume of PEO grafted to each AuNP from which the average number chains are deduced. The successful implementation of this approach is confirmed by measuring the conductivity of separated PEO aggregates down to about five chains each. The conductivity of the isolated aggregates shows Arhinus-like behavior in the whole temperature range, while in bulk, this is only seen below the glass transition. Additionally, the slope of the conductivity in the loss spectra is reduced in the aggregates, which suggests that intra-chain hopping dominates as opposed to inter-chain hopping in bulk. This might exemplify structural constraints that restrict charge mobility close to the surface.

CPP 53.4 Thu 16:00 ZEU 255

KCl modulated D2O Hydration and Subsequent Thermoresponsive Behavior of Poly(sulfobetaine)-Based Diblock Copolymer Thin Films — •Peixi Wang[1], Christina Geiger[1], Julija Reitenbach[1], Apostolos Vagias[5], Robert Cubitt[2], Viet Hildebrand[3], André Laschewsky[3], Christine M. Papadakis[4], and Peter Müller-Buschbaum[1,5] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching — [2]Institut Laue-Langevin, Grenoble — [3]Fraunhofer-Institut für Angewandte Polymerforschung, Potsdam-Golm — [4]TUM School of Natural Sciences, Soft Matter Physics, Garching — [5]MLZ, TUM, Garching

The salt effect of KCl on D2O hydration and subsequent thermoresponsive behavior of diblock copolymer (DBC) thin films, which feature a short zwitterionic poly(4-((3-methacrylamidopropyl) dimethylammonio) butane-1-sulfonate)) (PSBP) block and a long nonionic thermo-responsive poly(N-isopropylmethacrylamide) (PNIPMAM) block, is studied by in situ spectral reflectance (SR) and time-of-flight neutron reflectivity (ToF-NR) in combination with isotope sensitivity. The solvation-triggered phase transition upon D2O hydration and subsequent heating is probed in situ by Fourier transform infrared spectroscopy (FT-IR). Besides, the migration and/or aggregation of KCl domains inside the DBC thin films is also demonstrated by complementary methods, namely, X-ray reflectivity (XRR) and atomic force microscopy (AFM).

Photoisomerization of Arylazopyrazole Surfactants Drives Property Changes of Polyelectrolyte/Surfactant Mixtures — •Michael Hardt and Björn Braunschweig — University Münster, Center for Soft Nanoscience, 48149 Münster, Germany

Polyelectrolyte/surfactant (P/S) mixtures are in most cases static in nature, which renders them invariable for property changes unless massive changes in pH or ionic strength are applied. We have shown that mixtures of cationic photo-responsive arylazopyrazole (AAP) surfactants with NaPSS exhibit substantial changes in particle size and electrophoretic mobility [1] that can be easily triggered by light irradiation.

Here, we present new information on PDADMAC polyelectrolyte mixtures with three anionic AAP surfactants that have H, butyl and octyl terminal groups. The *E* and *Z* configurations of the AAP photoswitches show substantially different hydrophobic interactions that drastically alter their binding affinity to the PDADMAC. Measurements of the electrophoretic mobility clearly indicate that the *E/Z* photoisomerization of AAP surfactants causes a charge reversal of the P/S aggregates, while for the H-AAP also larger P/S aggregates in the bulk solution can be dissolved by UV irradiation and formed again with green light. Vibrational sum-frequency generation (SFG) spectroscopy reveals that similar to the changes in the bulk, the charging state at the air-water interface can be reversibly tuned by the light conditions. This has interesting consequences for soft matter materials such as foams [1] and emulsions.

CPP 53.6   Thu 16:45   ZEU 255
Grazing incidence x-ray scattering on lithium iron phosphate electrodes with polymer blend binders — •Fabian A.C. Apfelbeck[1], Julian E. Heger[1], Tianfu Guan[1], Matthias Schwartzkopf[2], Stephan V. Roth[2,3], and Peter Müller-Buschbaum[1,4] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching — [2]DESY, 22607 Hamburg — [3]Royal Institute of Technology KTH, 100 44 Stockholm — [4]MLZ, TU München, 85748 Garching
Lithium iron phosphate (LFP) is a widely used cathode for lithium ion batteries especially in vehicles due to its low cost, high safety, long cycle life and low toxicity. However, so far structural investigations are mainly limited to x-ray diffraction (XRD) techniques. In this project, we extend the investigation of these electrodes to grazing incidence techniques. Therefore, we study electrodes which consist of the active material lithium iron phosphate, carbon black as conducting agent and the polymeric binder polyvinylidenfluorid (PVDF). Additionally, we prepare several binder blends of the neutral PVDF and the single-ion conducting polymer poly(trifluoromethane) sulfonimide lithium styrene) (PSTF-SILi) since it is known, that a 1:1 wt% mixture of PVDF and a single-ion conducting polymer results in superior battery performance. We measure grazing incidence small/wide angle x-ray scattering (GISAXS/GIWAXS) and based on these data, we can understand the influence of the binder on the structure of the electrode. We can correlate ex-situ the morphological and structural data (GISAXS/GIWAXS) with electrochemical results (EIS).

CPP 53.7   Thu 17:00   ZEU 255
Comparative Study of Thermoelectric Transport Properties of Lithium- and Sodium-based Solid Polymer Electrolytes and their Tuning by Carbon-based Additives — •Maximilian Frank, Julian-Steven Schilling, and Jens Pflaum — Experimental Physics VI, University of Würzburg, 97074 Würzburg
Due to the high abundance of their atomic constituents, solution as well as easily scalable processing, and intrinsically low thermal conductivity, organic polymers have gained much attention for potential thermoelectric applications. In particular, ionic systems can generate significantly higher thermal voltages than electronic materials. In this work, we will compare our previous findings [1]

on the electrical and thermoelectric transport properties of a solution-processed methacrylate-based solid polymer electrolyte with new results obtained by variation of the conducting salt. Using impedance spectroscopy in a broad frequency range from 100 mHz to 510 kHz in a temperature range between 263 K and 353 K and by means of thermoelectric voltage measurements, we deduced the essential concentration-related differences in the application of LiTFSI and NaTFSI as conducting salts. As an extension, we demonstrate the possibility to efficiently tune the transport properties of these polymer electrolytes by carbon-based additives, which differ in their conductivity characteristics (semiconducting or metallic, 1D or 2D). A proof-of-concept thermoelectric generator verifies the functionality of our approach and substantiates the potential of mixed ionic and electronic materials for future TE applications. [1] M. Frank, J. Pflaum, *Adv. Funct. Mater.* **2022**.

Understanding Electron Hopping Mechanism in Organic Radical Batteries — •Souvik Mitra[1], Andreas Heuer[2], and Diddo Diddens[3] — [1]University of Muenster — [2]University of Muenster — [3]University of Muenster
In recent years, there has been an increasing interest in organic radical batteries (ORBs) due to their potentially high power density and availability of Cobalt free cathode materials [1]. Understanding charge transport in ORBs is still an open question due to the disordered behavior of the organic environment [2]. To understand the fundamental mechanism associated with charge hopping and ion transport we use reactive step MD (rs@md) [3]. The rs@md technique accounts for charge transfer reactions in classical MD simulation based on the rates of these reactions. We calculate these rates using the Marcus theory [4]. In this contribution, we explicitly study the Marcus curve for the TEMPO molecule (a very common redox component used in ORBs) in presence of various solvents and salts. We also study the Marcus coupling using quantum methods such as Frontier Molecular Orbital (FMO) [5] and Complete Active Space Self Consistent Field (CASSCF) [6] theories.

Fluid ferroelectric nematic fibres — •Alexander Jarosik and Alexey Eremin — Otto-von-Guericke Universität, Magdeburg, Germany
Nematics with a broken polar symmetry is one of the fascinating recent discoveries in soft matter. High spontaneous polarisation and the fluidity of the ferroelectric nematic NF phase make such materials attractive for future applications and interesting for fundamental research. We report the first example of metastable fluid fibres formed in the ferroelectric phase and characterise their polar and nonlinear optical properties. We discuss the filament stability in the frame of the polarisation-splay model of the ferroelectric nematic phase.

CPP 54: 2D Materials VIII

Time: Thursday 16:30–17:45   Location: MER 02

CPP 54.1   Thu 16:30   MER 02
Structure elucidation of 2D covalent organic frameworks — •Maryke Kouyate[1,3], Konrad Merkel[1], Dominik Pastoetter[2], Albrecht Ludwig Waentig[2], Xinliang Feng[2], and Frank Ortmann[1] — [1]Technical University of Munich, Munich, Germany — [2]TU Dresden, Dresden, Germany — [3]Fritz Haber Institute of the Max Planck Society, Berlin, Germany
We determine the structure of novel 2D framework materials (known as 2D polymers or 2D COFs) that are based on Diquinoxalino[2,3-a:2',3'-c]phenazine (HATNA) vertex units and different linkers (napthalene vs. pyrene). We simulate the unit cell parameters and stacking patterns with density functional theory. The studied COFs were synthesized and experimentally characterized by our collaborators. Our theoretical studies include extensive xyz scans to find the most energetically favorable stacking geometry. With the results of the xyz scans and the appropriate selection of the unit cell, good agreement is obtained with the experimental PXRD patterns, and individual XRD peaks can be assigned to specific in-plane or out-of-plane directions. Moreover, the simulated structures show a clear difference in the packing of the two COFs which are caused by differences in their linker units. This observation is also consistent with the differences in the experimental PXRD patterns. As a result, we can shed light on the actual cell parameters and stacking behavior.

How to calculate electron-hole interaction efficiently in large covalent organic frameworks? — •Konrad Merkel and Frank Ortmann — TU München, School of Natural Sciences

Solving the Bethe-Salpether equation for crystalline materials with many atoms per unit cell, such as covalent organic frameworks, is computationally very expensive and often not feasible. Established tools are usually not suitable for this class of materials because they have enormous memory requirements due to their large basis sets. An elegant solution is to use material-specific, tailored basis sets that allow a complete description with only a handful of basis functions and therefore require only a fraction of the computational resources. In our talk, we present a technique using Wannier functions as a suitable basis and computing Coulomb matrix elements in this basis. The fully parameterized exciton Hamiltonian is then solved using a linear scaling approach that allows efficient computation of spectral quantities such as the exciton DOS for materials with hundreds of atoms per unit cell.

CPP 54.3   Thu 17:00   MER 02
New Paradigm for Gas Sensing by Two-Dimensional Materials — •Udo Schwingenschlögl, Vasudeo Babar, and Sitansh Sharma — King Abdullah University of Science and Technology (KAUST), Physical Science and Engineering Division (PSE), Thuwal 23955-6900, Saudi Arabia
The adsorption behavior and electronic transport properties of CO and NH_3 molecules on para-C_3Si and meta-C_3Si monolayers are studied using first-principles calculations and the non-equilibrium Green's function method. The adsorption sites are determined along with their adsorption energies. It turns out that CO and NH_3 molecules physisorb on both monolayers. The current-voltage characteristics show that the para-C_3Si monolayer can be used to sense CO and NH_3 gases with high sensitivity. In contrast to other two-dimensional materi-

als, the sensing mechanism is not based on charge transfer but on the presence of Dirac states and their susceptibility to symmetry-breaking structural distortions. Journal Reference: J. Phys. Chem. C 123, 13104 (2019)

CPP 54.4   Thu 17:15   MER 02

Tunable gas permeation properties through sub-nanometer porous molecular thin carbon nanomembranes — •Vladislav Stroganov[1], Daniel Hüger[1], Tabata Noethel[1], Christof Neumann[1], Monika Kruk[2], Piotr Cyganik[2], and Andrey Turchanin[1] — [1]Friedrich Schiller University Jena, Jena, Germany — [2]Jagiellonian University, Kraków, Poland

Molecular thin carbon nanomembranes (CNMs) are 1 nm thick nanosheets with sub-nanometer porosity combined with high mechanical and chemical stability. These properties make them promising for the next generation of filtration and gas separation technologies. Here we investigated influence of the structure of molecular precursors on the gas permeation properties of a series of CNMs. The CNMs were synthesized from self-assembled monolayers of biphenyl substituted carboxylic acids on silver substrate $C_6H_5 - C_6H_4 - (CH_2)_n - COO|Ag$ (n = 2 - 6) via the electron-irradiation induced cross-linking. We study for this homologous sequence of CNMs the permeation of He, D_2 and D_2O vapors as a function of temperature. We demonstrate that even a smallest variation of the number of $-CH_2-$ units leads to a significant change in the permeation which enables the molecular design of these nanomembranes for nanofiltration.

CPP 54.5   Thu 17:30   MER 02

Vapor Adsorption on CNMs studied with Infrared Spectroscopy — •Jakob Kreie, Petr Dementyev, Neita Khayya, and Armin Gölzhäuser — Physics of Supramolecular Systems and Surfaces, Bielefeld University, Germany

Carbon nanomembranes (CNM) are made by electron induced cross-linking of aromatic self-assembled monolayers. Previous studies show that CNM enable rapid transport of water vapor. This may be related to a strong adsorption of water molecules on the CNM surface. A spectroscopic setup for infrared measurements of vapor adsorption on CNMs is designed to investigate the adsorption on the surface under realistic conditions. For this purpose, a reaction chamber in a polarization-modulation infrared reflection absorption spectroscope (PM IRAS) is connected to a vacuum system in order to be able to control the vapor environment.

First measurements are performed with a terphenyl-4-thiol carbon nanomembrane (TPT-CNM). The results show that even low vapor pressures of heavy water are sufficient to achieve strong adsorption on the surface of the TPT-CNM, which indicates a large influence of the surface effects on water transport through the membrane.

CPP 55: Members' Assembly

Report of the current Speaker team Election of the second deputy speaker Award of the poster Prize of the CPP Division Miscellaneous

Self-assembled optical metamaterials — •Ullrich Steiner — Adolphe Merkle Institute, Chemin des Verdiers 4, 1700 Fribourg

The self-assembly of block-copolymers gives rise to numerous 2D and 3D morphologies with characteristic pattern sizes on the 10 nm length scale. These polymer structures can be transformed into plasmonic metals to fabricate 2D metasurfaces and 3D metamaterials. These plasmonic replicas have the appropriate structure sizes for the coupling of plasmon resonances to the visible light spectrum, yielding interesting optical material.

This presentation will review recent progress in manufacturing and studying these materials and highlight interesting current developments.

CPP 56.2   Fri 10:00   GÖR 226

In Situ Monitoring of Self-Assembly and Plasmonic Shifts during the Growth of AgCu Alloy Nanostructures — •Matthias Schwartzkopf[1], André Rothkirch[1], Niko Carstens[2], Thomas Strunskus[2], Franziska C. Löhrer[3], Senlin Xia[3], Volker Körstgens[3], Peter Müller-Buschbaum[3,4], Franz Faupel[2], and Stephan V. Roth[1,5] — [1]DESY, Notkestr. 85, D-22607 Hamburg — [2]CAU zu Kiel, Kaiserstr.2, 24143 Kiel — [3]TUM, James-Franck-Str. 1, D-85748 Garching — [4]MLZ, Lichtenbergstr. 1, D-85748 Garching — [5]KTH, Teknikringen 56-58,SE-100 44 Stockholm

While magnetron sputtering is a versatile routine method in industry for the deposition of large area metal and alloy coatings, it can be also used for the preparation of functional nanocomposites with e.g. adjustable optical properties [1]. We investigated in real-time the formation of supported silver, copper, and silver-copper-alloy nanoclusters during sputter deposition on poly(methyl methacrylate) by combining in situ surface-sensitive X-ray scattering with optical spectroscopy [2]. While following the transient growth morphologies, we quantify the early stages of phase separation at the nanoscale, track the shifts of surface plasmon resonances, and quantify the growth kinetics of the nanogranular layers at different thresholds. We are able to extract the influence of scaling effects on the nucleation and phase selection and demonstrate a route to tailor accurately the plasmon resonances of nanosized, polymer-supported clusters. [1] Faupel et al., Adv. Eng. Mater. 2010, 12, 12, 1177-1190. [2] Schwartzkopf et al., ACS Appl. Nano Mater. 2022, 5, 3, 3832-3842.

CPP 56.3   Fri 10:15   GÖR 226

What happens to bovine serum albumin in-between two gold nanoparticles and how this biomolecule defines the plasmonic effect? — Nina Tverdokhleb, •Olga Guskova, Ziwei Zhou, Holger Merlitz, and Vladyslav Savchenko — Leibniz-Institut für Polymerforschung Dresden e. V.

In experiments, spherical gold nanoparticles (NPs) covered by bovine serum albumin (BSA) create 1D Au-BSA nanoarrays on a polymer film. The external mechanical strain applied to the film leads to plasmon-coupled circular dichroism (PCCD) enhancement. To explain this phenomenon, we perform all-atom MD simulations of plasmonic nanostructures, representing BSA in-between two gold NPs. The following steps were undertaken: (1) BSA was adsorbed on the gold wall (a model of NP) in implicit water with optimization of its geometry; (2) the second mobile gold wall was approaching adsorbed protein until the distance between NPs reaches the experimentally measured value; (3) mimicking mechanical stretching mentioned above, an external tensile force applied on the second wall has induced the backbone stretching of the initially compressed BSA. This process is accompanied by the crucial growth of BSA dipole moment along the directional deformation, restructuring of the protein secondary structure from helices to coils upon compression (2), the reorientation of the charged amino-acid residues, and subsequent partial back-folding of the secondary structure elements upon stretching (3). We correlate an observed plasmonic effect in the 1D Au-BSA arrays to the changes in dipole moment and chirality of BSA.

CPP 56.4   Fri 10:30   GÖR 226

Uniform and sensitive Raman signal by self-assembled plasmonic nanoparticle gratings — •Sezer Seçkin[1] and Tobias A. F. König[1,2] — [1]Leibniz-Institut für Polymerforschung e.V., Hohe Straße 6, 01069 Dresden — [2]Center for Advancing Electronics Dresden (cfaed), Technische Universität Dresden, 01062 Dresden

Despite recent advancements in this field, it is still challenging to manufacture SERS substrates that provide high sensitivity and uniformity over large areas. One can overcome this challenge by employing a colloidal approach such as directed self-assembly of plasmonic nanoparticles into ordered structures [König et al. Advanced Functional Materials 31.36 (2021): 2105054]. Here, we have produced highly ordered 1D plasmonic lattice structures by assembling nanoparticles of various sizes. With the help of the low optical loss of colloidal gratings, we studied the enhancement capabilities of the SERS substrates by the excitation of a fluorescent reporter Rhodamine 6G, at different wavelengths. We conducted the

polarization-dependent SERS enhancement by exciting colloidal gratings parallel and perpendicular to the polarization of the excitation lasers. Moreover, we studied the effect of the surface plasmon modes on the SERS enhancement at different orientations using the FDTD simulation. The mapping technique visually interpreted the SERS performances of other substrates, which supports the reproducibility and uniformity of the Raman signals over larger areas. Controlling the particle size while keeping the periodicity constant allows us to tune the SERS enhancement factor, which can be helpful for various sensing applications.

CPP 56.5   Fri 10:45   GÖR 226

Investigating Charge Transfers in Colloidal Photonic Crystal Slabs — •Swagato Sarkar[1] and Tobias A. F. König[1,2] — [1]Leibniz-Institut für Polymerforschung Dresden e.V., Institute of Physical Chemistry, Hohe Str. 6, 01069 Dresden, Germany — [2]Center for Advancing Electronics Dresden (cfaed), Technische Universität Dresden, Helmholtzstraße 18, 01069 Dresden

The challenges of large-scale and low-loss plasmonic charge transfers are systematically investigated by optical designs with colloidal 1D plasmonic lattice structures. These plasmonic lattices are used as couplers to confine the incident energy into the underlying titanium dioxide layers, thus acting as colloidal photonic crystal (cPhC) slabs. Conventionally, photodetection is possible at energy levels close to the semiconductor bandgap; however, with the observed plasmonic-photonic hybrid modes, the extended solar spectrum can be used for energy harvesting. The photo-amplified current is measured locally with simple two-point contact on the centimeter-sized nanostructure by applying a bias voltage. The optical concepts for metallic grating composed of nanobars are extended for the first time to colloidal self-assembled gold nanoparticle (AuNP) chains to make large-scale charge injection accessible at a reasonable cost. Further, the possibility of photodetection by electric field vectors lying both along and perpendicular to the grating lines can be achieved by tuning the plasmonic grating periodicities.

CPP 56.6   Fri 11:00   GÖR 226

Self-assembled plasmonic metasurfaces for sensing and photocatalysis — •Olha Aftenieva[1] and Tobias A.F. König[1,2] — [1]Leibniz-Institute for Polymer Research Dresden, Hohe Straße 6, 01169 Dresden, Germany — [2]Center for Advancing Electronics Dresden (cfaed), Technische Universität Dresden, 01062 Dresden, Germany

Self-assembly of colloids allows for robust and tunable manufacturing over centimeter-scaled areas. Here we present the soft lithographic approach for creating plasmonic lattices and demonstrate their usage for sensing applications and photocatalysis. First, a particular case of collective out-of-plane resonant coupling is considered. Such resonances are excited solely under oblique illumination with transverse magnetic polarization and provide field enhancement in the area above the metasurface that is easily accessible to an analyte and is particularly sensitive to the changes in the refractive index. On the other hand, we realize imprinting of such periodic plasmonic lattices on functional substrates, including glass, silicon wafers, carbon, gold, semiconductor, or polymer thin films, illustrating the versatility of the colloidal approach. In particular, the combination of titanium dioxide thin waveguiding layers and plasmonic metasurface gives rise to narrow-bandwidth guided plasmon-polariton modes. Moreover, it induces the generation of hot charge carriers and enhances photocatalytic processes. Thus, colloidal self-assembly of plasmonic metasurfaces presents an application-oriented approach that is of potential use for optical sensors, photonic circuit applications, or hybrid device manufacturing.

Invited Talk   CPP 56.7   Fri 11:30   GÖR 226

Simulating quantum systems with plasmonic waveguide arrays — •Stefan Linden — Physikalisches Institut, Universität Bonn, 53115 Bonn

Coupled waveguides provide a powerful platform to simulate the evolution of quantum mechanical tight-binding systems in a classical wave environment. The basis for this is the mathematical equivalence between the time-dependent Schrödinger equation and the paraxial Helmholtz equation. In this presentation, we report on the observation of the Wannier-Stark ladder and Bloch oscillations in arrays of plasmonic waveguides with a propagation constant gradient acting as an effective external potential. Moreover, we show that Floquet engineering is a powerful method to tailor the topological properties of plasmonic waveguide arrays. In this context, we demonstrate that time-periodic modulation of dissipation can restore transport quantization in fast Thouless pumps and report on the observation of the anomalous Floquet topological π-mode at optical frequencies.

Invited Talk   CPP 56.8   Fri 12:00   GÖR 226

single molecule detection on a smartphone microscope enabled by DNA origami biosensors — •Philip Tinnefeld — Department of Chemistry and Center for NanoScience, Ludwig-Maximilians-Universität München, Butenandtstr. 5-13, 81377 München, Germany

DNA nanotechnology and especially the DNA origami technique allow well-defined assembly of optically active components and sensing units for novel biosensing approaches. We here demonstrate single-molecule detection on a battery driven smartphone microscope enabled by fluorescence enhancement with DNA origami nanoantennas. As further examples, we show DNA origami membrane sensors for curvature and membrane potentials. Finally, DNA origamis are used for a novel superresolution approach combining graphene energy transfer, pMINFLUX and DNA PAINT that enables nanometric 3D superresolution close to the coverslip.

CPP 57: Complex Fluids and Colloids, Micelles and Vesicles II (joint session CPP/DY)

Time: Friday 9:30–13:00   Location: MER 02

Invited Talk   CPP 57.1   Fri 9:30   MER 02

Chiral transport of active and passive colloids — •Anke Lindner[1], Andreas Zöttl[2], Olivia du Roure[1], Eric Clement[1], Francesca Tesser[1], and Guangying Jing[3] — [1]PMMH-ESPCI, 10, rue Vauquelin, 75011 Paris, France — [2]Faculty of Physics, University of Vienna, Kolingasse 14-16, 1090 Wien, Austria — [3]School of Physics, Northwest University, Xi'an, 710127, China

Chirality-induced effects are at the origin of bacterial rheotaxis and particle drift in shear flows. Here we investigate such effects using a combination between experiments and theoretical modeling for two systems: E-coli bacteria and 3D printed micro-particles.

The micro-particles consist of a spherical head and a helical tail of different pitch and handedness. We investigate the chirality-induced reorientation dynamics using microfluidics and observe asymmetric orientation bistability perpendicular to the flow direction. We quantitatively explain our findings through a theoretical model without adjustable parameters considering particle elongation, chirality and head-heaviness, in very good agreement with experiments.

We then present a study of the transport of motile bacteria in shear flows. Experimentally, we obtain with high accuracy and for a large range of flow rates, the spatially resolved velocity and orientation distributions. They are in excellent agreement with the simulations of a kinematic model accounting for stochastic and microhydrodynamic properties and flagella chirality. In contrast to the micro-printed particles Brownian rotational noise plays a crucial role in bacterial rheotactic drift.

CPP 57.2   Fri 10:00   MER 02

Active and driven colloids interacting with vesicles — •Antonio Stocco, Vaibhav Sharma, Florent Fessler, and Carlos Marques — Institut Charles Sadron, CNRS University of Strasbourg

When a colloid is close to a lipid giant vesicle, the interaction between the Brownian particle and the fluctuating soft membrane affects not only the particle motion but also the membrane properties. The membrane may change its shape to accommodate the particle and partial or complete engulfment may occur as a function of the energy of adhesion, membrane tension and bending. Furthermore, the interaction between a micrometric solid particle and a giant vesicle membrane may lead to complex dynamics when the system is driven out of equilibrium. Here, we report our efforts with self-propelled Janus colloids and with bare colloids under optical trapping to mimic complex dynamics such as particle endocytosis, the motion of a self-propelled particle confined to a spherical membrane, or the physics of particle engulfment by a membrane. In a wide range of experimental conditions, we have observed that a self-propelled Janus colloid is able to perform orbital motion around a giant vesicle remaining in a non-engulfment state. Still, the active particle is able to impart a force of the order of 0.01 pN on the vesicle, which is however too small to trigger particle engulfment. By applying external forces in the 1-100 pN range, we were able to observe engulfment of bare and Janus colloids by a giant vesicle.

CPP 57.3   Fri 10:15   MER 02

Universal Casimir interaction and its relevance for colloidal and biophysical systems — •Tanja Schoger[1], Benjamin Spreng[2], Gert-Ludwig Ingold[1], Paulo A. Maia Neto[3], and Serge Reynaud[4] — [1]Universität Augsburg, Germany — [2]University of California at Davis, USA — [3]Universidade Federal do Rio de Janeiro, Brazil — [4]Laboratoire Kastler Brossel, France

Colloidal systems and biophysical interfaces involve electrolytic environments where the Debye screening is extremely efficient. Therefore, it was thought that the interaction induced by electromagnetic fluctuations could not give rise to long-range forces in such systems. It has now been shown and experimentally

verified [1] that the contribution to the Casimir force or retarded van der Waals force induced by low-frequency transverse magnetic fluctuations is not screened. There thus exists a contribution to the long-range interaction between two objects in an electrolyte two orders of magnitude larger than previously thought at distances as small as one hundred nanometres.

For two dielectric microspheres in salted water at room temperature, the force becomes universal for sufficiently large distances, in that it depends solely on the geometrical parameters and not on dielectric functions. While in general, a significant numerical effort is required to determine the Casimir interaction [2], we have also derived approximate simple expressions [3] accurate enough for most practical applications. - [1] L. Interparticle forces between real cement surfaces across aqueous and non-aqueous solvents — •Simon Becker and Regine von Klitzing — Soft Matter at Interfaces, TU Darmstadt, 64289 Darmstadt, Germany

Concrete and cement are highly abundant construction materials. Therefore, their flow behavior in early stages of processing is of great interest. By using chemical admixtures such as superplasticizers (e.g. polycarboxylate ethers - PCEs) their rheological performance can be enhanced. The rheology is governed by the forces between the particles and the forces between particles and the liquid phase.

The aim of this work is to map the force between cement surfaces across an electrolyte via colloidal probe atomic force microscopy (CP-AFM). Since cement hydrates in aqueous solutions the surface changes with time. The challenge is to disentangle different effects like hydration and roughness of the cement surfaces on the interaction. To prevent hydration of the cement the force measurements are conducted in ethanol solutions. For comparison the force measurements are carried out between two silica particles, between cement and silica as well as between cement and cement.

Furthermore, the time dependence of the cement surface due to hydration in water is mapped using tapping mode AFM. Moreover, the hydration time dependent interparticle force between cement surfaces is investigated in aqueous electrolyte solution with and without PCE to approach application related conditions.

Structure and interaction of surface charged polymeric micelles — Lingsam Tea, Lutz Willner, •Jörg Stellbrink, and Stephan Förster — JCNS-1, Forschungszentrum Jülich, 52425 Jülich, Germany

Soft colloids are ubiquitous in synthetic and biological matter and display macroscopically interesting structural and dynamical properties resulting from its hybrid microscopic structure. We established micelles formed by amphiphilic block copolymers as an easy and elegant model system to tailor colloidal softness [1].

In the present work, we introduce surface charges on n-alkyl-PEO-OH micelles resulting in electrostatic interactions in addition to the inherently present steric repulsion. These charges are precisely implemented by oxidation of only the terminal hydroxy group of the PEO block into a carboxy group. We studied intra- and interparticle structure by SANS over a broad range of concentrations, pH and ionic strength and demonstrate that the micellar form factor remains the same independent of the number of charges. However, in contrast to neutral micelles, the charged micelles typically reveal structure factor contributions even at very dilute concentration, arising from the here dominating long-range electrostatic repulsion. Structure factors in the liquid state are analyzed using competing effective interaction potentials. By increasing the concentration a liquid to crystal transition is observed for all systems, but for charged micelles at a much lower concentration compared to the uncharged micelles.

CPP 57.6   Fri 11:00   MER 02

Structure and dynamics of concentrated suspensions of PMMA-PDMS core-shell particles — •Joel Diaz Maier, Paul Tümmler, and Joachim Wagner — Institut für Chemie, Universität Rostock, 18051 Rostock, Germany

Sterically stabilized polymer particles with silicone based stabilizers find increasing interest as a novel colloidal model system with hard-sphere interactions. In this contribution, the largely unknown behavior of concentrated suspensions of PMMA-PDMS core-shell particles was investigated over a wide range of volume fractions employing static and dynamic light scattering experiments. Static structure factors extracted from scattered intensities are analyzed using integral equation theory. The wavevector-dependent short-time diffusion of the systems can be accurately described using $\delta\gamma$-expansion, based on interpolated experimental structure factors as a direct input. All investigated structural and dynamical properties closely follow theoretical predictions for hard-sphere systems, proving the suitability of these colloidal particles as an easily accessible model system for hard spheres.

CPP 57.7   Fri 11:30   MER 02

Inverse ISAsomes in biocompatible oils - formulation and characterisation — •Florian Trummer[1], Otto Glatter[2], and Angela Chemelli[2] — [1]Universität Stuttgart, Institut für Physikalische Chemie, Pfaffenwaldring 55, 70569 Stuttgart, Deutschland — [2]Technische Universität Graz, Institut für Anorganische Chemie, Stremayrgasse 9, 8010 Graz, Österreich

In contrast to their more common counterparts in aqueous solutions, inverse ISAsomes (internally self-assembled somes/particles) are formulated as kinetically stabilised dispersions of hydrophilic, lyotropic liquid-crystalline phases in non-polar oils. This contribution reports on their formation in bio-compatible oils and their structural characterisation with Small Angle X-Ray Scattering (SAXS), Dynamic Light Scattering (DLS) and optical microscopy [1]. By using these methods, we were able to demonstrate the presence of inverse hexosomes, inverse micellar cubosomes (Fd3m) and an inverse emulsified microemulsion in squalane with a polyethylene glycol (PEG) alkyl ether as the primary surfactant forming the internal self-assembled phase, which was stabilised by hydrophobised silica nanoparticles. Furthermore, an emulsified L_1-phase and inverse hexosomes were formed in triolein with the triblock-copolymer Pluronic P94 as the primary surfactant. In this case, stabilisation was achieved with a molecular stabiliser of type PEG-dipolyhydroxystearate. Finally, triolein was replaced with olive oil which also led to the successful formation of inverse hexosomes.

CPP 57.8   Fri 11:45   MER 02

Anomalous Screening Behavior of Nanometer-Sized Ions — •Thomas Tilger and Regine von Klitzing — Department of Physics, Technische Universität Darmstadt, Darmstadt, 64289, Germany

Natural colloidal dispersions have accompanied mankind in the form of blood or milk ever since. Besides this, artificial systems have gained a significant importance for our daily life during the last decades.

Therefore, it is of special interest to gain an understanding of which interparticle forces govern the stability of colloidal dispersions and how this stability can be tailored. The DLVO theory is a powerful framework to describe these interactions. While this description provides a good agreement with experimental data for small 1:1 electrolytes, larger deviations emerge for ions of higher valency and of larger dimensions. For a detailed examination of these border cases, we directly measure the forces between colloidal silica particles in aqueous electrolyte solutions containing nanometer-sized ions by the colloidal probe AFM (atomic force microscopy) technique.

Two different types of nano-ions were chosen as model systems, Keggin ions (silicotungstic acid, STA, a 1:4 system) and Terpyridine-Nickel-complexes with variable charge. Their electrostatic screening behavior reveals significant deviations between the calculated and measured ionic strengths, which indicates some unexpected phenomena.

CPP 57.9   Fri 12:00   MER 02

Charged, screened-charged and hard-sphere fluids studied by confocal microsopy, analytical theory and simulation. — Sahana Kale, Martin Oettel, and •Hans Joachim Schöpe — Universität Tübingen, Institut für angewandte Physik, Auf der Morgenstelle 10, 72076 Tübingen

We present a joint experimental and theoretical study investigating the fluid structure in direct and reciprocal space of PMMA particles dispersed in various solvents. Using decaline and CHB alone the structure can be well-described using PB-RMSA-Theory for monodisperse systems. Upon adding TBAB we observe that the surface charge can't be screened entirely. To model the fluid structure we use Monte Carlo simulations for a polydisperse hard core Yukawa System. Thus we get meaningful data for the effective charge and salt concentration. The results indicate behavior that is significantly different from HS. Surprisingly the situation is fundamentally different for particles dispersed in a mixture of decaline and TCE. Here all measured observables follow polydisperse Percus-Yevick theory.

CPP 57.10   Fri 12:15   MER 02

Bicontinuous Microemulsion in Porous Materials — •Margarethe Dahl[1], René Haverkamp[2], Larissa Doll[1], Thomas Hellweg[2], and Stefan Wellert[1] — [1]Institut für Chemie, Technische Universität Berlin, Germany — [2]Physikalische und Biophysikalische Chemie, Universität Bielefeld, Germany

While the bulk phase behavior of microemulsions has been intensively studied, the influence of a geometrical confinement has been widely neglected. Understanding the influence of geometrical restrictions yields both, fundamental insights and importance for applications, e.g. decontamination and enhanced oil recovery. In our study, controlled-pore silica glasses (CPGs) serve as confining matrices for bicontinuous microemulsions. Effects of the pore network and surface chemistry on phase behavior and structure of a model microemulsion are studied by using various CPGs with pore diameter between 75 – 1000 Å and ternary bicontinuous microemulsions (water/octane/$C_{10}E_4$). The naturally hydrophilic surfaces of the CPGs were hydrophobically modified to analyze the

influence of the surface polarity. We use imaging techniques (cryo-SEM), small angle scattering (SANS, SAXS) with measurements of the advancing contact angles inside the hydrophilic and hydrophobically modified pores (Washburn approach) to explore the microemulsion phase structure in bulk and inside the pores. In this talk, the results of these combined experiments will be presented and discussed.

CPP 57.11   Fri 12:30   MER 02

Diffusion and thermodiffusion of polymers in mixed solvents — •Daniel Sommermann, Jannik Kantelhardt, and Werner Köhler — Physikalisches Institut, Universität Bayreuth, Germany

We present experiments on diffusion and thermodiffusion of polymers in mixed solvents. So far, most works on thermodiffusion have dealt with binary systems or ternary mixtures of small molecules. Binary samples with polymers in solvents have been studied over both a broad concentration and polymer molar mass range. Only a few very recent experiments measured polymers in a binary solvent. In this work, samples made of polystyrene ($M_w = 4880\ g/mol$), toluene and cyclohexane have been analysed using multi-color optical beam deflection (OBD) and supporting single-color thermal diffusion forced Rayleigh scattering (TDFRS). While binary mixtures are readily characterized by one diffusion and one thermodiffusion coefficient, the number of coefficients increases to four plus two for ternaries. The measured signals show three well separated modes that can be assigned to the thermal diffusivity and the two eigenvalues of the mass diffusion matrix. We are particularly interested in the question, to what extent the dynamics of the large entity, the polymer, is coupled to the solvent-solvent dynamics, both with respect to diffusion and thermodiffusion. A first analysis supports the picture of an effective solvent whose internal dynamics is decoupled from the one of the polymer.

CPP 57.12   Fri 12:45   MER 02

Dynamic susceptibility of magnetic nanoplatelet suspensions — •Margaret Rosenberg[1], Sofia S. Kantorovich[1], and Philip J. Camp[2] — [1]Department of Physics, University of Vienna, Vienna, 1090, Austria — [2]School of Chemistry, The University of Edinburgh, David Brewster Road, Edinburgh EH9 3FJ, UK

Particle anisometry and anisotropy provide valuable control parameters to alter the self-assembly, and thermodynamic, rheological, and phase behaviour, of colloidal suspensions. This work is concerned with the dynamic magnetic susceptibility (DMS) of a ferrofluid with platelet-shaped anisotropic particles, which have a fixed out-of-plane dipole moment providing additional, magnetic anisometry. Such a colloidal suspensions is of particular interest as, above a threshold concentration, it exhibits a ferromagnetic nematic phase. Recent experimental work [1] has shown that the DMS spectrum exhibits multiple dynamical modes, suggesting that there might be clusters of particles with distinct rotational timescales. Using Brownian dynamics simulations, we explore the effects of varying nanoparticle concentration - and therefore microstructure - on the DMS, and explain the gap in relaxation times, and changes in the spectrum, that are observed experimentally.

CPP 58: Polymer Networks and Elastomers

Time: Friday 9:30–11:30   Location: ZEU 255

Invited Talk   CPP 58.1   Fri 9:30   ZEU 255
Studies of polymer thermosets using scattering techniques — •Mats Johansson — Department of Fibre & Polymer Technology, KTH Royal Institute of Technology, SE-100 44 Stockholm, Sweden

Thermoset polymers are complex macromolecular structures where the macroscopic properties depend on several different structural features such as crosslink density, rigidity on a molecular level, and internal secondary bond interactions. The final thermoset structure not only depend on the in-going monomers structure but also how these form the network i.e. the polymerization process. The presentation will describe how a combination of scattering techniques and traditional physical and chemical characterization techniques can reveal new insights on the structure / property relationship for thermoset polymers. It is moreover demonstrated that this approach also can be used to monitor the network formation in-situ i.e. how the structures evolves on a nanoscale during polymerization.

CPP 58.2   Fri 10:00   ZEU 255

Effect of π-π stacking interactions on mechanical properties of lignin-based thermosetting resins — •Iuliana Ribca[1], Benedikt Sochor[2], Marie Betker[1,2], Stephan V. Roth[1,2], Martin Lawoko[1], Michael A. R. Meier[3,4], and Mats Johansson[1] — [1]Department of Fibre and Polymer Technology, KTH Royal Institute of Technology, Stockholm, Sweden — [2]Deutsches-Elektronen Synchrotron (DESY), Hamburg, Germany — [3]Institute of Organic Chemistry (IOC), Materialwissenschaftliches Zentrum MZE, Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany — [4]Institute of Biological and Chemical Systems-Functional Molecular Systems (IBCS-FMS), Karlsruhe Institute of Technology (KIT), Eggenstein-Leopoldshafen, Germany

The transition towards a more sustainable global carbon economy can be achieved by replacing petroleum-based materials with bio-based alternatives. Lignin is the most abundant aromatic resource in nature and a largely unused by-product of the pulp and paper industry. It is considered a good replacement for fossil-based aromatics. One promising strategy for lignin valorization is to produce thermosetting resins. Further applications of these resins require the understanding of their physicochemical properties. An important role on these properties are playing π-π stacking interactions. Different configurations of π-π stacking interactions are favored between the lignin chains, due to the presence of aromatic rings. In this study, it was investigated the effect of π-π stacking interactions on mechanical properties of lignin-based thermosets by small and wide-angle X-ray scattering methods.

CPP 58.3   Fri 10:15   ZEU 255

Strain hardening of hydrogenated acrylonitrile butadiene rubber — •Christoph Gögelein[1] and Marjan Hemstede - van Urk[2] — [1]Arlanxeo Deutschland GmbH, Kaiser-Wilhelm-Allee 40, 51369 Leverkusen — [2]Arlanxeo Netherlands B.V., Urmonderbaan 24, 6167 RD Geleen, The Netherlands

Therban hydrogenated acrylonitrile butadiene rubber (HNBR) is a specialty elastomer used in the automotive and oil and gas markets. It is well known that HNBR with acrylonitrile (ACN) contents above 39 wt% shows strain-induced crystallization (SIC), caused by the crystallization of alternating ethylene-ACN units (Obrecht, 1986). For HNBR polymers with ACN contents lower than 36 wt%, crystallization occurs in longer ethylene units derived from hydrogenated butadiene sequences (Uschold & Finlay, 1974). Besides these well-established findings, there is an ongoing debate up to which temperature SIC occurs for HNBR (Narynbek Ulu, et al., 2017) (Shaw, 2019). Therefore, crystallization of the polymers was studied, using regular and isothermal differential scanning calorimetry at varying storage times. Furthermore, we investigated strain hardening behavior of HNBR networks with varying ACN contents from room temperature (RT) up to 100 ˚C, as well as at varying crosslink densities and filler loadings. Our results show that there is a significant strain hardening behavior for HNBR vulcanizates with high ACN content, i.e. for > 39 wt% ACN content. The effect is still observed at 60 ˚C, but not at 80 ˚C. Surprisingly, strain hardening doesn't enhance the fatigue lifetime for the samples under investigation.

CPP 58.4   Fri 10:30   ZEU 255

From Cellulose Model Surfaces to Elastic Papers — •Cassia Lux, Sabrina Kerz, and Regine von Klitzing — Department of Physics, Technische Universität Darmstadt, Darmstadt, 64289, Germany

Paper is a hierarchical material based on cellulose which allows functionalization on different length scales. The resulting multilateral use is especially crucial with regard to reducing plastic use and waste and replacing it with renewable and biodegradable resources. A novelty in terms of mechanical robustness and controllable fluid mechanics are elastic papers, prepared through the functionalization of the paper fibers with elastomeric particles that concentrate at the fiber-fiber-crossing points. In order to study the particle adsorption, planar cellulose model surfaces are prepared to mimic the surface of a cellulose fiber. The elastomeric core shell particles have a pH-responsive polycation shell, and their adsorption to the negative charged cellulose surface is studied in dependence of e.g. pH-value. The question we adress is how the properties of the cellulose surface and the particles affect the contact area between both, and what effect the adsorption has on the elastic behavior of the particles. A special focus is to resolve the core-shell structure of the particles by Indentation AFM.

CPP 58.5   Fri 10:45   ZEU 255

Structure, phase behavior and mechanical properties of the surface of amphiphilic co-polymer networks — •Kevin Hagmann[1], Nora Fribiczer[2], Sebastian Seiffert[2], Carolin Bunk[3], Frank Böhme[3], and Regine von Klitzing[1] — [1]Institute for Condensed Matter Physics, Technische Universität Darmstadt, D-64289 Darmstadt — [2]Department of Chemistry, Johannes Gutenberg University Mainz, D-55128 Mainz — [3]Leibniz-Institut für Polymerforschung Dresden e.V., D-01069 Dresden

The underlying study focuses on the structure, phase separation and mechanics of the surface of amphiphilic co-polymer networks (ACNs).[1] The amphiphilic networks are synthesized from tetrameric star-shaped polymers, combining tetra-poly(ethylene glycol) (hydrophilic) and tetra-poly(ϵ-caprolactone) (hydrophobic) to form a 3D gel network. The topology and near surface struc-

ture of the networks are studied with atomic force microscopy (AFM). We put special emphasis on AFM phase imaging under various solvent conditions to identify nanophase separation at the interface. Additionally, we like to present the relation between surface structure and swelling and the resulting mechanical and rheological properties laterally and orthogonally to the gel surface of ACNs. In order to evaluate heterogeneities and phase separation, the mechanical and rheological behavior at the interface of the ACNs will be presented on various length scales (nm - μm). The study shows that the environmental conditions have a strong effect on the gel structure and on nano/microrheological properties. [1] Hagmann et al.; Polymers 2022.

CPP 58.6 Fri 11:00 ZEU 255

A mean field model for reversible networks made of star polymers — •Michael Lang[1], Kiran Suresh Kumar[1,2], and Jens-Uwe Sommer[1,2] — [1]Leibniz-Institut für Polymerforschung Dresden, Institut Theorie der Polymere, Hohe Straße 6, 01069 Dresden, Germany — [2]Institut für Theoretische Physik, Technische Universität Dresden, Zellescher Weg 17, 01069 Dresden, Germany

We extend our recent approach [1] for linear equilibrium polymers with cyclization towards reversible networks made of star polymers. These model systems are particularly suited to test generalizations of the theory that account for the formation of cyclic network defects. Monte-Carlo simulation data and our mean field model demonstrate that the lack of pending loops in networks made by a hetero-complementary coupling of the stars leads to a pronounced shift of the position of the gel point of conventional networks towards lower concentrations. Larger cyclic structures in the networks, on the contrary, can develop a stabilizing effect on the network structure and can cause a reduction of the critical

concentration for gelation for a suitable set of system parameters. Remarkably, this leads then to the opposite effect of finite loops as known for conventional irreversible gels.

CPP 58.7 Fri 11:15 ZEU 255

Thermal Conductivity of Semicrystalline Polymer Networks: Crystallinity or Cross-Linking? — •Manoj Kumar Maurya[1], James Wu[2], Manjesh Kumar Singh[1], and Debashish Mukherji[2] — [1]Department of Mechanical Engineering, Indian Institute of Technology Kanpur, Kanpur, UP 208016, India — [2]Quantum Matter Institute, University of British Columbia, Vancouver, BC V6T 1Z4, Canada

Understanding the heat flow in polymers is at the onset of many developments in designing advanced functional materials. Here, however, amorphous linear polymers usually exhibit a very low thermal conductivity κ, often hindering their broad applications. In this context, two common routes to increase κ are via semicrystallinity and cross-linking. It can therefore be inferred that the combination of these two effects may result in a further increase of κ with respect to the systems where only one of these two effects is important. Using molecular dynamics simulations, we investigate κ in semicrystalline polymer networks. Contrary to a prior understanding, we show that a combination of cross-linking and crystallinity does not always increase κ. Instead, a delicate competition between the lattice periodicity, the cross-linker types, and the bond density dictates the tunability of κ in these complex macromolecular systems. These results are also compared with the existing experiments.

Atomistic and network models for graphene based macromaterials: role of intercalation, defects and dopants — •Florian Fuchs[1,2] and Jörg Schuster[1,2] — [1]Fraunhofer Insitute for Electronic Nano Systems (ENAS), Chemnitz, Germany — [2]Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, Chemnitz, Germany

The excellent properties of graphene can be utilized in macroscopic conductor materials if the individual flakes are decoupled from each other, for example by misalignment of the lattices or by intercalation. Such materials are promising candidates to replace metals for numerous electrical conductor applications [1].

We show the results of a network model [2,3] which relates the structural arrangement and the properties of the individual graphene flakes to the macroscopically observed electrical conductivity. By this model we assess the properties of the macromaterial as a function of relevant parameters such as flake size, packing density, the graphene flake conductivity, and the interlayer conductance.

On the flake-level, intercalation, doping, and defect healing control the conductivity of the graphene-based macromaterial. We performed density functional theory calculations of these processes. In our presentation we discuss the impact on the material quality by focussing on the in-plane and the out-of-plane conductivity.

Post-processing on graphene field-effect transistors by critical point drying — •Hamid Reza Rasouli[1], David Kaiser[1], Christof Neumann[1], Martha Frey[1], Ghazaleh Eshaghi[1], Thomas Weimann[2], and Andrey Turchanin[1] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena, 07743 Jena, Germany — [2]Physikalisch-Technische Bundesanstalt (PTB), 38116 Braunschweig, Germany

We report on a critical point drying (CPD) technique with supercritical carbon dioxide (S-CO2) as a post-processing step to enhance electrical performance of graphene field-effect transistors (GFETs). This technique is promising for integration into the industrial clean rooms environment and demonstrates high potential not only for GFETs but also for other electronic, photonic and optoelectronic devices based on 2D materials.

DS 1.3　Mon 10:00　SCH A 316

Intercalation of indenene in SiC/graphene interface — •Cedric Schmitt[1,2], Jonas Erhardt[1,2], Tien-Lin Lee[3], Timur Kim[3], Simon Moser[1,2], and Ralph Claessen[1,2] — [1]Physikalisches Institut, Universität Würzburg, D-97074 Würzburg, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, D-97074 Würzburg, Germany — [3]Diamond Light Source, Harwell Science and Innovation Campus, Didcot, UK

In the search for new quantum materials, ultrathin metals are highly interesting as they push bulk properties to the 2D limit and foster novel quantum effects. Unfortunately, unprotected metals are prone to oxidation in air, making them useless for transport devices. Here, we report about a capping method for 2D materials via metal intercalation. In this process an atomic metal monolayer is sandwiched between a SiC substrate and a graphene buffer layer, thus forming freestanding graphene, which protects the intercalated layer against oxidation. Previous intercalation studies focused mainly identifying stable allotropes but lack a detailed investigation of metal coverage and oxidation. Here, we study the intercalation of indenene, a monolayer of indium, which is a novel quantum material [1]. First experiments indicate the indenene layer to remain intact upon air exposure, indeed pointing to an effective protective function of the overlayer graphene. Furthermore, we observe an enlarged In-Si bond distance, which is expected to have a larger non-trivial energy gap.

Ultrafast photo-thermoelectric currents in graphene — •Xiaoyi Zhou, Nina Pettinger, Johannes Gröbmeyer, Philipp Zimmermann, and Alexander Holleitner — Walter Schottky Institut and Physics Department, Technische Universität München, Germany

Graphene as an optoelectronic material has attracted significant attention due to its interesting properties such as fast charge carrier relaxation rates, broadband optical absorption and high carrier mobilities. We apply an ultrafast on-chip pump-probe photocurrent spectroscopy to demonstrate an immediate thermoelectric photocurrent after a femtosecond laser pulse. We demonstrate that gate-tunable graphene junctions can be integrated into THz-circuits, paving the way for graphene-based ultrafast photodetectors and switches.

DS 1.5　Mon 10:30　SCH A 316

Twist angle dependent proximity induced spin-orbit-coupling in graphene/TMDC and graphene/TI heterostructures — •Thomas Naimer[1], Klaus Zollner[1], Martin Gmitra[2], and Jaroslav Fabian[1] — [1]Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Institute of Physics, Pavol Jozef Safarik University in Kosice, 04001 Kosice, Slovakia

We investigate the proximity-induced spin-orbit coupling in twisted heterostructures of graphene/transition-metal dichalcogenides (MoS_2, WS_2, $MoSe_2$, and WSe_2) as well as graphene/topological insulators (Bi_2Se_3 and Bi_2Te_3) from first principles. We establish that, regardless of the twist angle, the band offsets between the Dirac point and the substrate bands vary linearly with the strain, which is necessary for defining commensurate supercells. This relation allows to identify the apparent zero-strain band offsets and find a compensating transverse electric field correcting for the strain. The resulting corrected band structure is then fitted around the Dirac point to an established spin-orbit Hamiltonian, yielding the twist angle dependencies of the spin-orbit couplings. While for most structures a mix of Rashba and valley-Zeeman spin-orbit coupling is present, we also witness the emergence of Kane-Mele spin-orbit coupling in graphene/topological insulator structures at 30° twist angle. This work was funded by the Elite Network of Bavaria, the Deutsche Forschungsgemeinschaft (DFG), SFB 1277, SPP 2244 and by the European Union Horizon 2020 Research and Innovation Program under contract number 881603 (Graphene Flagship). DS 1.6　Mon 10:45　SCH A 316

Mobile trions in two-dimensional hybrid perovskites — Jonas David Ziegler[1], Yeongsu Cho[2], •Sophia Terres[1], Matan Menahem[3], Omer Yaffe[3], Takashi Taniguchi[4], Kenji Watanabe[4], Timothy C. Berkelbach[2], and Alexey Chernikov[1] — [1]TU Dresden, Dresden, Deutschland — [2]Columbia University, New York, USA — [3]Weizmann Institute of Science, Rehovot, Israel — [4]National Institute for Materials Science, Tsukuba, Japan

Two-dimensional hybrid perovskites represent natural quantum well systems composed of alternating organic and inorganic molecular layers. They combine an efficient coupling of electrons to a soft lattice with strong Coulomb interactions between the charge carriers. The latter leads to the formation of tightly bound excitons that determine the optical response of this class of materials. The interaction between excitons and free charge carriers, however, remains difficult to access in halide perovskites due to persistent challenges to introduce doping.

Here, we report experimental realization of electrically tunable, ultrathin two-dimensional perovskites, by combining them with hBN and multilayer graphene in field-effect transistor geometries. We demonstrate the formation of both negatively and positively charged exciton-electron complexes, known as trions with binding energies up to 46 meV. These values are a direct consequence of strong Coulomb interaction and scale with exciton binding energies, as demonstrated by theoretical calculations. The trions exhibit finite oscillator strength in absorption-like response, are localized at cryogenic temperatures, and exhibit thermally activated diffusion at 50 K.

DS 2: 2D Materials and their Heterostructures II: h-BN and WSe$_2$

Time: Monday 11:30–12:45   Location: SCH A 316

DS 2.1   Mon 11:30   SCH A 316

Engineering of exciton g-factors in van der Waals structures — •Tomasz Woźniak[1], Paulo Faria Junior[2], Andrey Chaves[3], Umm-e-hani Asghar[4], and Agnieszka Kuc[5] — [1]Wrocław University of Science and Technology, Poland — [2]Universitaet Regensburg, Germany — [3]Universidade Federal do Ceará, Brazil — [4]Jacobs Universitaet Bremen, Germany — [5]Helmholtz-Zentrum Dresden-Rossendorf, Germany

We develop a fully ab-initio based calculation scheme for excitonic g-factors, which describe their energy dependence on external magnetic field, and apply it to 1L TMDs and MoSe$_2$/WSe$_2$ heterobilayers, obtaining excellent agreement with experiments [1]. We identify a series of magneto-PL peaks in 1L WS$_2$ based on the calculated g-factors of excitons, trions and biexcitons, as well as phonon replicas of the dark trion [2]. We explain the reduction of g-factor measured in MoSe$_2$/WS$_2$ by the spatial confinement of the intralayer moiré exciton [3]. We find a significant strain dependence of excitonic g-factors and dipole strengths in 1L TMDs. It allows to explain the strain-induced hybridization of direct and indirect excitons in WS$_2$ [4,5]. We investigate a new class of hexagonal materials with formula MSi$_2$Z$_4$ (M: Mo, W; Z: N, P, As, Sb), which are isosymmetric to 1L TMDs. We find a new set of circularly polarized excitonic transitions with high binding energies and large positive g-factors [6].

DS 2.2   Mon 11:45   SCH A 316

Phase-locked photon-electron interaction without a laser applied to 2D Materials — •Nahid Talebi[1], Masoud Taleb[1], Mario Hentschel[2], Kai Rossnagel[1], and Harald Giessen[2] — [1]Institute for Experimental and Applied Physics, Kiel University, 24118 Kiel, Germany — [2]4th Physics Institute and Research Center SCoPE, University of Stuttgart, 70569 Stuttgart, Germany

Ultrafast electron-photon spectroscopy in electron microscopes commonly requires ultrafast laser setups. Photoemission from an engineered electron source is used to generate pulsed electrons, interacting with a sample that is excited by the ultrafast laser pulse at a specified time delay. Here, we present an inverse approach based on cathodoluminescence spectroscopy to introduce internal radiation sources in an electron microscope. Our method is based on a sequential interaction of the electron beam with an electron-driven photon source (EDPHS) and the investigated sample. An electron-driven photon source in an electron microscope generates phase-locked photons that are mutually coherent with the near-field distribution of the swift electron. We demonstrate the mutual coherence between the radiations from the EDPHS and the sample by performing interferometry with a combined system of an EDPHS and a WSe2 flake. Our method has the advantage of being simple, compact and operating with continuous electron beams. It will open the door to local electron-photon correlation spectroscopy of quantum materials, single photon systems, and coherent exciton-polaritonic samples with nanometric resolution.

DS 2.3   Mon 12:00   SCH A 316

Phase-locked photon-electron interaction without a laser applied to 2D Materials — •Nahid Talebi — Institute for Experimental and Applied Physics, Kiel University, 24118 Kiel, Germany

Ultrafast electron-photon spectroscopy in electron microscopes commonly requires ultrafast laser setups. Photoemission from an engineered electron source is used to generate pulsed electrons, interacting with a sample that is excited by the ultrafast laser pulse at a specified time delay. Thus, developing an ultrafast electron microscope demands the exploitation of extrinsic laser excitations and complex synchronization schemes. Here, we present an inverse approach based on cathodoluminescence spectroscopy to introduce internal radiation sources in an electron microscope. Our method is based on a sequential interaction of the electron beam with an electron-driven photon source (EDPHS) and the investigated sample. An electron-driven photon source in an electron microscope generates phase-locked photons that are mutually coherent with the near-field distribution of the swift electron. We demonstrate the mutual coherence between the radiations from the EDPHS and the sample by performing interferometry with a combined system of an EDPHS and a WSe2 flake. Our method has the advantage of being simple, compact and operating with continuous electron beams. It will open the door to local electron-photon correlation spectroscopy of quantum materials, single photon systems, and coherent exciton-polaritonic samples with nanometric resolution.

DS 2.4   Mon 12:15   SCH A 316

Mobile interlayer excitons at the Mott transition in Moiré-free heterostructures — •Edith Wietek[1], Mikhail M. Glazov[2], Matthias Florian[3], Takashi Taniguchi[4], Kenji Watanabe[4], Alexander Steinhoff[5], and Alexey Chernikov[1] — [1]Technische Universität Dresden — [2]Sankt Petersburg — [3]University of Michigan — [4]NIMS, Ibaraki — [5]Universität Bremen

Vertically stacked heterostructures of transition metal dichalcogenides present an exciting platform to study electronic and excitonic many-particle states. In this study we investigate propagation of excitons in these systems from low to very high densities to disentangle the effects of dipolar excitons from those stemming from moiré effects. We take advantage of hBN-encapsulated WSe2/MoSe2 heterostructures studied in the moiré-free limit of large, atomically reconstructed domains. Using ultrafast microscopy, we show that the interlayer excitons propagate freely even at cryogenic temperatures and low densities. At elevated exciton densities, we demonstrate that in addition to broadly assumed exciton-exciton repulsion, the non-linear increase of the diffusion coefficient also originates from efficient exciton-exciton annihilation. Remarkably, at the exciton ionization threshold of the Mott transition and beyond, we reveal a highly unusual regime of negative effective diffusion that persist for many 100's of ps after the excitation. This observation presents a particularly interesting case of non-equilibrium phenomena in composite many-particle systems, highlighting the rich physics of optical excitations in van der Waals heterostructures.

DS 2.5   Mon 12:30   SCH A 316

Atomic structures of single photon emitters in hexagonal boron nitride — •Tjorben Matthes[1], Anand Kumar[1], Chanaprom Cholsuk[1], and Tobias Vogl[1,2] — [1]Institute of Applied Physics, Friedrich-Schiller-University Jena, Albert-Einstein-Straße 15, 07745 Jena — [2]Fraunhofer-Institute for Applied Optics and Precision Engineering IOF, Albert-Einstein-Str. 7, 07745 Jena

Single photon emitters in solid-state crystals have received a lot of attention as building blocks for numerous quantum technology applications. Fluorescent defects in hexagonal boron nitride (hBN) stand out due to their high luminosity and robust operation at room temperature. The fabrication of identical emitters at pre-defined sites is still challenging, which hampers the integration of these defects in optical systems and electro-optical devices. Additionally, the atomic structure of many defects remain unclear or are subject to ambiguous guesswork. Here, we show an analysis on the atomic structures of defects we created by electron beam irradiation using a standard scanning electron microscope with deep sub-micron lateral precision. The emitters are created with a high yield and a reproducible spectrum peaking at 575 nm. We also present results on correlating crystal structure properties and polarization dynamics. Our results indicate that these emitters that all emitters are identical, which is a crucial advantage for the realization of quantum integrated devices, as well as for the identification of these fluorescent defects.

DS 3: Organic Thin Films, Organic-Inorganic Interfaces (joint session DS/CPP)

Time: Monday 11:30–12:45   Location: SCH A 315

DS 3.1   Mon 11:30   SCH A 315

Thickness dependency of the critical dose for beam-sensitive two-dimensional polymers — •David Mücke[1], Ute Kaiser[1], and Haoyuan Qi[1,2] — [1]Central Facility of Material Science Electron Microscopy, Universität Ulm, 89081 Ulm, Germany — [2]Center for Advancing Electronics Dresden (cfaed) & Faculty of Chemistry and Food Chemistry, Technische Universität Dresden, 01062 Dresden, Germany

For organic materials the achievable resolution in a TEM is limited by their resilience against electron irradiation. Due to that, increasing the critical dose of these sensitive materials is of highest importance. For layer stacked materials, where the thickness is easily controllable, the thickness dependency of the critical dose is a key feature. Aimed at gathering a better understanding of this effect, in our study this dependency was examined in more detail. To achieve this, the critical dose of a triazine-based 2D polymer[1] was measured for a wide thickness range. The polymer samples, obtained by mechanical exfoliation, ranged from 15 nm to 85 nm thickness. To obtain the critical dose of the polymer, sequences of electron diffraction patterns with a dose of only 0.5 e$^-$/A^2 where obtained. The measurements revealed, that the critical dose for amorphization of this polymer is only 1-2 e$^-$/A^2, independent of sample thickness.

DS 3.2   Mon 11:45   SCH A 315

Determining Anisotropic Effects in Strongly Coupled Metal Organic Hybrid Structures — •Maximilian Rödel[1], Jinhong Kim[2], Matthias Stolte[2], Luca Nils Philipp[3], Matthias Lehmann[2], Frank Würthner[2], Roland Mitric[3], and Jens Pflaum[1,4] — [1]Experimental Physics VI, University of Würzburg — [2]Institut für Organische Chemie and Center for Nanosystems Chemistry, University of Würzburg — [3]Institut für Physikalische und Theoretische Chemie, University of Würzburg — [4]Bavarian Center for Applied Energy Research, 97074 Würzburg

Coupling phenomena in metal organic hybrid structures enable unique possibilities to tune the properties of opto-electronic devices. Furthermore, the strong coupling between surface plasmons and excitons in organic semiconductors leads to novel hybrid states, which are termed plexcitons[1]. By means of a Kretschmann Set Up we investigate these plexcitonic states in oriented liquid crystalline perylene bisimide (PBI) thin films deposited via off-centered spin coating on gold surfaces which exhibiting J-type coupling [2]. The Alignment of the hydrogen-bonded PBI molecules and, thus, their transition dipoles results in long-range ordered films with a pronounced spatially anisotropy of structural and optical characteristics. These new states show a characteristic coupling strength of ≈27 meV. Understanding this directional correlation between molecular order and optical properties will enable new device concepts utilizing the presented opto-electronic directionality.

DS 3.3   Mon 12:00   SCH A 315

Long-term degradation in Blatter radical derivative thin films — •Ewa Nowik-Boltyk, Tobias Junghöfer, and Maria Benedetta Casu — Universität Tübingen, Institut für Physikalische und Theoretische Chemie, Auf der Morgenstelle 18, D-72076 Tübingen,GERMANY

Materials with a radical site are strong candidates for ground-breaking applications from energy storage to quantum computing. In this framework, Blatter radical derivatives are very attractive due to their chemical stability. We focus on the latest insights regarding the fundamental mechanisms of radical thin film long-term degradation, by comparing two Blatter radical derivatives, using X-ray-based techniques, such as photoelectron spectroscopy and absorption spectroscopy. Our findings indicate that air exposure affects the chemical and magnetic properties of the thin films.

DS 3.4   Mon 12:15   SCH A 315

Controlled Thermal Deposition of Organic Diradicals — •Tobias Junghöfer and Maria Benedetta Casu — Institut für Physikalische und Theoretische Chemie, Eberhard Karls Universität Tübingen, Germany

Using X-ray photoelectron spectroscopy (XPS) and atomic force microscopy (AFM) we demonstrate that it is possible to evaporate diradicals in a controlled environment obtaining thin films in which the diradical character is preserved. However, evaporation represents a challenge. The presence of two radical sites makes the molecules more reactive also in the case of very stable single radicals. We have explored the parameters that play a role in this phenomenon. We found that the higher the formation energies of the crystal, the more difficult is the evaporation of intact radicals. Large delocalization of the unpaired electrons helps the diradical to stand evaporation. The evaporation of different diradicals can be successfully addressed considering our findings.

DS 3.5   Mon 12:30   SCH A 315

Interaction of cyanoacrylate thin films with copper (oxide) in different processing atmospheres — •Philipp Moritz[1], Oliver Höfft[2], Lienhard Wegewitz[1], and Wolfgang Maus-Friedrichs[1] — [1]Clausthal Centre of Material Technology, Clausthal University of Technology, Agricolastrasse 2, 38678 Clausthal-Zellerfeld — [2]Institute of Electrochemistry, Clausthal University of Technology, Arnold-Sommerfeld-Strasse 6, 38678 Clausthal-Zellerfeld

The adhesive class of fast-curing cyanoacrylates plays an increasingly important role, especially in hybrid composites. However, the adhesion mechanism at the interface to the metal (oxide) substrates is not sufficiently understood.

To study the interactions, cyanoacrylate films of a few nm thickness are spin-coated onto metallic copper and copper oxide in (i) a normal air atmosphere and in (ii) an oxygen-free environment (O_2 partial pressure $< 10^{-20}$ mbar). The natively oxidized copper is deoxidized with a dielectric barrier discharge (DBD plasma) directly before the coating process.

Spectroscopic and microscopic methods are used to understand the underlying molecular interactions at the interface between cyanoacrylate and copper (oxide). The formation of hydrogen bonds as well as an ionic interaction can be observed. In addition, an influence of the oxide layer and the effects of the surrounding atmosphere can be seen.

DS 4: Thin Film Properties I

Time: Monday 15:30–17:00   Location: SCH A 316

DS 4.1   Mon 15:30   SCH A 316

Ultrafast laser induced structural motion in crystalline and amorphous gold — •Othmane Benhayoun[1], Emiliano Princippi[3], Bernd Bauerhenne[1], Dmitry S. Ivanov[2], and Martin E. Garcia[1] — [1]University of Kassel, Theoretical physics II, Kassel, Germany — [2]Moscow, Russia — [3]Elettra-Sincrotrone Trieste S.C.p.A., Trieste, Italy

A recent Ultrafast Electron Diffraction (UED) experiment showed a time-dependent nonuniform compression and expansion of a monocrystalline gold foil. This led to the time modulation of the Au Bragg peaks in both height and width. The same effect is however not observed in polycrystalline gold. We thus perform Molecular Dynamics - Two Temperature Model (MD-TTM) simulations aiming to understand the results of the experiment. In our simulations, we obtain similar peak oscillations and determine the major mechanisms that lead to such lattice dynamics.

DS 4.2   Mon 15:45   SCH A 316

Co-electrodeposition of compositionally complex Co-Cr-Fe-Mo-Ni alloy thin films — •Hongshuai Li, Martin Peterlechner, and Gerhard Wilde — Institute of Materials Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

A compositionally complex Co-Cr-Fe-Mo-Ni alloy with a face-centered cubic structure was successfully obtained by electrochemical deposition using a constant current density. An aqueous electrolyte with several additives was developed to accomplish the electrodeposition of films onto Cu substrates. The characterization reveals that the deposited films are metallic with a face-centered cubic structure, including impurities incorporated during deposition. In addition, mechanical tests were performed to study adhesion and hardness by nanoscratch tests and nanoindentation. Mechanical tests show a high hardness and nonetheless microscopically ductile behavior. The electrolytes developed in this study may be a promising approach for the electrodeposition of Co-Cr-Fe-Mo-Ni compositionally complex alloy coatings.

DS 4.3   Mon 16:00   SCH A 316

Thermally controlling the length of transition and alkali metal squarate wires — •Egzona Isufi Neziri[1,2], Karl-Heinz Ernst[1,2], and Christian Wäckerlin[3,4] — [1]Empa, Swiss Federal Laboratories for Materials Science and Technology, 8600 Dübendorf, Switzerland — [2]University of Zürich, 8006 Zürich, Switzerland — [3]Paul Scherrer Institute, 5232 Villigen, Switzerland — [4]EPFL, Swiss Federal Institute of Technology Lausanne, 1015 Lausanne, Switzerland

Low-dimensional metal-organic nanomaterials on surfaces can be engineered to yield promising, novel and highly customizable chemical/physical properties such as magnetism, electronic structure and catalytic properties. A variety of metal elements, including alkali, transition and even lanthanide metals have been used to direct the metal-organic assembly.

Here metal-organic structures obtained from squaric acid (H2C4O4) molecules, co-deposited with K and Ni atoms on a hot Au(111) surface, are studied by XPS and STM. We find that both K and Ni lead to the formation of condensed arrays of wires, composed of M-squarate (C4O4(2-)). Controlling the length of these wires is possible by a thermally activated process: Ni-squarate wires tend to get longer at higher temperatures while K-squarate wires get shorter.

DS 4.4   Mon 16:15   SCH A 316

Deep learning-supported in-situ HRTEM experiments on single-layer carbon — •Christopher Leist[1], Haoyuan Qi[1,2], and Ute Kaiser[1] — [1]Central Facility Materials Science Electron Microscopy, Ulm University, 89081 Ulm, Germany — [2]Faculty of Chemistry and Food Chemistry Dresden, Technische Universität Dresden, 01062 Dresden, Germany

We perform in-situ experiments on single-layer carbon using the Cc/Cs-corrected low-voltage transmission electron microscope SALVE, resolving structure and dynamics down to the level of the single atom. These types of experiments create large amounts of data both in terms of numbers of individual images acquired and the amount of information per image. Conventional image analysis methods, e.g., handcrafted filter kernels, often require heavy user supervision and tremendous time cost, posing strong limitations on the data volume making them inconvenient for use in these experiments. Deep learning in the form of

convolutional neural networks offers a reliable and effective way to handle large amounts of complex image data. Using simulated data we train a modified U-Net like neural network to identify atom positions and their structure i.e. polygons while at the same time removing contaminated areas from the evaluation in real micrographs. Thus, gaining the ability for both largescale statistical evaluation and mapping atomically-resolved the material's transformation.

DS 4.5   Mon 16:30   SCH A 316

Microstructure and mechanical properties of Ta-Al-B coatings — •Chun Hu[1], Shuyao Lin[1], Maximilian Podsednik[2], Andreas Limbeck[2], Nikola Koutná[1], and Paul H. Mayrhofer[1] — [1]Institute of Materials Science and Technology,TU Wien,Getreidemarkt 9,Vienna,A-1060,Austria — [2]Institute of Chemical Technologies and Analytics, TU Wien, A-1060 Wien, Austria

Alloying is a simple yet powerful tool to tune properties of hard coatings. Here we report stoichiometry, microstructure and hardness evolution of Al-alloyed TaB2-z coatings. Sputtering a stoichiometric TaB2 target results in sub-stoichiometric TaB1.23 with a mixed hexagonal-TaB2 (α-AlB2-type) and orthorhombic TaB structure. Co-sputtering an AlB2 target*with half the sputtering power density*increases the B content and strongly promotes the α-phase, while only little Al is incorporated (Ta0.997Al0.003B1.64). The coating shows a small grain size and the overall highest hardness. Further increasing the AlB2/TaB2 sputter ratio allows for B/Metal ratios of 1.97 and 2.29 with Al metal-fractions up to 48 at%. These coatings are single-α-phased with a smooth surface but gradually decreased hardness due to the increased AlB2-fraction. The structural evolutions are underpinned by ab initio calculations.

DS 4.6   Mon 16:45   SCH A 316

X-ray characterization of an above-RT bi-stable sublimable molecular spin-crossover Fe(II)-complex — •Yahya Shubbak[1], Miguel Gavara Edo[2], Arno Ehresmann[1], and Eugenio Coronado Mirales[2] — [1]Institute of Physics & Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, D-34132 Kassel — [2]Institute of Molecular Science (ICMol), University of València, S-46980 Paterna

Spin crossover (SCO) molecules are a promising type of material that can undergo reversible switching between low-spin (LS)- and high-spin (HS)-states upon external stimuli (heat, light, pressure, etc.)[1], making them useful for information technology, data storage, and optoelectronics[2]. However, most SCO molecules need to be cooled significantly for this transition to be observable. We have investigated the hitherto unknown electronic structure of the complex molecule bis[hydrotris(1,2,4-triazol-1-yl)borate]iron(II) ([Fe(HB(tz)3)2])[3] capable of above-RT transition by XPS and XAS measurements, since the distinct electronic structure in both spin-states unmistakably prove the transition between them. [1]P. Gütlich and H. A. Goodwin. Spin Crossover in Transition Metal Compounds I. Springer Berlin Heidelberg, May 2004. 356 pp. [2]E. P. Geest et al., Contactless Spin Switch Sensing by Chemo-Electric Gating of graphene. In: Advanced Materials (2020), p. 1903575. [3]S. Rat et al., Solvatomorphism and structural-spin crossover property relationship in bis[hydrotris(1,2,4-triazol-1-yl)borate]iron(ii). In: CrystEngComm 19.24 (2017).

Operando **infrared studies of confined water and protons in MXene** — •Mailis Lounasvuori — Helmholtz-Zentrum Berlin, Berlin, Germany

MXenes are a large family of 2-dimensional transition metal carbides, nitrides and carbonitrides with excellent potential for energy storage applications. Due to hydrophilic surfaces and weak attractive forces between the negatively charged layers, MXenes can retain significant amounts of water between the layers, and they can be intercalated with a variety of cations and molecules. Here, I will present our recent research efforts to apply *operando* infrared spectroscopy to probe the vibrational dynamics of water confined between Ti_3C_2 MXene sheets during electrochemical charging and discharging. Data for both lithium- and proton-containing electrolytes will be presented. Potential-dependent, reversible changes in the O-H stretching modes of confined water are observed that are specific to the cation. In acidic electrolyte, we observe a unique signature of confined hydrated protons which is not seen in the bulk.

DS 5.2   Tue 10:00   SCH A 316

Contact Printed Micro Circuit Boards - A Novel Platform for the Defect Free Integration of 2D Materials — •Christian N. Saggau[1], Sanaz Shokri[1,2], Yejin Lee[1,2], Mickey Martini[1,2], Tommaso Confalone[1], Genda Gu[3], Valentina Brosco[4], Domenico Montemurro[5], Valerii M. Vinokur[6], Kornelius Nielsch[1,2,7], and Nicola Poccia[1] — [1]Leibnitz Institute for Solid State and Materials Science Dresden, Dresden, Germany — [2]Institute of Applied Physics, Technische Universität Dresden, Dresden, Germany — [3]Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, USA — [4]Italian National Research Council, Institute for Complex Systems, Rome, Italy — [5]Department of Physics, University of Naples Federico II, Naples, Italy — [6]Terra Quantum AG, St. Gallen, Switzerland — [7]Institute of Materials Science, Technische Universität Dresden, Dresden, Germany

The 2D cuprate superconductor BSCCO, promises upon integration with CMOS electronics, on-chip high temperature superconducting single photon detectors or quantum interference device (SQUID). Unfortunately, its properties degrade quickly if exposed to elevated temperatures, solvents, oxygen or water. Here we present Hall devices with a record thin film Tc of 91 K, which is identical to the bulk value of the crystal. Electrical contacts were established through transfer-printable circuits embedded in SiNx nanomembranes. The membrane incapsulates the material shielding it from the environment, while via contacts are used to form the electrical contacts.

Probing magnetic ordering in air stable iron-rich van der Waals minerals — •Muhammad Zubair Khan[1], Apoorva Sharma[2], Sergio Valencia[3], Florian Kronast[3], Oleg E. Peil[4], Georgeta Salvan[2], Christian Teichert[1], and Aleksandar Matković[1] — [1]Institute of Physics, Montanuniversität Leoben, Austria. — [2]Institute of Semiconductor Physics, Technische Universität Chemnitz, Germany. — [3]Department of Spin and Topology in Quantum Materials, Helmholtz-Zentrum Berlin, Germany. — [4]Materials Center Leoben, Austria.

We demonstrate magnetic ordering in Fe-rich two-dimensional (2D) phyllosilicates: annite, minnesotaite, and biotite. These van der Waals (vdW) minerals, incorporate local moment baring iron (Fe) ions via magnesium (Mg) substitution. The phyllosilicate capping silicate/aluminate tetrahedral groups make monolayers air stable. Superconducting quantum interference device vibrating sample magnetometry (SQUID-VSM) was used probe long-range magnetic ordering in bulk. In-field magnetic force microscopy (MFM) confirmed the local magnetic moment at room temperature, present down to monolayers. X-ray photoelectron spectroscopy (XPS) were used to observe the Fe oxidation state and to establish a correlation with magnetic ordering. Further, magnetic ordering in thin flakes was probed via X-ray magnetic circular dichroism. Our study of Fe-baring vdW minerals may drive the development for controllable synthesis of novel 2D magnetic insulators.

DS 5.4   Tue 10:30   SCH A 316

Anisotropic Spontaneous Magnetostriction in Fe$_{3-x}$GeTe$_2$ — •Reinhard K. Kremer and Eva Brücher — MPI for Solid State Research, Stuttgart, Germany

By determining the lattice parameters as a function of temperature of the hexagonal van der Waals ferromagnet Fe$_{2.93(2)}$Ge$_{1.02(3)}$Te$_2$ we detect a spontaneous negative in-plane magnetostriction occuring below the Curie temperature. The spontaneous magnetostriction follows the square of the spontaneous magnetization and leads to an expansion of the hexagonal layers, and is clearly seen for the in-plane lattice parameter a, but less well pronounced perpendicular to the planes along c. Extrapolating to $T \to 0$ K we obtain a saturation spontaneous magnetostriction of $\lambda_{sp,a}(T \to 0) = -214(6) \times 10^{-6}$ and a volume magnetostriction $\lambda_{sp,vol}(T \to 0) \approx -450 \times 10^{-6}$, indicating that the spontaneous magnetostriction along c is very small. The linear thermal expansion coefficients at 295 K of Fe$_{2.93(2)}$Ge$_{1.02(3)}$Te$_2$ amount to $13.9(1) \times 10^{-6}$ K^{-1} and to $23.22(15) \times 10^{-6}$ K^{-1} for the in-plane and out of plane direction, respectively, indicating in a linear volume thermal expansion coefficient of $51.0(2) \times 10^{-6}$.

Defect nanostructure and its impact on magnetism of α-Cr_2O_3 thin films — •Ihor Veremchuk[1], Oskar Liedke[1], Pavlo Makushko[1], Tobias Kosub[1], Natascha Hedrich[2], Oleksandr Pylypovskyi[1], Fabian Ganss[1], Maik Butterling[1], René Hübner[1], Eric Hirschmann[1], Ahmed Attallah[1], Andreas Wagner[1], Kai Wagner[2], Brendan Shields[2], Patrick Maletinsky[2], Jürgen Fassbender[1], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V., Dresden, Germany — [2]Department of Physics University of Basel, Switzerland

Thin films of the magnetoelectric insulator Cr_2O_3 are technologically relevant for energy-efficient magnetic memory devices controlled by electric fields. We experimentally investigated the defect nanostructure of 250-nm-thick Cr_2O_3 thin films prepared under different conditions on single crystals of Al_2O_3 (0001) and correlate it with the integral and local magnetic properties of the samples. Positron annihilation spectroscopy reveals that the Cr_2O_3 thin films are characterized by the presence of complex defects at grain boundaries, formed by groups of monovacancies, coexisting with monovacancies and dislocations. The defect nanostructure strongly affects the magnitude of the electrical readout. Furthermore, the presence of larger defects like grain boundaries has a strong influence on the pinning of magnetic domain walls in thin films. We show that the Néel temperature is hardly affected by the formed defects in a broad range of deposition parameters.

DS 6.2   Tue 10:15   SCH A 315

Dynamics of phase transition in Lead-free Ferroelectric thin films — •Mallika Khosla[1], Jutta Schwarzkopf[1], Daniel Schmidt[2], Daniel Hensel[1], and Peter Gaal[1,2] — [1]Leibniz-Institut für Kristallzüchtung, Berlin,Germany — [2]Tailored x-ray products, Hamburg,Germany

In this contribution, we monitor the dynamics of the phase transition in Potassium Sodium Niobate (KNaxNb1-xO3) by taking snapshots of the structure after optical excitation using pulsed synchrotron radiation in a pump-probe scheme. Our sample is a 50 nm KNaxNb1-x O3 film grown on 20 nm thin SrRuO3 on TbScO3 substrate. The low-temperature phase displays a hierarchical order of domains and superdomains on sub-100 nm and on few um length scales, respectively. First, we show that laser heating with 7 ns pulses has a similar effect locally in terms of structural rearrangement as static heating of the whole sample volume. However, in our localized excitation the transient phase transition required to transform a similar volume fraction of the sample in the high temperature phase is about 5 times higher compared to static heating. Comparison with finite-element simulations of heat-transport in our sample shows that the phase transition dynamics does not exactly follow the temperature evolution in the ferroelectric film. In addition, time-resolved diffraction imaging experiments reveal that the stability of a spatial domain morphology has a nonlinear dependence on the local laser-induced temperature. Our results indicate that it is essential to resolve both the temporal and spatial coordinate to monitor the equilibration path of such phase transition.

DS 6.3   Tue 10:30   SCH A 315

Ferroelectric thin films studied by X-ray standing waves — •Le Phuong Hoang[1], Irena Spasojevic[2], David Pesquera[2], Gustau Catalan[2], Kai Rossnagel[3,5], Jörg Zegenhagen[4], Tien-Lin Lee[4], Ivan Vartanyants[5], Andreas Scherz[1], and Giuseppe Mercurio[1] — [1]European XFEL, Schenefeld, Germany — [2]Catalan Institute of Nanoscience and Nanotechnology, Barcelona, Spain — [3]Christian-Albrechts-Universität zu Kiel, Kiel, Germany — [4]Diamond Light Source, Didcot, UK — [5]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

We investigated the structural properties of ferroelectric $BaTiO_3$ thin films by X-ray standing waves with the goal to determine the atomic positions within the tetragonal unit cell in samples with different strain. Our samples consist of $BaTiO_3$ thin films grown by pulsed laser deposition (with a $SrRuO_3$ bottom electrode) on three different substrates $SmScO_3$, $GdScO_3$, $DyScO_3$ providing increasing compressive strain. All the samples were characterized by X-ray reflectivity (XRR) and reciprocal space mapping (RSM). We present X-ray photoelectron spectroscopy, X-ray diffraction and X-ray standing waves data measured at the Diamond Light Source that provide Ba and Ti atomic positions within the unit cells of sample surface. In this study we show a relation between atomic positions and compressive strain of ferroelectric $BaTiO_3$ thin films.

DS 6.4   Tue 10:45   SCH A 315

Exploring transition-metal substitution in $FeSe_2$ thin films formed by seleniation at various temperatures — •Luqman Mustafa[1], Andreas Kreyssig[1], Jill Fortmann[2], Aurelija Mockute[2], Alan Savan[2], Alfred Ludwig[2], and Anna E. Böhmer[1] — [1]Institute for Experimental Physics IV, Ruhr-Universität Bochum, Germany — [2]Materials Discovery and Interfaces, Institute for Materials, Ruhr University Bochum, Germany

Transition-metal dichalcogenides with orthorhombic marcasite structure have been extensively studied for their applications in light energy conversion and photoelectrochemical devices. Lately this structure type has also gained interest for its magnetic properties as a candidate for the newly-predicted altermagnetic order.

Using combinatorial deposition and ex-situ selenization at 250˚C, 350˚C and 430˚C, we have studied the substitution of iron with different TMs in $(Fe,X)Se_2$ thin films, (X= Co, Ni, Cr). This technique allowed to efficiently and quickly explore the possible ranges of substitution of TMs in this compound. We find that the marcasite structure of $(Fe,Co)Se_2$ forms with higher Co content when the selenization temperature is lower.

Our results represent an example for the agility of combinatorial deposition of thin films in exploring the phase diagrams of transition-metal dichalcogenides. It may be adapted for other systems, such as $FeSb_2$, and is therefore a unique tool to study a broad material family and its possible substitution ranges.

DS 7: 2D Materials and their Heterostructures IV

DS 7.1   Tue 11:15   SCH A 316

THz-Light Canalization by means of Phonon Polaritons in 2D van der Waals Materials — •Maximilian Obst[1,2], Tobias Nörenberg[1,2], Gonzalo Álvarez-Pèrez[3], Thales V.A.G. de Oliveira[4], Alexey Nikitin[5], Pablo Alonso-González[3], J. Michael Klopf[4], Susanne C. Kehr[1,2], and Lukas M. Eng[1,2] — [1]TU Dresden, Germany — [2]Würzburg-Dresden Cluster of Excellence - EXC 2147 (ct.qmat), Germany — [3]University of Oviedo, Spain — [4]HZDR, Dresden, Germany — [5]DIPC, Donostia-San Sebastian, Spain

Hyperbolic phonon polaritons (PhP) in anisotropic, 2D van der Waals materials present a promising platform to shrink THz optics into nm-sized volumes, as they enable ultra-high field confinement. Recently, controlled PhP dispersion tuneability was demonstrated at MIR wavelengths by vertically stacking two α-MoO_3-flakes under a well-defined twist-angle θ, introducing a topological transition, where PhPs propagate along one distinct direction (so-called 'canalized propagation')[1].

In this talk, we explore the THz dispersion tunability in twisted bilayer MoO_3 at frequencies ranging from $\nu = 8.28$ to 9.38 THz, for which the existence of hyperbolic PhP has been demonstrated recently [2], and where longer (THz) wavelengths make strong confinement even more desirable. We demonstrate the transition from hyperbolic to elliptic propagation of these PhPs by varying both θ and ν and report the very first observation of canalized PhPs in the THz spectral range, i.e., for $\nu = 8.67$ THz and $\theta = 50˚$.

Magnetically induced band splitting of the exfoliated antiferromagnet $MnPS_3$ revealed by temperature dependent μ-ARPES — •J. Strasdas[1], B. Pestka[1], M. Rybak[2], A. K. Budniak[3], N. Leuth[1], H. Boban[4], I. Cojocariu[4], D. Baranowski[4], V. Feyer[4], J. Avila[5], P. Dudin[5], Y. Amouyal[6], L. Plucinski[4], E. Lifshitz[3], M. Birowska[7], and M. Morgenstern[1] — [1]II. Institute of Physics B and JARA-FIT, RWTH-Aachen University, Germany — [2]Department of Semiconductor Materials Engineering Wrocław University of Science and Technology, Poland — [3]Schulich Faculty of Chemistry, Solid State Institute, Russell Berrie Nanotechnology insistute and Helen Diller Quantum Center, Technion, Israel Institute of Technology, Israel — [4]Forschungszentrum Jülich, Peter Grünberg Institute (PGI-6), Germany — [5]Synchrotron-SOLEIL, Université Paris-Saclay, France — [6]Department of Materials Science and Engineering, Technion, Israel Institute of Technology — [7]Institute of Theoretical Physics, University of Warsaw, Poland

We provide micron-scale angle-resolved photoelectron spectroscopy (μ-ARPES) of the exfoliated intralayer antiferromagnet (AFM) $MnPS_3$ above and below the Néel temperature in comparison with density functional theory (DFT) calculations. We demonstrate a splitting of parts of the Mn $3d_{z^2}$-bands induced by the

AFM ordering in line with DFT results. Related changes of adjacent S 3p-bands indicate a competing FM superexchange contribution. This novel access to the electronic band structure is found to be transferable to other AFM MPX_3 materials (M: transition metal, P: phosphorus, X: chalcogenide).

DS 7.3   Tue 11:45   SCH A 316
Twistronics of high temperature superconductors — •Nicola Poccia — Leibniz Institute for Solid State and Materials Research Dresden (IFW-Dresden)
Ideally, one would like to have quantum technologies that could work at higher temperature and at the same time show all the advantages of a twisted architecture as for example its revolutionary degree of electronic tunability. However, highly tunable superconductors that operate above liquid nitrogen are either not yet showed up using multi-layered graphene twisted heterostructures or the materials are very difficult to assemble in twisted heterostructures given their extreme sensitivity to the environmental conditions. Here we show a possible avenue towards the resolution of this problem, demonstrating how to engineer a new generation of the van der Waals heterostructures comprising atomically high temperature superconducting thin Bi2Sr2Can-1CunO2n+4 (where n = 1,2,3) crystals. The intended van der Waals constituent Bi2Sr2Can-1CunO2n+4 planes are twisted with respect to each other and make the Josephson junctions. We measure different quantum transport properties of the Josephson junctions in a wide range of twisted angles, indicating the high temperature superconducting topological nature of these systems. Finally, technological prospects on the realization of hybrid complex superconducting circuits will be given.

DS 7.4   Tue 12:00   SCH A 316
New magneto-polaron resonances in a monolayer of a transition metal dichalcogenide — Carlos Trallero-Giner[1,2], Darío G. Santiago-Pérez[3], and •Vladimir M. Fomin[1,4] — [1]Institute for Integrative Nanosciences (IIN), Leibniz IFW Dresden, D-01069 Dresden — [2]Havana University, Havana 10400, Cuba — [3]Universidad Autónoma del Estado de Morelos, CP 62209, Cuernavaca,

Morelos, México — [4]Moldova State University, MD-2009 Chişinău, Republic of Moldova

For transition metal dichalcogenide (TMD) semiconductors, the behavior of the magneto-polaron resonances (MPRs) is revealed as a function of the phonon symmetry inherent in the system. It is shown that the renormalized Landau energy levels are modified by the interplay of the long-range Pekar-Fröhlich (PF) and short-range deformation potential (DP) interactions. This interplay leads to a new series of MPRs involving the optical phonons at the center of the Brillouin zone. The coupling of the two Landau levels with the LO and A_1 optical phonon modes provokes resonant splittings of double avoided-crossing levels giving rise to three excitation branches. To explore the interplay between the MPR, the electron-phonon interactions (PF and DP) and the couplings between adjacent Landau levels, a full Green's function treatment for the evaluation of the energy and its life-time broadening is developed. A generalization of the two-level approach is performed for the description of the new MPR branches. The obtained results are a guideline for the magneto-optical experiments in TMDs, where three MPR peaks should be observable.

DS 8.1   Tue 11:30   SCH A 315
Growth of Sc(x)Ga(1-x)N on 6H-SiC by plasma assisted molecular beam epitaxy — •Fabian Ullmann[1,2], Aaron Giess[1,2], and Stefan Krischok[1,2] — [1]Institut für Physik, TU Ilmenau, Ehrenbergstraße 29, 98693 Ilmenau — [2]Institut für Mikro- und Nanotechnologien, TU Ilmenau, Gustav-Kirchhoff-Straße 7, 98693 Ilmenau
ScGaN can occure in different crystal orientations. Most important are the wurtzit and the rocksalt formation. In dependency of the Scandium concentration a phase tranistion between these orientations can be found.

Plasma assisted molecular beam epitaxy (PAMBE) in combination with reflective high electron energy diffraction (RHEED) was performed to create layers with different Scandium concentrations within ScGaN. To determine the concentration of the grown layers X-ray photoelectron spectroscopy (XPS) was used in the same vacuum chamber. Additionally, the surfaces were investigated by atomic force microscopy (AFM, in-situ) and scanning electron microscope (SEM) to gain information about the morphology of the surfaces and to confirm the gained crystal orientations investigations with X-ray diffraction (XRD) were made.

DS 8.2   Tue 11:45   SCH A 315
α-FeGe$_2$ films on GaAs(001) substrates grown by MBE and solid-phase epitaxy — •Moritz Hansemann, Michael Hanke, Achim Trampert, and Jens Herfort — Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany
Layered magnets show promising results towards advancements in the field of spintronics. Such materials exhibiting a ferro- and/or antiferromagnetic (FM/AFM) phases close to room temperature are especially on demand for future technologies.

Recently we discovered a novel metastable α-FeGe$_2$ phase sandwiched between two ferromagnetic Fe$_3$Si Heusler alloy metals. Comprehensive transmission electron microscopy (TEM) and X-ray diffraction (XRD) measurements revealed the layered structure and P4mm spacegroup, that is absent in bulk FeGe$_2$. By a combination of molecular beam and solid phase epitaxy we demonstrate the isolated growth of α-FeGe$_2$ on a GaAs(001) substrate. This is achieved by first growing Fe$_3$Si and covering it with amorphous Germanium in the thickness ratio of 1:3. Finally, a subsequent annealing forms the layered FeGe$_2$. Through a optimization of this process we are able to grow layers of extremely high quality with layer thicknesses down to 4 nm. The films are structurally characterized by atomic force microscopy, XRD, X-ray reflectivity and TEM measurements, which also demonstrate the importance of a smooth GaAs initial surface. First transport measurements showed metallic behavior and a ferromagnetic behavior at low temperatures.

DS 8.3   Tue 12:00   SCH A 315
Heteroepitaxial Growth of Ultrawide Bandgap Cubic Spinel Zn$_2$GeO$_4$ Thin Films by Pulsed Laser Deposition — •Jingjing Yu, Sijun Luo, and Marius Grundmann — Felix Bloch Institute for Solid State Physics, Faculty of Physics and Earth Sciences, Universität Leipzig, 04103 Leipzig
It is significant to explore new ultrawide bandgap oxides thin films with a bandgap larger than 4 eV for potential applications in power electronics and deep-UV photodetectors. Cubic spinel Zn$_2$GeO$_4$ is a high-temperature and high-pressure phase which was originally synthesized at 1600 °C and 3 GPa. To date the experimental results on physical properties and thin film growth of cubic spinel Zn$_2$GeO$_4$ are not available. In this study, we report the heteroepitaxial growth of cubic spinel Zn$_2$GeO$_4$ thin films on cubic spinel MgAl$_2$O$_4$ single crystal substrates by using pulsed laser deposition at about 800 °C. Combining the analysis results from XRD 2theta-omega scans and rocking curves with the AFM surface morphologies, it is concluded that the oxygen partial pressure of around 0.05~0.10 mbar is optimal for growing high-quality Zn$_2$GeO$_4$ epitaxial thin films. Phi-scan results confirm the single-domain epitaxy of (100)-, (110)- and (111)-oriented Zn$_2$GeO$_4$ epitaxial thin films grown on (100), (110) and (111) MgAl$_2$O$_4$ substrates, respectively. The dielectric function of the cubic spinel Zn$_2$GeO$_4$ epitaxial thin films was measured by spectroscopic ellipsometry, indicating a bandgap energy greater than 4.5 eV. This work advances the fundamental research on ultrawide bandgap cubic spinel Zn$_2$GeO$_4$ epitaxial thin films.

DS 8.4   Tue 12:15   SCH A 315
Rutile CuTiO$_2$ alloy thin films: lowered growth temperature and retained optical properties. — •Hao Lu[1,2], Martin Becker[1,2], and Peter J. Klar[1,2] — [1]Institute of Experimental Physics I, Justus-Liebig-University, Giessen — [2]Center for Materials Research (ZfM), Justus-Liebig-University, Giessen
Titanium dioxide(TiO$_2$) with a rutile structure and suitable bandgap may be advantageously employed as buffer layer and anti-reflection layer in VO$_2$-based smart windows coated on float glass by sputter deposition. The phase transition of the thermodynamically metastable phases, anatase and brookite, into the stable rutile phase occurs in pristine TiO$_2$ at temperatures about 600°C, which is higher than the melting point of float glass. Hence, we need to significantly reduce the growth temperature of rutile TiO$_2$ in order to deposit it as the film on float glass substrates.
Cu doping has been reported as a means for achieving this goal. We study series of TiO$_2$:Cu thin-film samples deposited on float glass to assess the growth window for rutile TiO$_2$:Cu deposited at temperature below 600°C. The samples are compared with reference TiO$_2$ thin-films deposited under the same conditions in terms of crystal structure and optical properties.

DS 8.5   Tue 12:30   SCH A 315

The challenge to grow β-(AlxGa1-x)2O3 on (100) off-oriented β-Ga2O3 by MOVPE — •Jana Rehm, Ta-Shun Chou, Arub Akhtar, Raimund Grüneberg, Saud Bin-Anooz, and Andreas Popp — Leibniz-Institut für Kristallzüchtung, Max-Born-Str. 2, 12489 Berlin, Deutschland

Although immense progress in homoepitaxial thin film growth of β-Ga2O3 on different substrate orientations has been achieved, β-Ga2O3 based high-efficiency devices are still limited by the materials intrinsic low thermal conductivity and electron mobility. Increasing the bandgap by alloying β-Ga2O3 with Al2O3 opens up the possibility to overcome the materials restraints and realize high-performance lateral β-(AlxGa1-x)2O3/Ga2O3 heterostructure devices. It has been shown that the crystal orientation plays an important role in the Al incorporation limit and band offsets where the (100) orientation is predicted to be the most promising orientation exhibiting the highest critical thickness and incorporated Al content. The role of off-oriented (100) β-Ga2O3 substrates is suggested to achieve the full advantage of β-(AlxGa1-x)2O3/Ga2O3 heterostructure with the benefit of potentially suppressing the formation of twin defects. For the first time, we report a comprehensive study on the growth of β-(AlxGa1-x)2O3 on off-oriented (100) β-Ga2O3 substrates using MOVPE. The influence of different growth parameters on the morphology and Al incorporation are systematically investigated by HR-XRD and AFM.

Flüssigphasen-Elektrochemie im Ultrahochvakuum unter XPS-Kontrolle — •Frank Endres — Institut für Elektrochemie, TU Clausthal

Ionische Flüssigkeiten zeichnen sich durch zwei interessante Eigenschaften aus. Zum einen haben sie sehr weite sog. elektrochemische Fenster, die Untersuchungen ermöglichen, die insbesondere in wässrigen Elektrolyten nicht möglich sind. Zum anderen haben sie sehr geringe Dampfdrücke, die die Untersuchung ionischer Flüssigkeiten unter den Bedingungen eines Ultrahochvakuums ermöglichen. In diesem Beitrag werden nun beide Ansätze kombiniert, indem elektrochemische Prozesse in ionischen Flüssigkeiten im Ultrahochvakuum mittels Photoelektronenspektroskopie untersucht werden. Ein Einblick in die Prozesse bei der elektrochemischen Reduktion von Tantalverbindungen, in die Prozesse bei der elektrochemischen Oxidation von Gold sowie in Disproportionierungsreaktionen bei der Reduktion von Galliumverbindungen wird gegeben.

Oxide thickness-dependent resistive switching characteristics of Cu/HfO$_2$/Pt ECM devices — •Taewook Kim[1], Tobias Vogel[1], Eszter Piros[1], Despina Nasiou[2], Nico Kaiser[1], Philipp Schreyer[1], Robert Winkler[2], Alexander Zintler[2], Alexey Arzumanov[1], Stefan Petzold[1], Leopoldo Molina-Luna[2], and Lambert Alff[1] — [1]Advanced Thin Film Technology Division, Institute of Materials Science, Technische Universität Darmstadt, Alarich-Weiss-Str. 2, 64287 Darmstadt, Germany — [2]Advanced Electron Microscopy Division, Institute of Materials Science, Technische Universität Darmstadt, Alarich-Weiss-Str. 2, 64287 Darmstadt, Germany

This study investigates the resistive switching mechanism and electrical conduction mechanism of the Cu/HfO$_2$/Pt MIM (Metal-Insulator-Metal) structure. In this study, we investigated the resistance switching characteristics of Cu/HfO$_2$/Pt samples. Specifically, we focus on changes in resistive switching characteristics as a function of oxide layer thickness. We noticed an interesting phenomenon of resistance switching property, that the reset switching occurs more sharply and abruptly in the sample with thick HfO$_2$ film. However, gradual reset is more dominant in the sample with thin HfO$_2$ film. Therefore, we devised the model (Thermally Assisted Electrochemical Mechanism) to explain the physical phenomenon. For better understanding, the conduction mechanism of Cu/HfO$_2$/Pt samples was also investigated. Cu/HfO$_2$/Pt has SCLC (Space Charge Limited Conduction) mechanism as the conduction mechanism. However, the mechanism is divided into several steps depending on the thickness of the oxide layer.

DS 9.3   Wed 10:15   SCH A 316

Substoichiometric conducting HfO$_x$ phases as novel type of electrodes with a built-in oxygen vacancy reservoir for RRAM applications — •Philipp Schreyer[1], Nico Kaiser[1], Eszter Piros[1], Tobias Vogel[1], Taewook Kim[1], Despoina Nasiou[2], Leopoldo Molina-Luna[2], and Lambert Alff[1] — [1]Advanced Thin Film Technology Division, TU Darmstadt, Alarich-Weiss-Str. 2, 64287 Darmstadt, Germany — [2]Advanced Electron Microscopy Division, TU Darmstadt, Darmstadt, Germany

Hafnium oxide is an outstanding candidate as the active material in RRAM due to its performance and proven CMOS compatibility. In previous studies, we have shown that electrically conducting hafnium oxide phases can be stabilized by significant oxygen deficiency [1,2]. While so far only the physical properties of these structures have been investigated, we reproduced the phases in RRAM configuration to investigate the device properties. Resistive switching was found to be absent in all deficient in-vacuo processed samples. They show ohmic conduction, confirming the conducting nature of the substoichiometric phases. However, when exposed to air, a thin oxidized layer forms at the surface which stabilizes reliable resistive switching. Note that the oxidation process is self-limited leading to reproducible oxide thicknesses of a few nm. We suggest that the substoichiometric phases may act as second electrode with an oxygen vacancy reservoir that stabilizes oxygen vacancy filaments in ultrathin layers of near-stoichiometric HfO$_2$. Electronic structure of epitaxial (Cr1-xMnx)2GaC thin films by X-ray absorption and optical spectroscopy — •Ivan Tarasov[1], Andrei Rogalev[2], Fabrice Wilhelm[2], Michael Farle[1], and Ulf Wiedwald[1] — [1]Faculty of Physics and Center for Nanointegration (CENIDE), University of Duisburg-Essen, 47057 Duisburg, Germany — [2]The European Synchrotron Radiation Facility (ESRF), 38000 Grenoble, France

Heteroepitaxial thin films of (Cr1-xMnx)2GaC MAX phase for x = of 0.13 - 1 were deposited on MgO(111), Al2O3(0001) and KAl3Si3O10(001) substrates by pulsed laser deposition at T = 500-600 ˚C. X-ray absorption near edge spectroscopy (XANES) spectra were collected at the Mn K-edge, Cr K-edge and Ga K-edge. Evidence of chemical disorder associated with (Mn, Cr) is observed. The similarity of the Cr K-edge spectra to Mn, and the presence of a strong X-ray linear dichroism signal for the Mn K-edge, indicates that Mn is substitutional for Cr in the MAX phase hexagonal lattice. With increasing of Mn content additional features attributed to a cubic antiperovskite structure are observed. Simulations of the XANES spectra confirm the origin of X-ray linear dichroism observed in the sample, which is due to the inherent nanolaminated structure of the MAX phase.

Perovskite-organic multiple quantum wells towards lasing — •Tobias Antrack[1], Martin Kroll[1], Markas Sudzius[1], Changsoon Cho[1], Paulius Imbrasas[1], Miguel Albaladejo-Siguan[1], Johannes Benduhn[1], Lena Merten[2], Alexander Hinderhofer[2], Frank Schreiber[2], Sebastian Reineke[1], Yana Vaynzof[1], and Karl Leo[1] — [1]IAPP, TU Dresden, Dresden, Germany — [2]Institut für Angewandte Physik, Universität Tübingen, Tübingen, Germany

Metal halide perovskites are of high interest due to their excellent electro-optical properties. Their high damage threshold makes them of special interest for high-fluence applications like lasing devices, and the possibility of production by vacuum deposition is promising for future large-scale industrial production. This technique allows precise thickness control and, therefore, the production of multiple quantum wells (MQWs). Such structures result in high charge carrier con-

centration and enhanced electron-hole recombination, making them promising for high-performance and fine-tunable materials. This work presents a comprehensive study of the optical properties of vacuum-deposited $CsPbBr_3$ perovskite MQWs with organic (TPBi) barrier layers. Blue shifts in absorption and emission spectra with decreasing well width demonstrate quantum confinement and are confirmed by simulations. Additionally, the photoluminescence quantum yield increases by up to 32 times from bulk material to the thinnest well layers. Amplified spontaneous emission (ASE) measurements show very low thresholds down to 7.3 μJ cm^{-2} for a perovskite thickness of 8.7 nm, which is significantly lower than previously observed for $CsPbBr_3$ thin films.

DS 10.3   **Wed 11:30**   **SCH A 316**

Defect-engineered magnetic field dependent optoelectronics of vanadium doped tungsten diselenide monolayers — •Christin Mädler[1,2], Katharina Nisi[1,2], Jonas Kiemle[1,2], Lukas Powalla[3], Alessio Scavuzzo[3], Tuan Dung Nguyen[4,5], Dinh Loc Duong[4,5], Marko Burghard[3], Alexander W. Holleitner[1,2], and Christoph Kastl[1,2] — [1]Walter Schottky Institut, Technical University of Munich, Am Coulombwall 4a, 85748 Garching, Germany — [2]Munich Center of Quantum Science and Technology (MCQST), Schellingstrasse 4, 80799 Munich, Germany — [3]Max-Planck-Institut für Festkörperforschung, Heisenbergstrasse 1, D-70569 Stuttgart, Germany — [4]Center for Integrated Nanostructure Physics (CINAP), Institut for Basic Science (IBS), Suwon 16419, Republic of Korea — [5]Department of Energy Science, Sungkyunkwan University, Suwon 16419, Republic of Korea

In this work, we investigate semiconducting WSe_2 monolayers, substitutionally doped with vanadium atoms, using low temperature luminescence and optoelectronic spectroscopy. V-dopants lead to a p-type doping character and an impurity-related emission ~ 160 meV below neutral exciton, both of which scale with the nominal percentage of vanadium dopants. Measurements using field-effect devices of 0.3% V-doped WSe_2 demonstrate bipolar carrier tunability. The doped monolayers display a clear magnetic hysteresis in photocurrent measurments for the studied range of carrier densities, whereas the valley polarization of the excitons reveals a non-linear g-factor without a magnetic hysteresis within the experimental uncertainty.

DS 10.4   **Wed 11:45**   **SCH A 316**

On the influence of the cation composition in reactively co-sputtered $Ag_xCu_{1-x}I$ thin films: Characterization of electrical, optical and structural properties — •Sofie Vogt, Christiane Dethloff, Jorrit Bredow, Tillmann Stralka, Holger von Wenckstern, and Marius Grundmann — Universität Leipzig, Felix-Bloch-Institut, Germany

CuI and its alloys are promising transparent p-type materials for complementary transparent devices. Polycrystalline thin films exhibit hole mobilities of about 19 cm^{2}V^{-1}s^{-1}, which is comparable to the electron mobility of commercially used indium-gallium-zinc-oxide thin films[1,2]. It has been shown that alloying CuI with Ag leads to a transition from p-type material to n-type material for $x \approx 0.5$[3]. This paves the way for $Ag_xCu_{1-x}I/Ag_yCu_{1-y}I$ based homojunction diodes. We present reactively co-sputtered $Ag_xCu_{1-x}I$ thin films in a range of $0.01 \le x \le 0.86$. The thin films were deposited on glass substrates and crystallized in the γ-phase up to $x \le 0.67$ and exhibit an additional AgI phase for higher Ag contents. An increase of the thin film resistivity from 2×10^{-4} Ωm to 30 Ωm was achieved by increasing the silver content from $x = 0.01$ to $x = 0.67$. All thin films are transparent in the visible light range and the expected decrease of the exciton binding energy up to $x \approx 0.5$ is observed, above which it remains constant.

DS 10.5   **Wed 12:00**   **SCH A 316**

Novel Energy-Filtered Field Stop Technology For Highly Blocking IGBTs — •Robert Koch[1], Marcel Gerold[1], Shavkat Akhmadaliev[2], Michael Rüb[1], and Elke Wendler[3] — [1]Ernst-Abbe-Hochschule, Fachbereich SciTec, Jena, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [3]Friedrich-Schiller-Universität, Physikalisch-Astronomische Fakultät, Jena, Germany

Insulated Gate Bipolar Transistors (IGBTs) require on the one hand adjustable switching behavior and on the other hand high blocking capability. The technology presented in this work aims at implementing continuous deep carrier profiles as field stop structures. We insert a micro-patterned silicon membrane (energy filter) into the primary ion beam. This broadens its energy spectrum in a well controlled way, allowing production of extended continuous profiles. The micro patterns are restricted to rectangular shapes, due to the KOH etching manufacturing process. This means, instead of using multiple implantation steps for field-stop formation, our approach results in tailored smooth profiles by using energy-filtered Hydrogen implantations in the range of 1500 to 2500 keV. The defect profiles generated by H-implantation, are transformed into hydrogen-related donors by annealing at 300 to 400 ˚C. The annealing efficiency is related to the implanted dose (10^{13} to 5×10^{15} cm^{-2}), annealing temperature, hold time and the process gas composition (H_2 content 2 %). The defect profiles caused by proton bombardment using an energy filter and subsequent annealing are analyzed by Spreading Resistance Profiling (SRP).

DS 11.1   **Wed 11:00**   **SCH A 315**

Resonante Mikrowellenabsorberschichten für Fusionsreaktoren — •Andreas Hentrich — Universität Stuttgart

Um einen Fusionsreaktor zu betreiben wird ein Heizsystem benötigt, im Falle des ITERs ist das eine Mikrowellenheizung bei 170GHz. Dies impliziert aber direkt, dass entsprechende Absorber vorhanden sein müssen, die den extremen Bedingungen innerhalb eines Fusionsreaktors standhalten. Ebendiese wurden für den ITER in Form einer gemischten Metall-Oxid-Schicht realisiert. Da geläufige Mikrowellenabsorber platzintensiv sind, wurde ein resonanter Absorptionsmechanismus genutzt, was Absorptivitäten von über 90% bei Schichtdicken von rund 100μm ermöglicht.

Der Absorptionsmechanismus wurde sowohl im Modell als auch durch Messungen verifiziert und quantifiziert. Es wurden die Reflektivitäten von vier verschiedenen Materialsystemen winkel-, schichtdicken- und polarisationabhängig bestimmt. Deren Materialeigenschaften wurden mit Hilfe der Modelle bestimmt und damit die Schichten hinsichtlich ihrer Absorptionseigenschaften optimiert.

DS 11.2   **Wed 11:15**   **SCH A 315**

The effect of photon recycling and back-grading on CIGS cell performance — •Seçil Güler[1,2], Uwe Rau[1,3], and Thomas Kirchartz[1,2] — [1]IEK-5 Photovoltaik, Forschungszentrum Jülich — [2]NST and CENIDE, Universität Duisburg-Essen — [3]Faculty of Electrical Engineering and Information Technology, RWTH Aachen University

Photon recycling, i.e. the reabsorption of photons created by radiative recombination within the solar cell, is the missing link between Shockley-Queisser model and classical diode theory. In order to determine the thermodynamic limits of solar cells, it is therefore necessary to consider the photon recycling process. This study aims at calculating the theoretical efficiency limits of Cu(In,Ga)Se2 (CIGS) solar cells using 1-dimensional drift-diffusion solvers by including the effect of photon recycling and bandgap grading. Simulations of current-voltage curves were performed by changing limiting factors such as back grading, back sur-face recombination velocity, electron and hole mobilities, and Shockley-Read-Hall (SRH) lifetime as well as the back reflection at the interface of the Mo/CIGS structure. We investigate under which circumstances photon recycling has a significant effect on device performance and study the optimum bandgap grading for different material properties.

DS 11.3   **Wed 11:30**   **SCH A 315**

Strategies to obtain chiral perovskites via surface modification — •Markus Heindl[1,2], Tim Kodalle[3], Natalie Fehn[2], Lennart Reb[2], Shangpu Liu[1,2], Constantin Harder[2,4], Maged Abdelsamie[3], Lissa Eyre[2,5], Ian Sharp[2], Stephan Roth[4,6], Peter Müller-Buschbaum[2], Alexander Urban[7], Aras Karouzian[2], Carolin Sutter-Fella[3], and Felix Deschler[1] — [1]Heidelberg University, Heidelberg, Germany — [2]Technical University of Munich, Garching, Germany — [3]Lawrence Berkeley National Laboratory, Berkeley, USA — [4]Deutsches Elektronen-Synchrotron (DESY), Hamburg, Germany — [5]University of Camebridge, Cambridge, Great Britain — [6]KTH Royal Institute of Technology, Stockholm, Schwede, — [7]Ludwig-Maximilians-Universität, Munich, Germany

The generation, manipulation and detection of light is a key requirement for a wide range of technologies. Thus, this field is in the constant focus of further technological advancement. Recent discoveries on the design of chiral metal-organic perovskites now promise cheap, sustainable materials for energy efficient generation and detection of polarized light. However, so far, the available pool of chiral perovskite materials is limited to a few one- and two-dimensional crystal structures.

Here, we present novel strategies to produce perovskite thin films with chiral surface modification directly. The resulting compound displays strong circular dichroism effects in the blue spectral region, which can be adjusted in their intensity by varying synthetic parameters. Furthermore, we perform an extensive structural investigation into the origin of these phenomena utilizing XRD and GIWAX experiments.

DS 11.4   Wed 11:45   SCH A 315

All-oxide thin-film varactors with Mn- and Ni-doped (Ba,Sr)TiO$_3$ for microwave applications — •Yating Ruan[1], Stipo Matic[2], Alexey Arzumanov[1], Philipp Komissinskiy[1], Rolf Jakoby[2], and Lambert Alff[1] — [1]Advanced Thin Film Technology, Institute of Materials Science, Technische Universität Darmstadt, Darmstadt, Germany — [2]Microwave Engineering and Technology, Technische Universität Darmstadt, Darmstadt, Germany

With a trend toward miniaturization of modern electronics, tunable microelectronic devices operating over a wide range of frequencies are required for mobile communications, high-speed data connections with the upcoming 5G and Internet of Things (IoT) technologies.

Here we present all-oxide thin-film tuneable capacitors (varactors) with single-crystalline films of a tunable dielectric perovskite Ba$_x$Sr$_{1-x}$TiO$_3$(BST) doped with Mn and Ni, grown epitaxially by pulsed laser deposition on a highly conducting thin-film oxide SrMoO$_3$ bottom electrodes with a room-temperature resistivity of 30 $\mu\Omega$cm. A partial substitution of the tetravalent Ti at B-sites of the BST perovskite structure with Mn and Ni in a trivalent or divalent state decreases a concentration of oxygen vacancies in the BST, leading to a reduction of the leakage current density of the varactor by 5 orders of magnitude down to 1 A/m^2. The low leakage current allows the thickness of the BST layers to go below 50 nm, enabling varactors tunable with low voltages.

DS 11.5   Wed 12:00   SCH A 315

Finite Volume Modeling of Two-Dimensional Memristive Devices for Neuromorphic Computing — •Benjamin Spetzler[1], Dilara Abdel[2], and Patricio Farrell[2] — [1]Technische Universität Ilmenau, Ilmenau, Germany — [2]Weierstrass Institute, Berlin, Germany

In recent years, memristive devices have shown considerable potential for realizing synaptic functionalities in neuromorphic computing systems. Here, we present numerical models to analyze the hysteretic behavior of memristive devices. A finite volume model self-consistently solves the semiconductor equations for the electrostatic potential and the quasi-Fermi levels of electrons and holes. Further, we include the dynamics of mobile dopants and briefly discuss the boundary conditions implemented for the calculation of the switching dynamics and the current-voltage characteristics. Simulations are compared with measurements on two-dimensional flake devices based on MoS2. The results are used to validate the simulations and discuss the underlying switching mechanisms. Implications for the design of memristive devices are derived and discussed.

This work was partially funded by the Carl-Zeiss Foundation via the Project MemWerk and the German Research Foundation (DFG) through the Collaborative Research Centre CRC 1461 "Neurotronics - Bio-Inspired Information Pathway" as well as the Leibniz competition.

Time: Wednesday 17:00–19:00   Location: P3

DS 12.1   Wed 17:00   P3

Growth and structural investigation of the SnBiTe stoichiometric series via MBE and TEM — •Xiao Hou[1], Abdur Rehman Jalil[2], Detlev Grützmacher[2], Claus Claus Michael Schneider[1], and Lukasz Plucinski[1] — [1]PGI-6, Forschungszentrum Jülich, Germany — [2]PGI-9, Forschungszentrum Jülich, Germany

A topological phase transition (TPT) can be induced to engineer the band structure. This TPT is a fascinating, yet complex phenomenon in condensed matter research. Upon changing the stacking order of layers having different spin-orbit coupling (SOC) strengths, one can achieve a topological phase transition between trivial and nontrivial states [1,2]. Here, the Sn$_x$Bi$_y$Te$_z$ (SBT) stoichiometric series is a classical example, in which a stacking-dependent topological phase transformation group is explored.

The epitaxial growth of three distinct compositions i.e. SnBi$_2$Te$_4$, SnBi$_4$Te$_7$, Sn$_2$Bi$_2$Te$_5$ is conducted on Si (111) substrates via molecular beam epitaxy (MBE). X-ray diffraction (XRD) is employed to characterize the crystal quality of the grown thin films. We have also used advanced transmission electron microscopy (TEM) to investigate the stacking order. High-angle annular dark-field imaging provided detailed information about the crystallinity and atomic arrangements of the layer stacks and also of various types of structural defects in the thin films. The link between the stacking order and the topological characteristics requires further investigation that is ongoing.

Thin film growth characterization of a mulitpurpose physical vapor deposition apparatus with the goal of investigating tailored perpendicular magnetic anisotropy systems — •Florian Ott, Christian Janzen, Arne Schröder, and Arno Ehresmann — Institute of Physics, University of Kassel, D-34132 Kassel

In recent years, systems of multilayered (ML) magnetic thin films consisting of ferromagnetic transition metals (TM) with noble metallic spacers displaying perpendicular magnetic anisotropy (PMA) have gained increased interest for applications in magnetic particle transport [1], controlled domain movement [1,2] and sensor technologies [3]. These TM-based PMA systems may rely on the precise modulation of layer growth additionally to the already very low thickness requirements [1]. As a result, a precise control of the growth conditions is necessary in order to produce these systems. This work focuses on the characterization of growth conditions and parameters inside a multipurpose physical vapor deposition (PVD) apparatus with the ultimate goal of creating and investigating engineered TM-based PMA systems. Strain and Lattice-Relaxation Effects of (Al,Ga)N/GaN Interfaces on 4D-STEM Signals — •Frederik Otto, Laura Niermann, Tore Niermann, and Michael Lehmann — Technical University of Berlin, Berlin, Germany

The immense increase in computation power over the past decades can be attributed to the decreasing size of semiconductor device structures. Preceding this trend, semiconductor research focuses on thin films and their interfaces with the surrounding substrate material.

At these interfaces of heterogeneous device structures, the atomic lattices are strained due to the mismatch of lattice constants of interfacing materials. Scanning-Transmission Electron-Microscopy (STEM) is capable of resolving strain at a nanometer scale, however, investigated specimens must be sufficiently thin to be electron transparent. For such thin specimens, the relaxation of the strained lattice at its surfaces cannot be neglected when measuring strain in an electron microscope.

Here, knowledge about the underlying strain and relaxation effects at the interface of (Al,Ga)N/GaN Quantum Wells (QWs) is obtained by comparing 4D-STEM measurements with simulations. By carefully choosing the experimental parameters, i.e., convergence angle and tilt, features of multiple scattering events are found in the measured diffraction discs perpendicular to the QW structure at every position of a 2D scanned area. These features are evaluated by comparison with corresponding simulations considering a strain field and relaxation effects as obtained from finite element calculations.

DS 12.4   Wed 17:00   P3

Comparative evaluation of EDS quantification methods for the analysis of Sc$_x$Al$_{1-x}$N films — •Hauke Honig[1], Rebecca Petrich[2], Lorenz Steinacker[1], Younes Slimi[2], Daniel Glöss[3], Stephan Barth[3], Hagen Bartzsch[3], Raphael Kuhnen[4], Dietmar Frühauf[4], Stefan Krischok[2], and Katja Tonisch[2] — [1]Technische Universität Ilmenau, Fachgebiet Werkstoffe der Elektrotechnik, IMN MacroNano*, 98693 Ilmenau — [2]Technische Universität Ilmenau, Fachgebiet Technische Physik I, IMN MacroNano*, 98693 Ilmenau — [3]Fraunhofer-Institut für Organische Elektronik, Elektronenstrahl- und Plasmatechnik FEP, 01277 Dresden, Germany — [4]Endress+Hauser SE+Co. KG, TTD Technologieentwicklung, 79689 Maulburg, Germany

The quantitative analysis of Sc$_x$Al$_{1-x}$N films with energy dispersive x-ray spectroscopy (EDS) poses some challenges due to peak overlaps and the thin film character. Standard-free and standard-based methods are compared regarding their reliability for the quantification of the Sc-content in sputtered films with $0 \leq x \leq 0.35$ and evaluated using reference samples that have been quantified with GDOES and EDS by Fraunhofer FEP. Therefore, parameters such as acceleration voltage, selection of standard materials and quantification models are considered. Theoretical spectrums generated with Monte-Carlo simulations are used to improve the selection of excitation energy in the small range between substrate influence and limits of the quantification models. The crystalline hexagonal structure is confirmed with XRD.

DS 12.5   Wed 17:00   P3

From Doping to Dilution: Local Chemistry and Collective Interactions of La in HfO_2 — •Oliver Rehm[1], Thomas Szyjka[1,2], Lutz Baumgarten[2], Claudia Richter[3], Yury Matveyev[4], Christoph Schlueter[4], Thomas Mikolajick[3,5], Uwe Schroeder[3], and Martina Müller[1] — [1]Uni Konstanz, Konstanz, Germany — [2]FZJ, Jülich, Germany — [3]NaMLab, Dresden, Germany — [4]DESY, Hamburg, Germany — [5]TU Dresden, Dresden, Germany

HfO_2-based thin films exhibit huge potential for the next generation of non-volatile memory applications, such as FeRAM or FeFET. The application of HfO_2-based thin films as active ferroelectrics (FE) in these devices face reliability issues like wake-up, imprint, and fatigue. The FE phase of HfO_2 is the metastable orthorhombic structure, for which La doping is considered a promising route for stabilization.

La:HfO_2 samples were grown by ALD with a range of La doping, from 3.5% to 33%, i.e., from the doping to dilution level. We link the local chemistry at the La lattice sites with local and collective electronic properties of the La:HfO2 matrix using HAXPES. The satellite structure of La 3d core level, the plasmonic excitation energies, and core-level rigid binding energy (BE) shifts are investigated. The emerging chemical phases and electronic properties are discussed as a function of La doping. From the evolution of the plasmon excitation energies and rigid BE shifts, it is concluded that electronic charge compensation by oxygen vacancies occurs for increasing La content.

DS 12.6   Wed 17:00   P3

Molecular Dynamics - Two Temperature Model simulations of gold — •Othmane Benhayoun[1], Emiliano Principi[3], Bernd Bauerhenne[1], Dmitry S. Ivanov[2], and Martin E. Garcia[1] — [1]University of Kassel, Theoretical physics II, Kassel, Germany — [2]Moscow, Russia — [3]Elettra-Sincrotrone Trieste S.C.p.A., Trieste, Italy

We aim to explain the results obtained from a recent Ultrafast Electron Diffraction (UED) experiment that showed periodic oscillations in both height and width of the (311) Au diffraction peak. The same effect is however not observed in polycrystalline gold. We have thus performed Molecular Dynamics - Two Temperature Model (MD-TTM) simulations to model more than 11 million atoms, enabling us to understand the underlying physical processes. In our simulations, we obtain similar peak oscillations and determine the major mechanisms that lead to such lattice dynamics.

DS 12.7   Wed 17:00   P3

In situ X-Ray Total Scattering Investigation of Thermal Annealing in Fe-CoSiB Metallic Glass Films — •Nicolas Hayen[1], Philipp Jordt[1], Lars Thormählen[2], Mathis Mewes[1], Ann-Christin Dippel[3], Olof Gutowski[3], Niklas Wolff[2], Lorenz Kienle[2], and Bridget Murphy[1,4] — [1]Institute of Experimental and Applied Physics, Kiel University, Germany — [2]Institute of Material Sciences, Kiel University, Germany — [3]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [4]Ruprecht Haensel Laboratory, Kiel University, Germany

Thin films of the iron-based metallic glass $(Fe_{0.9}Co_{0.1})_{78}\,Si_{12}B_{10}$ (FeCoSiB) are seen as a promising candidate for technical applications in high sensitivity magnetic field sensors and have been utilized extensively within the CRC 1261 "Biomagnetic Sensing". Thermal annealing of these films leads to a decrease in quality of the desired magnetic properties depending on the parameters of the annealing process.

In situ grazing incidence high-energy x-ray total scattering experiments were used to investigate the onset of structural changes occurring in the material. Films of thickness ranging from 0.05 to 1 μm were investigated under varied annealing conditions with temperatures up to 700°C. From these measurements we were able to observe two separate crystallization phase transitions and the emergence of textured structures. Further analysis of the scattering from the amorphous phase may give further insight into the initial structural changes the material undergoes during annealing and their influence on magnetic properties.

DS 12.8   Wed 17:00   P3

Synthesis of structurally defined graphene nanoribbons: Peri-tetracene and it's corresponding 1,1'-bitetracene precursor — •Maren Klein[1,2], John B. Bauer[2], Marie Wagner[1,2], Holger F. Bettinger[2], Thomas Chassé[1], and Heiko Peisert[1] — [1]Institute of Physical and Theoretical Chemistry, University of Tübingen, Germany — [2]Institute of Organic Chemistry, University of Tübingen, Germany

Band gap engineering of precise nanographenes has attracted much attention in the field of organic electronics as they show great electronic properties. One class of these promising nanographenes are acenes and their related peri-acenes. Acenes are linearly condensed polycyclic hydrocarbons whereas peri-acenes exhibit a two-dimensionally enlarged π system. As peri-acenes possess a diradical open-shell character, the synthesis is quite challenging. Here we demonstrate that peri-tetracene can be formed on-surface by annealing the deposited precursor molecule 1,1'-bitetracene on a Cu (111) surface. The unique 1,1'-bitetracene undergoes a surface-assisted cyclodehydrogenation which was investigated by

microscopic and spectroscopic techniques, as well as by DFT calculations. In the XAS spectra we could observe that the as-deposited molecule shows a vanishing intensity of $\pi^\star$ transitions at normal incidence (90°), which indicates a planarization of the molecule already before annealing and an almost flat lying adsorption geometry.

DS 12.9   Wed 17:00   P3

Study of cadmium-based thin films obtained by pulsed laser deposition — •Cristina Postolachi[1], Georgiana Bulai[1], Sandu Cibotaru[2], Alexandru Cocean[1], Bogdanel Silvestru Munteanu[3], Nicanor Cimpoesu[1,4], Silvia Garofilde[1], Georgiana Cocean[1], Iuliana Cocean[1], and Silviu Gurlui[1] — [1]Alexandru Ioan Cuza University of Iasi, Faculty of Physics, Atmosphere Optics, Spectroscopy and Laser Laboratory (LOASL), 11 Carol I Bld. 700506 Iasi, Romania — [2]Petru Poni Institute of Macromolecular Chemistry, Gr. Ghica Voda Alley, 41A, 700487 Iasi, Romania — [3]Alexandru Ioan Cuza University of Iasi, Faculty of Physics, 11 Carol I Bld. 700506 Iasi, Romania — [4]Gheorghe Asachi Technical University of Iasi, Faculty of Material Science and Engineering, 59A Mangeron Bld., Iasi, Romania

This study investigates the processes that occur when different chemical compounds of cadmium are mixed with selenium and are further used as targets for thin film growth by pulsed laser deposition. Here the interactions between these compounds in the laser induced plasma plume will be analyzed.

The aim of the investigation of the reactions that take place in the plasma plume at high vacuum is to obtain thin films of cadmium selenide. The thin films proprieties will be investigated with different techniques, such as Scanning Electron Microscopy coupled with Energy Dispersive Spectroscopy (SEM-EDX), X-ray Diffraction (XRD), profilometry, UV-VIS spectroscopy and others.

DS 12.10   Wed 17:00   P3

Fabrication of copper halide thin films by combinatorial PLD — •Christopher Walter, Felix-Florian Delatowski, Michael Bar, Holger von Wenckstern, and Marius Grundmann — Universität Leipzig, Felix Bloch Institute for Solid State Physics, Semiconductor Physics Group, Leipzig, Germany

Copper halides are promising p-type materials for transparent device applications due to their large direct band gaps ($E_g = 3-3.4\,eV$) [1]. Here we present the deposition of copper halide thin films by combinatorial pulsed laser deposition (PLD) and discuss their structural, morphological and optical properties as a function of different growth parameters [2]. At ambient conditions, CuI crystallizes in the cubic zinc-blende structure. XRD shows <111>-orientation for CuI independent from the used substrate material. CuBr and CuCl grow polycrystalline with the same crystal structure as CuI. However, with the incorporation of low iodine concentration, the crystallinity improves significantly. We find that the thin films exhibit very smooth surfaces with a roughness of $R_{RMS} = 0.8-1.6\,nm$ for the binary CuI, CuBr and CuCl systems under optimal parameters. Furthermore, using combinatorial PLD and a segmented target with one segment each of CuBr and CuI, ternary $CuBr_xI_{1-x}$ alloys were grown. Based on the resulting locally varying composition, the influence on structural and optical properties can be directly observed.

Electrical characterization of SnTe thin film topological crystalline insulator — •Negin Beryani Nezafat, Sepideh Izadi, and Gabi Schierning — Department of physics, Experimental physics, Bielefeld University, 33615, Bielefeld, Germany

Topological crystalline insulators (TCIs) with gapless metallic states and protected carrier transport offer unique electrical features. Band structure of these materials consists of conventional parabolic band diagram together with linear surface transport. In this work, SnTe thin film as a promising TCI is considered to be our model system. Therewith, SnTe thin films with different thicknesses are deposited on silicon substrate using RF magnetron sputtering. The resulting morphology characterization for rock-salt SnTe crystalline thin film fulfills stoichiometric ratio. Electrical characterization including temperature dependent resistivity, magnetoresistance and Hall analysis are performed using Van der Pauw configuration. These findings introduce SnTe thin film as a promising candidate for technical applications such as device fabrication.

DS 12.12   Wed 17:00   P3

Current probe AFM measurements on reactively co-sputtered $Ag_xCu_{1-x}I$ thin films — Tillmann Stralka, •Sofie Vogt, Christiane Dethloff, Jorrit Bredow, Holger von Wenckstern, and Marius Grundmann — Universität Leipzig, Felix-Bloch-Institut, Germany

CuI exhibits a high hole mobility of up to 44 cm^2/Vs in bulk crystals and of about 19 cm^2/Vs in polycrystalline thin films[1,2]. This, combined with high transparency in the visible light range, renders CuI an interesting material for transparent complementary devices. However, grain boundary (GB) conduction is dominating electrical properties and might inhibit device performance[3]. An-

nadi *et al.* showed that alloying with silver reduces the conductivity of $Ag_xCu_{1-x}I$ thin films and even results in switching from p-type to n-type[4].

We present topological and current probe (cp)-atomic force microscopy measurements on reactively sputtered $Ag_xCu_{1-x}I$ thin films with silver contents from x=0.1 to x=0.6. A strong decrease of the grain size with increasing silver content is observed. In addition, a decrease of the overall surface current is observed, which agrees well with electrical bulk characterizations. For $x \geq 0.39$ we observed that the current from tip to sample is mainly injected at grain boundaries while for large Ag content the injected current at GBs is negligible.

Analysis of the structural properties of $Li(Ni_{1/3}Co_{1/3}Mn_{1/3})O_{2-\delta}$ (NCM) thin film model cathodes — Julius Konstantin Dinter and •Matthias Elm — Center for Materials Research, Justus-Liebig-University Giessen Germany, Heinrich-Buff-Ring 16, 35392 Giessen

Lithium ion batteries often suffer from capacity fading due to undesired side reactions occurring at the cathode surface. To get a deeper understanding of these side reactions, 2D model system are necessary. For this purpose, NCM thin film cathodes were prepared via spin coating followed by annealing at high temperatures. Using these thin film cathodes allow us to perform various surface sensitive measurements such as Raman microscopy, AFM, ESM, SEM and EDX. As no additives are used, we are able to study the surface reaction occurring at the cathode active material in more detail using in-situ measurements. The results reveal structural changes of the surface accompanied by an increase of the cell resistance, which confirms the formation of an SEI. Furthermore, the electrochemical performance of thin films coated with Al_2O_3 using atomic layer deposition (ALD) were investigated. The analysis of the surface properties confirm that coating of the NCM-thin film suppresses the undesired surface reactions resulting in an improved long-term cycling stability.

DS 12.14   Wed 17:00   P3

Nanoscopic Investigation of the Monolayer $MoSe_2$-WSe_2 Lateral Heterostructures under Illumination — •Alexander Turchanin[1], Tobias Nörenberg[1], Ziyang Gan[2], Antony George[2], Andrey Turchanin[2], Susanne C. Kehr[1,3], and Lukas M. Eng[1,3] — [1]TU Dresden — [2]Friedrich Schiller University Jena — [3]Wuerzburg-Dresden Cluster of Excellence - EXC 2147 (ct.qmat)

Transition metal dichalcogenides (TMDCs) such as $MoSe_2$ and WSe_2, are inorganic semiconductor monolayers with great potential for integration into nanoscale devices. Monolayers of different TMDCs can be engineered into lateral or vertical heterostructures forming, e.g., 1D or 2D p-n junctions that strongly respond to light [1]. Here, lateral heterostructures of monolayer $MoSe_2$ and WSe_2 grown by chemical vapor deposition are studied at the nanometer length scale by Kelvin Probe Force Microscopy (KPFM) under visible to near-infrared light illumination, i.e. photon energies between 1.45 and 1.95 eV. This approach enables for the simultaneous recording of both the sample surface morphology and the local photoinduced surface potential. By employing the side-band KPFM demodulation [2], quantification of the local band-bending of this in-plane heterostructure is possible with superior sensitivity. Different alterations of the local surface potential are observed when choosing the light exposure above and below the individual TMDCs bandgap energies.

Electronic structure of MXenes determine from angle-resolved photoelectron spectroscopy — •Wei Yao[1], Dongqi Li[1,2], Jonas A. Krieger[1], Mihir Date[1], Emily C. McFarlane[1], Minghao Yu[1,2], Xinliang Feng[1,2], and Niels B.M. Schröter[1] — [1]Max-Planck Institute of Microstructure Physics, Halle (Saale), 06120, Germany — [2]Center for Advancing Electronics Dresden (cfaed) and Faculty of Chemistry and Food Chemistry, TU Dresden, Dresden, 01062, Germany

Transition metal carbides, also known as MXenes, have been one of the most fascinating two-dimensional material systems beyond graphene. Chemical substitution of the transition metal elements and terminal function groups have resulted in versatile and tunable electronic, optical and mechanical properties, with applications in energy storage, multifunctional sensors, transparent and flexible electrodes, electromagnetic interference shielding, or hydrogen evolution reaction catalysis [1]. However, to reveal the origins of the MXenes' exceptional properties, a deeper understanding of their electronic structure is required. Here we report the first micro-focused angle-resolved photoemission spectroscopy (ARPES) measurements of single MXene flakes, which will reveal the influence of the chemical environment on the the single-particle electronic band structure, as well as many-body effects reflected in its spectral function.

DS 12.16   Wed 17:00   P3

Mode-selective Raman Signal Enhancement in MoS_2/WS_2 Heterostructures — •Annika Bergmann[1], Mustafa Hemaid[1], Rico Schwartz[1], Ziyang Gan[2], Antony George[2], Andrey Turchanin[2], and Tobias Korn[1] — [1]Institute of Physics, University of Rostock, Germany — [2]Institute of Physical Chemistry, Friedrich Schiller University Jena, Germany

In the family of van der Waals materials, transition metal dichalcogenides (TMDCs) have attracted much attention in recent years. Stacking various TMDC materials forms heterostructures in which new phenomena, such as interlayer charge transfer and interlayer excitons [1] occur. However, for the observation of interlayer effects good contact between the constituent monolayers is crucial. Here, we investigate bilayer heterostructures that were formed by combining Chemical Vapor Deposition (CVD) grown MoS_2 and exfoliated WS_2 monolayers. Photoluminescence quenching is used as an indicator to evaluate the interlayer coupling. In addition, the out-of-plane (A_{1g}) phonon mode provides information on the interfacial contact [2]. We observe a selective enhancement of the WS_2 A_{1g} Raman mode in well-coupled MoS_2/WS_2 heterostructures compared to WS_2 monolayers or heterostructures with only poor contact. A systematic study of this phenomenon is presented to elucidate its microscopic origin.

DS 12.17   Wed 17:00   P3

Exfoliation of 2D materials for nanooptics — •Jakob Wetzel[1], Maximilian Obst[1,2], Susanne C. Kehr[1,2], and Lukas M. Eng[1,2] — [1]TU Dresden, Dresden, Germany — [2]Würzburg-Dresden Cluster of Excellence - EXC 2147 (ct.qmat), Dresden, Germany

The desire for smaller and more energy efficient optical components leads to the necessity of light confinement below the diffraction limit. This can be achieved e.g by phonon polaritons (PhPs) which are quasiparticles formed by the coupling of infrared photons with the optical phonons of a crystal. Particularly the related light confinement is enhanced when the PhPs are generated in anisotropic, 2D van der Waals materials such as MoO_3 and GeS [1, 2]. Therefore, flat and μm - sized nanosheets of such materials are required, which can be realized by mechanical exfoliation.

Here, we present an optimized exfoliation technique for MoO_3 and GeS resulting in the reproducible generation of 20 to 100 μm - sized flakes with a thickness of about 100 nm. We present a quick and easy to implement adaptation of the scotch-tape exfoliation technique as well as exemplary results based on optical microscopy images and atomic force microscopy.

DS 12.18   Wed 17:00   P3

hybrid resonant circuits with van der Waals materials — •haolin jin[1], giuseppe serpico[2], christian n. saggau[2], sanaz shokri[1], mickey martini[2], yejin lee[2], poya yang[1], sebastian seifert[1], uri vool[1], and nicola poccia[2] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]Leibnitz Institute for Solid State and Materials Science Dresden (IFW Dresden), Dresden, Germany

Van der Waals superconductors, especially heterostructures, are believed to exhibit novel superconducting phases. However, the standard measurement techniques designed for bulk superconductors are challenging to apply in 2D materials which cannot be grown in sufficient size and quality. Herein, we introduce an efficient method to explore the properties of 2D materials, by combining them into hybrid resonant circuits. The resonator can have a strong inductive interaction with a small-size superconducting sample, affecting its frequency response. However, creating superconducting contacts between the resonator and the 2D material is challenging, especially for air-sensitive materials where evaporation must be done in a protected glovebox. Here, we present a technique to make robust superconducting contacts to a 2D sample by using a flexible nanomembrane. The Niobium resonator circuit is fabricated on top of the nanomembrane, and via contacts connect it to the 2D materials. Through the circuit response, we can explore the properties of novel unconventional superconductors. Moreover, this hybrid circuit is a new type of quantum device for future quantum technology applications.

DS 12.19   Wed 17:00   P3

Phase transformations in few-layer transition metal phosphorus trichalcogenides studied by low-voltage TEM — •Alexander Storm[1], Janis Köster[1], Mahdi Asl-Gohrbani[2], Silvan Kretschmer[2], Tatiana Gorelik[1], Michael K. Kinyanjui[1], Arkady Krasheninnikov[2], and Ute Kaiser[1] — [1]Central Facility Materials Science Electron Microscopy, Ulm University, 89081 Ulm, Germany, — [2]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany,

In this work we study phase transformations in freestanding few-layer transition metal phosphorus trichalcogenides (TMPTs) induced by electron irradiation as well as thermal annealing in vacuum, using various analytical transmission elec-

tron microscopy techniques (TEM). In addition, our results are supported by ab-initio calculations.

We show that due to knock-on damage, first sulphur atoms are ejected in sulphur-based TMPTs at common TEM acceleration voltages (60kV - 300kV), which in turn leads to the formation of defects and strong modifications of the TMPT's properties [1]. For instance, we show that in few-layer MnPS3 and MnPSe3, stable, ultrathin α- and γ-MnS/MnSe phases are formed showing the reliability of this transformation in Mn based TMPTs. Eventually, we elucidate the emerging phases and transition temperatures for few-layer MnPS3, MnPSe3, FePS3, FePSe3, and NiPS3 induced by thermal annealing.

DS 12.20   Wed 17:00   P3

Encapsulating high-temperature superconducting twisted van der waals heterostructures blocks detrimental effects of disorder — •Yejin Lee[1,2], Mickey Martini[1,2], Tommaso Confalone[1], Sanaz Shokri[1,2], Christian Saggau[1], Daniel Wolf[1], Genda Gu[3], Kenji Watanabe[4], Takashi Taniguchi[4], Domenico Montemurro[5], Valerii Vinokur[6], Kornelius Nielsch[1,2], and Nicola Poccia[1] — [1]IFW Dresden, Dresden, Germany — [2]TU Dresden, Dresden, Germany — [3]Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, NY, USA — [4]NIMS, Tsukuba, Japan — [5]University of Naples Federico II, Naples, Italy — [6]Terra Quantum AG, Gallen, Switzerland

Van der Waals (vdW) heterostructures based on cuprate superconductors attract substantial interest of novel topological phases as well as technological applications. One of the hindrances for the progress is the detrimental effect of disorder on the properties of the vdW devices-based Josephson junctions. This work reports a novel method of fabricating twisted vdW heterostructures made of Bi2Sr2CuCa2O8+x, combining the employed cryogenic stacking using a solvent-free stencil mask technique and additionally covering the interface with insulating hexa boron nitride layers. We find that encapsulating the interface in the stacked systems overcomes detrimental effects of disorder providing highly coherent Josephson junction. This finding enables crucial improvement of its critical current and the Tc of the junctions up to their magnitudes in bulk intrinsic junctions.

DS 12.21   Wed 17:00   P3

In-situ formation of Mo_6Te_6 nanowire in single-layer 2H-$MoTe_2$ by annealing and electron irradiation — •Janis Köster[1], Silvan Kretschmer[2], Michael K. Kinyanjui[1], Alexander Storm[1], Fabian Rasper[1], Arkady V. Krasheninnikov[2], and Ute Kaiser[1] — [1]Electron Microscopy of Materials Science, Ulm University, Albert Einstein Allee 11, 89081 Ulm, Germany — [2]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany

Up to now, the fundamental understanding of transformations in 2D materials at the atomic scale are not fully characterized. Here, we demonstrate a route to locally transform freestanding single-layer (1H-) $MoTe_2$ [1] into 1D-Mo_6Te_6 nanowires [2] under electron beam irradiation and by heating. (HR)TEM at the Cc/Cs-corrected SALVE [3] microscope at 80 kV is used to analyse structural changes in the material. Combining the experimental data with the results of first-principles calculations, we explain energetics and stabilities of $MoTe_2$ monolayers and Mo_6Te_6 nanowires due to an interplay of electron-beam-induced energy input, atom ejection, and oxygen absorption. A detailed understanding of high-temperature solid-to-solid phase transformation in the 2D limit provides insights into the material's applicability for future device fabrication.

structural and magnetic properties of two dimensional (2D) Fe_xGeTe_2 and Fe $_xGaTe_2$ grown by molecular beam epitaxy (MBE) — •Atekelte Kassa, Hua Lv, Neha Aggrawal, Michael Hanke, Abbes Tahraoui, Manfred Ramsteiner, and Marcelo Lopes — Paul-Drude-Institut für Festkörperelektronik, Leibniz Institut im Forschungsverbund Berlin e.V., Berlin, Germany

2D materials with intrinsic functionality showed importance in fundamental condensed-matter science and for the development of advanced technologies, where 2D ferromagnetic materials have raised interest for developing low dimensional magnetic/spintronic devices. Yet maintaining 2D ferromagnetism at /above room temperature remains a challenge. This work presents our recent results on 2D ferromagnets of Fe_xGeTe_2 and Fe $_xGaTe_2$ ($3 \leq x \leq 5$) prepared using MBE. Films were grown at 300 °C using elemental fluxes of Fe, Ge (Ga), and Te on epitaxial graphene on SiC (0001). Epitaxial films with good structural quality were confirmed by reflection high-energy electron diffraction and X-ray Diffraction. Atomic force microscopy confirmed continuous and smooth surface growth. Raman spectroscopy results showed that the graphene layers remain structurally unaltered after MBE growth. Anomalous Hall effect investigations through Magneto-transport studies identified a perpendicular magneto anisotropy as well as a Curie temperature (T_c) above 300 K for both films with Fe

composition close to x=5. For Fe $_xGaTe_2$, T_c values around 380 K were obtained. These results make the studied ferromagnets promising for the development of novel spintronic devices based on 2D materials and heterostructures.

DS 12.23   Wed 17:00   P3

Towards engineering of tailored 2D single photon emitters (SPE) by encapsulating single dye molecules into few layer hexagonal boron nitride (hBN) — •Nils le Coutre, Tim Völzer, Paul Weinbrenner, Lisa Böhme, Franziska Fennel, Tobias Korn, Stefan Lochbrunner, and Friedemann Reinhard — University of Rostock, Rostock, Germany

We hypothesize that encapsulating dye molecules into multilayer hBN flakes overcomes photobleaching, for example by improved thermal conduction and airtight sealing. This would tackle one of the biggest barriers to the application of fluorescent dyes in various methods like optical nearfield microscopy or quantum sensing. I will present work to deposit dyes on exfoliated multilayer hBN flakes by different methods of physical vapor deposition (PVD) and liquid deposition, as well as initial studies on photostability by confocal microscopy. The large variety of available dye molecules will provide a rich toolbox for engineering of 2D SPEs, with greater flexibility than the limited set of intrinsic defects in 2D materials and bulk crystals.

DS 12.24   Wed 17:00   P3

Epitaxy and transfer of freestanding oxide perovskites — •Jeremy Maltitz, Duc Nguyen, Alev Yuvanc, Jens Martin, and Jutta Schwarzkopf — Leibniz Institut für Kristallzüchtung, Max-Born-Str. 2, 12489 Berlin, Deutschland

Fabrication of artificial 3D heterostructures is of increasing interest for a broad range of application, such as flexible sensor, memristors, or electronic skins. Layer transfer of thin films has established a new paradigm of material assembly and design in context of 2D-van-der-Waals crystals. Recently, freestanding oxide perovksites have been achieved by introducing a perovskite-like sacrificial layer (Sr3Al2O6) between substrate and functional film. In combination with layer transfer, the functional film can be placed on arbitrary substrates (e.g. silicon wafers). Additionaly, two functional layers (same or different) can be stacked with the opportunity to create moiré patterns by rotating the layers with respect to each other. Therefore, the influence of PLD growth parameter and thickness of SrTiO3/Sr3Al2O6 heterostructures are studied to improve the quality of freestanding SrTiO3 thin films. Furthermore, the solid-solution family of (Ba,Ca,Sr)3Al2O6 enables the possibility to tune the lattice parameter. This property was used to adjust the lattice parameter of the sacrificial layer to closely match the lattice parameter of SrTiO3. With improved growth parameter and lattice matched sacrificial layer, the crackformation of the freestanding film was reduced, paving the path towards the stacking of freestanding thin films.

DS 12.25   Wed 17:00   P3

Characterization of structural and magnetic properties of $SrRuO_3$ thin films — •Vitor de Oliveira Lima[1], Mai Hussein Hamed[1], Connie Bednarski-Meinke[1], Michael Faley[2], Emmanuel Kentzinger[1], and Thomas Brückel[1] — [1]Jülich Centre for Neutron Science (JCNS-2) and Peter Grünberg Institute (PGI-4), JARA-FIT, Forschungszentrum Jülich GmbH, Germany. — [2]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons (ERC), Forschungszentrum Jülich GmbH, Germany.

Proximity effects in Ferromagnet/Superconductor Heterostructures (F/S-H) have demonstrated high potential for development of new devices for spintronic and quantum computing application. $SrRuO_3$ (SRO) has attracted much attention among transition metal oxides for being the only 4d oxide to show itinerant ferromagnetism and metallic conductivity. In this work, we are characterizing the crystal structure as well the magnetic properties of SRO thin films for further application in F/S-H with $YBa_2Cu_3O_{7-x}$ superconducting films. The samples were prepared on STO (001) single crystals by High-Oxygen Pressure Sputtering. SRO thin films are epitaxial and have smooth surface. Magnetometry indicate that samples have out-of-plane magnetic anisotropy and paramagnetic-ferromagnetic transition at approximately 150 K, which corresponds to the SRO with Ru^{4+} Curie temperature, and two transitions at lower temperatures, that may be related to another Ru oxidation state. The samples stoichiometry will be further investigated by Rutherford Backscattering Spectroscopy.

DS 12.26   Wed 17:00   P3

Charge-to-spin conversion in the quasi-two-dimensional electron gas emerging at the doped interface between $LiNbO_3$ and $LaAlO_3$ — •Igor Maznichenko[1,2], Sergey Ostanin[1], Ingrid Mertig[1], and Paweł Buczek[2] — [1]Institute of Physics, Martin Luther University Halle-Wittenberg, D-06099 Halle, Germany — [2]Department of Engineering and Computer Sciences, Hamburg University of Applied Sciences, Berliner Tor 7, D-20099 Hamburg, Germany

We anticipate that the functional use of a solid electrolyte lithium niobate in $LaAlO_3/LiNbO_3$ heterostructure allows one to tune the quasi-two-dimensional electron gas (q2DEG) which emerges there. This phenomenon can be achieved by charging and discharging $LiNbO_3$. Here, on the basis of *ab initio* calculations of the hydrogen-doped $LaAlO_3/LiNbO_3$ interface, we demonstrate how the

q2DEG and its spin polarization appear. The out-of-plane electric polarization of $LaAlO_3/LiNbO_3$ forces the H dopants to accommodate at the Al-terminated interface. This results in the formation of the q2DEG, whose spatial extent is about 1.5 nm along the stacking direction.

DS 12.27   Wed 17:00   P3

Preparation of oxide ferroelectric membranes by epitaxial sacrificial layers — •Jonas Wawra[1,2], Robin Adlung[1,2], Kornelius Nielsch[1,2], and Ruben Hühne[1] — [1]Institute for Metallic Materials, Leibniz IFW Dresden, Germany — [2]Institute of Applied Physics, TU Dresden, Germany

Oxide ferroelectric thin films are used in a variety of applications due to their strong remnant polarization and excellent dielectric, piezoelectric and optoelectric properties. However, well performing and robust materials require a high crystalline quality and orientation, which is commonly achieved by growing the desired ceramic on comparably thick and rigid substrates at high temperatures. This procedure prohibits in most cases the incorporation in advanced organic heterostructures and limits their utilization in flexible devices. One idea to overcome the discrepancy between processing and implementation is the use of a sacrificial layer during growth, which allows to release the functional material as a thin membrane afterwards and enables a transfer to flexible substrates. Here, we present our approach by growing different fully epitaxial hetero-structures of $La_{0.7}Sr_{0.3}MnO_3$ (which can be wet-etched in a hydrochloric acid solution), conducting $SrRuO_3$ and ferroelectric $Ba_{1-x}Sr_xTiO_3$ on oxide single crystal substrates by pulsed laser deposition. Different sample architectures were used to obtain a diversity of membranes that allow us to study their microstructure and functional properties with methods like X-ray diffraction, scanning probe microscopy, dielectric and ferroelectric measurement techniques to compare them to similar films still clamped on a substrate.

DS 12.28   Wed 17:00   P3

Resistive switching and oscillations in $NdNiO_3$ and $SmNiO_3$ planar thin film devices — •Farnaz Tahouni-Bonab[1], Theodor Luibrand[1], Claribel Domínguez[2], Jennifer Fowlie[2], Stefano Gariglio[2], Rodolfo Rocco[3], Soumen Bag[3], Lorenzo Fratino[3], Marcelo Rozenberg[3], Jean-Marc Triscone[2], Reinhold Kleiner[1], Dieter Koelle[1], Javier del Valle[1], and Stefan Guénon[1] — [1]Physikalisches Institut, Center for Quantum Science (CQ) an LISA+, Universität Tübingen, 72076 Tübingen, Germany — [2]Department of Quantum Matter Physics, Université de Genève, 1211 Geneva, Switzerland — [3]Université Paris-Saclay, CNRS, Laboratoire de Physique des Solides, 91405 Orsay, France

Recently, there has been growing interest in strongly correlated materials that undergo a temperature-driven insulator-to-metal transition in the emerging research field of neuromorphic computing. Of particular interest are resistive switching phenomena for emulating integrate-and-fire behavior or self-sustained oscillations for spike train generation. In this study, we used a combination of wide field microscopy and electrical transport measurements to investigate thin film devies of the charge transfer insulators $NdNiO_3$ and $SmNiO_3$. Current-voltage characteristics and photomicrographs reveal resistive switching via an intermediate state with a blurry metallic filament. The intermediate state is accompanied by oscillations in the 10 kHz frequency range that have a characteristic saw-tooth shape indicative of a relaxation oscillator. The intermediate state can be suppressed by changing the slew rate of the current source.

DS 12.29   Wed 17:00   P3

Determining the brazeability of copper surfaces via spectroscopic ellipsometry — •Friedrich Bürger, Lienhard Wegewitz, and Wolfgang Maus-Friedrichs — Clausthal Centre of Material Technology, Clausthal University of Technology, Agricolastr. 2, 38678 Clausthal-Zellerfeld

In Brazing, surface conditions play a fundamental role in determining the joint strength. Not all changes of the surface, like thick oxide layers or oil films, may be immediately apparent and therefore will only be noticed when the brazing process failed. Since most methods of determining brazeability work by performing a brazing process and evaluating the results they can only be performed on samples. This does not represent variation of surfaces within a batch of material. To fill this gap a nondestructive method to determine brazeability is needed. Spectroscopic ellipsometry (SE) is an optical measurement method commonly used to characterize the optical properties of surfaces and thin films. To evaluate if SE can be used to distinguish surface states of copper surfaces that negatively impact the joint strength, different surfaces were prepared. The selected surface states were a reference condition, ground surfaces, oxidized surfaces and different oil films on the reference surface. Those surfaces were characterized by confocal laser scanning microscopy (CLSM) and X-Ray photoelectron spectroscopy (XPS) to determine their morphology and chemical composition. SE-measurements were performed subsequently. Except for the ground states all surfaces showed distinct features in their SE-spectra, suggesting identification via SE is possible.

DS 12.30   Wed 17:00   P3

Microscopic theory of X-ray absorption spectroscopy — •Joris Sturm, Dominik Christiansen, Malte Selig, and Andreas Knorr — Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

X-ray absorption near-edge spectroscopy (XANES) and extended X-ray absorption fine structure (EXAFS) are two widely used methods to investigate the structure of solid states. [1,2,3].

In this contribution, we present a self-consistent Maxwell-Bloch approach based on Heisenberg equations of motion for a unified description of XANES and EXAFS for 2D solid-state materials and apply it to the exemplary material graphene. For XANES we reproduce the experimentally observed absorption peaks and polarization-dependent selection rules of the included orbitals. Furthermore, the rigorous treatment of the Bloch wave interference allows us to calculate the Fourier transformed EXAFS spectrum [2] predicting so far uninterpreted features which have not been assigned within point-scattering theory [1].

Ultrafast vibrational dynamics of CH-stretch modes of surface adsorbates — •Tim Lämmerzahl, Nelli Kremer, and Eckart Hasselbrink — University Duisburg-Essen

The understanding of energy transfer between different modes in one molecule, which is called internal vibrational energy redistribution (IVR), is crucial for further development in the field of rate theory and for applications in molecular electronics. As a model we study adsorbate monolayers of a single species using time-resolved two-color pump probe sum frequency spectroscopy.

Previously, we revealed that the coupling between valence vibrations is faster than a few ps and equilibrates with bending and torsion modes on a tens of ps time scale in fatty acid monolayers [1]. Now we moved on to conducting surfaces (e.g. gold) and used different terminated alkanethiols. Since gold surfaces exhibit a strong non-resonant (NR) signal, which is usually the dominant source of noise, we used the technique by Dlott et al.[2] to suppress the NR signal. Results from a study of alkylthiols with different headgroups on gold will be presented.

Dynamics of the response of thiol monolayers to rapid heating — •Matthias Linke and Eckart Hasselbrink — Universität Duisburg-Essen, Germany

Energy transport between metal substrates and molecules as well as intramolecular energy transport between vibrations is still not well understood, even though systems such as thiols on gold were studied extensively. Self-assembled molecular films are an ideal model system such as their characterization attracted much interest over the last decades, especially in the field of nanotechnology. It is well established that thiols adsorb easily and reproducibly on gold substrates by self-assembly. Sum-frequency generation vibrational spectroscopy (SFGvS) can be used for characterization of such systems, since it is inherently sensitive to surface species, interfaces at which centrosymmetry is broken. We adsorbed different thiols on Au-surfaces and heated the substrate by focussing an additional 25 ps 532 nm laser beam on the backside of the sample. Absorption of the photons leads to temperature jumps in the metal which can be assessed by tracking the reflectivity changes of the sample. Tracking the spectral changes via SFGvS at different delays between the pump and probe pulses can be done to assess the temperature effects induced in the substrate and the molecules and time constants can be extracted. The effect of the probing of different head groups (NO_2, CN, CH_3) and variation of the spacer group are studied in this work.

DS 12.33   Wed 17:00   P3

In-situ spectroscopic ellipsometry measurement and analysis of native SiO2 behavior under different atmosphere and temperature — •Younes Slimi[1,2], Jannis Waldmann[1], Rüdiger Schmid-Gund[1], and Stefan Krischok[1] — [1]Technische Universität Ilmenau, Fachgebiet Technische Physik I, Weimarer Strafte 32, 98693 Ilmenau, Germany — [2]Ferhat Abbas University, Institut of optics and precision mechanics, Optics and Applied Photonics laboratory 19000 Setif, Algeria

the most common wafer used in the semiconductor industry nowadays is silicon (Si), the latter oxidizes when left to its own devices. these silicon oxide layers' behavior was investigated using In-situ Spectroscopic ellipsometry to obtain optical constants and thin film thicknesses under different atmospheres (nitrogen, dry air) and temperatures. We found changes in the refractive index and thickness of the SiO2 layer under different conditions due to oxidation and material ablation. These results are meant to be used as possible references for future Electrochemical cells for in-situ Spectroscopic ellipsometry measurement for water splitting devices.

Daniel Söderberg[2,5], and Stephan V. Roth[1] — [1]DESY, 22607 Hamburg — [2]Fibre and Polymer Technology, KTH, 10044 Stockholm, Sweden — [3]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching — [4]Institute for X-ray Physics, Goettingen University, 37077 Goettingen — [5]WWSC, KTH, 10044 Stockholm, Sweden — [6]MLZ, TUM, 85748 Garching — [7]Leibniz-Institut für Polymerforschung Dresden e.V., Abteilung Werkstofftechnik, 01069 Dresden
The fabrication of sustainable, thin, and flexible electrical devices on an industrial scale will be an important challenge in the future. Nanocomposites, consisting of conductive nanoparticles like silver nanowires (AgNWs) and a sustainable matrix material like cellulose nanofibrils (CNFs), can meet these requirements. Here, we report on the nanoscale structure and the corresponding optoelectronic properties of a sprayed CNFs-AgNWs nanocomposite electrode. Adding CNF to the aqueous AgNW-based spray ink improves the dispersion and distribution of the AgNWs. This, and the cold-welding of the AgNW junctions enhance the conductivity of the electrode greatly. Finally, we demonstrate the electrode's high transmittance, resilience under multiple cycles of bending deformations, and its long-term stability.

Detecting nitrogen-vacancy-hydrogen centers on the nanoscale using nitrogen-vacancy centers as local sensors in CVD-diamond — •Christoph Findler, Gerhard Wolff, Karolina Schüle, Rémi Blinder, Priyadharshini Balasubramanian, Johannes Lang, Christian Osterkamp, and Fedor Jelezko — Institute for Quantum Optics, Ulm University, Albert-Einstein-Allee 11, D-89081 Ulm, Germany
The negatively-charged nitrogen-vacancy center (NV) in diamond has attracted a lot of attention in the field of quantum technologies as it shows coherence times up to milliseconds at room temperature and enables optical polarization and coherent control of the electron spin. Apart from NV centers, the spin bath in diamond grown by chemical vapor deposition (CVD) consists mainly of substitutional nitrogen (P1) and negatively charged nitrogen-vacancy-hydrogen (NVH) defects which are usually analyzed by electron paramagnetic resonance (EPR) spectroscopy. In nm-thick epitaxial layers, however, the total number of paramagnetic spins becomes eventually too low for state-of-the-art EPR spectrometers. This problem can be solved by switching to a confocal microscope and studying the NV centers optically. Here, we show that 15NV ensembles can be employed as local sensors to estimate the density of non-fluorescent 15NVH and P1 centers in 15N-doped (100)-diamond layers and even get insight into the spatial distribution and correlation of P1 and 15NVH on the micrometer scale using a wide-field microscope.

DS 12.36   Wed 17:00   P3

Tailoring Optical Properties in Transparent Highly Conducting Perovskites by Cationic Substitution — •Mahdad Mohammadi, Ruiwen Xie, Niloofar Hadaeghi, Aldin Radetinac, Alexey Arzumanov, Philipp Komissinskiy, Hongbin Zhang, and Lambert Alff — Institute of Materials Science, Technische Universität Darmstadt
$SrMoO_3$, $SrNbO_3$, and $SrVO_3$ are remarkable highly conducting d^1 (V, Nb) or d^2 (Mo) perovskite metals with an intrinsically high transparency in the visible. A key scientific question is how the optical properties of these materials can be manipulated to make them suitable for application as transparent conductors and emergent plasmonics. In this work, it is demonstrated for the first time how $3d/4d$ cationic substitution in perovskites shifts the optical transition energy and plasma frequency. At the example of the solid solution $SrV_{1-x}Mo_xO_3$ we show that the absorption and reflection edges can be shifted to the edges of the visible, resulting in a material that has the potential to outperform ITO due to its extremely low sheet resistance. For $x = 0.5$, a resistivity of 32 *Ωcm (12 Ω/sq.) is paired with a transmittance above 84 % in the whole visible spectrum. Quantitative comparison between experiments and electronic structure calculations show that the shift of the plasma frequency is governed by the interplay of d-band filling and electronic correlations.

Influence of dielectric Layers on the optomechanical Properties of Polymer Membranes in a Fiber Cavity — •Andreas Reuss[1], Stefan Linden[1], Hannes Pfeifer[2], Lukas Tenbrake[2], and Alexander Fassbender[1] — [1]Physikalisches Institut, Universität Bonn, Germany — [2]Institut für Angewandte physik, Universität Bonn, Germany
Fiber cavities are an attractive platform for optomechanical experiments as they can combine direct fiber-coupled optical access, small cavity lengths, high optical finesse, and an open resonator volume. Direct laser writing allows for a fast and flexible way to add polymer drums as mechanical resonators directly on the end facets of a fiber cavity. These membrane-in-the-middle systems show a rather large optomechanical coupling strength despite of the low reflectivity due to the maximized intensity differences on the two membrane interfaces. A disadvantage of direct laser written structures are the comparatively large mechanical losses of the used resist, which limit the mechanical quality factor of the membranes to several hundred at cryogenic temperatures. Therefore, we are interested how the deposition of different dielectric layers influences the optomechanical response of the polymer membranes. By using materials with high young's modulus, like MgF_2, we aim to reduce overall mechanical losses and therefore increase the optomechanical response.

DS 12.38   Wed 17:00   P3

IST 312 - an unconventional phase change material? — •Maria Häser, Peter Kerres, Sophia Wahl, Carl-Friedrich Schön, and Matthias Wuttig — I. Physikalisches Institut (IA), RWTH Aachen University, 52056 Aachen Germany
Chalcogenide-based Phase Change Materials (PCM) are a prominent candidate for energy-efficient memory devices. This material class shows a significant difference in its optical properties between the amorphous and crystalline phases: The former phase shows more insulating characteristics. In contrast, the almost metallic properties characterise the crystalline state. However, enabling fast switching between insulators and a real metal would broaden the field of application of PCMs.

In this study, the unusual phase change material In_3SbTe_2 (IST) has been investigated, which shows a metallic-like behaviour in its crystalline phase. The dielectric functions of both phases were determined using optical measurements (FTIR, Ellipsometry). Additionally, DFT calculations and XRD measurements were performed to better understand the unusual property change.

DS 12.39   Wed 17:00   P3

Characterization of the interaction of acrylic polymers with gold and silica surfaces — •Sascha Jan Zimmermann, Philipp Moritz, and Wolfgang Maus-Friedrichs — Clausthal Centre of Material Technology, Clausthal University of Technology, Agricolastr. 2, 38678 Clausthal-Zellerfeld
Adhesives play a key role in the 21st century. In particular, hybrid material composites can be joined in this way while saving weight. To advance this technology, a fundamental understanding of adhesive interactions, particularly to metal (oxide) substrates, is required.

In order to investigate these interactions, nanometer thin planar polymer films were deposited on the model substrates of silicon oxide and gold. This was done for the polymers poly(methyl methacrylate) and poly(glycidyl methacrylate) applying a spin coating process. X-ray photoelectron spectroscopy (XPS), Metastable Impact Electron Spectroscopy (MIES) and Ultraviolet photoelectron spectroscopy (UPS) were used to analyze the chemical interactions at the interface.

In the case of PMMA, the XPS measurements show the presence of a caboxylate ion, which indicates probable ionic interactions. A varying chemical shift and the changes in the MIES spectra indicate additional hydrogen bonds. In the case of PGMA, no interactions were detected by the applied measurement methods.

DS 12.40   Wed 17:00   P3

Photoinduced charge injection into single-layer WSe2 via deposited dye molecules — •Tim Völzer[1,2], Alina Schubert[1,2], Julian Schröer[1], Rico Schwartz[1], Tobias Korn[1,2], and Stefan Lochbrunner[1,2] — [1]Institute of Physics, University of Rostock, Albert-Einstein-Str. 23, 18059 Rostock, Germany — [2]Department "Life, Light and Matter", University of Rostock, Albert-Einstein-Str. 25, 18059 Rostock, Germany
The deposition of molecules allows the functionalization of 2D semiconductors as well as the fabrication of hybrid structures exhibiting charge separation after optical excitation that can be exploited in optoelectronic devices. Here, we investigate the charge transfer from optically excited molecules of the dye Perylene Orange (PO) into a monolayer of tungsten diselenide ($1L$-WSe_2) by means of low-temperature micro-photoluminescence spectroscopy: In comparison to the blank $1L$-WSe_2, the proportion of charged trion versus neutral exciton emission is expected to change as the PO molecules are deposited and excited. In contrast, when reducing the pump photon energy below the PO absorption band, the emission spectrum would remain identical. Thus, we aim to control the light-induced charge injection into the WSe_2 by tuning the pump wavelength.

DS 12.41   Wed 17:00   P3

Theoretical insights into the monolayer adsorption and characterization of HB238 Merocyanine on Ag(100) surface — •Ritu Tomar, Thomas Bredow, Anna Kny, and Moritz Sokolowski — Clausius Institute of Physical and Theoretical Chemistry, University of Bonn, Germany
Merocyanines (MCs) are intriguing compounds that can be used as efficient absorbers for organic solar cells. We studied the adsorption of HB238 merocyanine on the surface of Ag (100) using STM and SPA-LEED experiments, which

suggested that HB238 self-organizes as chiral tetramers upon adsorption. The molecular structure was significantly different from the typical configuration in the bulk phases of HB238. It is critical to control the structure and morphology of merocyanine films to enhance light absorption and optimize their optoelectronic properties. Therefore, we performed quantum chemical calculations to corroborate our experimental findings. Initially, we screened the HB238 conformers and used the most stable structure to determine the optimal adsorption orientation of HB238 on the Ag surface using the semi-empirical method GFN1-XTB in DFTB+. HB238 preferentially adheres face-on to the Ag surface. Next, we optimized the tetramer models at the DFT level to analyze the assembly of chiral tetramers while maintaining supercell lattice constant values, as in the experiment. We then relaxed the HB238 molecules on the Ag 3-layer slab model and fixed the bottom two layers using the GGA method in VASP. However, rapid and effective system convergence was achieved only using the ASE/LBFGS optimization algorithm.

DS 12.42   Wed 17:00   P3

Modelling liquid flow through nanopores on the nanoscale — •Rustam Durdyyev[1], Christian R. Wick[1], and Ana-Sunčana Smith[1,2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, PULS Group, Institute for theoretical physics, Interdisciplinary Center for Nanostructured Films (IZNF), Cauerstrasse 3, 91058 Erlangen, Germany — [2]Division of Physical Chemistry, Ruder Bošković Institute, Zagreb, Croatia

Liquid chromatography is one of the most important separation techniques and has proceeded mainly along empirical knowledge from the expansive collection of experimental data by using chromatographic methods, spectroscopic methods and technical innovations in column packing, particle technology and equipment design. However, a classic liquid chromatography column, is a cylinder densely packed with mesoporous silica particles whose surface has been mostly chemically modified. In this work, we investigated the physisorption of water to functionalized silica surfaces and hydrophilicity properties of surface by molecular dynamics simulations. We built on previously gathered knowledge on chromatography to establish a unified picture of stationary phase and solute mobility in liquid chromatography. In analogy to previous studies, we utilized a crystalline SBA-15 structure as starting point for our modeling approach. Furthermore, we investigate the effect of functionalization using different loadings with silanol group (Si-OH) and trimethylsilyl groups (O-SI-(CH3)3). With this strategy, we hope to understand the effect of functionalization of silica on the physisorption of water molecules at the nanometer scale.

DS 12.43   Wed 17:00   P3

Optimizing two-dimensional materials for biomolecule detection using machine learning techniques — •Calin-Andrei Pantis-Simut[1,2,3], Amanda Teodora Preda[1,2,3], Nicolae Filipoiu[1,2], and George Alexandru Nemnes[1,2,3] — [1]Horia Hulubei National Institute of Physics and Nuclear Engineering (IFIN-HH), Str. Reactorului no.30, P.O.BOX MG-6, Magurele, Romania — [2]University of Bucharest, Faculty of Physics, 077125 Magurele-Ilfov, Romania — [3]Research Institute of the University of Bucharest (ICUB), Sos. Panduri 90, Bucharest Romania.

The problem of correctly identifying the biomarkers associated with specific pathologies is of great interest nowadays for rapid diagnoses. The transport properties of different active layers like beta-arsenate, phosphorene, graphene, or Al-doped MoSe2 were investigated in the presence of certain biomolecules. Additionally, predictions of biomolecular compounds with tunable gaps were reported as well as carbon nanotube-based. Our study brings a detailed analysis of 2D semiconductor heterostructures in contact with biomarkers of respiratory diseases, which exhibit large tunabilities in transport properties. As a first step, by using DFT simulations, the electronic properties of the systems are analyzed under different doping conditions and nanostructuring. In a second step, a large number of systems will be considered for transport calculations and the results will define the input for machine learning procedures. This involves the mapping between structural information and transport properties. In the end, an analysis of the sensor's limit of detection and regeneration is performed.

DS 12.44   Wed 17:00   P3

Microstructure investigation of pulsed laser deposited GeTe-Sb$_2$Te$_3$ heterostructures — •Sonja Cremer[1], Lennart Voss[2], Nils Braun[1], Lorenz Kienle[2], and Andriy Lotnyk[1,3,4] — [1]Leibniz Institute of Surface Engineering, Leipzig — [2]Faculty of Engineering, University of Kiel — [3]Laboratory of Infrared Materials and Devices, Ningbo University — [4]College of Physics and Optoelectronic Engineering, Harbin Engineering University

Heterostructured phase change materials are an auspicious candidate to overcome high power consumption and resistance drift, hindering the implementation of Ge-Sb-Te based thin films for neuromorphic computing. Aiming at future systematic performance improvement, the impact of deposition parameters on the microstructure of GeTe-Sb$_2$Te$_3$ heterostructures (HSs) was investigated. HSs were grown at RT onto SiO$_2$/Si by PLD. Combining advanced TEM with XRD the microstructure was investigated in-depth. Energy and number of laser pulses affect the layer thickness and composition. The low energy and number

of pulses lead to pronounced intermixing and hence to the formation of a single GeSb$_2$Te$_4$ layer. Besides, the local structure of the layers within the HS differs. While GeTe layers are amorphous, Sb$_2$Te$_3$ layers are polycrystalline and contain nanocrystals featured by varying sizes, defects and multiple phases. Thus, deposition parameters mainly affect the morphology and chemical composition of GeTe-Sb$_2$Te$_3$ HSs. However, the main factor influencing the crystallinity of the HS layers is the alloy itself. Financial support by the DFG (No. 445693080) is acknowledged. We thank A. Mill for assistance in FIB preparation.

Dynamics of ion beam-induced defects in phase-change materials investigated by in-situ optical measurements — •Sebastian Gratz, Marcel Buch, Martin Hafermann, and Carsten Ronning — Institute of Solid State Physics, Friedrich-Schiller-Universität Jena, 07743 Jena, Germany

Phase-change materials (PCMs) provide the ability of reversible, repeatable and rapid switching between amorphous and crystalline states. These transformations are accompanied with drastic changes of the electrical and optical properties, which is already been used in rewritable optical data storage or phase-change electronic memory. The transitions can be triggered by external thermal, optical, or electrical stimuli. The most extensively studied PCMs are pseudo-binary (GeTe)$_m$(Sb$_2$Te$_3$)$_n$ chalcogenide compounds (m, n being integer values), short GST. Ion irradiation was recently introduced to induce structural disorder and amorphize initially crystalline GST films. There are multiple studies that investigated the effect of defect engineering of GST compounds. However, there is still a lack of understanding of the dynamic effects, such as dynamic annealing of defects during the ion irradiation process. Furthermore, the direct impact of the specific GST stoichiometry on the ion-beam induced disorder has not been observed yet. Thus, we investigated the dynamics of defect formation for different GST stoichiometries, such as Ge$_1$Sb$_2$Te$_4$ (m=1, n=1), Ge$_1$Sb$_4$Te$_7$ (m=1, n=2), and Ge$_2$Sb$_2$Te$_5$ (m=2, n=1), via in-situ optical measurements during ion irradiation at different temperatures.

DS 12.46   Wed 17:00   P3

Preparation and characterization of Cu-Te phases using focused ion beam — •Nils Braun[1], Vladimir Roddatis[2], Agnes Mill[1], Sonja Cremer[1], Hagen Bryja[1], Lennart Voss[3], Lorenz Kienle[3], and Andriy Lotnyk[1,4,5] — [1]Leibniz Institute of Surface Engineering e.V. (IOM) — [2]GFZ German Research Centre for Geosciences — [3]Institute for Materials Science, Faculty of Engineering, University of Kiel — [4]Laboratory of Infrared Materials and Devices, The Research Institute of Advanced Technologies, Ningbo University — [5]College of Physics and Optoelectronic Engineering, Harbin Engineering University

In this work, we prepared different nanoscale Cu-Te phases from Cu - Sb$_2$Te$_3$ system using FIB. Copper chalcogenides have shown promising thermoelectric properties, e.g. high efficiency and tunability. Sb$_2$Te$_3$ thin layers are epitaxially grown on p-type Si (111) substrates and polycrystalline Sb$_2$Te$_3$ thin film are grown on a SiO$_2$ coated wafer using PLD. A standard cross-section FIB preparation method is used. Samples are investigated using advanced TEM methods and XRD. Dependent on beam current used during FIB lamella preparation and Sb$_2$Te$_3$ layer thickness, hole formation in the Cu layer, thickness change and chemical changes of the Sb$_2$Te$_3$ layers are observed. In specimen prepared from the heated samples Sb$_2$Te$_3$ and Cu-Te grains are found. In polycrystalline Sb$_2$Te$_3$ specimen the intercalation of Cu and formation of new Cu-Te phases is observed. We thank P. Hertel for magnetron sputtering. We acknowledge the financial support by the German Research Foundation (DFG 448667535).

DS 12.47   Wed 17:00   P3

Investigation of the insights of a TiN-PEALD process in a remote capacitively coupled plasma ALD reactor — •Jan Biedinger, Jan-Michael Schmalhorst, and Günter Reiss — Bielefeld University, Faculty of Physics, Germany

Atomic Layer Deposition (ALD) is a deposition technique of great interest due to precise and reproducible layer control, large-area uniformity and conformal coating. As it bases on chemical surface reactions, it is important to understand the mechanism of an ALD process. In the presented study, the effect of different process parameters (temperature, plasma power, plasma pulse length, NH$_3$ flow, plasma pressure) was studied in a titaniumnitride (TiN) plasma-enhanced ALD process, consisting of sequential pulsing of tetrakis(dimethylamido)titanium (TDMAT) and a NH$_3$ plasma. X-ray reflectivity and 4-point probe measurements were performed to determine the growth rate, roughness, density and electrical resistivity of all TiN films, respectively. Additionally, Auger electron spectroscopy revealed information about the chemical composition. By combining in-situ mass spectrometry data, where plasma species as well as reaction products could be identified during the process, with these ex-situ results, the process could be described in more detail. During the NH$_3$ step, the release of dimethylamine groups was observed, which decreased gradually with time. This correlates with the decline of carbon content by increasing the NH$_3$ step time. Moreover, it was observed that the plasma species (hydrogen and nitrogen radicals) seems to be responsible for decreasing the oxygen content and hence, improving thin film quality.

DS 12.48 Wed 17:00 P3

Epitaxial growth of $Ag_xCu_{1-x}I$ on Al_2O_3 (0001) — •E. Krüger[1], V. Gottschalch[2], G. Benndorf[1], R. Hildebrandt[1], A.L. Pereira[1], M. Bar[1], E. Abo El Fadl[1], S. Blaurock[2], S. Merker[2], C. Sturm[1], M. Grundmann[1], and H. Krautscheid[2] — [1]Universität Leipzig, Felix-Bloch-Institut für Festkörperphysik, Germany — [2]Universität Leipzig, Institut für Anorganische Chemie, Germany

Copper iodide (CuI) and related alloy compounds are of great interest as suitable materials for applications in fully transparent optoelectronic devices. While CuI exhibits intrinsic p-type conductivity with excessive high hole densities typically around $10^{18} - 10^{19}$ cm^{-3}, it was recently shown that the carrier density can be strongly reduced for $Ag_xCu_{1-x}I$ alloy and even n-type conductivity can be achieved for high Ag contents [1]. Here we present the epitaxial growth of $Ag_xCu_{1-x}I$ thin films on Al_2O_3 (0001) substrates using sublimation technique [2]. We demonstrate that $Ag_xCu_{1-x}I$ thin films with $x \leq 0.5$ exclusively exhibit the zincblende γ-phase, while a coexistence of zincblende γ- and wurtzite β-phases is observed for Ag-rich alloy compositions. In addition we provide the epitaxial relationships between the different $Ag_xCu_{1-x}I$ phases and the Al_2O_3 substrate. Moreover, we present another deposition approach based on a solid-state reaction between CuI and AgI, which allows the preparation of single-phase γ-$Ag_xCu_{1-x}I$ films up to $x = 0.7$.

Growth of CoO Thin Films for Application in Superconductor - Magnet Heterostructures — •Amy McGlinchey — Trinity College Dublin, Ireland

Cobalt monoxide, CoO, is an antiferromagnet (AF) with a Néel temperature of 293K. It is utilised to pin the magnetisation of Co layers via exchange bias and is employed in magnetic heterostructures. The interaction between ferromagnet (F) and AF layers is predicted to generate long-range spin-triplet superconductivity in F-S-AF heterostructures [1]. CoO is a good candidate for the AF due to its low Néel temperature, which facilitates in-field cooling through the transition improving magnetic homogeneity. For the most part, CoO is synthesized by the oxidation of Co thin films or using techniques such as spray pyrolysis and pulsed laser deposition. In this work, we focus on the growth of CoO by molecular beam epitaxy, investigating the crystalline quality of the CoO as a function of deposition conditions. We have optimised these conditions to grow single crystalline CoO(100) thin films on MgO(100) substrates. As a second step towards a F-S-AF heterostructure, we also investigate the superconducting properties of Nb grown on CoO films. Due to the proximity effect, the properties of the niobium - especially at low thickness relevant to heterostructures - will be influenced by the CoO magnetic and interface structure [2]. 1. L. G. Johnsen et al., Phys. Rev. B, 103, L060505 (2021). 2. G. A. Bobkov et al., Phys. Rev. B, 106, 144512 (2022).

DS 12.50 Wed 17:00 P3

Potential of La-doped SrTiO3 thin films grown by metal-organic vapor phase epitaxy for thermoelectric applications — •Mohamed Abdeldayem[1], Aykut Baki[1], Carlos Morales Sánchez[3], Jan Ingo Flege[3], Detlef Klimm[1], Andreas Fiedler[1], Oliver Bierwagen[2], and Jutta Schwarzkopf[1] — [1]Leibniz Institut für Kristallzüchtung, Berlin, Germany — [2]Paul Drude Institut für Festkörperelektronik, Berlin, Germany — [3]Brandenburgische Technische Universität Cottbus, Brandenburg, Germany

Conversion of waste heat energy into electrical energy by exploiting the thermoelectric effect in solids promises a great contribution to energy harvesting concepts. However, most thermoelectric materials use toxic Pb or Te. Recently, La-doped SrTiO3 has gained a lot of interest as a potential candidate for thermoelectric devices for its good thermoelectric properties, chemical and thermal stability. In this paper, we report the homoepitaxial growth of La-doped SrTiO3 thin films by metalorganic vapor phase epitaxy (MOVPE) technique, which works at high oxygen partial pressures and offers upscaling potential for industry. The adjustment of charge carrier concentration, necessary for thermoelectric power factor optimization, was performed by introducing a defined amount of the metal-organic precursor La(tmhd)3 and tetraglyme to the liquid precursor solution. X-ray diffraction and atomic force microscopy verified a pure perovskite phase with high structural quality. The electrical conductivity increases linearly with the La concentration in the gas phase, which is attributed to the substitution of La+3 ions on the Sr+2 sites inferred from photoemission spectroscopy.

DS 12.51 Wed 17:00 P3

Ultrathin alumina membrane: A new opportunity for constructing stable sodium metal anodes — •Jiajia Qiu, Changfan Xu, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Unstable solid electrolyte interphase (SEI) remains a major bottleneck for sodium metal batteries due to the mossy or dendritic growth of Na in the repetitive stripping/plating process. Recently, nanostructured modification of Na and Al2O3 coatings have been reported as two effective solutions to address this is-

sue. Accordingly, with almost identical pore regularity and precisely controlled geometrical structure, ultrathin alumina membrane (UTAM) is utilized as a functional layer to effectively protect the Na anode of Na-metal batteries for the first time in this work. The mossy or dendritic growth of Na has been suppressed due to the UTAM protection, resulting in a uniform electrodeposition interface. UTAM significantly improved the Coulombic efficiency while avoiding short circuit risks. And it has the potential to be applied to other metal anodes. The novel design of a UTAM-protected metal Na anode may bring in new opportunities for next-generation high performance Na metal batteries.

DS 12.52 Wed 17:00 P3

Contact printed micro circuit boards for thermoelectric circuits in van der Waals high temperature twisted cuprate heterostructures — •Sanaz Shokri[1,2], Christian N Saggau[1], Kornelius Nielsch[1,2], and Nicola Poccia[1] — [1]Institute for Metallic Materials, IFW Dresden, Dresden,Germany, IFW Dresden — [2]Institute for Materials Science, Dresden University of Technology

Recently, thermoelectric measurement has been established as an indicator of the topological nature of material due to its sensitivity to the Berry curvature. Nernst effect, which is defined as a generation of transverse electric field by a longitudinal temperature gradient in the presence of a magnetic field, in particular, is a powerful tool to investigate the area above superconductivity transition temperature where the transverse electrical signals become very small. Twisted Bi2Sr2CaCu2O8+δ (BSCCO) van der Waals heterostructures have exhibited topological superconductivity. Nevertheless, the BSCCO is too fragile to make a complex circuit like thermoelectric. Therefore, we developed the whole thermoelectric circuit like Seebeck and Nernst, embedded within inorganic SiN so called nanomembrane and transferred it on the optimally doped BSCCO flake inside the Ar-filled glovebox to encapsulate the BSCCO flakes and contact it at the same time. We used Pt as a heater and gold as the thermocouples and will calibrate our measurements based on the heat losses through a thermal insulating substrate and nanomembrane as well.

DS 12.53 Wed 17:00 P3

Preparation and characterization of Zn1-xMgxO thin films obtained by the aerosol deposition method for UV radiation detector — •Vadim Morari — Techical University of Moldova, D. Ghitu Institute of Electronic Engineering and Nanotechnologies, Chisinau, Republic of Moldova

Zn1-xMgxO ternary oxide solutions with wide band gap were prepared by the aerosol spray deposition method [1] using zinc acetate and magnesium acetate as precursors. This technique offers the possibility of rapid deposition of homogeneous thin films with good electrical and optical properties. It is suitable for growing high-quality thin films on Si, quartz, glass or sapphire substrate, with relatively large areas at low cost due to vacuum-free equipment, low temperatures during deposition, low defect density and low environmental impact. The obtained thin films were characterized by scanning electron microscopy (SEM), energy dispersive X-Ray analysis (EDX), X-Ray Diffraction (XRD), Raman spectroscopy and optical absorption spectroscopy. The investigation of photosensitivity revealed that multilayer ZnMgO structures with different Mg content are more sensitive than single-layer films in a wide spectral range from visible to the ultraviolet (UV-C) radiation.

Heterostructure diodes based on reactively co-sputtered $Ag_xCu_{1-x}I$ thin films — •Jorrit Bredow, Sofie Vogt, Christiane Dethloff, Holger von Wenckstern, and Marius Grundmann — Universität Leipzig, Felix-Bloch-Institut, Germany

Copper iodide (CuI) is a transparent p-type semiconductor that exhibits high hole mobilities of up to 25 cm^2/Vs in polycrystalline thin films[1]. This renderes CuI an interesting candidate for the fabrication of transparent heterostructure diodes, such as p-CuI/n-ZnO[2], or p-CuI/n-AgI[3]. CuI further exhibits a low resistivity, which was shown to be increased with an increasing fraction of silver (Ag) in $Ag_xCu_{1-x}I$ thin films[4]. Moreover, a transition from p-type to n-type material of the $Ag_xCu_{1-x}I$ thin films for $x \approx 0.5$ was observed[4]. However, the $Ag_xCu_{1-x}I$ thin films were prepared with the Bädeker method, i.e. the iodization of metallic Ag_xCu_{1-x} thin films.

We present transparent heterostructure diodes based on the ternary compound $Ag_xCu_{1-x}I$. The $Ag_xCu_{1-x}I$ thin films were deposited using reactive co-sputtering of metallic Cu and Ag in Ar and I atmosphere. The feasibility of pn-heterojunction diodes with varying silver content is presented.

SnTe topological insulator thin film for field-effect transistors — •Sepideh Izadi, Negin Beryani Nezafat, and Gabi Schierning — Department of physics, Experimental physics, Bielefeld University, 33615, Bielefeld, Germany
Topological insulators (TIs) as a new class of quantum materials are one of the potential interests for device fabrication. The unique electrical characteristics of TIs arises from robust metallic states passing through the bulk semiconducting band gap within the material. These surface states with high electrical mobility are considered as an efficient factor regarding high performance transistor. We herein present SnTe topological insulator as a potential candidate for active layer in field-effect transistor (FET). In this work the results of SnTe transistor device fabrication is reported using bottom gate approach. Therewith, Si3N4 and Al2O3 are applied as gate insulating material which are deposited using magnetron sputtering and atomic layer deposition (ALD), respectively. The provided findings and analysis in this work paves the way for SnTe electrical device characterization.

DS 12.56   Wed 17:00   P3
Electric field induced laser-assisted polarization switching dynamics in ferroelectric thin films — •Rekikua Sahilu Alemayehu[1], Matthias Rössle[2], and Matias Bargheer[1,2] — [1]Institute for Physics & Astronomy, University of Potsdam, Karl-Liebknecht-Str 24-25, 14476 Potsdam, Germany — [2]Helmholtz Zentrum Berlin, Albert-Einstein-Str. 15, 12489 Berlin, Germany
Nucleation and growth of domains with opposite polarization moderates the electric field-induced polarization reversal process in ferroelectric materials. Accordingly, the domain wall velocity governs the timescale of polarization switching. Achieving the ultimate switching time in ferroelectrics is a fundamental quest to improve the device response time. Here we show laser-assisted polarization switching dynamics in metal-ferroelectric-metal heterostructure via heat and strain waves induced by a femtosecond laser pulse.

DS 12.57   Wed 17:00   P3
Engineering Vertical Memristive Devices with TMDC Thin Films — •Anna Linkenheil[1,2], Theresa Scheler[3,2], Ole Gronenberg[4], Hendrik Gross[4], Michaela Blum[3,2], Tzvetan Ivanov[1,2], Benjamin Spetzler[1], Frank Schwierz[1], Peter Schaaf[3,2], Lorenz Kienle[4], and Martin Ziegler[1,2] — [1]Micro- and Nanoelectronic Systems, Faculty of Electrical Engineering and Information Technology, TU Ilmenau, Ilmenau, Germany — [2]Institute of Micro- and Nanotechnologies, MacroNano*, TU Ilmenau, Ilmenau, Germany — [3]Materials for Electrical Engineering and Electronics, Faculty of Electrical Engineering and Information Technology, TU Ilmenau, Ilmenau, Germany — [4]Synthesis and Real Structure, Faculty of Engineering, Kiel University, Kiel, Germany
Transition metal dichalcogenides (TMDCs) represent a class of promising materials for memristive devices, which become increasingly important for emerging information processing approaches. In particular, homogeneous thin-films of few layers thickness have advantageous properties for memristive devices, such as excellent scaling behavior combined with the potential integration into planar wafer technology. Here, we assess the electrical properties of sputtered MoS_2 based devices and analyze the material. The devices were fabricated in a 4-inch wafer thin film technology, allowing for a systematic electrical investigation. Various electrode materials as well as oxidation treatments and their respective influences on device performance are evaluated using Transmission Electron Microscopy (TEM), revealing probable switching mechanisms and their origin.

DS 13: Optical Analysis of Thin Films I

Time: Thursday 9:30–11:00   Location: SCH A 316

Invited Talk   DS 13.1   Thu 9:30   SCH A 316
Towards Catalytic Applications of Infrared Laser Polarimetry — •Andreas Furchner[1] and Karsten Hinrichs[2] — [1]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Division Energy and Information, Schwarzschildstraße 8, 12489 Berlin, Germany — [2]Leibniz-Institut für Analytische Wissenschaften – ISAS – e.V.
Infrared (IR) polarimetry and ellipsometry are well-established non-destructive spectroscopic techniques for studying the refractive and absorptive properties of thin films and surfaces with monolayer sensitivity. This spectral range is particularly suited for investigating chemical composition, molecular interactions, anisotropy, conductivity, as well as changes and reactions at surfaces and interfaces.

The incorporation of quantum cascade lasers (QCLs) in novel IR polarimeter designs has pushed the boundaries of the achievable spatial and temporal resolution well into the sub-mm and sub-second range, respectively. Laser-based polarimeters thus enable hyperspectral and time-resolved amplitude–phase measurements with novel application potential. Probing individual laser pulses delivers time resolutions of 10 μs, spectral sweeps in 100 ms, and hyperspectral maps in minutes.

This presentation focuses on recent instrumental developments, such as the combination of QCLs with single-shot designs, that pave the way towards the application of IR laser polarimetry in thin-film catalysis. Here, surface reactions have to be studied *in situ* and *operando* in order to resolve the evolution of surface species and temporary adsorbates.

DS 13.2   Thu 10:00   SCH A 316
Large area functional thin film properties mapping using in-line hyperspectral imaging during roll-to-roll magnetron sputter deposition — Florian Gruber[2], Patrick Schlenz[1], Steffen Bieder[4], Eric Schneider[4], Jolanta Szelwicka[1], Julio Hernandez[3], Christian Sternemann[4], and •Steffen Cornelius[1] — [1]Fraunhofer FEP, Winterbergstrasse 28, 01277 Dresden, Germany — [2]Fraunhofer IWS, Winterbergstrasse 28, 01277 Dresden, Germany — [3]Norsk Elektro Optikk AS, Ostensjoveien 34, 0667, Oslo, Norway — [4]Fakultät Physik/DELTA, Technische Universität Dortmund, August-Schmidt-Straße 1, 44227 Dortmund, Germany
Roll-to-roll (R2R) coating processes of flexible substrates are established for cost-efficient thin film functional materials production for applications like energy efficient windows and solar cells. However, even small variations of thickness and/or composition homogeneity may affect the final product performance. Due to the high throughput of coated surface area in R2R coating the ex-situ material characterization is very time consuming, often destructive and offers no possibility for in-situ process monitoring and/or quality control.

The NanoQI EU-H2020 project develops a powerful in-line technology combining hyperspectral imaging with X-ray reflectivity via a machine learning algorithms, enabling large area (0.5m x 100m) high resolution (<1mm) high speed (m/min) thin film properties imaging. The combinatorial thickness mapping of a binary metal-oxide double layer (thickness up to 120nm) on PET substrate will be discussed in detail - aiming to achieve a thickness accuracy of only a few %.

DS 13.3   Thu 10:15   SCH A 316
Developing an open source ellipsometry analysis workflow — •Florian Dobener[1], Marius Müller[2], Carola Emminger[1,3], Chris Sturm[3], Tamás Haraszti[4], Marius Grundmann[3], and Sandor Brockhauser[1] — [1]Department of Physics, Humboldt-Universität zu Berlin, Germany — [2]Institute of Experimental Physics I, Justus-Liebig-University Giessen, Germany — [3]Felix-Bloch Institut für Festkörperphysik, Universität Leipzig, Germany — [4]DWI Leibniz Institute for Interactive Materials, Aachen, Germany
Optical and geometric characteristics of multilayer material stacks are not accessible from ellipsometric data in a direct way. The optical model applied to the data is the key, which allows understanding of these properties. Accordingly, there exist a lot of different software tools to construct such models, which vary in their model implementation and are often closed source. Comparing, reproducing and using data from literature can therefore be challenging. Here, we present the open source ellipsometry software pyElli. It implements specific dispersion models from manufacturers and from literature. Furthermore, it allows for easy construction of non-standard measurement tasks, e.g. combining different measurements or using uncommon measurement parameters. Together with the recent NeXus ellipsometry standard, the NOMAD research data management platform and its interactive Jupyter based toolkit, we show how pyElli contributes to an open ellipsometry workflow. This open workflow is a standardised and reproducible way of analysing ellipsometry data and adds to the goal of making ellipsometry data FAIR.

DS 13.4   Thu 10:30   SCH A 316
IR dual-comb polarimetry of anisotropic nanofibers — •Karsten Hinrichs[1], Brianna Blevins[2], Andreas Furchner[3], Nataraja Sekhar Yadavalli[2], Sergiy Minko[2], Raphael Horvath[4], and Markus Mangold[4] — [1]Leibniz-Institut für Analytische Wissenschaften - ISAS e.V., Schwarzschildstraße 8, 12489 Berlin, Germany — [2]Department of Chemistry, The University of Georgia — [3]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Division Energy and Information, Schwarzschildstraße 8, 12489 Berlin, Germany — [4]IRsweep AG, Laubisruetistrasse 44, 8712 Staefa, Switzerland
In this work an anisotropic nanofiber scaffold is investigated non-invasively under ambient conditions by infrared dual-comb polarimetry (IR - DCP). Amplitude and phase spectra at various azimuthal sample rotations are correlated with the orientation of characteristic vibrational transition dipole moments. IR - DCP is proven as a new method for the spectral analysis (here 1200 cm-1 to 1300 cm-1) of such anisotropic samples in very short measurement times (0.065 ms) at 1.4 cm-1 spectral resolution. Such capabilities are in particular interesting for imaging applications, time resolved studies and hyperspectral spectroscopy

of anisotropic samples. In difference to classical ellipsometry which measures phase differences, IR - DCP can measure s- and p-polarized phases separately. We acknowledge financial support by the EU through EFRE 1.8/13 and the Horizon 2020 grant 820419 and by the BMBF through CatLab (03EW0015A/B).

DS 13.5   Thu 10:45   SCH A 316

Orientation in thin spider silk films at silicon substrates evidenced by dichroic FTIR spectroscopy — •Martin Müller[1,2], Mirjam Hofmaier[1,3], Sarah Lentz[4], Thomas Scheibel[4], and Andreas Fery[1,3] — [1]Leibniz-Institut für Polymerforschung Dresden e.V., Institut für Physikalische Chemie und Physik der Polymere, Dresden, Germany — [2]Technische Universität Dresden, Lehrstuhl für Makromolekulare Chemie, Dresden, Germany — [3]Technische Universität Dresden, Lehrstuhl für Physikalische Chemie Polymerer Materialien, Dresden, Germany — [4]Universität Bayreuth, Lehrstuhl für Biomaterialien, Bayreuth, Germany

Biomedically relevant spider silk films were deposited on unscratched and parallelly scratched silicon substrates and checked for conformation and orientation by dichroic transmission (T-) and ATR-FTIR spectroscopy. Films (d=0-200 nm) were casted from hexafluoroisopropanol solutions of recombinantly engineered spider silk proteins. Both FTIR methods revealed little b-sheet (<10%) and much disordered structure (>80%) from Amide I band analysis. Dichroic ratios R of Amide I components close to isotropic films were found by T- and ATR-FTIR indicating no orientation. Whereas, silk films after swelling in MeOH vapor revealed higher b-sheet (>30%) and lower disordered structure amounts (<60%). By T-FTIR isotropic R values of Amide I components assigned to antiparallel b-sheet were found indicating no in-plane orientation, while ATR-FTIR revealed R values significantly deviating from isotropy indicating out-of-plane orientation. Orientation was independent on scratching and increased decreasing d.

DS 14: Thin Oxides and Oxide Layers

Time: Thursday 9:30–11:15   Location: SCH A 315

DS 14.1   Thu 9:30   SCH A 315

Strain effects of the electronic and magnetic properties of thulium iron garnet films — •Sibylle Gemming[1], Georgeta Salvan[1], Apoorva Sharma[1], Oana T. Ciubotariu[2], and Manfred Albrecht[2] — [1]Institute of Physics, TU Chemnitz — [2]Institute of Physics, U Augsburg.

Rare earth iron garnets are magnetic insulators, in which two structurally distinct iron centers form sublattices, which couple antiferromagnetically. The overall magnetization of the compounds results from the alignment of the local magnetic moments of the 4f electrons at the rare earth sites and is sensitive to external effects such as temperature and strain. We performed gradient-corrected density-functional calculations including spin-orbit and correlation corrections to study the property-thickness relation of thin thulium iron garnet films that had been grown epitaxially under tensile strain on a doped gallium gadolinium garnet substrate. We could rationalize the observed growth modes for different film thicknesses with strain arguments and correlate it with the observed electronic properties (Funding: DFG, GE 1202/12-1)

DS 14.2   Thu 9:45   SCH A 315

Optoelectronic Properties of Al-doped ZnO Films Prepared by ALD and Flash Lamp Annealing — •Guoxiu Zhang[1,2], Oliver Steuer[1], Yu Cheng[1], Yi Li[1], Kaiman Lin[1], Shengqing Zhou[1], Yufei Liu[2,3], and Slawomir Prucnal[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, Bautzner Landstrasse 400, Dresden, 01328, Germany — [2]Key Laboratory of Optoelectronic Technology & Systems (Chongqing University), Ministry of Education, Chongqing 400044, China — [3]Faculty of Science and Engineering, Swansea University, Swansea SA2 8PP, UK

Zinc oxide (ZnO) is a wide-band-gap semiconductor considered for transparent and flexible optoelectronics. Effective and controlled doping of ZnO can be realized by substitution Zn or O atoms with metal or non-metal elements like H, Al, Ga for n-type doping and e.g. group V elements for p-type doping. In this work, we have investigated the optoelectronic properties of *-doped ZnO with Al. 100 nm thick Al-doped ZnO (AZO) films were deposited on Si wafers by atomic layer deposition (ALD) varying the distance between Al-layers. After ALD process samples were annealed using ms-range flash lamp annealing (FLA) in either nitrogen or oxygen atmosphere. The highest carrier concentration estimated from Hall-effect measurements is 2.7 *1021 cm-3 and the resistivity is 8.8*10-4 Ωcm, for AZO films where the Al-*-layer is separated by 20-layers of Zn. In general annealing in N2 atmosphere promotes n-type doping while annealing in O2 leads to the formation of highly resistive films.

DS 14.3   Thu 10:00   SCH A 315

Strain Engineering of Buffer Layers: A Way to Overcome Film/Substrate Lattice Misfit — •Pia Henning[1], Ulrich Ross[2], Karen Stroh[1], Vitaly Bruchmann-Bamberg[1], and Vasily Moshnyaga[1] — [1]I. Physikalisches Institut, Georg-August-Universität Göttingen, Germany — [2]Institut für Materialphysik, Georg-August-Universität Göttingen, Germany

A fundamental problem in thin film physics is the film/substrate lattice misfit and the related epitaxial strain. An especially important role plays stress for perovskite manganites, e.g. colossal magnetoresistive $(La_{0.6}Pr_{0.4})_{0.7}Ca_{0.3}MnO_3$ (LPCMO), yielding a suppression of the metal-insulator and ferromagnetic phase transition for LPCMO thin films grown on standard perovskite substrates, like SrTiO3 (STO, tensile stress) and LaAlO3 (LAO, compressive stress). We propose a route to engineer the strain via LAO buffers epitaxially grown on STO substrates by means of metalorganic aerosol deposition to obtain epitaxial stress-free LPCMO films. By changing the LAO thickness in the range d_{LAO}~2-35 nm and precisely tuning the stress in it, an ideal lattice adjustment between LPCMO and LAO has been achieved. This allows us to grow stress-free epitaxial LPCMO/LAO/STO(100) thin and ultrathin (d_{LPCMO}~10 nm) films with bulk properties. The structure and microstructure of these films as well as the stress distribution within layers was studied by X-ray diffraction and high resolution transmission electron microscopy. A generalization of this method on other film/buffer/substrate combinations has been proposed.

DS 14.4   Thu 10:15   SCH A 315

Transfer and Thermal Processing of Freestanding Oxide Membranes — •Yu-Jung Wu, Varun Harbola, Sander Smink, Sarah C. Parks, and Jochen Mannhart — Max Planck Institute for Solid State Research, Heisenbergstraße 1, 70569 Stuttgart, Germany

Epitaxial films of complex oxides have gained interest due to their wide-ranging physical properties, including high-temperature superconductivity, magnetism, ferroelectricity, and multiferroicity. The conventionally grown single-crystalline oxide thin films are usually bound to their substrates, which imposes constraints on their properties and usage. Therefore, growth techniques have recently been developed that enable lifting-off freestanding complex oxide membranes by wet etching of oxide buffer layers. To achieve transfer of large-area oxide films, we have systematically studied growth and transfer of a variety of thin films, grown on aluminate and manganite wet-etchable buffer layers. Various oxide membranes were successfully transferred with good quality and up to 3x 2 mm2 area with minimal cracking. Furthermore, after thermal processing the stack of the transferred membrane on sapphire, the transferred membrane starts dewetting, yielding nanostructures. This work is not only expected to enable a wide range of oxide films to be transferred in high quality for fundamental studies and applications in oxide electronic devices but also serves as a starting point for crystalline nano-structuring of oxide materials.

DS 14.5   Thu 10:30   SCH A 315

Tungsten-oxide thin films characterized by Positron Annihilation Spectroscopy — •Vassily Vadimovitch Burwitz[1], Annemarie Kärcher[2,3], Lucian Mathes[1], Thomas Schwarz-Selinger[3], Maik Butterling[4], Eric Hirschmann[4], Maciej Oskar Liedke[4], Andreas Wagner[4], and Christoph Hugenschmidt[1] — [1]Heinz Maier-Leibnitz Zentrum, TU München — [2]TU München — [3]Max-Planck-Institut für Plasmaphysik, Garching bei München — [4]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiation Physics

For future nuclear fusion reactors it is foreseen that tungsten is used as inner wall cladding. Understanding the formation and behaviour of radiation induced defects in tungsten is therefore important for their safe operation. Tungsten monocrystal model systems are studied by positron annihilation Doppler-broadening spectroscopy (DBS) and positron annihilation lifetime spectroscopy (PALS) to foster the understanding of the type and evolution of these defects. Both methods are sensitive tools when examining the defect type and concentration. However, data obtained by either of these methods is influenced by any thin oxide film on the surface of a sample. Such a film is present on any tungsten sample exposed to air, therefore its effect on DBS and PALS results needs to be known for their correct interpretation. In this work we measured tungsten-oxide thin films grown by thermal and electro-chemical methods as well as by exposure to air by DBS and PALS. The DBS measurements were performed using a moderated β^+ emitter, the PALS measurements at an accelerator-based positron source.

DS 14.6   Thu 10:45   SCH A 315
Monitoring switching process in Fe_3O_4/STO heterostructures via in-situ instrument — •Yifan Xu[1], Mai Hussein Hamed[1,2], Connie Bednarski-Meinke[1], Asmaa Qdemat[1], Steffen Tober[1], Emmanuel Kentzinger[1], Oleg Petracic[1], and Thomas Brückel[1] — [1]Jülich Centre for Neutron Science (JCNS-2) and Peter Grünberg Institut (PGI-4), JARA-FIT, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — [2]Faculty of Science, Helwan University, 11795 Cairo, Egyp

The ability to tune magnetic oxide phases via redox reactions across their heterointerfaces could lead to useful spintronic and memristive device applications. By applying a small electric field, oxidation/reduction occurs at the heterointerface and leads to a reversible phase transition. In this talk, we present the preparation and characterization of epitaxial Fe$_3$O$_4$ thin films grown on TiO$_2$-terminated Nb:STO via pulsed laser deposition (PLD). Using magnetometry, we detect the Verwey transition; a strong indicator of the oxygen content in the Fe$_3$O$_4$ films. We observe the disappearance in the Verwey transition temperature with an applied positive electric field. This could be explained by oxygen diffusion through the interface which then leads to a reversible phase transition from Fe$_3$O$_4$(magnetite) to γ-Fe$_2$O$_3$(maghemite). Using ex-situ x-ray diffraction (XRD), we observe the structural transitions from (001) to (111) in the out-of-plane direction influenced by the applied voltage. Interestingly, by grazing-incidence small-angle X-ray scattering, we observe a change in the magnetite domain size for the sample after applying the electric field.

DS 14.7   Thu 11:00   SCH A 315
Engineering magnetic anisotropy by Rashba spin-orbit coupling in 3d-5d oxide heterostructures — •Megha Vagadia, Jaya Prakash Sahoo, Ankit Kumar, Suman Sardar, Tejas Tank, and D.S. Rana — 1Department of Physics, Indian Institute of Science Education and Research Bhopal, M.P. 462066, India

In recent times, Rashba spin-orbit coupling (SOC) has been successfully employed for the emergence of exotic phenomena at the quantum oxide interfaces. In these systems, the combined effect of charge transfer, broken symmetries, and SOC yields intriguing interfacial magnetism and transport properties. However, role of Rashba SOC, particularly without applied bias, in modulating magnetic anisotropy of oxide heterostructures is unexplored. Here, we provide insight into tuning transport phenomena by the charge transfer driven Rashba SOC in CaMnO3/CaIrO3 heterostructures. Rashba SOC remarkably enhances the anomalous Hall conductivity and reconstructs the Berry curvature. From the anisotropy magnetoresistance measurements, we demonstrate that Rashba SOC is instrumental in tailoring magnetic anisotropy where magnetization easy-axis rotates from the out-of-plane direction to the in-plane direction. The ability to tune Rashba SOC and resulting competing magnetic anisotropies provides a route to manipulate electronic band structure for the origin of non-trivial spin texture useful for spin-orbitronics applications.

DS 15: Optical Analysis of Thin Films II

Time: Thursday 11:15–12:45   Location: SCH A 316

Invited Talk   DS 15.1   Thu 11:15   SCH A 316
In-Situ Optical Investigation of Electrochemically Induced Conformational Changes at Solid Liquid Interfaces: A Source of new Electronic States — •Christoph Cobet — Linz School of Education, Center for Surface- and Nanoanalytics (ZONA), Johannes Kepler University, Altenbergerstr 69, A-4040, Linz, Austria

The electrical potential between an electrolyte and a solid electrode, whether it is a metal, semiconductor, polymer or a bio-membrane, could induce considerable changes in the conformational appearance. In biological systems such conformation changes are well-known e.g. as a control element for the chemistry on one or both sides of a membrane. In periodically ordered thin films or at surfaces, one can observe conformation changes at the atomic length scale which could induce new electronic properties. The interfacial electrical potential is in all cases a very versatile control element. On the one hand, it allows to change the chemical formation potential over a huge range which is otherwise only accessible for example by rather extreme temperature or pressure differences. On the other hand, it offers a very precise control of the thermodynamic equilibrium conditions. With the help of in-situ optical methods like spectroscopic ellipsometry (SE) and reflection anisotropy spectroscopy (RAS), we could study the interplay of the potential induced charge accumulation, the conformational changes and the evolution of (self) localized electronic states. The mechanisms will be discussed by two examples: The electrochemical doping and formation of polarons in polymers and the formation of surface quantum well states at a metal-electrolyte interface.

DS 15.2   Thu 11:45   SCH A 316
Singlet fission and triplet dynamics in pentacene embedded in a surface-anchored metal-organic framework — •Martin Richter[1], Zhiyun Xu[2], Philipp Ludwig[3], Pavel Kolesnichenko[1], Uwe Bunz[3], Christof Wöll[2], and Petra Tegeder[1] — [1]Physikalisch-Chemisches Institut, Universität Heidelberg — [2]Institut für Funktionelle Grenzflächen, Karlsruher Institut für Technologie — [3]Organisch-Chemisches Institut, Universität Heidelberg

It has been observed, that the rate of singlet fission in pentacene and the lifetime of the generated triplets strongly depend on the molecular arrangement.[1]

Here, a cofacial orientation of pentacene molecules is achieved by embedding them in a surface anchored metal-organic framework (SURMOF). Transient absorption spectroscopy has been used to analyze the ultrafast dynamics as well as long lived states after photoexcitation. The observed difference absorption spectra indicate, that after the initial excitation a singlet excited state generates a correlated triplet pair within a few picoseconds that retains singlet character. Subsequent dynamics show the formation of a long-lived species (47us) with triplet character. This exceeds by far the observed lifetime of triplets generated in pentacene thin films (10ns) and may enhance triplet harvesting capabilities in photovoltaic devices.[2]

Birefringence of orthorhombic DyScO3: Towards a terahertz quarter-wave plate — •Jingwen Li, Chia-Jung Yang, Jannis Lehmann, Nives Strkalj, Morgan Trassin, Manfred Fiebig, and Shovon Pal — D-MATL, ETH Zurich, Switzerland

The energy scale of THz light corresponds to plenty of the fundamental collective excitations in materials, such as phonons, magnons, and heavy fermions. This makes THz light an ideal tool to investigate the low-energy excitations and non-equilibrium processes in solid-state systems. With the growing interest in studying the aforementioned collective phenomena, manipulating the polarization of THz light becomes necessary. However, prevailing THz waveplates, such as quarter-wave plates (QWPs) for generating circularly polarized THz light, typically suffer from various problems, including bulky size, complex fabrication, or narrow working ranges. Here, we present a broadband THz QWP based on a 50-μm-thick (110)-cut orthorhombic DyScO$_3$ (DSO) crystal. We show a polarimetry measurement to verify the polarization of the output CP-THz light and prove that our DSO plate behaves like a QWP over a broad frequency range of 0.50-0.70 THz with a phase tolerance of ±3%. We believe that our results expand the choices of broadband THz QWPs, as well as the possibilities of simple and compact achromatic THz QWPs by combining DSO crystals. Most importantly, as a common substrate for growing various thin films, DSO shows its potential as a compact built-in broadband THz waveplate for thin film research with circularly polarized THz light. [1]

[1] Appl. Phys. Lett. **118**, 223506 (2021).

DS 15.4   Thu 12:15   SCH A 316
Temperature Dependence of Coherent Phonon Oscillations in Metavalently Bonded Solids — •Timo Veslin[1], Felix Hoff[1], Julian Mertens[1], Jonathan Frank[1], and Matthias Wuttig[1,2,3] — [1]I. Institute of Physics (IA), RWTH Aachen University — [2]Jülich-Aachen Research Alliance (JARA FIT and JARA HPC) — [3]PGI 10 (Green IT), Forschungszentrum Jülich GmbH

Femtosecond optical pump probe measurements are carried out in order to detect changes in the reflectivity of the material response of MBE grown metavalently bonded (MVB) materials on sub-ps timescales. MVB differs significantly from metallic, ionic and covalent bonding. Examination of reflectivity changes due to the coherent phonon response provides insight into the ultrafast lattice dynamics and relaxation of MVB materials. To this end, the mechanism of displacive excitation of coherent phonons (DECP) is used to analyse the highly symmetric A1 modes. The material response consists of the ultrafast carrier excitation and a slower carrier relaxation together with a damped harmonic phonon oscillation measured in the transient reflectivity trace. The temperature dependence of the frequency, lifetime and oscillation amplitude of the coherent phonon A1 mode in Sb2Te3, GeTe and Bismuth will be presented. This allows to identify phonon coupling effects and dephasing mechanisms, as well as the temperature dependence of phonon frequencies. Furthermore, the results are supported by optical and structural data recorded at room temperature. These measurements will help to better understand the MVB mechanism which governs phase change materials.

DS 15.5 Thu 12:30 SCH A 316

Identification of different polymorphs of a zone-cast perylene diimide derivative with low-frequency Raman and infrared scanning near-field microscopy — •Nadine von Coelln, Christian Huck, Niklas Herrmann, Petra Tegeder, and Jana Zaumseil — Institute of Physical Chemistry, Heidelberg University, Germany

Small-molecule organic semiconductors are prone to form multiple thin film polymorphs. As their charge transport characteristics may vary substantially, effective and fast polymorph characterization techniques are necessary. Here, zone-cast films of perfluorobutyl dicyanoperylenecarboxydiimide ($PDIF-CN_2$) were studied with X-ray diffraction (XRD), confocal low-frequency Raman mi-croscopy and infrared scanning near-field microscopy (IR-SNOM). Based on low-frequency Raman spectra and XRD, two different thin film polymorphs of $PDIF-CN_2$ were identified, which form depending on the solvents used for deposition. While confocal Raman microscopy is limited in the spatial resolution of areas, the near-field infrared technique (IR-SNOM) offers the unique possibility of both infrared microscopy and spectroscopy with a spatial resolution down to ~10 nm. We demonstrate that it is possible to discriminate between neighboring crystalline regions of the two $PDIF-CN_2$ polymorphs by means of IR-SNOM using slight differences in IR absorption. As a non-destructive technique, IR-SNOM may even enable in-situ investigations of thin semiconducting films in functional devices.

DS 16: Thermoelectric and Phase Change Materials; Layer Deposition

DS 16.1 Thu 11:30 SCH A 315

A Multiscale Simulation Method for Deposition Processes: Micrometer-scale Off-Lattice Film Growth with Atomistic Precision — •Erik E. Lorenz[1] and Jörg Schuster[2,1] — [1]Center for Mikrotechnologies, Chemnitz University of Technology, Chemnitz, Germany — [2]Fraunhofer Institute for Electronic Nano Systems ENAS, Chemnitz, Germany

We present a multiscale method for the simulation of thin film deposition processes such as PVD, CVD and ALD. By combining Kinetic Monte Carlo (KMC) methods for adsorption event sampling and Molecular Dynamics (MD) for adsorption simulation and nanostructure relaxation with a graph-based triangulating bulk-surface representation, fast and efficient highly-parallel surface growth simulations are facilitated.

The enhancement of KMC-MD coupling with a graph-based bulk-surface representation enables efficient subdomain decompositions, bulk KMC event insertions and removals, and the robust and constant-time update of connected subdomain. Using the same graph structure, the effects of further computational improvements such as incident particle ray tracing, surface diffusion and limited KMC time warping are shown.

We demonstrate the growth of atomistic copper seed layers on a Tantalum substrate for micrometer-scale electronic devices in parallelized simulation runs saturating over 1000 CPU cores, and compare it to established methods.

DS 16.2 Thu 11:45 SCH A 315

Characterization and optimization of MgZnO thin films with steep lateral composition gradient — •Laurenz Thyen, Max Kneiss, Holger von Wenckstern, and Marius Grundmann — Universität Leipzig, Felix-Bloch-Institut für Festkörperphysik, Linnéstraße 5, 04103 Leipzig, Germany

The materials magnesium- and zinc-oxide have been widely investigated in the past. Corresponding step graded ternary alloy thin films of $Mg_xZn_{1-x}O$ have been of great interest [1]. Pulsed laser deposition (PLD) has been used to grow laterally and vertically graded thin films [2]. The precise control of chemical composition is of great importance for possible applications. Additionally, in the course of miniaturization of electrical devices like wavelength-selective multi-channel UV photodetectors, a well-defined steep slope of the material gradient will be beneficial [3,4].

In this contribution the properties of $Mg_xZn_{1-x}O$ thin films with lateral compositional gradient grown by pulsed laser deposition will be discussed. In order to obtain information about the material composition of the thin films, energy-dispersed X-ray spectroscopy, spatially resolved ellipsometry and micro-photoluminescence spectroscopy measurements have been conducted. Moreover, steep lateral gradients with a slope of up to 20 % Mg/mm were realised.

Physical properties of $Ni_xCu_{1-x}I$ thin films deposited by magnetron co-sputtering — •Christiane Dethloff, Sofie Vogt, Daniel Splith, Holger von Wenckstern, and Marius Grundmann — Felix-Bloch-Institut, Universität Leipzig, Deutschland

The highly conductive, p-type semiconductor CuI is subject to various doping approaches to tailor optical and electrical properties [1-4]. As recently shown [5], doping CuI with Ni reduces its high hole density of up to 2×10^{19} cm^{-3} [4]. After surpassing a threshold of 15 % Ni content, a carrier conversion, as observed by Annadi *et al.*, turns the $Ni_xCu_{1-x}I$ alloy into an n-type semiconductor, which predestines $Ni_xCu_{1-x}I$ to fabricate p-n-homojunctions.

We present our investigations regarding morphology, electrical and possible ferromagnetic properties of $Ni_xCu_{1-x}I$ thin films with varying Ni contents. The deposition was conducted by reactive magnetron co-sputtering of metallic Cu and Ni in an iodine and argon athmosphere. X-ray and scanning electron mi-croscope as well as Hall-effect and conductivity measurements were used to investigate the thin films. First measurements yielded a low resistivity of 5×10^{-3} Ωm for x=0.035.

Self-assembled droplet etching during semiconductor epitaxy for versatile quantum structures — •Christian Heyn, Ahmed Alshaikh, and Robert Blick — Center for Hybrid Nanostructures (CHyN), University of Hamburg

As a fundamental extension of conventional epitaxy, we describe the integration of self-assembled top-down strategies into the bottom-up molecular beam epitaxy (MBE) of semiconductor quantum structures (QS). The samples are fabricated using standard solid-source MBE without any additional equipment. Ga, Al, or In droplets are formed on a GaAs or AlGaAs surface driven by the minimization of surface and interface energies in Volmer-Weber mode. The metal droplets drill self-assembled nanoholes into the semiconductor surface which is called local droplet etching (LDE). Afterwards, the nanoholes are filled with a material different from the substrate for the generation of QS. This presentation discusses the general mechanism of LDE, the influence of the process parameters on the density, size, and shape of the resulting nanoholes, as well as an intermixing with substrate material. For LDE with Ga droplets on AlGaAs, a crystalline wall formed around a nanohole represents a GaAs quantum ring. Further strain-free QS are created by filling of nanoholes drilled using Al droplets in AlGaAs with GaAs. The size and shape of the resulting QS is controlled by the initial nanohole, the amount of deposited material for hole filling, and capillary. Examples are QS that are shaped like the shell of a cone and vertically coupled quantum dot molecules.

DS 16.5 Thu 12:30 SCH A 315

Interplay of Glass Dynamics and Crystallization Kinetics of Photonic Phase Change Materials Sb2S3 & Sb2Se3 — •Felix Hoff[1], Julian Pries[1], Maximilian J. Müller[1], Eric N. Lensker[1], and Matthias Wuttig[1,2,3] — [1]I. Institute of Physics (IA), RWTH Aachen University — [2]Jülich-Aachen Research Alliance (JARA FIT and JARA HPC) — [3]PGI 10 (Green IT), Forschungszentrum Jülich GmbH

Due to their large bandgaps, the chalcogenide phase-change materials (PCM) antimony sulfide Sb2S3 and antimony selenide Sb2Se3 are interesting for photonic applications in the visible and telecommunication wavelength range. They are promising for photonic integrated circuits or tunable metasurfaces. While recent literature focuses on the optical properties and the resulting applications, a systematic quantification of the amorphous glass phase, as well as its influence on the process of crystallization under different conditions, is missing. In this work, both the standard glass transition and fragility of antimony sulfide are presented and discussed. Sb2S3 is found to crystallize from the undercooled liquid phase for all technologically relevant heating rates spanning over six orders of magnitude. In contrast, Sb2Se3 appears to show a glass transition only for higher heating rates. This can be used to explain the unusual temperature dependence of its crystallization mechanism in thin films.

DS 16.6 Thu 12:45 SCH A 315

Seebeck coefficient inversion in highly doped organic semiconductors — •Morteza Shokrani[1], Kai Xu[2], Tero-Petri Ruoko[2], Dorothea Scheunemann[1], Hassan Abdalla[2], Hengda Sun[2], Chi-Yuan Yang[2], Yuttapoom Puttisong[2], Nagesh Kolhe[3], José Silvestre Mendoza Figueroa[2], Jonas Pedersen[2], Thomas Ederth[2], Weimin Chen[2], Magnus Berggren[2], Samson Jenekhe[3], Daniele Fazzi[4], Martijn Kemerink[1,2], and Simone Fabiano[2] — [1]Heidelberg University, Germany — [2]Linköping University, Sweden — [3]University of Washington, USA — [4]University of Cologne, Germany

The investigation of the thermoelectric properties of organic semiconductors (OSC) with the aim of increasing their efficiency as active material in thermoelectric generators has attracted attention for the past years. The maximum efficiency of the energy conversion process in a thermoelectric material is set by zT, which is proportional to electrical conductivity and Seebeck coefficient (S) squared. A common way of increasing zT is by doping, which typically increases the charge carrier density and electrical conductivity, while decreasing S. The

sign of S is often used to determine the polarity of the majority charge carriers in OSC. In recent years, a surprising change in the sign of S has sometimes been observed to occur in highly doped OSC. Here, by combining conductivity and S measurements with kinetic Monte Carlo simulations, it is shown that density of state filling in combination with the opening of a hard Coulomb gap around the Fermi energy is responsible for the sign inversion

Invited Talk DS 17.1 Thu 16:15 SCH A 316
In-situ optical spectroscopy on electrochemical interfaces: From OER electrocatalysts to "smart" electro-switchable interfaces — •MARTIN RABE — Department of Interface Chemistry and Surface Engineering, Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Str. 1, 40237 Düsseldorf
We employ electrochemical in-situ optical spectroscopies, namely IR- and Raman-spectroscopy as well as UV/vis-spectroscopic ellipsometry to understand fundamental processes at electrolyte/solid interfaces. Here, different examples from our research will be presented and discussed. 1: Electrocatalytically active manganese and nickel oxides during the anodic oxygen evolution reaction (OER) were studied. The formation, phase transitions and dissolution processes in these metal oxides is shown to govern their activity and stabilities on metallic electrodes. These material properties play a major role for the improvement of electrocatalysts for the sluggish OER in hydrogen production by the electrochemical water splitting. 2: The impact of the electrochemical Ge-OH to Ge-H surface termination on germanium interfaces was studied, which is accompanied by a switching of the interface hydrophobicity. The formation of a hydrophobic gap at semiconductor/electrolyte interface gives access to study fundamental properties of the water solvation layers. Furthermore, it is shown how the macroscopic change of the hydrophobicity can be employed as a "smart" electro-switchable surface that allows to reversibly control the adsorption and orientation of bio-macromolecules, a process that is potentially useful for novel bio sensing applications.

Invited Talk DS 17.2 Thu 16:45 SCH A 316
The physics of low symmetry semiconductors: Gallium oxide for the future of green energy as example — •MATHIAS SCHUBERT — Department of Electrical and Computer Engineering, University of Nebraska-Lincoln, Lincoln, Nebraska 68588, USA — NanoLund and Solid State Physics, Lund University, 22100 Lund, Sweden
The physics of Gallium arsenide (zincblende structure) and Gallium nitride (wurtzite structure) led to disruptive technologies driven by extreme properties such as small effective mass, large direct bandgap, and piezoelectric polarization. Gallium reappears in a monoclinic crystal structure Oxide with enormous prospects for applications in power electronics for the future of green energy.

Numerous new phenomena hitherto unknown for traditional semiconductors occur in monoclinic symmetry semiconductors such as non-parallel phonon-plasmon scattering, hyperbolic shear polaritons, splitting of associated transverse and longitudinal phonon modes, non-degenerate highly anisotropic fundamental excitonic band-to-band transitions, directional band offsets, and complex defect spin interactions within the highly anisotropic host lattice. The influences of composition, strain, doping, and defects are discussed for Gallium oxide and related alloys, and special emphasis is given to new semiconductor physics, and consequences for thin film growth and device designs are pointed out. Methods such as generalized ellipsometry, the optical Hall effect, Terahertz electron paramagnetic resonance ellipsometry, and density functional perturbation theory computations are employed for characterization and analysis.

Invited Talk DS 17.3 Thu 17:15 SCH A 316
Spectroscopic ellipsometry studies of optical constants in highly excited semiconductors — •STEFAN ZOLLNER — New Mexico State University, Las Cruces, NM, USA
Spectroscopic ellipsometry is an optical reflection technique with polarized light. Most commonly, it is used to measure the thicknesses of thin-film layers, such as SiO_2 on Si. But it can also be used to study the energies and broadenings of elementary excitations in solids, such as electrons (band gaps, transport), infrared active phonons, and their interactions. We previously reported precision measurements of the complex refractive index of germanium near the direct band gap, which allowed us to compare our results quantitatively with theoretical predictions from Fermi's Golden Rule, based on k.p theory and including the excitonic interaction between electrons and holes. Going further, we can investigate how many-body effects impact the properties of electrons in highly excited semiconductors. Large carrier concentrations can be achieved through doping, thermal excitation of electron-hole pairs in small band-gap semiconductors, or optical excitation with ultrafast lasers. In this talk, I will report recent ellipsometry results for the temperature-dependent dielectric function of InSb near the direct band gap and the transient dielectric function of Ge near the E_1 and $E_1+\Delta_1$ transitions from femtosecond pump-probe ellipsometry. I will also point out the theoretical approach needed to explain these data sets.

DS 18: Members' Assembly

Time: Thursday 18:00–19:00 Location: SCH A 315

DY 1: Tutorial: Physics Meets Machine Learning (joint session DY/TUT/TT)

Machine learning has revolutionized many application fields such as computer vision and natural language processing. In physics there is a growing interest in using machine learning to enhance the analysis of experimental data and to devise and optimize experiments or numerical simulations. On the other hand physicists use their intuition and methods from statistical physics and complex systems theory to better understand the working principles of modern machine learning methods. This tutorial session introduces some subfields within this area and the basic methods involved.

Organized by Sabine Andergassen (Tübingen), Martin Gärttner (Heidelberg), Moritz Helias (Jülich), and Markus Schmitt (Cologne)

Time: Sunday 16:00–18:15   Location: HSZ 01

Tutorial   DY 1.1   Sun 16:00   HSZ 01
Machine Learning for Quantum Technologies — •Florian Marquardt — Max Planck Institute for the Science of Light and Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany
Machine learning is revolutionizing science and technology. In the past few years, it has become clear that it promises significant benefits as well for the development of quantum technologies. In this tutorial I will first give a brief introduction to neural networks. I will then discuss a number of areas and examples in which machine learning is being successfully applied in this context. These include measurement data analysis and quantum state representation, approximate quantum dynamics, parameter estimation, discovering strategies for hardware-level quantum control, the optimization of quantum circuits, and the discovery of quantum experiments, discrete quantum feedback strategies, and quantum error correction protocols.

Tutorial   DY 1.2   Sun 16:45   HSZ 01
The Unreasonable Effectiveness of Gaussians in the Theory of Deep Neural Networks — •Zohar Ringel — Racah Institute of Physics, Hebrew University in Jerusalem
Physical Sciences are in many ways the success story of explaining fundamental phenomena using simple math [1]. The fact that physical phenomena could be arranged in that manner is remarkable. Yet this simplicity does not necessarily carry over to life sciences or data sciences. Indeed prominent authors have argued against our desire to rely on neat mathematical structures when analyzing big data [2].

In the past half-decade several results have emerged which balance mathematical simplicity with data-induced complexity. These could be seen as a middle ground between the above juxtaposing views. The common divider here is the use of Gaussian distributions as approximants of various different quanti-ties in deep neural networks (DNNs). Specifically these Gaussians emerge when describing outputs of DNNs with random weights, outputs of trained DNNs at random times, outputs of fixed DNNs over random input data, and fluctuations of hidden DNN pre-activations. In this tutorial I will present these quantities, provide arguments supporting their Gaussianity, and outline several theoretical implications.

Tutorial   DY 1.3   Sun 17:30   HSZ 01
Computing learning curves for large machine learning models using the replica approach — •Manfred Opper — Inst. für Softwaretechnik und Theor. Informatik, TU Berlin — Centre for Systems Modelling and Quantitative Biomedicine, University of Birmingham, UK
Methods of statistical physics have been used for a long time to mathematically analyse the typical performance of machine learning models in the limit where both the number of data and the number of parameters (such as network weights) is large. By defining Boltzmann-Gibbs probability distributions over parameters where the cost function of the machine learning problem plays the role of a hamiltoninan, one can derive analytical expressions for training errors and generalisation errors using the corresponding partition functions and free energies in terms of a usually small number of order parameters.

Since the models depend on a set of random data to be learnt, additional appropriate statistical (so-called quenched) averages of free energies over this 'disorder' have to be performed. The replica approach is a prominent analytical tool from the statistical physics of disordered systems to solve this nontrivial technical challenge.

In this tutorial I will give an introduction to this approach. Starting with an explicit calculation for simple single layer perceptrons, I will then argue how the method can be applied to more complex problems such as kernel machines (support vector machines and Gaussian processes) and multilayer networks.

DY 2: Focus Session: Physics Meets ML I – Machine Learning for Complex Quantum Systems (joint session TT/DY)

Modern machine learning methods open new perspectives on the high-dimensional data arising naturally in complex quantum systems. The applications range from the analysis of experimental observations over optimal control to the enhancement of numerical simulations in and out of equilibrium. This focus session brings together experts in the field to discuss recent progress and promising directions for future research.

Invited Talk   DY 2.1   Mon 9:30   HSZ 03
Enhanced variational Monte Carlo for Rydberg atom arrays — •Stefanie Czischek — Department of Physics, University of Ottawa, Ottawa, Canada, K1N 6N6
Rydberg atom arrays are promising candidates for high-quality quantum computation and quantum simulation. However, long state preparation times limit the amount of measurement data that can be generated at reasonable timescales. This restriction directly affects the estimation of operator expectation values, as well as the reconstruction and characterization of quantum states.

Over the last years, neural networks have been explored as a powerful and systematically tuneable ansatz to represent quantum wave functions. Via tomographical state reconstruction, such numerical models can significantly reduce the amount of necessary measurements to accurately reconstruct operator expectation values. At the same time, neural networks can find ground state wave functions of given Hamiltonians via variational energy minimization.

While both approaches experience individual limitations, a combination of the two leads to a significant enhancement in the variational ground state search by naturally finding an improved network initialization from a limited amount

of measurement data. Additional specific modifications of the neural network model and its implementation can further optimize the performance of variational Monte Carlo simulations for Rydberg atom arrays and provide significant insights into their behaviour.

Invited Talk DY 2.2 Mon 10:00 HSZ 03
Data mining the output of quantum simulators – from critical behavior to algorithmic complexity — •Marcello Dalmonte — Abdus Salam International Centre for Theoretical Physics, Trieste (I)

Recent experiments with quantum simulators and noisy intermediate-scale quantum devices have demonstrated unparalleled capabilities of probing many-body wave functions, via directly probing them at the single quantum level via projective measurements. However, very little is known about to interpret and analyse such huge datasets. In this talk, I will show how it is possible to provide such characterisation of many-body quantum hardware via a direct and assumption-free data mining. The core idea of this programme is the fact that the output of quantum simualtors and computers can be construed as a very high-dimensional manifold. Such manifold can be characterised via basic topological concepts, in particular, by their intrinsic dimension. Exploiting state of the art tools in non-parametric learning, I will discuss theoretical results for both classical and quantum many-body spin systems that illustrate how data structures undergo structural transitions whenever the underlying physical system does, and display universal (critical) behavior in both classical and quantum mechanical cases. I will conclude with remarks on the applicability of our theoretical framework to synthetic quantum systems (quantum simulators and quantum computers), and emphasize its potential to provide a direct, scalable measure of Kolmogorov complexity of output states.

Invited Talk DY 2.3 Mon 10:30 HSZ 03
Reinforcement learning for quantum technologies — •Florian Marquardt — Max Planck Institute for the Science of Light and Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany

Complex quantum devices require sophisticated control. Discovering such control strategies from scratch with the help of machine learning will enable us to keep pace with the ever-increasing demands encountered when scaling up quantum computers. In this talk, I will describe how the field of reinforcement learning can deliver on this promise. I will present examples ranging from the optimization of quantum circuits to the model-based discovery of better quantum feedback strategies. Moreover, in a recent collaboration with our experimental colleagues, we could show how to train a novel latency-optimized neural network by reinforcement learning in an experiment, acting on a superconducting qubit in cycles of less than one microsecond.

Invited Talk DY 2.4 Mon 11:00 HSZ 03
Machine learning of phase transition — •Christof Weitenberg — Universität Hamburg, Institut für Laserphysik, Hamburg, Germany

Machine learning is emerging as vital tool in many sciences. In quantum physics, notable examples are neural networks for the efficient representation of quantum many-body states and reinforcement learning of preparation and read-out routines. In this talk, I will present our results on machine learning of quantum phase transitions using classification techniques. This approach works very well even on noisy experimental data both with supervised and unsupervised machine learning, as we demonstrate for quantum simulators based on ultracold atoms. Next to the practical advantages, such techniques might in the future reveal phase transitions, for which conventional order parameters are not known.

15 min. break

DY 2.5 Mon 11:45 HSZ 03
Machine learning optimization of Majorana hybrid nanowires — •Matthias Thamm and Bernd Rosenow — Institut für Theoretische Physik, Universität Leipzig

As the complexity of quantum systems such as quantum bit arrays increases, efforts to automate expensive tuning are increasingly worthwhile. We investigate machine learning based tuning of gate arrays using the CMA-ES algorithm for the case study of Majorana wires with strong disorder. We find that the algorithm is able to efficiently improve the topological signatures, learn intrinsic disorder profiles, and completely eliminate disorder effects. For example, with only 20 gates, it is possible to fully recover Majorana zero modes destroyed by disorder by optimizing gate voltages.

DY 2.6 Mon 12:00 HSZ 03
Model-independent learning of quantum phases of matter with quantum convolutional neural networks — •Yu-Jie Liu[1], Adam Smith[2], Michael Knap[1], and Frank Pollmann[1] — [1]Technical University of Munich, 85748 Garching, Germany — [2]University of Nottingham, Nottingham, NG7 2RD, UK

Quantum convolutional neural networks (QCNNs) have been introduced as classifiers for gapped quantum phases of matter. Here, we propose a model-independent protocol for training QCNNs to discover order parameters that are unchanged under phase-preserving perturbations. We initiate the training sequence with the fixed-point wavefunctions of the quantum phase and then add translation-invariant noise that respects the symmetries of the system to mask the fixed-point structure on short length scales. Without the translational invariance or other additional symmetries, we prove that a phase-classifying QCNN cannot exist. We illustrate this approach by training the QCNN on phases protected by time-reversal symmetry in one dimension, and test it on several time-reversal symmetric models exhibiting trivial, symmetry-breaking, and symmetry-protected topological order. The QCNN discovers a set of order parameters that identifies all three phases and accurately predicts the location of the phase boundary. The proposed protocol paves the way towards hardware-efficient training of quantum phase classifiers on a programmable quantum processor.

DY 2.7 Mon 12:15 HSZ 03
Simulating spectral functions of two-dimensional systems with neural quantum states — •Tiago Mendes Santos[1], Markus Schmitt[2], and Markus Heyl[1] — [1]University of Augsburg, Augsburg, Germany — [2]Forschungszentrum Jülich, Jülich, Germany

Spectral functions are key tools to characterize and probe condensed matter systems. Simulating such quantities in interacting two-dimensional quantum matter is, however, still an outstanding challenge. This work presents a numerical approach to simulate spectral functions using Neural Quantum States. As the key aspect, our scheme leverage the flexibility of artificial-neural-network wave functions to access spectral properties by simulating the dynamics of localized excitations with the time-dependent variational Monte Carlo. For demonstration, we study the dynamical structure factor (DSF) of models describing two-dimensional quantum phase transitions, namely, the quantum Ising and a square-lattice Rydberg Atom Arrays model in a regime of parameters relevant to quantum simulators. When combined with deep network architectures whose number of variational parameters increase at a mild polynomial expense with the number of spins, we showcase that our approach reliably describes the DSF for unprecedented system sizes and time scales.

DY 2.8 Mon 12:30 HSZ 03
Efficient optimization of deep neural quantum states toward machine precision — •Ao Chen and Markus Heyl — Center for Electronic Correlations and Magnetism, University of Augsburg, 86135 Augsburg, Germany

Neural quantum states (NQSs) have emerged as a novel promising numerical method to solve the quantum many-body problem. However, it has remained a central challenge to train modern large-scale deep network architectures, which would be key to utilize the full power of NQSs and to make them competitive or superior to conventional numerical approaches. Here, we propose a minimum-step stochastic reconfiguration (MinSR) method that reduces the optimization complexity by orders of magnitude while keeping similar accuracy as compared to conventional stochastic reconfiguration. In this talk, I will show MinSR allows for an accurate training on unprecedentedly deep NQS with up to 64 layers and more than 10^5 parameters in the spin-1/2 Heisenberg J_1-J_2 models on the square lattice. With limited numerical resources, partly obtained on single workstations, we find that this approach yields better variational energies as compared to existing NQS results and we further observe that the accuracy of our ground state calculations approaches different levels of machine precision on modern GPU and TPU hardware.

DY 2.9 Mon 12:45 HSZ 03
Time-dependent variational principle for quantum and classical dynamics — •Moritz Reh[1], Markus Schmitt[2], and Martin Gärttner[1,3,4] — [1]Kirchhoff-Institut für Physik, Universität Heidelberg, Im Neuenheimer Feld 227, 69120 Heidelberg, Germany — [2]Institut für Theoretische Physik, Universität zu Köln, 50937 Köln, Germany — [3]Physikalisches Institut, Universität Heidelberg, Im Neuenheimer Feld 226, 69120 Heidelberg, Germany — [4]Institut für Theoretische Physik, Universität Heidelberg, Philosophenweg 16, 69120 Heidelberg, Germany

The solution of many-body quantum dynamics is a challenging feat due to the curse of dimensionality, hindering the exploration of dynamics beyond a mediocre number of qubits. Neural Networks can variationally approximate the state of interest and therefore present a promising tool as they allow to efficiently represent the quantum state at the expense of truncating the Hilbert space.

We present such a scheme that is aimed at solving dissipative quantum dynamics using a probabilistic framework, i.e. the so-called POVM-formalism and demonstrate it for spin chains of up to 40 spins. We then show that the generality of the approach allows us to translate this formalism directly to the case of partial differential equations in high dimensions, defeating the exponential growth of grid cells when adding dimensions.

Spiral waves within a bistability parameter region of an excitable medium — •Vladimir Zykov and Eberhard Bodenschatz — Max Plank Institute for Dynamics and Self-Organization, D-37077, Goettingen, Germany

Spiral waves are a well-known and intensively studied dynamic phenomenon in excitable media of various types. Most studies have considered an excitable medium with a single stable resting state. However, spiral waves can be maintained in an excitable medium with bistability. Our calculations, performed using the widely used Barkley model, clearly show that spiral waves in the bistability region exhibit unique properties. For example, a spiral wave can either rotate around a core that is in an unexcited state, or the tip of the spiral wave describes a circular trajectory located inside an excited region. The boundaries of the parameter regions with positive and negative cores have been defined numerically and analytically evaluated. It is also shown that the creation of a positive or *negative* core may depend on the initial conditions, which leads to hysteresis of spiral waves.

DY 4.2 Mon 9:45 ZEU 250

Band Pattern Formation in a Suspension of Red Blood Cells During Centrifugation in a Percoll Density Gradient — •Felix Maurer, Thomas John, Christian Wagner, and Alexis Darras — Dynamics of Fluids, Experimental Physics, Saarland University, 66123 Saarbrücken, Germany

Percoll is a suspension of silica nanoparticles often used to establish density gradients and separate biological matter in centrifugation protocols. When red blood cells (RBCs) sediment in a Percoll medium, they form patterns of discrete bands. While this is a popular approach for RBC age separation, the mechanisms involved in band formation were unknown. In a series of experiments we could show that the formation of those patterns could be explained by cell aggregation. We developed a new continuum model to describe the volumetric RBC density under the influence of attractive pair interaction. Our numerical solutions are characterized by pattern formation and transitions between the equilibrium states depending on aggregation energy and initial volumetric RBC concentration.

DY 4.3 Mon 10:00 ZEU 250

A missing amplitude equation — •Tobias Frohoff-Hülsmann[1] and Uwe Thiele[1,2] — [1]Institute of Theoretical Physics, WWU Münster — [2]Center for Nonlinear Science (CeNoS), WWU Münster

Amplitude (or envelope) equations describe the spatiotemporal dynamics of the essential linear mode(s) in the vicinity of a stability threshold and represent universal equations for spatially extended systems [3]. They are determined by the type of linear instability, the symmetries and whether or not conservation laws are present [5, 6]. For systems without conservation laws these equations are well studied, e.g. the complex Ginzburg-Landau equation [1]. However, the presence of conservation laws is highly relevant for a wide spectrum of pattern forming systems, e.g. for certain reaction diffusion (RD) systems [2, 4]. Here, we review the basic types of linear instabilities in the presence of conservation laws and show that there are relevant cases for which the amplitude equation is still unknown. We focus on such a missing case and derive an amplitude equation relevant for practically important RD systems.

The universal CHEOPS, the path to it, and applications — Andre Förtsch and •Walter Zimmermann — Theoretische Physik, Universität Bayreuth

Solutions to fundamental questions in the field of nonequilibrium phase transitions are presented. What are the 'generic transport equations for oscillatory phase separation' (GTOPS) in systems described by conserved fields? GTOPS cover both classical and oscillatory phase separation. But what is the universal equation for oscillatory phase separation, i.e., the counterpart of the famous universal complex Ginzburg-Landau equation (cGLE) for an unconserved order parameter [1]? It is the 'Cahn-Hilliard model extended to oscillatory phase

separation' (CHEOPS) that includes the model in [2] as a special case. By generalizing methods from [3-6] CHEOPS is derived from GTOPS or even from a chemotaxis model for two species. Examples of surprising solutions of GTOPS and CHEOPS (patterns) are presented and some of them are also illustrated by a so-called minimal model (MIMO).

Quasi-steady interface flows in simple reaction-diffusion systems — •Tobias Alexander Roth, Henrik Weyer, and Erwin Frey — Arnold Sommerfeld Center for Theoretical Physics and Center for NanoScience, Department of Physics, Ludwig-Maximilians-Universität München, München, Germany

Intracellular protein patterns are essential features of living systems. A well-studied framework for describing simple protein systems are 2-component reaction-diffusion systems that preserve mass (2cMCRD). These genuine nonequilibrium systems can not be written in terms of a variational approach: there is neither a free energy nor a classical surface tension. Interestingly, it was found that the long-term evolution of these reaction-diffusion systems, however, is phenomenologically similar to the interface dynamics of phase-separating thermodynamic systems.

Here we show that an interface line in 2cMCRD systems obeys a flow, that interpolates between two paradigmatic limits: the two-sided Mullins-Sekerka flow and the area-preserving geodesic curvature flow. This generalised flow conserves area and minimises the interface length. One can tune its character by the time scale of diffusive mass redistribution compared to reactive turnover.

DY 4.6 Mon 11:00 ZEU 250

Amplitude expansion of the phase-field crystal model on deformable surfaces — •Lucas Benoit–Maréchal, Marco Salvalaglio, Ingo Nitschke, and Axel Voigt — Institute of Scientific Computing, TU Dresden, Dresden, Germany

The Phase Field Crystal (PFC) model describes lattices at diffusive timescales but atomic lengthscales, thus requiring subatomic resolution meshes. To remedy this restriction, the complex amplitude expansion (APFC) was developed, whereby the amplitude of the density fluctuations is modeled instead of the density itself, enabling simulations at mesoscales that retain atomistic features.

We extend the two-dimensional APFC model to include out-of-plane displacements in order to study the coupling between crystal defects and surface deformation, paving the way for applications such as the topological tuning of mechanical properties of crystalline sheets.

To validate our model, we compare representative settings with atomistic simulations from the PFC model and Molecular Dynamics and find, within certain limits that we discuss, excellent agreement between all models.

DY 4.7 Mon 11:15 ZEU 250

Laminar chaos in systems with quasiperiodic delay — •David Müller-Bender[1] and Günter Radons[1,2] — [1]Institute of Physics, Chemnitz University of Technology, 09107 Chemnitz, Germany — [2]ICM - Institute for Mechanical and Industrial Engineering, 09117 Chemnitz, Germany

A new type of chaos called laminar chaos was found in singularly perturbed dynamical systems with periodic time-varying delay [Phys. Rev. Lett. 120, 084102 (2018)]. It is characterized by nearly constant laminar phases, which are periodically interrupted by irregular bursts, where the intensity levels of the laminar phases vary chaotically from phase to phase. In this paper, we demonstrate that laminar chaos can also be observed in systems with quasiperiodic delay, where we generalize the concept of conservative and dissipative delays to such systems. It turns out that the durations of the laminar phases vary quasiperiodically and follow the dynamics of a torus map in contrast to the periodic variation observed for periodic delay. Theoretical and numerical results indicate that introducing a quasiperiodic delay modulation into a time-delay system can lead to a giant re-

duction of the dimension of the chaotic attractors. By varying the mean delay and keeping other parameters fixed, we found that the Kaplan-Yorke dimension is modulated quasiperiodically over several orders of magnitudes, where the dynamics switches quasiperiodically between different types of high- and low-dimensional types of chaos.

Details can be found in the preprint [arXiv:2210.04706 (2022)].

DY 4.8   Mon 11:30   ZEU 250

Pulse generation in opto-electronic neurons with time-delayed feedback —
•Jonas Mayer Martins[1], Svetlana V. Gurevich[1], and Julien Javaloyes[2]
— [1]Institute for Theoretical Physics, University of Münster, Wilhelm-Klemm-Str. 9 and Center for Nonlinear Science (CeNoS), University of Münster, Corrensstrasse 2, 48149 Münster, Germany — [2]Departament de Física and IAC-3, Universitat de les Illes Balears, C/ Valldemossa km 7.5, 07122 Mallorca, Spain
We study a neuromorphic circuit composed of a nano resonant tunneling diode (RTD) operated in the excitable regime, where the diode generates, when triggered, an all-or-nothing electrical response pulse. This pulse is fed into a nano laser diode (LD), which in turn emits an optical pulse that is re-injected with time delay back into the RTD. Our theoretical analysis of this time-delayed opto-electronic nonlinear system describes how such neuron-like excitability can lead to sustained periodic pulsations due to the time-delayed feedback. We derive a bifurcation diagram through numerical continuation, unveiling the rich dynamics of the system. Furthermore, direct numerical simulations of the RTD-LD reveal emerging solitons that may serve as memory for information. Opto-electronic neurons like the RTD-LD are particularly interesting because they allow for fast computations at very low energy consumption and are therefore promising candidates for new computational architectures that mimic the brain.

DY 4.9   Mon 11:45   ZEU 250

Spontaneous vortex formation by microswimmers with retarded attractions
— Xiangzun Wang[1], •Pin-Chuan Chen[2], Klaus Kroy[2], Viktor Holubec[3], and Frank Cichos[1] — [1]Peter Debye Institute for Soft Matter Physics, Leipzig University, 04103 Leipzig, Germany — [2]Institute for Theoretical Physics, Leipzig University, Postfach 100 920, 04009 Leipzig, Germany — [3]Department of Macromolecular Physics, Faculty of Mathematics and Physics, Charles University, 18000 Prague, Czech Republic
In recent experiments done in the Molecular Nanophotonics Group in the Peter Debye Institute, thermophoretic microswimmers are observed to self-assemble into bi-stable orbital modes due to retarded attractive interactions.

A single agent which is attracted to an immobilized target with a time delay can be described by a time-local overdamped Langevin equation with a potential determined by time delay, and the transition in between the two stable modes is well predicted by Kramers' escape rate. Simulations of multiple agents attracted to one target also show that the collective behavior can be reduced to a one-agent description; however, the experiments (with up to 16 agents) show otherwise.

The discrepancy between the results are attributed to additional effects in experiments.

We further show results of extended simulations with larger number of agents, which demonstrate two transitions depending solely on the time delay.

DY 4.10   Mon 12:00   ZEU 250

Stochastic pH oscillator confined to lipid vesicles — •Arthur Straube[1], Stefanie Winkelmann[1], and Felix Höfling[2,1] — [1]Zuse Institute Berlin — [2]Institut für Mathematik, Freie Universität Berlin
We study an urea-urease-based pH oscillator confined to lipid vesicles serving as an open reactor [1,2]. In contrast to conventional pH oscillators in closed reactors, the exchange with the vesicle exterior periodically resets the pH clock that switches the system from acid to basic, resulting in self-sustained oscillations. Stochastic simulations for microscopically small vesicles predict a significant statistical variation of the oscillation period. Although the mean period remains remarkably robust for vesicle sizes down to nearly 200 nm, the periodicity of the rhythm is gradually destroyed for smaller vesicles [1]. We analyze the structure of the limit cycle, which controls the dynamics for giant vesicles and dominates the strongly stochastic oscillations in small vesicles of submicrometer size. We derive reduced two-variable models, amenable to analytic treatments, and show that the accuracy of predictions, including the period of oscillations, is highly sensitive to the choice of the reduction scheme [2]. The accurate description of a single pH oscillator is crucial for rationalizing experiments and understanding communication of vesicles and synchronization of rhythms.

Sampling from the rule 150 fractal though an iterated stochastic process —
•Jens Christian Claussen — University of Birmingham, UK
A widely known, but surprising way of sampling points from the Sierpinski fractal is through an iterated stochastic process where in each time step one of three operators is applied, which can be interpreted from their number representation, or as a geometric operation. While the Sierpinski fractal can also be generated by the rule 90 elementary cellular automaton (ECA), the ECA rule 150 generates a fractal pattern with a 2-step self-similarity resembling a generalization of a Fibonacci iteration [1]. Here we show that the rule 150 fractal can be generated without a 2-step iteration. We introduce a set of 6 operators, which allow to generate the rule 150 fractal from a stochastic process. We show that these 6 operators can be reduced to 4 operators, by adding one operator to the 3 operators from the rule 90 case. The operators for the rule 150 can be interpreted both from their number representation and geometrically. Further each point of the rule 150 fractal can be represented by a any base-6 number, or by a 4-letter symbolic sequence with a grammar restriction.

Invited Talk   DY 5.1   Mon 9:30   MOL 213
Extreme events, entropies and instantons for turbulence and water waves —
•Joachim Peinke, André Fuchs, and Matthias Wächter — Inst. of Physics, University of Oldenburg, Germany
Complex systems like turbulence and ocean waves can produce extreme events like large changes in wind speed or monster waves. It has long been debated whether coherent structures or special statistical properties are essential for the understanding. Here we show a comprehensive stochastic approach for Lagrangian and Eulerian turbulence, as well as, for waves, leading to a joint multi-point statistic. We consider cascade trajectories through scales as realizations of a stochastic Langevin process that can be deduced from data. Knowledge of the stochastic equations allows determination of the entropy production of each cascade trajectory. Trajectories with negative entropies are linked to large fluctuations like extreme wind speeds or monster waves. Thus entropy seems to select different structures. Furthermore, negative and positive entropy values are balanced by rigorous fluctuation theorems, so that extreme and normal fluctuations are mutually dependent. In this way the entropy concept links statistics with the coherent structure approach. Finally, trajectories concentrate around an optimal path, called instanton, which is the minimum of an effective action given by the estimated stochastic equations. Entropons, defined as instantons conditioned on fixed entropy values, pinpoint the trajectories responsible for the emergence of non-Gaussian statistics at small scales. Ann. Rev. Cond. Matt. Phys. 10, 107-132 (2019), EPL 137, 53001 (2022), Phys. Rev. Lett. 129, 034502 (2022)

DY 5.2   Mon 10:00   MOL 213

Discrete and Continuous Symmetry Reduction for Minimal Parametrizations of Chaotic Fluid Flows — •Simon Kneer and Nazmi Burak Budanur — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany
Mathematical laws that govern fluid motion preserve their shape under translation, rotation, and reflection of coordinates. Consequently, most hydrodynamic systems of interest exhibit a set of symmetries, the action of which on the fluid states commutes with the dynamics. In complex flows, typical non-laminar fluid states are not invariant under these symmetries. Thus, each solution of the system has many dynamically equivalent symmetry copies. For data-driven model reduction methods, such as undercomplete Autoencoders, this multiplicity is not desired since it results in an artificial inflation of the training data which does not yield any physical insight. We consider this problem in the sinusoidally-driven Navier-Stokes equations in two dimensions, i.e. Kolmogorov flow, which is symmetric under continuous translations as well as discrete rotations and reflections. We formulate a symmetry reduction that combines first Fourier mode slicing with invariant polynomials that yields a fully invariant formulation of the corresponding dynamical system. Through this symmetry reduction, we are able to find a minimal approximation to the inertial manifold of this system as well as ordinary differential equations on this manifold that describe the dynamics.

DY 5.3 Mon 10:15 MOL 213

Spontaneous symmetry breaking for extreme vorticity and strain in the three-dimensional Navier-Stokes equations — •Timo Schorlepp[1], Tobias Grafke[2], Sandra May[3], and Rainer Grauer[1] — [1]Institute for Theoretical Physics I, Ruhr-University Bochum, Germany — [2]Mathematics Institute, University of Warwick, United Kingdom — [3]Department of Mathematics, TU Dortmund University, Germany

We investigate the spatio-temporal structure of the most likely configurations realizing extremely high vorticity or strain in the stochastically forced three-dimensional incompressible Navier-Stokes equations. Most likely configurations are computed by numerically finding the highest probability velocity field realizing an extreme constraint as solution of a large optimization problem. High-vorticity configurations are identified as pinched vortex filaments with swirl, while high-strain configurations correspond to counter-rotating vortex rings. We additionally observe that the most likely configurations for vorticity and strain spontaneously break their rotational symmetry for extremely high observable values. Instanton calculus and large deviation theory allow us to show that these maximum likelihood realizations determine the tail probabilities of the observed quantities. In particular, we are able to demonstrate that artificially enforcing rotational symmetry for large strain configurations leads to a severe underestimate of their probability, as it is dominated in likelihood by an exponentially more likely symmetry-broken vortex-sheet configuration.

Delayed onset in spanwise rotating compressible convection — •Kevin Lüdemann and Andreas Tilgner — Institute for Astrophysics and Geophysics, Göttingen, Germany

We are investigating compressible convection with spanwise rotation in direct numerical simulations meaning that the direction of gravity and the axis of rotation are perpendicular to each other. This is a model for the equatorial region of gas planets like Jupiter or Earth's outer core. Both consist of compressible liquids ranging many orders of magnitude in density variations for Jupiter to about 20 percent of density changes for earth outer core. We are more interested in moderate density changes since those are realizable in laboratory experiment like the one performed in Lyon. From a parameter study in the number of density scale heights controlling the compressibility and the Ekman number controlling the global rate of rotation, we find that the onset of convection is delayed by compressibility and rotation. Additionally, a horizontal drift of the many slender convection rolls has been found at the onset for high rotation rates. An extensive study is presented highlighting these unforeseen results.

Offshore wind: Evidence for two-dimensional turbulence and role of sea horizon — •So-Kumneth Sim[1], Joachim Peinke[2], and Philipp Maass[1] — [1]Fachbereich Physik, Universität Osnabrück, Germany — [2]Insitut für Physik & ForWind, Universität Oldenburg, Germany

We analyze offshore wind speeds with a time resolution of one second over a period of 20 months [1]. Wind speed power spectra show a scaling behavior that is governed by three- and two-dimensional turbulence [2]. The latter is observed for frequencies lower than a crossover frequency f_{2D}. An analysis of the third moment (third-order structure function) of wind speed fluctuations provides strong evidence of this transition to two-dimensional turbulence [3]. We argue that $f_{2D} \sim \bar{v}/d$, where $\bar{v}$ is the mean wind speed and d the distance between the measurement device and the sea horizon. For the regime of two-dimensional turbulence, two scaling regimes are predicted, which originate from an inverse energy and an enstrophy cascade. Our results indicate that the scaling due to the inverse energy cascade occurs at low frequencies and is followed by the scaling of the enstrophy cascade at higher frequencies. This in agreement with the theoretical prediction but contrary to earlier observations.

Convective turbulent superstructures in Rayleigh-Benard convection — •Hiufai Yik[1], Stephan Weiss[1,2], and Eberhard Bodenschatz[1] — [1]Max Planck Institute for Dynamics and Self-Organization — [2]Max Planck Center for Complex Fluid Dynamics

We report experimental results on turbulent superstructures in high-turbulence thermal convection. The 0.7 m high, 3.5 m wide and 0.35 m deep rectangular cell was installed in the Göttingen U-Boot and filled with sulphur hexafluoride at pressures up to 19 bar. Convection in this installation can be investigated up to Rayleigh numbers Ra = 10^13 at Prandtl numbers of about 0.8. More than 200 thermistors were distributed in the upper and lower plates for temperature and heat flux measurements, and 20 additional thermistors in the centre of the cell to measure the fluid temperature along the longitudinal axis. We report the results on turbulent superstructures and their dependence on heat transport and boundary conditions. For this purpose, the upper and lower plates of the convection cell were each divided into 4 sections, with an independent temperature control allowing both homogeneous and inhomogeneous temperature boundary conditions and the selection of different turbulent superstructures.

Statistical field theory for a stochastic linear advection-stretching model for turbulence — Lukas Bentkamp, Maurizio Carbone, and •Michael Wilczek — Theoretical Physics I, University of Bayreuth, 95440 Bayreuth

A major obstacle in developing a statistical field theory of turbulence is the analysis of the functional equations that govern the complete statistics of the flow field. Simplified models of turbulence may help to develop such a statistical framework. In this contribution, we discuss the stochastic linear advection and stretching of an incompressible passive vector field as a model for small-scale turbulence. The model encompasses non-Gaussian statistics due to an intermittent energy flux from large scales to small scales, thereby displaying hallmark features of turbulence. We explore this model using the Hopf functional formalism, which naturally leads to a decomposition of the complex non-Gaussian statistics into Gaussian sub-ensembles based on different realizations of advection and stretching.

This project has received funding from the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (Grant agreement No. 101001081).

Description of laminar-turbulent transition of an airfoil boundary layer measured by differential image thermography using directed percolation theory — •Tom T. B. Wester, Joachim Peinke, and Gerd Gülker — ForWind, University of Oldenburg, Institute of Physics, Oldenburg, Germany

Transition from laminar to turbulent flow is still a challenging problem. Recent studies indicate a good agreement when describing this phase transition with the directed percolation theory. This study presents a new experimental approach by means of differential image thermography (DIT) enabling to investigate this transition on the suction side of a heated airfoil. The results extend the applicability of the directed percolation theory to describe the transition on curves surfaces. The experimental effort was for the first time an agreement between all three universal exponents of the (1+1)D directed percolation for such airfoil application. Furthermore, this study proves that the theory holds for a wide range of flows, as shown by the various conditions tested. Such a large parameter space was not covered in any examination so far. The findings underline the significance of percolation models in fluid mechanics and show that this theory can be used as a high precision tool for the problem of transition to turbulence.

How to generate turbulence with highest Reynolds numbers in the wind tunnel — •Lars Neuhaus, Michael Hölling, and Joachim Peinke — ForWind, University of Oldenburg, Institute of Physics, Oldenburg, Germany

In order to study objects like buildings, vehicles or wind turbines under the influence of wind fluctuations, the generation of laboratory flows that resemble atmospheric turbulence is of prime importance. This is where active grids come into play, allowing to excite the wind tunnel flow in a user-defined way. With a blockage induced flow design, it is possible to recreate atmospheric flows through their time series or to create single coherent structures such as gusts defined by industrial standards. In addition, it is possible to generate turbulence with large integral length scales through a random driving that follows a stochastic process. Velocity fluctuations with correlation lengths and thus integral scales much larger than the transverse dimensions of the wind tunnel can be generated. By combining active grid excitation with fan speed modulation, it is additionally possible to generate a flow characterized by an inertial range of four decades and an integral Reynolds number of $2 * 10^7$. By a newly developed active grid it is furthermore possible to vary the turbulent properties over height to mimic height dependencies found in the atmosphere and also to generate a turbulent non-turbulent interface.

Noether's theorem in statistical mechanics — •Sophie Hermann and Matthias Schmidt — Universität Bayreuth, Bayreuth, Deutschland

Noether's Theorem is familiar to most physicists due its fundamental role in linking the existence of conservation laws to the underlying symmetries of a physical system. Typically the systems are described in the particle-based context of classical mechanics or on the basis of field theory. We apply Noether's calculus of invariant variations to thermal systems, where fluctuations are paramount and one aims for a statistical mechanical description, both in and out of equilibrium. Generating functionals, such as the free energy, yield mechanical laws under continuous translational and rotational symmetry operations. The resulting global theorems express vanishing of total internal and total external forces and torques. Local sum rules interrelate density correlators, as well as static and time direct correlation functions via infinite hierarchies, including memory. We demonstrate that this approach is consistent with the earlier work in equilibrium, and that it enables one to go, with relative ease, beyond the sum rules that these authors formulated. For anisotropic particles, systematic coupling of orbital and spin motion is identified. The theory allows to shed new light on the spatio-temporal coupling of correlations in complex systems. We present novel exact and nontrivial identities that apply to time-dependent problems and driven and active fluids.

DY 6.2   Mon 10:15   ZEU 160

Mean-field brittle yielding of amorphous solids — •Jack T. Parley[1] and Peter Sollich[1,2] — [1]Institut für Theoretische Physik, University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany — [2]Department of Mathematics, King's College London, London WC2R 2LS, UK

We study the brittle yielding of athermal amorphous solids within the celebrated Hébraud-Lequeux mean-field elastoplastic model, which incorporates the sign-varying nature of Eshelby interactions as a Gaussian mechanical noise. As in finite-dimensional particle simulations, we find a critical value of the initial disorder, below which yielding in the limit of quasistatic shear becomes a discontinuous non-equilibrium transition. We find evidence that in this limit yielding cannot be described as a spinodal instability, in contrast to the behaviour found in driven random magnets or depinning-like models. At small but finite shear rates, we show that the tail exponents characterising the decay of the plastic yield rate function on either side of its peak at the transition are related to the athermal aging exponents. We finally derive analytically the scaling with shear rate of the peak susceptibility at the random critical point, and discuss the connection to avalanches in finite-size systems.

Bringing the power of Monte Carlo methods to long-range-interacting molecular systems — •Philipp Höllmer[1], A. C. Maggs[2], and Werner Krauth[3] — [1]University of Bonn, Germany — [2]ESPCI Paris, France — [3]École normale supérieure de Paris, France

Molecular simulations are widespread in molecular sciences to study, e.g., protein folding. Here, chemical systems are modeled empirically by a set of atomic positions with parameterized interaction potentials. Nowadays, molecular-dynamics (MD) simulations are predominantly used to study long-range-interacting molecular systems because of their superior computational complexities and Newtonian dynamics when compared to traditional Markov-chain Monte Carlo (MCMC) simulations. We argue that both disadvantages of traditional reversible MCMC are overcome by event-chain Monte Carlo (ECMC), which is a family of non-reversible MCMC methods.

In this talk, we will explore how ECMC samples the equilibrium Boltzmann distribution exactly, although it uses non-equilibrium dynamics and never computes the total system potential. We will discuss how ECMC's sole restriction of the global-balance condition yields a great freedom to implement quickly decorrelating dynamics beyond Newtonian's dynamics of MD. Finally, we will demonstrate $\mathcal{O}(N \log N)$ scaling for ECMC's decorrelation of an N-body system of a commonly used long-range-interacting water model. This matches the performance of MD without ever discretizing time or space.

DY 6.4   Mon 10:45   ZEU 160

Virial coefficients of hard, anisotropic particles in two- to four-dimensional Euclidean spaces — •Markus Kulossa, Daniel Weidig, and Joachim Wagner — Institut für Chemie, Universität Rostock, 18051 Rostock, Germany

We compare virial coefficients up to order eight for anisotropic, hard particles in two- to four-dimensional Euclidean spaces in dependence on their aspect ratio. The virial coefficients of both, convex shapes such as stadia, spherocylinders and hyperspherocylinders and concave shapes such as dumbbells in two to four dimensions are analyzed. Since the second virial coefficient of hard objects equals their mutual excluded D-dimensional volume per particle, analytically obtained expressions for the second virial coefficients serve as a test

for orientation-dependent overlap algorithms. In first approximation, a nearly universal dependence of reduced virial coefficients on the excess part of the mutual excluded volume is observed for third and higher order virial coefficients.

Geometric Bounds on the Power of Adiabatic Thermal Machines — •Joshua Eglinton[1,2] and Kay Brandner[1,2] — [1]School of Physics and Astronomy, University of Nottingham, Nottingham NG7 2RD, United Kingdom — [2]Centre for the Mathematical and Theoretical Physics of Quantum Non-equilibrium Systems, University of Nottingham, Nottingham NG7 2RD, United Kingdom

The laws of thermodynamics put fundamental bounds on the efficiencies of thermal machines. These Carnot bounds can typically be attained only if the machine is operated quasi-statically, which leads to vanishing power output. We present a new family of power-efficiency trade-off relations that imply a quadratic decay of power at Carnot efficiency, for devices operating between two fixed temperatures. Notably, these relations depend only on geometric quantities such as the thermodynamic length of the driving cycle and hold for essentially any thermodynamically consistent micro-dynamics such as classical Markov-jump processes, adiabatic Lindblad dynamics or coherent transport. This analysis is based on a new general scaling argument, with which we show that the efficiency of such devices reaches the Carnot bound only if heat-leaks between the baths can be fully suppressed. Furthermore, we find that their power is in fact determined by second-order terms in the temperature difference between the two baths, which are neglected in standard linear-response theory.

Hard rods on a 2D lattice system — •Michael Zimmermann — Universität Tübingen, Tübingen, Deutschland

An exact solution for the equilibrium density for a hard rod system on a 1D continuous system was found by Percus [1]. For lattice systems of hard rods, Lafuente and Cuesta established a method based on Rosenfeld's fundamental measure theory to find the exact solution in 1D and to extrapolate from this result to a density functional in higher dimensions [2,3]. But already in 2D theoretical properties differ from respective simulation results [4], such as the onset of demixing between rods of different orientation. In this talk we will discuss some possible extensions of the Lafuente-Cuesta functional for improving the excess free energy functional and for better approximations of density distributions in 2D hard rod lattice systems.

Mean first-passage times of continuous-time random walkers determined through Wiener-Hopf integral equations — •Marcus Dahlenburg[1,2] and Gianni Pagnini[1,3] — [1]BCAM-Basque Center for Applied Mathematics, Alameda de Mazarredo 14, 48009 Bilbao, Basque Country, Spain — [2]Institute for Physics & Astronomy, University of Potsdam, 14476 Potsdam, Germany — [3]Ikerbasque-Basque Foundation for Science, Plaza Euskadi 5, 48009 Bilbao, Basque Country, Spain

Asymmetric continuous-time random walks in continuous-space characterised by waiting-times with finite mean and by jump-amplitudes with both finite mean and finite variance are governed by an advection-diffusion equations in the asymptotic limit. The mean first-passage time (MFPT) of such an advective-diffusive system on a halfline results to be finite when the advecting drift is in the direction of the boundary. In our investigation we derive an inhomogeneous Wiener-Hopf integral equation that allows to avoids approximated results in the asymptotic limits and leads indeed to the exact determination of the MFPT. This quantity depends on the average of the waiting-times only but it conserves the information about the whole distribution of the jump-amplitudes. Through the case study of asymmetric double-exponential distributions of the jump-amplitudes one may identifies a length-scale, that defines the transition from starting points near the boundary to starting points far-away from the boundary where the MFPT loses the information about the exact shape of the jump-amplitudes' distribution and only conserves their mean.

A combinatorial approach to the many-body density of levels and the Bethe approximation — •Carolyn Echter, Georg Maier, Juan-Diego Urbina, and Klaus Richter — Institut für Theoretische Physik, Universität Regensburg, Regensburg, Germany

The Bethe formula, originally derived in [1] to estimate the density of levels of heavy nuclei, has become a widely used approximation for the many-body density of levels of a non-interacting fermionic system, appropriate for large numbers of particles and energies in a system-dependent range. Notably, in the case of equally spaced single-particle energy levels, it coincides with the asymptotic result for the number of unrestricted partitions of an integer known from analytic number theory [2]. An explanation is suggested by the combinatorics of distributing integer amounts of energy to particles obeying given statistics. We present a combinatorial derivation of the exact many-body density of levels for various particle statistics in the case of a constant single-particle density of states, thereby adding to existing discussions [3,4] and explaining the asymptotic agreement of Bethe's approximation with number theoretical partition functions. We compare numerically with semiclassical results and make suggestions towards a bosonic analogue of the Bethe formula based on our observations.

Integral Equations in Statistical Mechanics: A Size-effect Study — •Jose Mauricio Sevilla Moreno and Robinson Cortes-Huerto — Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany

Integral equations (IE) are in the core of statistical mechanics of liquids as they connect the local structure with thermodynamic properties as compressibility, activity coefficients and excess entropy. IE are normally defined in the grand canonical ensemble and calculated in the thermodynamic limit (TL). By contrast, computer simulations are performed with finite-size systems and mimic the TL using periodic boundary conditions (PBC). This proceeding introduces several finite-size contributions whose effects must be identified and corrected in order to approximate the simulation results to the TL. In this talk, we present a generic method to compute IE from molecular dynamics simulations. In our approach, we define finite-size IE, integrating them in Fourier space to trivially introduce PBC. This procedure allows us to identify and isolate ensemble, finite-volume domains and PBC effects and accurately obtain the corresponding thermodynamic quantities in the TL or artificially for any finite size system. To validate our method, we compute isothermal compressibilities, chemical potentials and excess entropies of simple liquids and liquid mixtures, including water and aqueous alcohol solutions, showing good agreement with results available in the literature.

A Multiscale Approach for Large-Scale Proton Dynamics Simulations — •Christian Dressler[1] and Daniel Sebastiani[2] — [1]TU Ilmenau, Institute of Physics, Theoretical Solid State Physics — [2]MLU Halle-Wittenberg, Institute of Chemistry, Theoretical Chemistry

We present a multiscale simulation approach for the calculation of proton diffusion/conduction in disordered organic and inorganic materials. We combine quantum chemical calculations for elementary reactions between the ions and surrounding molecules with molecular dynamics simulations for the incorporation of local dynamical heterogeneities at the nanometer/nanosecond scale. Data from both levels are integrated in a stochastic propagation scheme (Monte Carlo or Markov matrix approach) for the simulation of proton transfer at much larger time and length scales. The approach allows for an atom-level resolution of ion dynamics with quantum chemical accuracy but with final length- and time-scales of micrometers and milliseconds. As a proof-of-principle simulation, we have computed the explicit dynamics of a non-equilibrium process in an 8 μm CsH_2PO_4 system during 5 ms. Finally, we demonstrate the application potential of the scheme by computing the proton conductivity of a nanostructured CsH_2PO_4 fuel cell membrane with respect to the porosity.

DY 6.11   Mon 12:45   ZEU 160

Population Annealing and the Role of Resampling in Population Annealing — •Denis Gessert[1,2], Martin Weigel[3], and Wolfhard Janke[1] — [1]Institut für Theoretische Physik, Leipzig University, Postfach 100920, D-04009 Leipzig, Germany — [2]Centre for Fluid and Complex Systems, Coventry University, Coventry CV1 5FB, United Kingdom — [3]Institut für Physik, Technische Universität Chemnitz, D-09107 Chemnitz, Germany

Studying equilibrium properties of thermodynamic systems with rough free-energy landscapes particularly challenges standard Markov chain Monte Carlo techniques such as the Metropolis algorithm. Sampling can be improved by using generalized ensemble methods, one of which is Population Annealing (PA). Although PA is not expected to outperform its contenders in terms of time complexity, it is particularly well suited for parallel execution with no theoretical limit on the level of parallelism, which makes it a viable option on modern HPC.

In PA a population of replicas is collectively cooled down. At each temperature a population control step is carried out before applying some replica-independent update moves. This population control is realized by means of resampling. Here, we compare various different resampling methods and their performance in PA applications. Using the $d = 2$ Ising model as a benchmark system, we identify two resampling methods that appear preferable over the widely used multinomial resampling. Further, we point out when different resampling choices affect the statistical quality of the simulation outcome and obtain some model-independent guiding principles for the choice of PA parameters.

Collective dipole reorganization in magnetostructures — •Wafflard Adrien, Vandewalle Nicolas, and Opsomer Eric — GRASP, Institut de Physique B5a, Université de Liège, Liège, BE

Playing with spherical neodymium magnets that you find in your favorite toy market is really addicting. By assuming they are uniformly magnetized, magnetic beads behave as point-like dipoles. For scientists, those inexpensive objects demonstrate how dipolar particles self-assemble into various structures ranging from 1D chains to 3D crystals. We show that magnetotubes and magnetocrystals can self-buckle, i.e. change their geometry, above a critical aspect ratio. The underlying dipolar ordering is found to exhibit a collective reorganization, altering the mechanical stability of the entire system. We identify the conditions in which these phenomena occur and conjecture that in chains, square or cubic magnetostructures, neighboring dipoles reorientate in order to form the longest possible chains. This suggests that a wide variety of magnetostructures, including well known stable structures, may collapse due to reorientation of dipoles.

How is the growth of ferromagnetic granular networks controlled by an orthogonal magnetic field? — Matthias Biersack[1], •Ali Lakkis[1], Oksana Bilous[2], Pedro A. Sanchez[2], Sofia S. Kantorovich[2], and Reinhard Richter[1] — [1]University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — [2]Computational and Soft Matter Physics, Faculty of Physics, University of Vienna, 1090 Vienna, Austria

We are exploring in experiments the aggregation process in a shaken granular mixture of glass and magnetized steel beads, occuring in a horizontal vessel after the shaking amplitude is suddenly decreased. Then the magnetized beads form a transient network that coarsens in time into compact clusters, following a viscoelastic phase separation [1]. A homogeneous magnetic field oriented in plane has been observed to "unknot" network structures orthogonal to the field [2]. Here we focus on the impact of a magnetic field B_z oriented orthogonally to the plain of the network. We measure the average number of neighbours $\bar{k}(t)$ and the efficiency $E(t)$ of the emerging networks. Both can be fitted by a logistic growth function for $B_z \in [0, 2]$ mT, unveiling that its characteristic time τ increases by about ten. Our results demonstrate that via dipole-dipole repulsion the field reduces the mobility of isolated steel beads, thus hindering the growth of the networks. The experimental results are compared with those of numerical simulations.

Dynamic light scattering from single macroscopic particles — Lisa Künstler[1], Raphael Kessler[1], Matthias Sperl[1,2], and •Philip Born[1] — [1]Institut für Materialphysik im Weltraum, Deutsches Zentrum für Luft- und Raumfahrt (DLR), 51170, Köln, Germany — [2]Institut für Theoretische Physik, Universität zu Köln, 50937, Köln, Germany

Here we present a methodology to extract information from the fluctuations in light scattered from moving single granular particles. We first describe the experimental setup and the associated theoretical framework required to isolate contributions to the intensity autocorrelation function emerging from translational and from rotational particle motion [1]. We subsequently present an approach to extract the angular velocity and the translational speed of the granular particles from the light scattering data. The approach is applied to a small ensemble of granular particles in an hour-glass-like experiment to determine the granular temperature with a dynamic light scattering measurement. The results

indicate the next steps to be taken to eventually develop a thermometer for fluidized granular media based on dynamic light scattering.

Shear jamming and free surface deformation enable reciprocal swimming in granular materials — •Hongyi Xiao, Achim Sack, and Thorsten Pöschel — Institute for Multiscale Simulations, Friedrich-Alexander-Universität Erlangen-Nürnberg, Cauerstraße 3, 91058 Erlangen, Germany

Swimming with reciprocal motion is desirable due to its simplicity, but it is prohibited in Newtonian fluids at low Reynolds number as stated by the scallop theorem. Such a constraint can be broken in fluids with complex rheology. In this study, we show that propulsion generation with reciprocal motion in granular materials is enabled by a prolonged hysteresis in the material response, which originates from a combination of jamming-induced material rigidity and plastic deformation of the free surface. Using both lab experiments and discrete element method simulations, a reciprocal swimmer mimicking a scallop was constructed and buried in a tank of polydisperse granular particles. The swimmer consists of two wings that open and close with geometrical and temporal symmetry. The resistive force, the swimmer's displacement, and the deformation of the free granular surface were measured. Results indicate that net propulsion force is generated when the swimmer is tethered, and net displacement is generated when the swimmer is released. Small amplitude oscillatory experiments confirm the existence of an elastic regime at small strains, and free surface deformation measurement reveals its influence at large strains. Furthermore, a secondary symmetry breaking mechanism due to a cooperative effect of the wings is also identified.

Phase space characterization of three-dimensional nucleation of glass spheres — •Frank Rietz[1,2] and Matthias Schröter[2] — [1]University of Magdeburg, Department of Nonlinear Phenomena — [2]Max Planck Institute for Dynamics and Self-Organization (MPIDS), Göttingen

Packings of macroscopic spheres serve as a model system for studying atomic states. In many compactification protocols, the spheres do not form nuclei and remain in the state of random close packing. By cyclically shearing a packing of 50000 spheres, we can cross this boundary and observe a transition from a disordered to a crystallized state [1]. The three-dimensional temporal positions of the spheres are tracked by refractive index-matched scanning [2]. The description of disordered states and the nature of random close packing are open scientific problems. In our case, we describe the nucleation process by partitioning the packing into local groups of four touching spheres. These groups of spheres are tracked during the crystallization process and their contacts and relative orientation are recorded in a phase space diagram. By comparing the states before and after crystallization with the states that avoid crystallization, we show whether there are conditions under which the spheres statistically tend to crystallize.

Non-convex particles under shear in a split bottom cell — •Mahdieh Mohammadi[1], Ahmed Ashour[2], Dmitry Puzyrev[3], Torsten Trittel[3], and Ralf Stannarius[3] — [1]Technische Hochschule Brandenburg — [2]Future University of Egypt — [3]Otto-von-Guericke-Universität Magdeburg

We study dynamical features of surface flow in the top layer of a granular bed containing non-convex tetrapod and hexapod particles in a split-bottom shear cell. Different heights of granular beds were prepared and examined. Based on Particle Image Velocimetry and Particle Tracking Velocimetry, angular and radial displacements of particles on the surface of the ensemble were derived in dependence on the number of rotations of the bottom disk. Stereoscopic measurements of surface fluctuations of the bed during shearing turn out to be a key factor in this study to characterize heap and sink formation phenomena, which are related to the secondary flow of the grain ensembles in the bulk. We acknowledge support of DPG with project STA 425/40 and DLR with project EVA (50WM2048), and stimulating discussion with K. Harth.

DY 7.7   Mon 11:45   ZEU 147

Forces on obstacles suspended in flowing granular matter — •Jing Wang[1], Bo Fan[2], Tivadar Pongó[3], Tamás Börzsönyi[2], Raúl Cruz Hidalgo[3], and Ralf Stannarius[1] — [1]Institute of Physics, Otto von Guericke University Magdeburg, Magdeburg, Germany — [2]Institute for Solid State Physics and Optics, Wigner Research Centre for Physics, Budapest, Hungary — [3]Física y Matemática Aplicada, Facultad de Ciencias, Universidad de Navarra, Pamplona, Spain

We investigate the force on a spherical obstacle exerted by a flowing granular material. A sphere suspended in a discharging silo experiences mechanical forces both from the weight of the overlaying layers and from friction of the surrounding moving granular material. When the flow stops due to clogging of the silo, in experiments with hard frictional glass beads, the force on the obstacle remains exactly the same as during flow. In contrast, for nearly frictionless soft hydrogel particles the force decreased considerably after the flow stopped. The dependence of the total force on the obstacle diameter is qualitatively different for the two types of material: It grows quadratically with the sphere diameter of the obstacle for hydrogel spheres, while it grows much weaker, nearly linearly with the obstacle diameter, in a bed of hard frictional glass spheres.

Free cooling dynamics and energy partition in 3D granular gas mixtures — •Dmitry Puzyrev[1], Adrian Niemann[1], Kirsten Harth[2,3], Torsten Trittel[1], and Ralf Stannarius[1] — [1]Institute of Physics and MARS, Otto von Guericke University, 39106 Magdeburg — [2]Department of Engineering, TH Brandenburg, 14770 Brandenburg an der Havel — [3]MARS and MRTM, OVGU, 39106 Magdeburg

Granular gases are nonlinear systems that exhibit fascinating dynamical behavior far from equilibrium, including unusual cooling properties, clustering and violation of energy equipartition. Our study focuses on 3D microgravity experiments with dilute ensembles of rod-like particles and their mixtures. In drop tower experiments at ZARM, we studied granular cooling of mixtures of rods with two different diameters. The confirmation of Haff's equation [2] describing the energy decay is of particular interest. Experimental data analysis suggests different cooling rates, and the violation of energy equipartition between the rotational and translational degrees of freedom for the mixture components. Particle detection and tracking was performed with Machine Learning-aided approach [3]. The software will be available as a Python library that can be extended to other 3D and 2D particle tracking problems.

The authors acknowledge support from DLR in projects EVA (50WM2048) and VICKI (50WM2252).

Effect of particle size on the suction mechanism in granular grippers — •Angel Santarossa, Olfa D'Angelo, Achim Sack, and Thorsten Pöschel — Institute for Multiscale Simulation, Friedrich-Alexander Universität Erlangen-Nürnberg, Cauerstraße 3, 91058 Erlangen, Germany

Granular grippers are highly adaptable soft actuators able to grasp objects of different shapes and sizes. They consist of an elastic membrane partially filled with a granulate. Their operating principle relies on the reversible jamming transition of granular materials. The filled membrane can be deformed and reshaped when pressed onto an object. When the air within the membrane is evacuated, the granulate hardens, creating forces to hold and manipulate the object. Three mechanisms contribute to the holding force of granular grippers: frictional forces, geometrical constraints, and suction effects. Using X-ray computed tomography, we link the activation of suction to the size of the particles. We show that a gripper filled with small particles (average diameter $d \approx 0.12$ mm) conforms to a high degree around the object than with larger particles (average diameter $d \approx 4$ mm), thus enabling the formation of air-tight seals. When the gripper is pulled off, simulating the lifting of an object, vacuum pressure is generated in the sealed cavity at the interface gripper-object. If the particles are too large, the gripper does not conform tightly enough around the object, leaving gaps at the interface gripper-object. These gaps prevent the creation of sealed vacuum cavities between the object and the gripper, impeding the suction mechanism from operating.

Visualization of flow dynamics for Poly-dispersed dense granular suspension in various sections of pipe — •Himanshu P Patel and Günter K Auernhammer — Leibniz-Institut für Polymerforschung Dresden e. V., Hohe Straße 6, D-01069 Dresden, Germany

The study of flow dynamics in non-Newtonian media with polydispersed dense granular suspension, e.g., slurry, mud, concrete, still lacks quantification on the flow parameters linked to shear induced particle migration and insight about flow at center and at wall in closed pipes.

We developed transparent granular system that is a granular suspension of particles suspended in non-Newtonian media (particle volume fractions of 30%

to 48%) [1]. The non-Newtonian granular system has yield stress and plastic viscosity and is well index matched. The rheological characteristics of the model system is tunable through its composition of additives.

We analyze gravity-assisted continuous flow of millimetric sized particles. We perform tracking of flow at different sections of pipe. The flow analysis revels understanding on the relaxation of such flow and the development of velocity

profile within the length of pipe, we observe this using camera at entry and exit of pipe and later a 3D setup to observe flow at near end of pipe. This gives quantitative values into the particle migration to understand the effect of polydispersity and particle flow.

Novel phenomena and analysis methods in oscillator networks: higher-order interactions, higher-order averaging, and inference — •Hiroshi Kori — The University of Tokyo, Japan
Synchronization of oscillator networks is essential for functionalization of systems. Examples include heart pacemaker, circadian clock, and locomotion, to name a few. In this talk, after reviewing a general background, I will present recent studies with an emphasis on novel phenomena and analysis techniques. (i) A network of three oscillators shows complex synchronization transitions when the

network structure or overall coupling intensity is varied [1]. The transition is analyzed using a higher-order averaging method. (ii) In the assembly of noisy oscillators with a three-body interaction, synchronized state appears only transiently and its persistent time increases exponentially with the interaction strength of three-body coupling. (iii) I will present our proposed inference methods of coupling intensity from spike data [2] and the phase from oscillatory time series [3].

From Dual Unitarity to Generic Quantum Operator Spreading — •Michael A. Rampp, Roderich Moessner, and Pieter W. Claeys — Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany
Dual-unitary circuits are paradigmatic examples of exactly solvable yet chaotic quantum many-body systems, but solvability naturally goes along with a degree of non-generic behaviour. By investigating the effect of weakly broken dual-unitarity on the spreading of local operators we study whether, and how, small deviations from dual-unitarity recover fully generic many-body dynamics. We present a discrete path-integral formula for the out-of-time-order correlator and use it to recover a butterfly velocity smaller than the light-cone velocity, $v_B < v_{LC}$, and a diffusively broadening operator front, two generic features of ergodic quantum spin chains absent in dual-unitary circuit dynamics. We find that the butterfly velocity and diffusion constant are determined by a small set of microscopic quantities and that the operator entanglement of the gates plays a crucial role.

Harnessing the exponential Hilbert space dimension of quantum systems for reservoir computing — •Niclas Götting[1,2], Frederik Lohof[1,2], and Christopher Gies[1,2] — [1]Institute for Theoretical Physics, University of Bremen, Bremen — [2]Bremen Center for Computational Material Science, University of Bremen, Bremen
With the ever growing prevalence of machine learning in science and industry, the machine learning paradigm of reservoir computing has gained new attention. While classical reservoir computers have proven to be able to solve various prediction tasks by exploiting the complex dynamics of classical systems, their quantum counterparts are yet to be fully explored.

Coherent quantum systems exhibit properties like superposition and quantum entanglement, which in principle lead to an exponential scaling of the reservoir phase space dimension with respect to the number of quantum particles. The question arises if these quantum reservoir computers (QRCs) can energy and space efficiently outperform their classical analogues in complex prediction tasks.

As a first step we investigate the transverse-field Ising model as a QRC to find the link between the properties of the quantum network, the phase space dimension, and the performance of the QRC.

Giant Residual Current from Ultrafast AC Driving of Bloch Electrons — •Adrian Seith, Jan Wilhelm, and Ferdinand Evers — Institut für Theoretische Physik, Universität Regensburg
In recent experiments, residual currents were seen to survive long after the laser illumination has died out[1]. Motivated by a vision of a "light-wave electronics", the effect has been utilized to design a petahertz logical gate[2].

In this work, we theoretically study residual currents of Bloch electrons and demonstrate that residual currents can be as large as the maximum current during illumination.

Based on a perturbative expansion of the semiconductor-Bloch equations, we derive an analytical formula; it explains the strong dependence of residual cur-

rents on the model parameters and the laser pulse shape. In particular, our formula allows to optimize pulse shapes for maximizing the residual currents' magnitude reaching values order of magnitudes larger than observed in recent experiments.

Time-local generator of non-Markovian quantum dynamics by iterating its memory kernel — Maarten Wegewijs[1], Jan Vanberg[2], and •Konstantin Nestmann[2] — [1]Peter Grünberg Institute, Forschungszentrum Jülich, Germany — [2]Institute for Theory of Statistical Physics, RWTH Aachen University
The time-convolutionless generator (TCL) $\mathscr{G}$ of a quantum master equation (QME) has been found to be the fixed point $\mathscr{G} = \hat{\mathscr{K}}[\mathscr{G}]$ of the Nakajima-Zwanzig memory kernel $\mathscr{K}$ of the equivalent QME with time-convolution[a]. Here we investigate the calculation of $\mathscr{G}$ by iterating $\hat{\mathscr{K}}$ directly in the stationary limit starting from any initial guess to construct approximations to the dynamics. We show that the local stability of the iteration is connected to the long-time dynamics using an extended but still tractable version of the dissipative Jaynes-Cummings model. The iteration automatically selects the asymptotically most relevant decay and oscillation frequency, providing a non-perturbative Markovian semigroup approximation. Linearization about the fixed point allows to extract the amplitude of this approximation in the full dynamics, providing a non-perturbative initial-slip correction. Around the strongly non-Markovian regime (non-CP divisibility) the iteration stability can be either lost, or, remarkably, enhanced, yielding an additional fixed point. The global iteration stability is counter-intuitive: convergence to the main locally stable fixed point is guaranteed by starting from an initial guess "far away" with frequencies in the "wrong", *non*-physical half-plane. Performance of quantum registers in diamond in the presence of spin impurities — •Dominik Maile and Joachim Ankerhold — Institut for Complex Quantum Systems, Ulm University
The Nitrogen Vacancy Center in diamond coupled to addressable surrounding nuclear spins forms a versatile building block for future quantum technologies. While previous activities focused on sensing with only a single or very few spins in operation, recently multi-qubit registers have been successfully implemented for quantum information processing. Further progress requires a detailed understanding of the performance of quantum protocols for consecutive gate operations and thus, beyond established treatments for relaxation and dephasing. In this talk (see also [1]), we provide such an analysis for a small spin registers with up to four spins built out of NV and environmental constituents in presence of ensembles of interacting impurity spins. Adapting a cluster correlation expansion, we predict coherence properties as well as fidelities for GHZ- and Bell-gate operations. The influence of the volume density and the geometry of the spin-bath consisting of substitutional nitrogen atoms are also taken into account.

Quantum Zeno manipulation of quantum dots — Naser Ahmadiniaz[1], Martin Paul Geller[2], Jürgen König[2], Peter Kratzer[2], Axel Lorke[2], •Gernot Schaller[1], and Ralf Schützhold[1,3] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, 01328 Dresden, Germany — [2]Fakultät für Physik and CENIDE, Universität Duisburg-Essen, Lotharstraße 1, 47057 Duisburg, Germany — [3]Institut für Theoretische Physik, Technische Universität Dresden, 01062 Dresden, Germany

We investigate whether and how the quantum Zeno effect, i.e., the inhibition of quantum evolution by frequent measurements, can be employed to isolate a quantum dot from its surrounding electron reservoir. In contrast to the often studied case of tunneling between discrete levels, we consider the tunneling of an electron from a continuum reservoir to a discrete level in the dot. Realizing the quantum Zeno effect in this scenario can be much harder because the measurements should be repeated before the wave packet of the hole left behind in the reservoir moves away from the vicinity of the dot. Thus the required repetition rate could be lowered by having a flat band (with a slow group velocity) in resonance with the dot or a sufficiently small Fermi velocity or a strong external magnetic field. We also consider the anti-Zeno effect, i.e., how measurements can accelerate or enable quantum evolution.

Winding Number Statistics for Parametric Chiral Random Matrices — •Nico Hahn[1], Mario Kieburg[2], Omri Gat[3], and Thomas Guhr[1] — [1]University of Duisburg-Essen — [2]University of Melbourne — [3]The Hebrew University of Jerusalem

The winding number is a concept in complex analysis which has, in the presence of chiral symmetry, a physics interpretation as the topological invariant belonging to gapped phases of Fermions. We analytically study the statistical properties of this topological quantity. To this end, we set up a random matrix model for a chiral system with a parametric dependence. We address two chiral symmetry classes, the chiral unitary class without any further symmetries and the chiral symplectic class with additional time reversal symmetry. These classes are referred to as AIII and CII in the tenfold way of topological insulators and superconductors.

Simulating Non-Markovian Qubit Dynamics on a Quantum Processor — •Mirko Rossini, Dominik Maile, Joachim Ankerhold, and Brecht Donvil — Institute for Complex Quantum Systems and IQST

We propose a novel scheme to simulate the open system dynamics of a qubit. We go beyond the completely positive framework and consider linear, trace and Hermicity-preserving but not necessarily positivity-preserving evolution maps. We call these maps general dynamical maps. These maps naturally arise as the solution of general time-local master equations and for finite-dimensional systems they can always be decomposed as the difference between two completely positivity maps. We bring this difference into a form suitable for quantum simulation.

We illustrate our scheme by implementing two examples on IBMQ quantum processors: in the first example, we simulate the evolution of a general time local master equation both from an initial time when the evolution map is guaranteed to be completely positive and from an intermediate time when it is not. With our second example, we show that the simulation of non-completely positive maps gives the ability to recover the initial state of Lindbladian evolution.

Quantum Non-Markovianity made simple through extended states — Meng Xu[1], Yaming Yan[2], Qiang Shi[2], Joachim Ankerhold[1], and •Jürgen T. Stockburger[1] — [1]Institute for Complex Quantum Systems and IQST, Ulm University — [2]Beijing National Laboratory for Molecular Sciences, Chinese Academy of Sciences

We present a recent computational treatment of non-Markovianity [1] in open-system quantum dynamics. Focusing more on intrinsic timescales than on properties of a quantum channel and its generator, we extend the Hierarchical Equations of Motion (HEOM) approach through a highly efficient decomposition of environmental correlation functions into complex exponentials. Complex dynamics at ultralow temperatures and long reservoir timescales becomes tractable by this approach. We demonstrate that our version of the HEOM approach is closely related to an entire family of extended-state approaches, with our new approach being favored through a comparably low number of auxiliary dimen-

sions. The accurate reproduction of long-time algebraic tails in an open-system correlation function provides a benchmark result.

The Influence of Dynamical Phases on a Quantum Processor based Reservoir Computer — •Brecht Donvil, Mirko Rossini, Dominik Maile, and Joachim Ankerhold — ICQ and IQST, University of Ulm, Ulm, Germany

Reservoir computing is subbranch of machine learning where a physical system, the reservoir, is used to perform computational tasks instead of a large neural network which has to be trained. In the last years, quantum systems systems are being explored as potential reservoirs[1,2,3]. While most of the research has focussed on Ising spin systems, recently it was shown that also quantum processors can serve as reservoirs. The authors of [3] illustrated this fact by successfully implementing reservoir computing on an IMBQ quantum processor.

The dynamical phase of the reservoir can influence its performance on certain information processing tasks. For example, the authors of [2] found that the transverse-field Ising model performs best on examples of memory related tasks on the edge of the ergodic phase. The work I present here concerns quantum processor based reservoir computing as proposed in [3]. I consider simple circuit layout which is know to exhibit a dynamical phase transition between a localised and ergodic phase. I show the influence of the dynamical phase of the circuit on its information processing capacity and its performance as a readout device.

String order in measurement-induced symmetry-protected topological phases — •Raúl Morral[1], Frank Pollmann[1,3], and Izabella Lovas[1,2] — [1]Department of Physics, TFK, Technische Universität München, James-Franck-Straße 1, D-85748 Garching, Germany — [2]Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CA 93106, USA — [3]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany

We study measurement-induced symmetry protected topological (SPT) order in a wide class of quantum random circuit models, by combining calculations within the stabilizer formalism with tensor network simulations. We construct a family of quantum random circuits, generating the out-of-equilibrium version of all generalized cluster models, and derive a set of non-local string order parameters to distinguish symmetry protected topological phases. We apply this framework to study the random circuit realization of the XZX cluster model, and use the string order parameter to demonstrate that the phase diagram is strikingly stable against extending the class of unitary gates in the circuit, from Clifford gates to Haar unitaries. We then turn to the XZZX generalized cluster model, and demonstrate the coexistence of SPT order and spontaneous symmetry breaking, by relying on string order parameters and a connected correlation function. Our results pave the way to study the properties of a wide range SPT phases in quantum random circuit models with efficient tensor network methods.

DY 9.12   Mon 17:00   MOL 213

Quasiclassical and exact approaches to dissipative nonadiabatic quantum dynamics — •Graziano Amati[1], Johan Runeson[2], and Jeremy Richardson[3] — [1]Albert Ludwigs Universitaet Freiburg, Hermann Herder Str. 3, 79104 Freiburg, Germany — [2]Physical and Theoretical Chemistry Laboratory, Oxford University, South Parks Road, Oxford, OX1 3QZ, UK — [3]Laboratory of Physical Chemistry, ETH Zuerich, 8093 Zuerich, Switzerland

The study of many relevant processes in nature from photosynthesis, to radiation damage, to vision, depends on an accurate description of the electronic nonadiabatic dynamics. The brute-force simulation of nonadiabatic systems happens to be a computationally intensive task, given that the complexity of dynamic simulations scales exponentially with time and with the size of the system. Recently developed of 'spin mapping' approaches allow to recast a wide class of quantum nonadiabatic models onto quasiclassical systems of spins, whose dynamics exhibit a favorable linear or polynomial scaling in complexity. In my contribution I will firstly compare the accuracy in the long-time relaxation of several quasiclassical methods, borrowing ideas from classical ergodic theory. I will then discuss how to further improve the reliability of the long-time predictions of spin mapping techniques, by coupling these methods to the formalism of the non-Markovian generalized quantum master equation. I will then introduce the recent 'ellipsoid mapping' approach, a detailed-balance-preserving extension of spin mapping suited to study systems in thermal equilibrium.

Chiral motion of actively driven objects in discrete steps towards a remote target — •Andreas M. Menzel — Otto-von-Guericke-Universität Magdeburg, Magdeburg, Germany

We address the motion of chiral actively driven objects that move in discrete steps on a flat substrate [1]. While closed polygon-shaped trajectories are found in the case of unperturbed motion, the dynamics becomes surprisingly rich and nonlinear, if the objects additionally head for a fixed remote target. In that situation, cycloidal-like, straight, zigzag-type, doubled zigzag, quadrupled zigzag, and further period-doubled types of trajectory emerge, besides chaotic behavior. Additionally, we investigate the motion of crowds of such objects under explicit mutual alignment interaction. In the absence of fluctuations, collective orientational ordering occurs also in the chaotic regime, in combination with spatial gathering of the particles. Conversely, fluctuations and polydispersity in target alignment counteract orientational ordering. Our results may apply to various types of actively driven objects, for instance, light-responsive bacteria, laser-controlled colloidal particles, or hoppers on vibrated substrates.

Polar flocks with discretized directions: the active clock model approaching the Vicsek model — •Matthieu Mangeat, Swarnajit Chatterjee, and Heiko Rieger — Universität des Saarlandes, Saarbrücken, Germany

We study the off-lattice two-dimensional q-state active clock model (ACM) [EPL **138**, 41001 (2022)] as a natural discretization of the Vicsek model (VM) [PRL **75**, 1226 (1995)] describing flocking. The ACM consists of particles able to move in the plane in a discrete set of q equidistant angular directions, as in the active Potts model (APM) [EPL **130**, 66001 (2020); PRE **102**, 042601 (2020)], with a local alignment interaction inspired by the ferromagnetic equilibrium clock model. A collective motion emerges at high densities and low noise. We compute phase diagrams of the ACM and explore the flocking dynamics in the region, in which the high-density (polar liquid) phase coexists with the low-density (gas) phase. We find that for a small number of directions, the flocking transition of the ACM has the same phenomenology as the APM, including macrophase separation and reorientation transition from transversal to longitudinal band motion as a function of the particle self-propulsion velocity. For a larger number of directions, the flocking transition in the ACM becomes equivalent to the one of the VM and displays microphase separation and only transverse bands, i.e. no reorientation transition. Concomitantly also the transition of the $q \to \infty$ limit of the ACM, the active XY model, is in the same universality class as the VM. We also construct a coarse-grained hydrodynamic description akin to the VM.

DY 10.3 Mon 15:30 ZEU 160

Tracer-induced temperature difference in motility-induced phase separation — •Lukas Hecht, Iris Dong, and Benno Liebchen — Institut für Physik kondensierter Materie, Technische Universität Darmstadt, Hochschulstr. 8, D-64289 Darmstadt, Germany

Previous studies of overdamped active Brownian particles (ABPs) mixed with passive tracers have shown that self-propulsion can induce motility-induced phase separation (MIPS) for large enough particle density and self-propulsion speed [1]. Here, we present our study on overdamped ABPs mixed with inertial passive tracers. We show that MIPS features different kinetic temperatures in the dense and the dilute phase if the passive tracers are sufficiently heavy (inertial). Remarkably, unlike for underdamped ABPs [2,3], neither the overdamped ABPs nor the passive tracers alone would feature such a temperature difference in coexisting phases. The observed temperature difference is accompanied by a violation of the equipartition theorem and strongly depends on the self-propulsion speed and the particle density. This allows us to tune the temperature difference from a cold dense and hot dilute phase to the counterintuitive opposite case in which the dense phase is hotter than the dilute phase. These findings open a route to create active materials with a persistent temperature profile by inserting active particles and tuning their self-propulsion speed accordingly.

Collective motion in two-dimensional colloidal systems with effective (active) self-propulsion due to time-delayed feedback — •Robin A. Kopp and Sabine H. L. Klapp — ITP, TU Berlin, Berlin, Germany

In recent years, delayed feedback in colloidal systems has become an active and promising field of study [1,2], key topics being history dependence and the manipulation of transport properties. Here we study the dynamics of a two-dimensional colloidal suspension, subject to time-delayed feedback, where time-

delayed feedback can be interpreted as a mechanism of effective self-propulsion, i.e., activity [3]. To this end we perform overdamped Brownian dynamics simulations, where the particles interact through a Weeks-Chandler-Andersen potential. Furthermore, each particle is subject to a Gaussian, repulsive feedback potential, that depends on the difference of the particle position at the current time, and at an earlier time. We observe and quantitatively study the emergence of dynamical clustering and collective motion characterized by a nonzero mean velocity and provide a possible explanation for the underlying mechanism combining single-particle and mean-field-like effects.

Inverted Sedimentation of Active Particles in Unbiased ac Fields — •José Carlos Ureña Marcos and Benno Liebchen — Institut für Physik Kondensierter Materie, TU Darmstadt, Darmstadt, Germany

Biological microswimmers can steer autonomously and use this ability to perform sophisticated tasks. Synthetic microswimmers do not yet reach the same degree of autonomy, and need to be controlled externally if they are to carry out tasks such as targeted cargo delivery or microsurgery. While much progress has been made recently to control their motion based on external forces or gradients, e.g. in light intensity, which have a well-defined direction or bias, little is known about how to steer APs in situations where no permanent bias can be realized.

Here, we show that ac fields with a vanishing time average provide an alternative route to steering APs. We exemplify this route for inertial APs in a gravitational field, observing that a substantial fraction of them persistently travels in the upward direction upon switching on the ac field, resulting in an inverted sedimentation profile at the top wall of a confining container. Our results offer a generic control principle which could be used in the future to steer active motion, to direct collective behaviors and to purify mixtures.

Long-range communications enable the hierarchical self-organization of active matter — •Igor Aronson[1], Alexander Ziepke[2], Ivan Maryshev[2], and Erwin Frey[2] — [1]Pennsylvania State University, USA — [2]Ludwig-Maximilians-University, Munich, Germany

The most distinct markers of life are the ability to move (locomotion), consume energy (metabolism), process information, and form multi-cellular aggregates. Many biological systems exhibit long-range signaling strategies for evolutionary advantage. We explore the multi-scale self-organization of interacting self-propelled agents that locally process information transmitted by chemical signals. The communication capacity dramatically expands their ability to form complex structures, allowing them to self-organize through a series of collective dynamical states at multiple hierarchical levels.

The consequent study shows that information exchange by acoustic waves between the self-propelled units creates a slew of multifunctional structures. Each unit is equipped with an acoustic emitter and a detector in this realization. The swarmers respond to the resulting acoustic field by adjusting their emission frequency and migrating toward the strongest signal. We find self-organized structures with different morphology, including snake-like self-propelled entities, localized aggregates, and spinning vortices. Our results provide insights into the design principles of communicating active particles capable of performing complex tasks.

Arrested by heating — •Corinna C. Maass[1,2], Prashanth Ramesh[2,1], and Maziyar Jalaal[3] — [1]University of Twente, Enschede, Netherlands — [2]MPI for Dynamics and Self-organization, Göttingen, Germany — [3]Universiteit van Amsterdam, Amsterdam, Netherlands

Active droplets are a class of microswimmers driven by chemical reactions at the droplet interface. Typically, the activity is powered by an advection-diffusion instability in the chemohydrodynamic fields around the droplet that is characterised by the Péclet number Pe of chemical transport. With increasing Pe, higher hydrodynamic modes at the interface cause the droplet to transition from inactivity, to steady, to reorienting, to fully unsteady motion. Here, we demonstrate that it is possible to change Pe reversibly and in situ by thermally activated changes in the chemical enviroment, and thereby to control the motility of the droplet.

Chiral active particles with non-reciprocal couplings: results from particle-based simulations — •Kim L. Kreienkamp and Sabine H. L. Klapp — Technische Universität Berlin, Germany

Non-reciprocal interactions manifest their drastic impact on the collective dynamics of active matter systems by changing, for example, the general type of observed instabilities [1] and leading to time-dependent states [2,3]. In particular, the combination of non-reciprocity and chirality in terms of intrinsically rotating chiral active particles ("circle swimmers") reveals intriguing non-trivial time-dependent collective dynamics [1].

After having developed an understanding of the collective dynamics on the continuum level in previous work [1], we here present first results of particle-based simulations of chiral active particle systems with non-reciprocal alignment couplings. Indeed, quantitative predictions from continuum approaches are somewhat limited by the approximations made during the coarse-graining process. Thus, the first goal of our particle-based simulations is to explore the validity of the previously obtained continuum results regarding the overall state diagram. Second, we aim at investigating microscopic aspects of the various time-dependent states. Finally, we discuss possibilities to characterize the thermodynamic behavior of the non-reciprocal chiral system based on the stochastic trajectories obtained in particle-resolved simulations.

Lattice-induced freezing in active systems unveils dynamic crystallites with square ordering — •Aritra K. Mukhopadhyay[1], Peter Schmelcher[2,3], and Benno Liebchen[1] — [1]Technische Universität Darmstadt, 64289 Darmstadt, Germany. — [2]Zentrum für Optische Quantentechnologien, Universität Hamburg, Luruper Chaussee 149, 22761 Hamburg, Germany. — [3]The Hamburg Centre for Ultrafast Imaging, Universität Hamburg, Luruper Chaussee 149, 22761 Hamburg, Germany.

Active matter, comprising self-propelled particles like bacteria, colloidal microswimmers, or granular microflyers is currently attracting enormous attention for its ability to self-organize into complex nonequilibrium structures. In this work, we report on a new state of dynamic active crystallites, which occurs when exposing active particles to a spatially periodic potential. These crystallites require activity to emerge, adopt the structure of the underlying lattice (e.g.

square rather than hexagonal close packing), and are continuously in motion. This new phase unifies the structural properties of crystals with the dynamical properties of disordered fluids. Our work thus unveils a route to creating a new state of active materials with an intrinsic structure that can be externally controlled.

Shape-dependent collective motion: cohesive groups and cargo transport of colloidal rods — Philipp Stengele, •Anton Lüders, and Peter Nielaba — Universität Konstanz, Konstanz, Deutschland

In active toy model systems where colloids interact via predefined social interaction rules as well as steric collisions, the shape of the individual particles strongly influences emerging collective behavior. We study this based on two example systems using Brownian dynamics simulations (without hydrodynamic interactions). Firstly, we investigate a simple perception model in which colloidal rods move actively if predefined visual stimuli exceed a certain threshold. Here, we find an aspect ratio range where the rods form a dilute cohesive group with a time-independent particle distribution. If the aspect ratio surpasses this range, the rods slowly drift apart. Secondly, we look into the cargo capture and transport of a passive rod using a dense swarm of active spheres which form a hexagonal cage with a cavity for the cargo. Again, the aspect ratio of the rod proves to be crucial, as we find geometric restrictions that must be met to stabilize the cavity. Our work underlines that the shape (here, the aspect ratio) of the particles in active matter systems must be carefully considered while defining interaction rules to perform specific tasks.

DY 10.11   Mon 18:00   ZEU 160

Active Chiral Nematics — •Rüdiger Kürsten[1,2,3] and Demian Levis[1,2] — [1]Departament de Física de la Matèria Condensada, Universitat de Barcelona, Barcelona, Spain — [2]Universitat de Barcelona Institute of Complex Systems (UBICS), Barcelona, Spain — [3]Institut für Physik, Universität Greifswald, Greifswald, Germany

We study inherently chiral self-propelled particles in two dimensions that are subjected to nematic alignment interactions and rotational noise. By means of both, homogeneous and spatially resolved mean field theory we identify various different flocking states. We confirm the presence of the predicted phases using agent-based simulations. We emphasize that special care has to be taken within the simulations in order to avoid artifacts. We present a non-standard simulation technique in order to avoid those artifacts.

DY 11: Focus Session: Physics Meets ML II – Understanding Machine Learning as Complex Interacting Systems (joint session DY/TT)

Machine-learning has recently entered and is now transforming many fields of science, enabling discoveries in a data-driven manner. As a scientific method, however, ML often lacks one defining feature: Explainability. We here seek discussions with pioneers in understanding, explaining, and improving machine learning methods from the point of view as a physical system of interacting elements. In fact, the history of approaching neuronal networks and problems of inference and learning as a problem of statistical physics has a long history, with a number of important discoveries early on. The close relation between spin glasses and neuronal networks are being currently exploited to address pressing questions, such as the remarkable generalization properties of neuronal networks despite their massive overparameterization and their behavior reminiscent of renormalization group transformations.

The challenge of structured disorder in statistical physics — •Marc Mezard — Bocconi University, Milano

Statistical physics offers many interesting tools to study machine learning. In most cases it needs to use a statistical ensemble of data. Most of the theoretical work has relied on unstructured data. Yet, the highly structured character of data used in training deep networks is a crucial ingredient of their performance. Modelling structured data, analyzing the learning and the generalization of deep networks trained on this data, are major challenges. This talk will describe several recent developments in this direction.

Adaptive Kernel Approaches to Feature Learning in Deep Neural Networks — •Zohar Ringel — Racah Institute of Physics, Hebrew University in Jerusalem

Following the ever-increasing role of deep neural networks (DNNs) in our world, a better theoretical understanding of these complex artificial objects is desirable. Some progress in this direction has been seen lately in the realm of infinitely overparameterized DNNs. The outputs of such trained DNNs behave essentially as multivariate Gaussians governed by a certain covariance matrix called the kernel. While such infinite DNNs share many similarities with the finite ones used in practice, various important discrepancies exist. Most notably the fixed kernels of such DNNs stand in contrast to feature learning effects observed in finite DNNs. Such effects are crucial as they are the key to understanding how DNNs process data. To accommodate such effects within the Gaussian/kernel viewpoint, various ideas have been put forward. Here I will provide a short overview of those efforts and then discuss in some detail a general set of equations we

developed for feature learning in fully trained/equilibrated DNNs. Interestingly, our approach shows that DNNs accommodate strong feature learning via mean-field effects while having decoupled layers and decoupled neurons within a layer. Furthermore, learning is achieved not by compression of information but rather by increasing neuron variance along label-relevant directions in function space.

DY 11.4   Mon 16:30   ZEU 250
Interpreting black-box ML with the help of physics — •Miriam Klopotek — University of Stuttgart, SimTech Cluster of Excellence EXC 2075, Stuttgart, Germany

Complexity is an unavoidable part of systems with emergent or even so-called intelligent capabilities. Ultimately, it stems from the many microscopic constituents with multiple possible states, which introduces a vast space of degrees of freedom. This is true both for many-body systems as well as modern machine learning (ML) systems. Today, the latter suffer notoriously from the 'black-box problem', i.e. they are inherently opaque. We argue that an engagement with physics can offer deep insights ultimately for a theory of operation and thus an interpretation, as well as powerful ways to assess their reliability and shortcomings. We show some results for a case study with beta-variational autoencoders (β-VAEs) [1], which we trained on data from a well-characterized model system of hard rods confined to 2D lattices [2].

Invited Talk   DY 11.5   Mon 17:00   ZEU 250
Analysing the dynamics of message passing algorithms — •Manfred Opper[1,2] and Burak Cakmak[1] — [1]Institut für Softwaretechnik und Theoretische Informatik, Technische Universität Berlin, 10587, Germany — [2]Centre for Systems Modelling and Quantitative Biomedicine, University of Birmingham, B15 2TT, United Kingdom

Message passing algorithms are deterministic methods which are designed for efficiently computing marginal statistics for probabilistic, Bayesian data models used in machine learning and statistics. Such algorithms have been developed in parallel within the machine learning and the statistical physics communities. They often provide highly accurate approximations at a much higher speed compared to exact Monte Carlo sampling. The fixed points of such algorithms can be analysed for high dimensional models (under the assumption of specific data distributions) using the replica method of statistical physics. In this talk we will focus on the dynamical properties of the algorithms. Applying dynamical functional techniques to the nonlinear dynamics, the degrees of freedom which interact via a random matrix can be decoupled in the limit of large systems resulting in exact stochastic single node dynamics. For general dynamical models, it is hard to further analyse this effective dynamics due to the occurence of memory terms. Surprisingly, for message passing algorithms memory terms are absent and exact results for convergence rates and stability can be derived for specific data distributions.

Solving the Bethe–Salpeter equation with exponential convergence — •Markus Wallerberger[1], Hiroshi Shinaoka[2], and Anna Kauch[1] — [1]TU Wien, Vienna, Austria — [2]Saitama University, Japan

The Bethe–Salpeter equation plays a crucial role in understanding the physics of correlated fermions, relating to optical excitations in solids as well as resonances in high-energy physics. Yet, it is notoriously difficult to control numerically, typically requiring an effort that scales polynomially with energy scales and accuracy. This puts many interesting systems out of computational reach.

Using the intermediate representation and sparse modeling for two-particle objects on the Matsubara axis, we develop an algorithm that solves the Bethe–Salpeter equation in $O(L^8)$ time with $O(L^4)$ memory, where L grows only logarithmically with inverse temperature, bandwidth, and desired accuracy. This opens the door for computations in hitherto inaccessible regimes. We benchmark the method on the Hubbard atom and on the multiorbital weak-coupling limit, where we observe the expected exponential convergence to the analytical results. We then showcase the method for a realistic impurity problem.

Making machines untangle the parquet equations — •Samuel Badr[1], Anna Kauch[1], Hiroshi Shinaoka[2], Karsten Held[1], and Markus Wallerberger[1] — [1]TU Wien, Vienna, Austria — [2]Saitama University, Saitama, Japan

Diagrammatic theories at the two-particle level are increasingly important in understanding the subtle interplay of phenomena occurring in strongly correlated electron systems. The parquet equations are a centerpiece of many such theories, since they are the simplest unbiased topological classification of two-particle diagrams. However, due to their eponymous interlocking structure, the parquet equations are vexingly difficult to solve, requiring prohibitive amounts of memory.

We tackle this problem using the recently developed, machine learning inspired, techniques: firstly, the overcomplete intermediate representation, a highly compressed model for two-particle objects which is guaranteed to converge exponentially; secondly, a sparse set of Matsubara frequencies tailored to the structure of the parquet equations. This allows us to perform convolutions and frequency shifts at no loss of accuracy.

We benchmark our solver for the Hubbard atom, where we reproduce analytic results, and then showcase the solver for more extended systems.

Unraveling structural and dynamical features in glassy fluids using machine learning — •Laura Filion[1], Frank Smallenburg[2], and Rinske Alkemade[1] — [1]Debye Institute for Nanomaterials Science, Utrecht University, Netherlands — [2]Laboratoire de physique des Solides, Université Paris-Saclay, France

Developments in machine learning (ML) have opened the door to fully new methods for studying phase transitions due to their ability to extremely efficiently identify complex patterns in systems of many particles. Applications of machine learning techniques vary from the use of developing new ML-based order parameters for complex crystal structures, to locating phase transitions, to speeding up simulations. The rapid emergence of multiple applications of machine learning to statistical mechanics and materials science demonstrates that these techniques are destined to become an important tool for soft matter physics. In this talk, I will briefly present an overview of the work my group is doing on using ML to study soft matter systems, with a focus on how ML can be used to explore new connections between structure and dynamics in supercooled liquids.

In particular, I will present a strategy to fit the dynamics in glassy systems using advanced hierarchical order parameters combined with simple linear regression. Additionally, I will present a method for extracting the cage structure of a glassy configuration, and demonstrate that this information significantly improves our ability to predict glassy dynamics over a broad range of time scales.

How are mobility and friction related in viscoelastic fluids? — •Juliana Caspers[1], Nikolas Ditz[2], Karthika Krishna Kumar[2], Felix Ginot[2], Clemens Bechinger[2], Matthias Fuchs[2], and Matthias Krüger[1] — [1]Institute for Theoretical Physics, Georg-August Universität Göttingen, 37073 Göttingen, Germany — [2]Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany

The motion of a colloidal probe in a viscoelastic fluid is described by friction or mobility, depending on whether the probe is moving with a velocity or feeling a force. While the Einstein relation describes an inverse relationship valid for Newtonian solvents, both concepts are generalized to time-dependent memory kernels in viscoelastic fluids. We theoretically and experimentally investigate their relation by considering two observables: the recoil after releasing a probe that was moved through the fluid and the equilibrium mean squared displacement (MSD). Applying concepts of linear response theory, we generalize Einstein's relation and thereby relate recoil and MSD, which both provide access to the mobility kernel. With increasing concentration, however, MSD and recoil show distinct behaviors, rooted in different behaviors of the two kernels. Using two theoretical models, a linear two-bath particle model and hard spheres treated by mode-coupling theory, we find a Volterra relation between the two kernels, explaining differing timescales in friction and mobility kernels under variation of concentration.

DY 16.2   Tue 10:15   MOL 213

Can liquid-state theory predict jamming of hard particles? — •Carmine Anzivino[1], Mathias Casiulis[2], Amgad Moussa[3], Stefano Martiniani[2], and Alessio Zaccone[1] — [1]Department of Physics "A. Pontremoli", University of Milan, via Celoria 16, 20133 Milan, Italy — [2]Center for Soft Matter Research, Department of Physics, New York University, New York 10003, USA — [3]Syngenta AG, 4058 Basel, Switzerland

By generalizing the notion of maximally random jammed (MRJ) state [1,2] to that of MRJ-line, we show [3] that it is reasonable to assume the most random branch of jammed states to undergo crowding in a way qualitatively similar to an equilibrium liquid. We then prove that, for hard-sphere systems, liquid-state theories can be succesfully used to estimate the RCP density, when the latter is identified with the densest isostatic point, i. e. the densest among the MRJ states with z=6.

Our finding is further enforced by the analysis of polydisperse systems. Either in the case of bidisperse and polydisperse hard spheres our prediction of the RCP density is in very good agreement with simulations, for a large values of size ratios and polydispersity.

DY 16.3   Tue 10:30   MOL 213

2D crystals of squares and the tetraic phase — •Peter Keim — Max-Planck-Institut für Dynamik und Selbstorganisation, Göttingen

Squares (5 micron edge-length) were manufactured from a photo-resist using a 3D nanoprinter (nanoscribe GT). In aqueous solution, particles sediment by gravity to a thin cover slide where they form a mono-layer of Brownian particles. The curvature of the cover slide can be adjusted from convex to concave, which allows to vary the area-density of the mono-layer from 700 to 1500 particles in the field of view. For low densities, the squares are free to diffuse and form a 2D fluid while for high densities they form a quadratic crystal. In analogy to 2D-melting by topological defects with an intermediate hexatic phase for isotropic particles (KTHNY-theory and Nobel-price 2016), a four-folded bond-order correlation function is used to resolve a tetratic phase with quasi-long-range orientational order but short rang translational order.

DY 16.4   Tue 10:45   MOL 213

Transient microrheology unveils the presence of two relaxation processes in viscoelastic fluids — •Félix Ginot[1], Juliana Caspers[2], Luis Frieder Reinalter[1], Karthika Krishna Kumar[1], Matthias Krüger[2], and Clemens Bechinger[1] — [1]Fachbereich Physiks Universität Konstanz, 78457 Konstanz, Germany — [2]Institute for Theoretical Physics, Georg-August Universität Göttingen, 37073 Göttingen, Germany

We experimentally investigate the transient dynamics of a colloidal probe particle in a viscoelastic fluid after the driving force acting on the probe is suddenly removed. In this situation, the probe exhibits a strong backward recoil, with two distinct timescales. While the first timescale naturally originates from the viscoelastic properties of the fluid, the second timescale arises from the coupling between the probe and the bath. These experimental observations are in excellent agreement with a microscopic model which considers the probe particle to be coupled to two bath particles via harmonic springs. Interestingly, this model exhibits two sets of eigenmodes corresponding to reciprocal and non-reciprocal force conditions, and which can be experimentally confirmed in our experiments. We expect our findings to be relevant under conditions where particles are exposed to non-steady shear forces as this is encountered e.g. in microfluidic sorting devices or the intermittent motion of motile bacteria within their natural viscoelastic surroundings.

Phason strain-free growth of quasicrystals based on purely local rules and without repair mechanism — Stefan Wolf[1], Michael Engel[2], and •Michael Schmiedeberg[1] — [1]Institute of Theoretical Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany — [2]Institute for Multiscale Simulation, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

We introduce a simple model for the growth of colloidal quasicrystals where new particles are sequentially added according to specific local rules to the system in three dimensions. Subsequent changes to the particles are not allowed, i.e., no phasonic rearrangements can occur once a particle has been placed into the system. Our findings demonstrate that the purely local energetic rules are sufficient to obtain complex long-ranged order. Thus, phasonic rearrangements or fluctuations might be important to facilitate the formation of almost perfect quasicrystals [1-3] but they are not indispensable.

Magnus force on microscopic spinning objects moving through non-Markovian baths — Xin Cao[1], •Debankur Das[2], Niklas Windbacher[1], Felix Ginot[1], Matthias Kruger[2], and Clemens Bechinger[1] — [1]Fachbereich Physik, University Konstanz, 78464 Konstanz, Germany — [2]Institut für Theoretische Physik, Universität Göttingen, 37077 Göttingen Germany

When a spinning object moves through a fluid or air, its direction of motion becomes deflected due to the Magnus force that is perpendicular both to the moving direction and the spinning axis. Since the Magnus effect is caused by inertial effects within the surrounding medium, it should vanish at micro scales where viscous forces dominate over inertia. Recent experiments have observed the phenomenon similar to Magnus effect when a spinning colloids and there aggregates are externally driven through a viscoelastic fluid. Even though the deflection force shows a similar dependence on the spinning and translating velocity of the particles as in case of Magnus forces, its sign is reversed. Here, we

have developed a theory of such motions which doesnot rely on the inertial effects but caused explicitly by the memory effect of the viscoelastic fluid. To better elucidate our theory we corroborate our results with experiments. Our theory successfully captures the density relaxation timescales of the viscoelastic fluid. Further we proposed viable theoretical predictions which can be verified with further experiments.

DY 16.7 Tue 11:45 MOL 213

Preferential alignment of colloidal dumbbells with recoil direction — •Karthika Krishna Kumar[1], Félix Ginot[1], Juliana Caspers[2], Matthias Krüger[2], and Clemens Bechinger[1] — [1]Fachbereich Physik, Universität Konstanz, Germany — [2]Institute for Theoretical Physics, Georg-August Universität Göttingen, Germany

Unlike Newtonian fluids, viscoelastic fluids can store and dissipate energy on much longer timescales leading to non-Markovian dynamics. Hence, probing viscoelastic fluids using colloidal particles reveal complex dynamics in microscopic lengthscales. A consequence of this is the recoil behavior of a colloidal particle after dragging it through a viscoelastic fluid. In this work, we use a pair of colloidal particles stuck together due to depletion interactions forming a dumbbell-shaped structure. This gives the advantage of resolving the orientational component in addition to the translational components of the particle motion. Surprisingly, we report that the axis of the dumbbell tends to align with the direction of the motion during a recoil. The amplitude of this orientational component follows a non-linear trend even in the regime where translational recoil amplitudes show a linear increase with shear velocity. This behavior can no longer be explained by the linear two-bath particle model which is able to explain the bi-exponential translational recoils. Furthermore, the amplitude of this re-orientation increases with the initial angle at which the dumbbell is dragged. This points to an asymmetric distribution of elastic energy between the two particles of the dumbbell which might cause this effect.

DY 16.8 Tue 12:00 MOL 213

Entropic phase diagram of twisted convex particles — •Poshika Gandhi and Anja Kuhnhold — Institute of Physics, University of Freiburg, Germany

The field of liquid crystal simulations has, over the years, benefitted immensely from the study of purely entropy driven systems. Since Onsager's[1] predictions of the existence of a nematic phase in long rods, the list of known phases of hard rod-like particles has grown to include phases like smectics and cholesterics.

An important parameter in the formation of these phases is the particle shape anisotropy. By considering unusual particle shapes new phases can be discovered. Recently, Dussi and Dijkstra[2] showed the formation of stable chiral nematic phase in twisted polyhedral particles using only entropic interactions.

We used Monte Carlo NVT simulations to produce phase diagrams of a different class of twisted particles - convex triangular and rectangular prisms. The results show a host of previously undiscovered phases arising from the shape anisotropy parameters like twist angle and aspect ratios.

DY 16.9 Tue 12:15 MOL 213

Optimizing the Structure of Acene Clusters — •Philipp Elsässer and Tanja Schilling — Institute of Physics, University of Freiburg, Germany

In the production of organic solar cells, neutral acene cluster beams are used to create thin films. The molecules in these clusters can be arranged in various ways. Most types of acene molecules are quasi two dimensional with one long

axis - they prefer stacked or herring-bone structures. Additionally, the positions of the molecules in a cluster may vary. Thus, the exact way of how they arrange has a strong influence on the overall energy of the cluster.

We have investigated the structures of anthracene, tetracene, and pentacene clusters with up to 30 molecules. In order to find the configurations at the global minimum with respect to the positions of the atoms, we applied the Basin-Hopping Monte-Carlo (BH) algorithm to atoms described by the polymer-consistent force field - interface force field (PCFF-IFF). We studied for these cluster structures the relative stability between different sizes of clusters, as well as the accessibility of the global minimum at different temperatures.

DY 16.10 Tue 12:30 MOL 213

Ergodicity breaking in overpacked colloidal hard spheres — •Hans Joachim Schöpe — Universität Tübingen, Institut für angewandte Physik, Auf der Morgenstelle 10, 72076 Tübingen

The ergodic hypothesis is an essential prerequisite for the applicability of statistical mechanics in thermodynamic equilibrium. Direct experimental evidence of the validity of the ergodic hypothesis is extremely rare. Furthermore, the question arises to what extent - if at all - ergodicity exists in non-equilibrium. We have realized a novel dynamic light scattering experiment, which makes it possible to determine the probability distribution of relaxation-times in colloidal suspensions. We present here a systematic study of the relaxation-time distribution in colloidal hard spheres at the transition from equilibrium to non-equilibrium. In thermodynamic equilibrium, we can impressively confirm the ergodic hypothesis and show that the fluctuations are of a Gaussian nature. Out of equilibrium, we can detect non-Gaussian behavior, which increases rapidly with increasing undercooling (overpacking). The ergodic hypothesis is no longer fulfilled in non-equilibrium. Furthermore, we observe that the metastable fluid ages in the induction stage, the non-Gaussian fluctuations increase in the time before crystallization sets in. To what extent these fluctuations cause crystallization must be clarified in the future.

DY 16.11 Tue 12:45 MOL 213

Coacervates from a polyelectrolye and a small polyion: preparation, phase behavior and theoretical modeling — Lucy Coria-Oriundo[1], Eugenia Apuzzo[2], Santiago Herrera[1], Marcelo Ceolín[2], Gabriel Debais[1], Fernando Battaglini[1], and •Mario Tagliazucchi[1] — [1]Universidad de Buenos Aires, Bs.As., Argentina — [2]Universidad Nacional de la Plata, Bs.As., Argentina.

A mixture of oppositely charged polyelectrolytes, under the proper experimental conditions, can undergo liquid-liquid phase separation. The resulting polymer-rich phase is usually known as polyelectrolyte coacervate. This work reports liquid coacervates composed of a small polyanion (ferricyanide) and branched poly(ethyleneimine) (BPEI), a polycation. The phase diagram of the system was measured as a function of the concentration of both components at fixed pH = 6 and a concentration of added NaCl of 0.5 M. The salt resistance of the coacervate was studied and it was found that the coacervate is stable up to [NaCl] = 1.35 M. The phase diagram and salt-resistance experiments were modeled with a statistical-thermodynamics formalism that models the association of the oppositely charged species as a pseudo-chemical-equilibrium. The model fits very well the experimental data and was used to analyze the differences between polymer-polymer and polymer-small ion coacervates. Finally, the diffusion coefficient of ferricyanide within the coacervated (measured with cyclic voltammetry) was shown to increase 10 times when the concentration of added NaCl was increased from 0 to 1.2 M.

On-the-fly adaptive sparse grids for coupling high-fidelity and coarse-grained models — •Tobias Hülser, Sina Dortaj, and Sebastian Matera — Fritz-Haber-Institut der MPG, Berlin, Germany

Most simulations of continuum models require the repetitive evaluation of some non-linear functions. If the latter are only given by the outcome of some high-fidelity simulation, these evaluations can easily become the computational bottleneck of the coupled simulation. To overcome this limitation, computationally efficient machine-learning models have become popular as surrogates of the high-fidelity model in the continuum scale simulation. However, if the input dimension of these models is high, the training of the surrogate often requires infeasible numbers of simulations, the so-called curse of dimensionality. We present an on-the-fly adaptive sparse grids approach, which lifts these limitations. This exploits that, on the one hand, sparse grids are only mildly affected by the curse of dimensionality and allow for an adaptive, local error based training set design. On the other hand, we utilize that, during a continuum simulation, only a small low-dimensional subset of the high-dimensional input space of the

high-fidelity model is visited. We therefore construct the surrogate on the fly during the continuum simulation, only generating the high-fidelity data which is needed to interpolate this subset.

We demonstrate the approach on exemplary physical-chemical models from the field of heterogeneous catalysis. We find that our approach can significantly reduce the number of high-fidelity evaluations compared to the direct coupling.

Reservoir Computing using Active Matter Model Systems: A Physics Viewpoint — •Mario U. Gaimann and Miriam Klopotek — Stuttgart Center for Simulation Science (SimTech), Cluster of Excellence EXC 2075, University of Stuttgart, Germany

Spatio-temporal prediction of chaotic systems is a challenging problem that is relevant for many fields (weather, finance, energy, and other dynamic systems). Recurrent neural networks and specifically neuron-based reservoir computing were previously used to approach this problem [1,2]. However, these learning systems are typically treated as black boxes, and do not incorporate reasoning

or analysis in terms of physical laws and dynamics. Here we study the non-equilibrium dynamics of simple active matter models serving as reservoir computing substrates [3]. This allows us to determine and interpret the state of our reservoir and relate the learning problem to other generic phenomena in statistical physics. With this knowledge we aim to understand optimal conditions for learning in relation to critical states and physical constraints.

DY 17.3   Tue 10:30   ZEU 160

Machine Learning Percolation: Does it understand the physics? — •Djénabou Bayo[1,2], Andreas Honecker[2], and Rudolf A. Römer[1] — [1]Departement of Physics, University of Warwick, Coventry, CV47AL, United Kingdom — [2]Laboratoire de Physique Théorique et Modélisation (LPTM) (CNRS UMR8089), CY Cergy Paris Université, 95302 Cergy-Pontoise, France
The percolation model is one of the simplest models in statistical physics displaying a phase transition at a critical site occupation probability p_c. The hallmark of the percolation transition is the emergence of a spanning cluster of connected neighboring sites across the lattice. Machine learning (ML) approaches to percolation have shown that the non-spanning ($p < p_c$) and the spanning ($p > p_c$) phases can be identified reasonably well with supervised deep learning (DL) strategies for classification based on convolutional neural networks (CNNs). Surprisingly, the role of the spanning cluster seems to be less prominent in such DL methods. Here, we show that CNNs, when trained with the site occupation probabilities p as labels, can classify not only the two phases $p < p_c$ and $p > p_c$, but also according to the many individual p's. Nevertheless, the same CNNs struggle when trying to predict the emergence of the spanning cluster. Indeed, when we train with correlation lengths or the existence of the spanning cluster, the results suggest that the CNNs seem to rely mostly on the p's as a proxy measure. This suggests that the essential physics of the spanning cluster is not actually what determines the DL results.

DY 17.4   Tue 10:45   ZEU 160

Bayesian deep learning for error estimation in the analysis of anomalous diffusion — •Henrik Seckler[1] and Ralf Metzler[1,2] — [1]Institute for Physics & Astronomy, University of Potsdam, 14476 Potsdam-Golm, Germany. — [2]Asia Pacific Centre for Theoretical Physics, Pohang 37673, Republic of Korea
Modern single-particle-tracking techniques produce extensive time-series of diffusive motion in a wide variety of systems, from single-molecule motion in living-cells to movement ecology. The quest is to decipher the physical mechanisms encoded in the data and thus to better understand the probed systems. We here augment recently proposed machine-learning techniques for decoding anomalous-diffusion data to include an uncertainty estimate in addition to the predicted output. To avoid the Black-Box-Problem a Bayesian-Deep-Learning technique named Stochastic-Weight-Averaging-Gaussian is used to train models for both the classification of the diffusion model and the regression of the anomalous diffusion exponent of single-particle-trajectories. Evaluating their performance, we find that these models can achieve a well-calibrated error estimate while maintaining high prediction accuracies. In the analysis of the output uncertainty predictions we relate these to properties of the underlying diffusion models, thus providing insights into the learning process of the machine and the relevance of the output.

DY 17.5   Tue 11:00   ZEU 160

A machine learned classical density functional for orientational correlations in the Kern-Frenkel model for patchy particles — •Alessandro Simon[1,2] and Martin Oettel[1] — [1]Institute for Applied Physics, University of Tübingen, Germany — [2]Max Planck Institute for Intelligent Systems, Tübingen, Germany
Models of patchy particles in a generic form (hard spheres decorated with a fixed number of attraction sites), posses an interesting phase behaviour, despite their apparent simplicity. This includes gel-formation and a vanishing fluid density at the gas-liquid coexistance, as the number of attractive patches and temperature is decreased. Using simulations of a symmetric four-patch model, we examine the orientational order of the particles and the effects of their tetrahedral symmetry on the expansion of density profiles and pair correlations in rotational invariants. Building on an existing classical density functional model which is formulated on the basis of Wertheim's theory for associating liquids and does not resolve orientational correlations [Stopper et al. J. Chem. Phys. 149, 224503 (2018)], we construct an improved density functional using machine learning and show that it yields the correct orientation distribution in slit-like geometries.

Classification of Gel Networks using Graph Convolutional Neural Networks — •Matthias Gimperlein and Michael Schmiedeberg — FAU Erlangen-Nürnberg, Erlangen, Germany

The structural properties of gel networks are important for the mechanical properties of the corresponding gels. We analyze gel networks and their structure using a machine learning approach based on graph convolutional networks (GCN) employing only the local neighborhood of particles as input information.

Using these we define a GCN-Autoencoder to reconstruct adjacency matrices of networks and quantitatively analyze in which properties the prediction of the network differs from the original input. This includes analysis on the abstract graph level as well as on the real physical network level.

Furthermore we use GCNs to classify gel networks depending i.e. on the loopsizes which are present in the network. Our goals include getting robust classification of strongly or weakly connected gel networks, predictions of minimal connecting structures and an insight how - according to an artificial intelligence - gel networks look like.

DY 17.7   Tue 11:45   ZEU 160

A 3-layer injection-locked multimode semiconductor laser neural network — •Elizabeth Robertson[1,3], Romain Lance[2], Anas Skalli[2], Xavier Porte[2], Janik Wolters[1,3], and Daniel Brunner[2] — [1]Deutsches Zentrum für Luft-und Raumfahrt, 12489 Berlin, Germany — [2]Institut FEMTO-ST, Université Bourgogne Franche-Comté, CNRS UMR6174, Besançon, France — [3]Technische Universität Berlin, Institut für Optik und Atomare Physik, 10623 Berlin, Germany
Optical hardware implementations of artificial neural networks (ANNs) have become a hot topic of research due to the inherent parallelism, potentially high speed and energy efficiency of optics [1]. Semiconductor laser networks are of specific interest as they are highly non-linear systems, which can be modulated at high throughput [2]. Previous work using spatial modes as nodes of an ANN, illustrated the use of multimode large area VSCELs for neural network computing in a fully parallel substrate, without pre- or post-processing [3,4]. We further expand this concept to a three-layer network consisting of mutually coupled multimode VSCELs, injection locked to a DFB laser. Here, information is fed into the network by modulating the injection laser, and boolean output weights are implemented using a digital micromirror device. We present an outline of the system, investigate its locking behavior and non-linear response. [1] Huang C. et al., Advances in Physics: X 7, 1 (2022) [2] Skalli A. et al., Opt. Mater. Efficiently compressed time series approximations — •Paul Wilhelm[1] and Marc Timme[1,2] — [1]Chair for Network Dynamics, Institute of Theoretical Physics and Center for Advancing Electronics Dresden (cfaed), TU Dresden, Germany — [2]Lakeside Labs, Klagenfurt, Austria
Time series emerge from a broad range of applications, for instance as stock market pricing, electrocardiographic recordings or trajectories in chaotic dynamical systems. Long time series require an approximation scheme for compressing and storing, analyzing or predicting them.

How can we construct efficient approximations? Continuous, piecewise linear functions with variable knots that mark the end points of each segment are easy to handle and often used. However, fitting the knots is highly nonlinear and only feasible with a lucky initial guess. Here we propose a novel method that exploits repeating motifs in the data and thereby avoids fitting each knot independently, significantly accelerating the construction of the approximation.

Starting from the beginning of a time series, the method iteratively integrates subsequent data points. For each extension, it tries to reuse parts of the already existing function to approximate the yet uncovered data points. If successful, each motif is approximated only once and reused multiple times. As a result, the knots of the function are interdependent and can thus be represented in compact form. In contrast to deep neural networks that also find a piecewise linear approximation, our approach offers a efficient and explainable method and thereby a novel perspective onto why and how deep neural networks may work.

DY 17.9   Tue 12:15   ZEU 160

Active Learning Strategies for Molecular Dynamics with Machine-learned Potentials — •Shubham Sharma[1] and Mariana Rossi[1,2] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [2]Fritz Haber Institute of the Max Planck Society, Berlin, Germany
Machine-learning potentials (MLPs) have allowed the efficient modelling of complex atomistic systems with ab-initio accuracy. Normally, the construction of sufficiently large and diverse reference datasets, using first-principles calculations, is a bottleneck for training. Therefore, several active-learning strategies have been proposed, which aim to make the training more efficient, especially when used together with molecular-dynamics techniques [1]. In this work, we explore building protocols for training sets of high-dimensional neural-network potentials (HDNNPs), targeting specifically weakly-bound condensed-phase systems. For that, we show how we can use and augment the committee-model framework within the i-PI code [2]. We show results for acene-based molecular crystals and discuss the advantages and limitations of different learning strategies to treat different crystal polymorphs, at various thermodynamic conditions. [1] C. Schran et. at., J. Chem. Phys. **153**, 104105 (2020). [2] V. Kapil et. al., Comput. Phys. Commun. **236**, 214 (2019).

DY 17.10   Tue 12:30   ZEU 160
Machine learning-based prediction of dynamical clustering in excited granular media — •Sai Preetham Sata, Dmitry Puzyrev, and Ralf Stannarius — Institute of Physics and MARS, Otto von Guericke University Magdeburg, Universitätsplatz 2, D-39106 Magdeburg, Germany
Granular gases excited by external force tend to undergo gas-like to cluster transitions when the filling fraction of particles reaches sufficient value. In order to understand the clustering dynamics, experiments were performed in microgravity [1,2]. A numerical simulation model based on DEM is available. By varying geometrical and material parameters, a phase diagram is obtained. Cumulative distribution functions of the density profiles and uniform distribution profiles

are obtained and the maximum distance between these curves is compared to the Kolmogorov-Smirnov (KS) test threshold to detect gas-cluster transitions. We aim to predict the formation of dynamical clusters with the use of machine learning techniques as an alternative to DEM simulations, requiring much less computational effort. We confirm the reliability of the predictions for relatively well-studied spherical beads, with the perspective of analysis of clustering of more complicated particle shapes.

This study is supported by DLR projects VICKI and EVA (50WM2252 and 50WM2048)

DY 18: Nonlinear Dynamics, Synchronization and Chaos

Time: Tuesday 10:00–12:15   Location: ZEU 147

DY 18.1   Tue 10:00   ZEU 147
Synchrony at Weak Coupling in the Complexified Kuramoto Model — •Moritz Thümler[1], Shesha G.M. Sriniva[2], Malte Schröder[1], and Marc Timme[1,3] — [1]Chair for Network Dynamics, Institute of Theoretical Physics & Center for Advancing Electronics Dresden (cfaed), TU Dresden — [2]Institute of Physics and Material Sciences, Universite du Luxembourg — [3]Lakeside Labs, Klagenfurt, Austria
We present the finite-size Kuramoto model analytically continued from real to complex variables and analyze its collective dynamics. For strong coupling, synchrony appears through locked states that constitute attractors, as for the real-variable system. However, synchrony persists in the form of *complex locked states* for coupling strengths K below the transition $K^{(\text{pl})}$ to classical *phase locking*. Where complex locked states are stable, their imaginary parts indicate which units belong to the locked population in the original, real-variable system. We uncover a second transition at $K' < K^{(\text{pl})}$ below which complex locked states become linearly unstable yet still exist for arbitrarily small coupling strengths. The results open up a path towards a new field of network dynamics with variables complexified by analytic continuation.

DY 18.2   Tue 10:15   ZEU 147
Predicting tipping points in driven nonlinear systems — •Gwendolyn Quasebarth[1], Moritz Thümler[1], and Marc Timme[1,2] — [1]Chair for Network Dynamics, Institute for Theoretical Physics and Center for Advancing Electronics Dresden (cfaed), Technical University of Dresden, Dresden, Germany — [2]Lakeside Labs, Lakeside B04b, Klagenfurt, Austria
Tipping points mark parameter values beyond which a system qualitatively changes its collective dynamics, often in undesired ways. Standard response theory for nonequilibrium nonlinear systems predicts local deviations around a stable fixed point via a polynomial in the amplitude ϵ of the driving signal. However, such standard response theories (of arbitrary order in ϵ) necessarily fail to predict nonequilibrium tipping points. Here, we propose a novel nonlinear response theory that overcomes the constraints of polynomial response theory of any order. We illustrate our findings in a class of sinusoidally driven damped nonlinear oscillators.

DY 18.3   Tue 10:30   ZEU 147
Pseudo-laminar chaos from on-off intermittency — •David Müller-Bender[1], Rahil N. Valani[2], and Günter Radons[1,3] — [1]Institute of Physics, Chemnitz University of Technology, 09107 Chemnitz, Germany — [2]School of Mathematical Sciences, University of Adelaide, Adelaide, South Australia 5005, Australia — [3]ICM - Institute for Mechanical and Industrial Engineering, 09117 Chemnitz, Germany
In finite-dimensional, chaotic, Lorenz-like wave-particle dynamical systems one can find diffusive trajectories, which share their appearance with that of laminar chaotic diffusion [Phys. Rev. Lett. 128, 074101 (2022)] known from delay systems with lag-time modulation. Applying, however, to such systems a test for laminar chaos, as proposed in [Phys. Rev. E 101, 032213 (2020)], these signals fail such test, thus leading to the notion of pseudo-laminar chaos. The latter can be interpreted as integrated periodically driven on-off intermittency. We demonstrate that, on a signal level, true laminar and pseudo-laminar chaos are hardly distinguishable in systems with and without dynamical noise. However, very pronounced differences become apparent when correlations of signals and increments are considered. We compare and contrast these properties of pseudo-laminar chaos with true laminar chaos.

Details can be found in the preprint [arXiv:2211.01278 (2022)].

DY 18.5   Tue 11:15   ZEU 147
On the Correlation of Functionality and Lyapunov Stability in Oscillator-based Ising machines — •Bakr Al Beattie[1], Maximiliane Noll[2], Hermann Kohlstedt[2], and Karlheinz Ochs[1] — [1]Ruhr-Universität Bochum, Lehrstuhl für digitale Kommunikationssysteme, Bochum, Deutschland — [2]Christian-Albrechts-Universität zu Kiel, Lehrstuhl für Nanoelektronik, Kiel, Deutschland
Oscillator-based Ising machines are a promising analog approach for dealing with combinatorial optimization problems that are classified as NP (nondeterministic polynomial). The idea is to mimic the Ising model by coupling electrical oscillators that behave like the spins of the Ising model. Here, the coupling should somehow map the Ising Hamiltonian onto the energy of electrical system. With this contribution, we demonstrate numerical evidence demonstrating the correlation between the Ising machine*s functionality and stability. We make use of the well-known Kuramoto model to describe a coupled oscillator network and show stability to be the key property that makes an Ising machine solve optimization problems. Furthermore, we give an answer to the question: when has an Ising machine finished solving a mapped problem?

DY 18.6   Tue 11:30   ZEU 147
Manifolds of equilibrium states in ensembles of globally coupled oscillators — •Michael Zaks — Humboldt Universität zu Berlin, Berlin, Germany
Global fields generated by ensembles of coupled oscillators are responsible for many unusual kinds of collective behavior. Among their most striking effects are existence of numerous constants of motion and a drastic reduction in the number of degrees of freedom. Here, we offer a simpler approach, restricted to the widespread situations in which the number of parameters defining the action of the global fields is smaller than the overall number of elements in the ensemble. In the phase space of such ensembles, high-dimensional manifolds composed of the equilibrium states can generically arise. Existence of these manifolds is not related to symmetries. In the simplest cases, such continua of steady states are attracting or repelling as a whole; in general, however, their stability with respect to transversal perturbations varies in the course of the motion along the manifold. Remarkably, the suggested mechanism does not require that all oscillators are identical: the sufficiently strong global field is able to counteract diversity among the ensemble units and halt the temporal evolution.

DY 18.7   Tue 11:45   ZEU 147
X-ray imaging of the sonoluminescent cavitation bubble collapse with single XFEL pulses — •Hannes Paul Hoeppe[1], Atiyeh Aghelmaleki[2], Juan Manuel Rosselló[3], Malte Vassholz[1], Markus Osterhoff[1], Daniel Schwarz[4], Johannes Hagemann[4], Robert Mettin[2], Anders Madsen[5], and Tim Salditt[1] — [1]Institute for X-ray Physics, Georg-August-University, Göttingen, Germany — [2]Third Institute of Physics, Georg-August-University, Göttingen, Germany — [3]Faculty of Mechanical Engineering, University of Ljubljana, Ljubljana, Slovenia — [4]Center for X-ray and Nano Science, Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [5]European X-Ray Free-Electron Laser Facility, Schenefeld, Germany
We study the dynamics and in particular the collapse of a single cavitation bubble in water. A cavitation bubble is trapped and driven by an ultrasonic field leading to nonlinear radial oscillations. During its periodic collapses, extreme pressure and temperature is reached which can lead to the formation of a plasma

core and the emission of light. The fast evolving pressure, density and temperature distribution and the shape of the bubble during its collapse has so far only been accessible by simulations. Full-field X-ray phase contrast imaging provides quantitative information of the density distribution of the sample. Implemented at X-ray free-electron lasers, this enables the investigation of fast processes and extreme states of matter with a unique contrast. We present the evolution of the bubble's density profile during the sonoluminescent collapse and the current state of analysis.

DY 18.8   Tue 12:00   ZEU 147

Quantum synchronization in a network of dissipatively coupled linear oscillators — •Juan Moreno[1], Christopher W Wächtler[2], and Alexander Eisfeld[1] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Department of Physics,University of California Berkeley, CA, 94720-7300

Synchronization in classical systems has a long history and by now is a very well understood phenomenon. However, the question whether the classical notions of synchronization can be extended to the quantum regime has only recently been addressed in investigations of classically inspired models like quantum Van der Pol oscillators as well as models without classical analog. Inspired by the theoretical prediction that two-level atoms are able to synchronize even without interacting directly [1], we investigate a network of dissipatively coupled quantum harmonic oscillators. Within a mean-field approximation we find that the network is able to synchronize. For the fully quantum system described in terms of a Lindblad master equation we analyze various measures that have been proposed in the literature. Additionally, we investigate the Liouvillian spectrum in order to draw connections between the spectrum and the synchronization measures.

Bit-Flipping based on Stability Transition of Coupled Spins — •Maximilian F. I. Kieler and Arnd Bäcker — TU Dresden, Institut für Theoretische Physik, Dresden, Germany

A bipartite spin system is proposed for which a bit-flipping mechanism between two states is possible when the coupling is varied. The states correspond in the semiclassical limit to equilibrium points showing a stability transition from elliptic-elliptic stability to complex instability. Based on the classical system we find a universal scaling for the transfer time, which even applies in the deep quantum regime.

DY 21.2   Tue 14:15   MOL 213

New type of scarring in quantum chaotic scattering — •Jan Robert Schmidt and Roland Ketzmerick — TU Dresden, Institut für Theoretische Physik, Dresden, Germany

We study the three-disk scattering system, which is a paradigmatic example for quantum chaotic scattering. It is shown that any resonance state can be described by a product of a multifractal pattern of classical origin and universal, exponentially distributed fluctuations, as found for optical microcavites [1]. The first factor is determined by averaging resonance states with similar lifetime and is compared to an approximate conditionally-invariant measure from open chaotic maps [2]. A new type of scarring along ray segments, unrelated to periodic-orbit scarring, was recently observed in (partially open) optical microcavities [1]. Ray-segment scarring is just as well observed in the (fully open) three-disk system and has been overlooked for 30 years.

Manipulating light inside a microcavity with phase-space tailoring — Yan-Jun Qian[1], Hui Liu[1], Qi-Tao Cao[1], •Julius Kullig[2], Kexiu Rong[1], Cheng-Wei Qiu[3], Jan Wiersig[2], Qihuang Gong[1,4], Jianjun Chen[5], and Yun-Feng Xiao[1,4] — [1]Peking University, Beijing, China — [2]Otto-von-Guericke-University Magdeburg, Magdeburg, Germany — [3]National University of Singapore, Singapore, Singapor — [4]Shanxi University, Taiyuan, China — [5]Beijing Normal University, Beijing, China

We report on a novel powerful method for purposely manipulating light inside an optical microcavity. Via small absorptive, reflective or refractive elements embedded in the interior of the microcavity the photon transport is controlled in the phase space. Thus, phase-space tailoring allows for a spatial and tempral

control of the light confinement enabling a manipulation of the far-field emissson pattern or the quality-factor.

DY 21.4   Tue 14:45   MOL 213

A spectral duality in graphs and microwave networks — •Tobias Hofmann[1], Junjie Lu[2], Ulrich Kuhl[1,2], and Hans-Jürgen Stöckmann[1] — [1]Fachbereich Physik, Philipps-Universität Marburg, 35032 Marburg, Germany — [2]Institut de Physique de Nice, CNRS, Université Côte d'Azur, 06108 Nice, France

Quantum graphs and their experimental counterparts, microwave networks, are ideally suited to study the spectral statistics of chaotic systems. The graph spectrum is obtained from the zeros of a secular determinant derived from energy and charge conservation. Depending on the boundary conditions at the vertices, there are Neumann and Dirichlet graphs. The first ones are realized in experiments, since the standard junctions connecting the bonds obey Neumann boundary conditions due to current conservation. On average, the corresponding Neumann and Dirichlet eigenvalues alternate as a function of the wave number, with the consequence that the Neumann spectrum is described by random matrix theory only locally, but adopts features of the interlacing Dirichlet spectrum for long-range correlations. Another spectral interlacing is found for the Green's function, which in contrast to the secular determinant is experimentally accessible. This is illustrated by microwave studies and numerics.

DY 21.5   Tue 15:00   MOL 213

Quantum Coherent Spin-Bath Dynamics and The Impact of Interactions on Quantum Memory Effects — •Tobias Boorman and Bernd Braunecker — University of St Andrews, St Andrews, United Kingdom

Using a robust theoretical framework, we systematically extract the joint-coherent dynamics of an impurity spin coupled to a strongly correlated material as the central process of a magnetic resonance. This framework enables a complete dynamical picture, extending beyond the usual high-temperature approximation that underpins the contemporary understanding of spin-bath decoherence, and allowing one to probe even further to the sub-thermal time regime, where quantum memory effects are the dominant feature. As a theoretically and experimentally accessible model of a strongly correlated conductor, we take the Luttinger liquid as a prototype to study how interactions alter the response of the bath to the impurity. Taken under the lens of the framework, we find that the joint quantum-coherent dynamics manifests itself as a rapid and seemingly instantaneous initial slip prior to the spin decoherence, whilst interactions within the bath play a role in modulating the amplitude and rate of this feature. We fit this understanding into a wider picture of magnetic resonance in interacting systems at intermediate temperatures, improving upon the known interaction-induced modifications of high-temperature approximations.

Reservoir Computing using Quantum Dot Lasers — •Huifang Dong, Lina Jaurigue, and Kathy Lüdge — Institute of Physik, Technische Universität Ilmenau, Weimarer Str. 32, 98684 Ilmenau, Germany.

Time-multiplexed reservoir computing is a machine-learning approach which is well suited for implementation using semiconductor lasers subject to optical feedback. In such a delay-based setup the feedback has two important roles; it directly influences the memory of the system and it generates the high dimensional transient dynamics needed for good computational performance [1]. However, commonly used and commercially available quantum well semiconductor lasers are dynamically very sensitive to optical feedback, which can make the implementation of such systems difficult. Implementation and on-chip integration of optical reservoir computing become feasible with quantum dot lasers, as they emit at the telecommunication wavelength and are less sensitive to unwanted reflections [2]. Using typical benchmark tasks for time series prediction we show that quantum dot lasers show good computing performance that can be further optimized by proper delay time tuning.

Studying sequence property relationships with neural networks — •Huzaifa Shabbir[1], Jens Uwe Sommer[1,2], and Marco Werner[1] — [1]Leibniz Institute for Polymer Research Dresden, Germany. — [2]Technische Universität Dresden

In this work, we investigate the relationships between chemical sequence and property space for various sequence lengths with the help of neural networks (NN). Two different systems are investigated for this purpose: system I comprises copolymer sequences and their free energy of interaction with a lipid bilayer membrane. System II consists of metallic nanoparticle sequences and their plasmonic spectrum. We compare the performance of different neural network architectures such as feed-forward NNs and gated recurrent unit (GRU) networks in terms of their interpolation and extrapolation capacity between different sequence lengths. We show that the GRU is particularly suitable to transfer the learned patterns from smaller sequence lengths to enhance significantly the learning result for larger sequence lengths.

DY 22.3   Tue 14:30   ZEU 160
Modelling dynamic 3D-heat transfer for laser material processing using physics-informed neural networks (PINNs) — •Michael Moeckel and Jorrit Voigt — TH Aschaffenburg, Würzburger Str. 45, 63743 Aschaffenburg

Machine learning (ML) algorithms are increasingly applied to fit complex models to empirical data and to predict on dynamical system behaviour. However, such models are not intrinsically protected from violating causality or other, well-understood physical laws. Black-box ML models offer limited interpretability. Extending ML models by including physical knowledge in the optimization procedure is known as physics-based and data-driven modelling. A promising recent development are physics informed neural networks (PINN), which en-

sure consistency to physical laws and measured data via appropriately designed optimization routines. Here we model the 3D time-dependent temperature profile following the passage of a laser focus at the surface of some material using PINNs. In this setting, we discuss aspects of numerically efficient training for PINNs, e.g. on a set of varying collocation points. The results from the PINN agree with finite element simulations, proving the suitability of the approach. The proposed models can be smoothly integrated in monitoring systems and naturally extend to the joint analysis of measurement data and dynamical behaviour encoded in governing equations.

DY 22.4   Tue 14:45   ZEU 160
Optical convolutional neural network with atomic nonlinearity — •Mingwei Yang[1,2], Elizabeth Robertson[1,2], Luisa Esguerra[1,2], Kurt Busch[3,4], and Janik Wolters[1,2] — [1]Deutsches Zentrum für Luft- und Raumfahrt, Institute of Optical Sensor Systems, Berlin, Germany. — [2]Technische Universität Berlin, Berlin, Germany. — [3]Humboldt-Universität zu Berlin, Institut für Physik, AG Theoretische Optik & Photonik, Berlin, Germany. — [4]Max-Born-Institut, Berlin, Germany.

Due to their inherent parallelism, fast processing speeds and low energy consumption, free-space-optics implementations have been identified as an attractive possibility for analog computations of convolutions [1,2]. However, the efficient implementation of optical nonlinearities for such neural networks still remains challenging. In this work, we report on the realization and characterization of a three-layer optical convolutional neural network where the linear part is based on a 4f-imaging system and the optical nonlinearity is realized via the absorption profile of a cesium atomic vapor cell. This system classifies the handwritten digital dataset MNIST with 83.96% accuracy, which agrees well with corresponding simulations. [1] H. J. Caulfield and S. Dolev, *Why future supercomputing requires optics,* Nat. Photonics 4, 261*263 (2010). [2] M. Miscuglio, Z. Hu, S. Li, J. K. George, R. Capanna, H. Dalir, P. M. Bardet, P. Gupta, and V. J. Phase Diagram of the J_1-J_2 Ising Model from Unsupervised Learning: Neural Networks vs Image Comparison — •Burak Çivitcioğlu[1], Andreas Honecker[1], and Rudolf A. Römer[2] — [1]Laboratoire de Physique Théorique et Modélisation, CNRS UMR 8089, CY Cergy Paris Université, Cergy-Pontoise, France — [2]Department of Physics, University of Warwick, Coventry, CV4 7AL, United Kingdom

Machine learning methods have been shown to be one of the novel approaches in identifying the phases and phase transitions in models of statistical physics. Here, we study the performance of unsupervised learning in the J_1-J_2 Ising model. We benchmark the results for phase diagram reconstruction using variational autoencoders (VAEs) against straightforward image comparison. We show that such image comparison can result in accuracies that are akin to that of VAEs.

Microscopic theory for the shear-induced structure distortion in concentrated suspensions of spherical colloids — •Carmine Anzivino[1], Francesco Leone[1], Luca Banetta[2], Michael S. Murillo[3], and Alessio Zaccone[1] — [1]Department of Physics "A. Pontremoli", University of Milan, via Celoria 16, 20133 Milan, Italy — [2]Department of Applied Science and Technology, Politecnico di Torino, Corso Duca degli Abruzzi 24, 10129, Turin, Italy — [3]Department of Computational Mathematics, Science and Engineering, Michigan State University, East Lansing, Michigan 48824, USA

We combine an analytical solution of the Smoluchowski convection-diffusion equation that fully takes into account the boundary-layer structure, with generalized integral equations of the liquid state. We investigate the shear-induced structural distortion in suspensions of spherical colloids, in concentrated regimes of packing fraction so far explored only by means of numerical simulations [1].

For hard spheres, our findings are in very good parameter-free agreement with numerical data from literature [2]. In addition, our scheme predicts (for the first time) a consistent enhancement of the structure factor S(k) at vanishing k, upon increasing the shear rate, which we argue may signal the onset of a shear-induced phase transition from the isotropic phase to a non-uniform one.

DY 23.2   Tue 14:15   ZEU 250
Coupling of a particle-based solver to a fluctuating hydrodynamic reservoir through an adaptive resolution simulation approach — •Abbas Gholami[2], Rupert Klein[1], and Luigi Delle Site[1] — [1]Freie Universität Berlin, Berlin, Germany — [2]Max Planck Institute for Polymer Research, Mainz, Germany

Adaptive Resolution Simulation (AdResS) is a multi-resolution approach for coupling different particle-based regions. In AdResS, a fully atomistic subregion (open system) is in contact with reservoirs of non-interacting particles through a small buffer region. In this approach, a thermostat and an external (thermodynamic) force are applied in the reservoir and buffer regions to ensure the same behaviour as the reference simulation. Coupling a particle-based domain with a continuum reservoir will significantly reduce computational costs while preserving satisfactory precision in different regions.

This work uses a novel algorithm to couple the AdResS particle-based simulator to a Navier-Stokes Landau-Lifshitz solver. The coupling algorithm suggests that the proper thermodynamic force for the AdResS simulation will be interpolated among a set of pre-calculated thermodynamic forces based on the resulting

continuum state at the interface region. On the other hand, to pass the information from the particle side to the continuum reservoir, the result of the AdResS simulation will apply to the corresponding continuum cells with proper interface values. The accuracy of this coupling algorithm is demonstrated through various numerical scenarios with different initial conditions.

The orientation field generated by a moving defect: multivalued solutions of the diffusion equation — •Jacopo Romano, Benoit Mahault, and Ramin Golestanian — Max Planck Institute for Dynamics and Self-Organization

Point-like topological defects are singular configurations that occur in a variety of in and out of equilibrium systems with two-dimensional orientational order. As they are associated with a nonzero circulation condition, the presence of defects induces a long-range perturbation of the orientation landscape around them. Their effective dynamics is thus generally described in terms of quasi-particles interacting through the orientation field they produce, which in the simplest setting is described by the diffusion equation. Due to the multivaluedness of the orientation field, its expression for a defect moving with an arbitrary trajectory cannot be obtained via simple techniques and is often approximated by that of a static defect. Here, we propose a solution to this problem that relies on particular gauge invariance properties of the proper multivalued field derivatives. Our approach allows to derive the exact expression for the orientation created by multiple moving defects, which we find to depend on their past trajectories and thus to be nonlocal in time. Performing various expansions in relevant regimes, we show how improved approximations with respect to the static defect solution can be obtained. Moreover, our results lead to so far unnoticed structures in the orientation field of moving defects which we discuss in light of existing experimental results.

Perturbative and Semiclassical Expansions in Quantum Thermodynamics Using a Modified Keldysh Contour — •Sadeq S. Kadijani, Vasco Cavina, Massimiliano Esposito, and Thomas L. Schmidt — Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg, Luxembourg

Modified Keldysh contours are a versatile tool for calculating moment generating functions (MGFs) in the context of quantum thermodynamics and quantum transport theory, and are the backbone of both Green's functions (GFs) and path

integral approaches to open quantum systems. By using a different modification of the Keldysh contour, we will construct a perturbation expansion of the MGFs and discuss its semi-classical expansion. Using the symmetry property of the modified contour, we prove that the perturbative expansion obtained in this way satisfies the fluctuation theorem (FT) in every order of perturbation theory. We show that the contribution of the different diagrams can be added to obtain a general expression of the work statistics in terms of a sum of independent Poisson processes.

To further investigate the work MGF we apply the Feynman path integral techniques to the modified contour. In this way, the MGF can be written in terms of the action, which depends on the fields running on the modified contour. The action can be used to obtain a semiclassical expansion of the MGF, which is then used to compute explicitly the zeroth (classical) and the first quantum correction to the work MGF.

DY 23.5 Tue 15:00 ZEU 250

Effect of Frequency-Dependent Viscosity on Molecular Friction in Liquids — •Henrik Kiefer[1], Domenico Vitali[2], Benjamin Dalton[3], Laura Scalfi[4], and Roland Netz[5] — [1]Freie Universität Berlin, Department of Physics, Berlin, Germany — [2]Freie Universität Berlin, Department of Physics, Berlin, Germany — [3]Freie Universität Berlin, Department of Physics, Berlin, Germany — [4]Freie Universität Berlin, Department of Physics, Berlin, Germany — [5]Freie Universität Berlin, Department of Physics, Berlin, Germany

A fundamental problem in molecular dynamics is the relation between the frequency-dependent friction of a molecule in a liquid and the hydrodynamic properties of the liquid. We investigate this connection in the case of a water molecule moving in liquid water using all-atomistic molecular dynamics simulations and linear hydrodynamic theory. For this, we analytically calculate the frequency-dependent friction of a sphere with finite surface slip moving in a non-Newtonian compressible fluid by solving the linear transient Stokes equation, including frequency-dependent shear and volume viscosities, which are both determined from MD simulations of bulk liquid water. By fitting the effective sphere radius and the slip length, the frequency-dependent friction and velocity autocorrelation function from the transient Stokes equation and simulations quantitatively agree with the frequency-dependent friction of a single water molecule moving in liquid water, as defined by the generalized Langevin equation from MD simulation trajectories, provided accurate frequency-dependent viscosities are used.

Dynamical phase transitions in trap models and universality classes of aging — •Diego Tapias[1] and Peter Sollich[1,2] — [1]Institute for Theoretical Physics, University of Göttingen, Germany — [2]Department of Mathematics, King's College London, London, UK

We investigate how aging and driving by trajectory biasing interact in two mean field models of glassy dynamics, widely known as trap models. We show that similarly to kinetically constrained models, the equilibrium state of the unbiased system above the glass transition temperature is located at the coexistence of two dynamical phases (active and inactive). In contrast, below this temperature, we find two different nonequilibrium scenarios: energetic (or activated) aging that is destroyed by any dynamical bias towards low activity, which we call "fragile aging", and entropic aging that is stable against the existence of such a dynamical bias, which we refer to as "robust aging". We conjecture that these categories have broader relevance as universality classes for aging dynamics in glassy systems.

DY 24.2 Tue 14:15 ZEU 147

Fragile to strong crossover as general glassy feature — •Anshul Deep Singh Parmar and Andreas Heuer — Institute of Physical Chemistry, University of Münster, Corrensstrasse 28/30, 48149 Münster, Germany

As a liquid is cooled below the melting temperature, the dynamics become increasingly sluggish with the degree of supercooling, known as fragility. The fundamental question is whether the liquid ceases to flow at some finite temperature, the material undergoing the glass transition, or dynamics diverge smoothly to zero temperature. This is a central question of pivotal importance for unraveling the nature of glass and theoretical understanding, concealing with astronomical long observation times.

We circumvent this infeasibility by taking advantage of swap Monte Carlo with multi-billion speedups for equilibration well beyond the glass transition. Our investigation of a wide range of system sizes and temperatures across the experimental glass transition unveils the nature of the energy landscape. We observe a notable deviation from the Gaussian nature of the potential-energy landscape. Rapid depletion of states is associated with the glassy bottom of the landscape.

unveiling the fragile to strong crossover is the general glassy behavior. Our result ultimately rules out the finite-temperature divergence and establishes the conceptualized Arrhenius description of the dynamics at low temperatures. Our findings are critical in advancing the investigation of glass in an experimental and theoretical framework.

DY 24.3 Tue 14:30 ZEU 147

A solution to the plasticity of glasses based on topological physics — •Alessio Zaccone — Department of Physics, University of Milan, 20133 Milano, Italy

I will start by reviewing the microscopic theory of linear elasticity in amorphous solids which, from first-principles consideration of non-centrosymmetry in the particle contact environment, leads to mathematical predictions of elastic moduli in quantitative parameter-free agreement with numerical simulations of random jammed packings [1]. This theory fully accounts for the extra non-affine displacements which arise due to the lack of centrosymmetry in disordered solids. I will then show that non-affinity of particle motions gives rise to well-defined topological defects (dislocation-like topological defects, DTDs) which have recently been discovered in the displacement field of glasses [1] and later confirmed in [2]. The norm of the associated Burgers vector of these defects can be used as an accurate predictor of the onset of plastic flow and yielding of glasses, and, in combination with Schmid's law, it can explain the phenomenon of shear banding via self-organization of DTDs in slip systems at 45 degrees with respect to flow direction [4]. Broader implications of a unifying topological field theory of liquids and the glass transition will also be mentioned. [1] A. Zaccone and E. Scossa-Romano, Phys. Rev. B 83, 184205 (2011) [2] Z. W. Confinement induced relaxations and phase behavior of a nanoconfined ionic liquid crystal — •Mohamed Aejaz Kolmangadi[1], Andreas Schönhals[1], Li Zhuoqing[2], and Patrick Huber[2] — [1]Bundesanstalt für Materialforschung und -prüfung (BAM), Berlin, Germany — [2]Technical Univeristy Hamburg TUHH and DESY

We investigate the molecular dynamics and electrical conductivity of a linear shaped guanidinium based ILC confined in self-ordered nano porous alumina

oxide membranes of pore size ranging from 180nm down to 25nm by employing broadband dielectric spectroscopy (BDS) and calorimetry. Calorimetric investigation reveals a complete suppression of the columnar - isotropic transition, while the plastic crystalline - columnar transition temperature decreases with inverse pore size and deviates from the Gibbs - Thomson equation. For the bulk case, BDS detects two relaxation modes in the crystalline phase, the gamma relaxation and the α1 relaxation, and two relaxation modes in the columnar phase, the α2 and α3 relaxation. For the confined case, all relaxation modes slow down

compared to the bulk. However, for the least pore size (25 nm), the α2 relaxation is absent. We discuss the possible molecular origins of the different relaxation modes observed. For the bulk ILC, a clear jump of 4 orders of magnitude in the absolute values of DC conductivity occurs at the transition from the plastic crystalline to hexagonal columnar phase, for the confined ILC, this transition is smooth. DC conductivity is reduced for the confined case, except for the 25nm, where the values is similar to the bulk.

DY 25: Many-Body Quantum Dynamics (joint session DY/TT)

Time: Wednesday 9:30–13:00   Location: MOL 213

Invited Talk   DY 25.1   Wed 9:30   MOL 213
Many-body localization from Hilbert- and real-space points of view — •Ivan Khaymovich[1], Giuseppe De Tomasi[2], Frank Pollmann[3], and Simone Warzel[3] — [1]Nordic Institute for Theoretical Physics, Stockholm, Sweden — [2]University of Illinois Urbana-Champaign, USA — [3]Technical University Munich, Germany

Many-body localization (MBL), known as a generic mechanism to break quantum ergodicity, has been recently shown to be not the Hilbert-space Anderson localization. Instead, the MBL eigenstate occupies a fractal support [1-2], with extensive number of configurations. On the other hand, the well-established and accepted by the community picture of an emergent set of local integrals of motion [3] provides the structure of the MBL in the real space.

In this talk, I will provide the observable (later measured in the experiment [4]) which combines the fractality in the Hilbert space with the presence of local integrals of motion [2]. This observable, being the radial profile of the eigenstate over the Hamming distance, keeps the information about both the Hilbert-space fractal dimensions and the real-space localization lengths and uncovers the structure of these measures across the MBL transition. Phenomenological picture behind this behavior is consistent with the Kosterlitz-Thouless scenario of the MBL transition, suggested in the literature.

Bridging classical and quantum many-body information dynamics — •Andrea Pizzi[1,2], Daniel Malz[3,4], Andreas Nunnenkamp[5], and Johannes Knolle[6,4,7] — [1]Department of Physics, Harvard University, Cambridge 02138, Massachusetts, USA — [2]Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, United Kingdom — [3]Max-Planck-Institute of Quantum Optics, Hans-Kopfermann-Str. 1, 85748 Garching, Germany — [4]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany — [5]Faculty of Physics, University of Vienna, Boltzmanngasse 5, 1190 Vienna, Austria — [6]Department of Physics, Technische Universität München, James-Franck-Stra. 1, 85748 Garching, Germany — [7]Blackett Laboratory, Imperial College London, London SW7 2AZ, United Kingdom

The fundamental question of how information spreads in closed quantum many-body systems is often addressed through the lens of the bipartite entanglement entropy. Among its most striking features are unbounded linear growth in the thermodynamic limit, asymptotic extensivity in finite-size systems, and measurement-induced phase transitions. Here, we show that these key qualitative features emerge naturally also for the classical bipartite mutual information, the natural classical analogue of the quantum entanglement entropy. Key for this observation is treating the classical many-body problem on par with the quantum one, that is, explicitly accounting for the exponentially large probability distribution. Our analysis is supported by extensive numerics on prototypical cellular automata and Hamiltonian systems.

DY 25.3   Wed 10:15   MOL 213
Performance boost of a collective qutrit refrigerator — •Dmytro Kolisnyk[1] and Gernot Schaller[2] — [1]Jacobs University Bremen, Campus Ring 1, 28759 Bremen, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, 01328 Dresden, Germany

A single qutrit with transitions selectively driven by weakly-coupled reservoirs can implement one of the world's smallest refrigerators. We analyze the performance of N such fridges that are collectively coupled to the reservoirs. We observe a quantum boost, manifest in a quadratic scaling of the steady-state cooling current with N. As N grows further, the scaling reduces to linear, since the transitions responsible for the quantum boost become energetically unfavorable. Fine-tuned inter-qutrit interactions may be used to maintain the quantum boost for all N and also for not-perfectly collective scenarios.

DY 25.4   Wed 10:30   MOL 213
Hidden Phase of the Spin-Boson Model — •Florian Otterpohl[1,2], Peter Nalbach[3], and Michael Thorwart[2,4] — [1]Center for Computational Quantum Physics, Flatiron Institute, New York, New York 10010, USA — [2]I. Institut für Theoretische Physik, Universität Hamburg, Notkestraße 9, 22607 Hamburg, Germany — [3]Fachbereich Wirtschaft und Informationstechnik, Westfälische Hochschule, Münsterstraße 265 46397 Bocholt, Germany — [4]The Hamburg Centre for Ultrafast Imaging, Luruper Chaussee 149, 22761 Hamburg, Germany

A quantum two-level system immersed in a sub-Ohmic bath experiences enhanced low-frequency quantum statistical fluctuations which render the nonequilibrium quantum dynamics highly non-Markovian. Upon using the numerically exact time-evolving matrix product operator approach, we investigate the phase diagram of the polarization dynamics. In addition to the known phases of damped coherent oscillatory dynamics and overdamped decay, we identify a new third region in the phase diagram for strong coupling showing an aperiodic behavior. We determine the corresponding phase boundaries. The dynamics of the quantum two-state system herein is not coherent by itself but slaved to the oscillatory bath dynamics.

DY 25.5   Wed 10:45   MOL 213
Exploring anomalies by many-body correlations — •Klaus Morawetz — Münster University of Applied Sciences, Stegerwaldstrasse 39, 48565 Steinfurt, Germany — International Institute of Physics- UFRN, Campus Universitário Lagoa nova,59078-970 Natal, Brazil

The quantum anomaly can be written alternatively into a form violating conservation laws or as non-gauge invariant currents seen explicitly on the example of chiral anomaly. By reinterpreting the many-body averaging, the connection to Pauli-Villars regularization is established which gives the anomalous term a new interpretation as arising from quantum fluctuations by many-body correlations at short distances. This is exemplified by using an effective many-body quantum potential which realizes quantum Slater sums by classical calculations. It is shown that these quantum potentials avoid the quantum anomaly but approaches the same anomalous result by many-body correlations. A measure for the quality of quantum potentials is suggested to describe these quantum fluctuations in the mean energy. Consequently quantum anomalies might be a short-cut way of single-particle field theory to account for many-body effects. This conjecture is also supported since the chiral anomaly can be derived by a completely conserving quantum kinetic theory. [Eur. Phys. J. B 92 (2019) 176, Phys. Lett. A 383 (2019) 1362, Phys. Status Solidi B (2021) 2100316]

DY 25.6   Wed 11:00   MOL 213
Non-Markovian Stochastic Schrödinger Equation: Matrix Product State Approach to the Hierarchy of Pure States — Xing Gao[1], Jiajun Ren[2], Zhigang Shuai[2], and •Alexander Eisfeld[3] — [1]Sun Yat-sen University, Shenzhen, Guangdong, China — [2]Tsinghua University, Beijing, China — [3]MPI-PKS, Dresden

We derive a stochastic hierarchy of matrix product states (HOMPS) for non-Markovian dynamics in open quantum system at finite temperature, which is numerically exact and efficient. HOMPS is obtained from the stochastic hierarchy of pure states (HOPS) by expressing HOPS in terms of formal creation and annihilation operators. The resulting stochastic first order differential equation is then formulated in terms of matrix product states and matrix product operators. In this way the exponential complexity of HOPS can be reduced to scale polynomial with the number of particles. The validity and efficiency of HOMPS is demonstrated for the spin-boson model and long chains where each site is coupled to a structured, strongly non-Markovian environment.

Controlling Many-Body Quantum Chaos — •Lukas Beringer[1], Steven Tomsovic[1,2], Juan Diego Urbina[1], and Klaus Richter[1] — [1]Institut für Theoretische Physik, Universität Regensburg, D-93040 Regensburg, Germany — [2]Department of Physics and Astronomy, Washington State University, Pullman, WA USA

Targeting in classical chaos control problems makes optimal use of the system's exponential instabilities to direct a given initial state to a predetermined final target state. A generalization to chaotic quantum systems in the semiclassical regime is possible [1], but also requires controlling an initially localized evolving quantum state's spreading. A coherent procedure of this kind enables directing highly excited, far-out-of-equilibrium states from an initial to some final target quantum state. Such methods have been successfully developed and applied to initially minimum uncertainty wave packets in a quantum kicked rotor system. The aim of our work is to extend those procedures to bosonic many-body systems. More specifically, we demonstrate how to make a localized quantum initial state follow special chaotic mean-field solutions of a Bose-Hubbard system toward an arbitrary localized target final state.

DY 25.9 Wed 12:00 MOL 213

Environment-induced decay dynamics of antiferromagnetic order in Mott-Hubbard systems — •Gernot Schaller[1], Friedemann Queisser[1,2], Nikodem Szpak[3], Jürgen König[3], and Ralf Schützhold[1,2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, 01328 Dresden, Germany — [2]Institut für Theoretische Physik, Technische Universität Dresden, 01062 Dresden, Germany — [3]Fakultät für Physik and CENIDE, Universität Duisburg-Essen, Lotharstraße 1, 47057 Duisburg, Germany

We study the dissipative Fermi-Hubbard model in the limit of weak tunneling and strong repulsive interactions, where each lattice site is tunnel-coupled to a Markovian fermionic bath. For cold baths at intermediate chemical potentials, the Mott insulator property remains stable and we find a fast relaxation of the particle number towards half filling. On longer time scales, we find that the antiferromagnetic order of the Mott-Néel ground state on bipartite lattices decays, even at zero temperature. For zero and nonzero temperatures, we quantify the different relaxation time scales by means of waiting time distributions, which

can be derived from an effective (non-Hermitian) Hamiltonian and obtain fully analytic expressions for the Fermi-Hubbard model on a tetramer ring.

Arrow of time concept based on properties of Lanczos coefficients — •Christian Bartsch, Mats H. Lamann, Robin Heveling, Lars Knipschild, Jiaozi Wang, Robin Steinigeweg, and Jochen Gemmer — Fachbereich Physik, Universität Osnabrück, Barbarastraße 7, DE-49076 Osnabrück

We introduce an arrow of time concept based on a specifically defined class of arrow of time functions (ATF) consisting of a limited number of Krylov space generating observables. These ATF'S are found to be essentially monotonously decaying in time which is measured by some quantifying parameter. The ATF's are constructed to be upper bounds for pertinent autocorrelation functions. Employing certain features of the Lanczos coefficients and the wave package-like excitation moving on the Krylov chain, we find reasonable agreement with corresponding numerics.

DY 25.11 Wed 12:30 MOL 213

Fast Time-Evolution of Matrix-Product States using the QR decomposition — •Jakob Unfried[1,2], Johannes Hauschild[1], and Frank Pollmann[1,2] — [1]Department of Physics, TFK, Technical University München, James-Franck-Straße 1, D-85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany

Numerical simulations of quantum many-body dynamics in and out of equilibrium is essential for the understanding of a wide range of physical phenomena. Efficient matrix product state simulation techniques, such as time evolution block decimation (TEBD), are widely successful in extracting experimentally relevant signatures, such as dynamical correlation functions. We propose and benchmark a modified TEBD algorithm that uses a truncation scheme based on the QR decomposition instead of the singular value decomposition (SVD). The modification reduces the scaling with the dimension of the physical Hilbert space d from d^3 down to d^2. Unlike the SVD, the QR decomposition allows for highly efficient implementations on GPU hardware. In a benchmark simulation of a global quench in a quantum clock model, we observe a speedup of orders of magnitude comparing the QR based scheme on a GPU to the SVD based TEBD on CPU.

DY 25.12 Wed 12:45 MOL 213

Simulating infinite temperature spin dynamics by a dynamic mean-field theory — •Timo Gräßer[1], Kristine Rezai[2], Alexander O. Sushkov[2], and Götz S. Uhrig[1] — [1]Condensed Matter Theory, TU Dortmund University, Otto-Hahn Straße 4, 44221 Dortmund, Germany — [2]Department of Physics, Boston University, Boston, MA 02215, USA

We develop a dynamic mean-field theory for spin systems at infinite temperature (spinDMFT) [1]. The idea is to replace the large environment of a spin by a dynamic mean-field which displays a random Gaussian temporal evolution. Its autocorrelations are self-consistently linked to the quantum mechanic expectation values of spin-spin correlations. This approach becomes exact in the limit of large lattice coordination numbers. We improve the approach by considering spin clusters quantum-mechanically (cluster spinDMFT). The extended model is able to describe dynamic spin correlations measured in recent experiments [2] where an inhomogeneous spin-$\frac{1}{2}$ ensemble on a diamond surface is probed using nitrogen-vacancy centers as sensors.

DY 26: Focus Session: From Inter-individual Variability to Heterogeneous Group Dynamics and Disorder in Active Matter (joint session DY/BP/CPP)

The study of active particle dynamics has developed into a vibrant field of multidisciplinary research, including such diverse systems as bacterial colonies, cellular self-organization, synthetic colloids and microrobots as well as macroscopic systems like locusts, flocks of birds, schools of fish or pedestrians. Whereas many studies in the past focused either on the random transport of individual particles or on the interplay of temporal fluctuations (noise) and interactions (velocity alignment or attraction/repulsion), there is now an increasing interest in the question how structural disorder and inter-individual variability, i.e., different motility characteristics of individuals, shape the active particle dynamics and emergent pattern formation of groups. The presence of structural or quenched disorder raises furthermore the immediate question how to bridge data and models based on (short time) tracking data, given the simultaneous presence of temporal fluctuations. With this focus session, we aim at bringing researchers from statistical physics and biophysics together to discuss this interdisciplinary topic and exchange ideas on common challenges arising in different application areas.

Invited Talk   DY 26.1   Wed 9:30   ZEU 160
More is different: High-throughput 3D tracking reveals bacterial navigation strategies — •Katja Taute — Rowland Institute at Harvard, Harvard University, Cambridge, MA, USA — Department of Biology, Microbiology, LMU München, 82152 Martinsried, Germany

How microbes navigate environmental chemical gradients has implications that range from health to climate. The behavioral mechanisms underlying chemotaxis are unknown for most species because of a lack of techniques capable of bridging scales from individual navigation behavior to the resulting population-level performance. We present a multiscale 3D chemotaxis assay that combines high-throughput 3D bacterial tracking with microfluidically created chemical gradients. Large datasets of 3D trajectories yield the statistical power required to assess chemotactic performance at the population scale, while simultaneously resolving the underlying 3D navigation behavior for every individual. Applying this technique to the well-studied model bacterium Escherichia coli, we uncover dramatic, previously unknown heterogeneity in chemotactic performance. We investigate the underlying behavioral mechanisms and discuss potential implications at the population level.

Invited Talk   DY 26.2   Wed 10:00   ZEU 160
Variability and heterogeneity in natural swarms — •Gil Ariel — Bar Ilan University, Ramat Gan, Israel

Collective motion of large-scale natural swarms, such as moving animal groups or expanding bacterial colonies, have been described as self-organized phenomena. Thus, it is clear that the observed macroscopic, coarse-grained swarm dynamics depend on the properties of the individuals of which it is composed. In nature, individuals are never identical, and may differ in practically every parameter. Hence, intra-group variability and its effect on the ability to form coordinated motion is of interest, both from theoretical and a biological points of view. In this talk, I will review and examine some of the fundamental properties of heterogeneous collectives in nature, with an emphasis on two widely-used model organisms - swarming bacteria and locusts. Theoretical attempts to explain the observed phenomena will be discussed in view of laboratory experiments, highlighting their successes and failures. While heterogeneity typically discourages collectivity, there are several natural examples where it has an opposite effect.

Effect of individual differences on the jamming transition in traffic flow — •Yi-Chieh Lai and Kuo-An Wu — Department of Physics, National Tsing Hua University, 30013 Hsinchu, Taiwan

The individual difference, particularly in drivers' distance perception, is introduced in the microscopic one-dimensional optimal velocity model to investigate its effect on the onset of the jamming instability seen in traffic systems. We show analytically and numerically that the individual difference helps to inhibit the traffic jam at high vehicle densities while it promotes jamming transition at low vehicle densities. In addition, the jamming mechanism is further investigated by tracking how the spatial disturbance travels through traffics. We find that the jamming instability is uniquely determined by the overall distribution of drivers' distance perception rather than the spatial ordering of vehicles. Finally, a generalized form of the optimal velocity function is considered to show the universality of the effect of the individual difference.

Distinct impacts of polar and nematic self-propulsion on active unjamming — Varun Venkatesh[1], •Chandana Mondal[2], and Amin Doostmohammadi[1] — [1]Niels Bohr Institute, University of Copenhagen, Blegdamsvej 17, 2100 Copenhagen, Denmark — [2]UGC-DAE CSR, University Campus, Khandwa Road, Indore 452017, India

We explore, by MD simulations, the jamming-unjamming transition in a dense system of active semiflexible filaments. In particular, we characterize the distinct impact of polar vs nematic driving for different filament rigidities and at varying densities. Our results show that high densities of dynamic active filaments can be achieved by only changing the nature of the active force, nematic or polar. Interestingly, while polar driving is more effective at unjamming the system at high densities below confluency, we find that at even higher densities, nematic driving enhances unjamming compared to its polar counterpart. The effect of varying the rigidity of filaments is also significantly different in the two cases: While for nematic driving, lowering the bending rigidity unjams the system, we find an intriguing reentrant jamming-unjamming-jamming transition for polar driving as the filament rigidity is lowered. While the first transition (unjamming) is driven by softening due to reduced rigidity, the second transition (jamming) is a cooperative effect of ordering and coincides with the emergence of nematic order in the system. Together, through a generic model of self-propelled flexible filaments, our results demonstrate how tuning the nature of self-propulsion and flexibility can be employed by active materials to achieve high densities without getting jammed.

Superstatistical Analysis and Modelling of Complex Dynamical Systems — •Claus Metzner[1,2], Christoph Mark[2], Ben Fabry[2], Patrick Krauss[1], Achim Schilling[1], Maximilian Traxdorf[3], and Holger Schulze[1] — [1]Neuroscience Lab, University Hospital Erlangen, Germany — [2]Biophysics Lab, Friedrich-Alexander Universität Erlangen-Nürnberg — [3]Department of Otorhinolaryngology, Head and Neck Surgery, Paracelsus Medical University, Nuremberg, Germany

On longer time scales, complex systems often pass through different dynamical attractors and thus produce 'anomalous' distributions and correlations when analyzed with conventional statistical tools. We argue that the most appropriate way of describing such systems is by hierarchical multilevel models, in which the lowest level is a relatively simple random walk model that can generate the observed time series on short time scales, but which depends on latent hyperparameters that are themselves time-dependent and controlled by the higher levels of the model. First, our Bayesian method is introduced for the sequential inference of those gradual or abrupt parameter changes. We then review possible applications of the superstatistical framework in such diverse fields as biophysics, neuroscience, finance, or policy assessment. Finally, we discuss more recent extensions of the method for model selection and the use of machine learning models for estimating complex likelihood functions.

DY 26.6   Wed 11:45   ZEU 160
How to infer parameter distributions in heterogeneous populations of active particles — •Jan Albrecht[1], Robert Grossmann[1], and Manfred Opper[2,3] — [1]Institute of Physics and Astronomy, University of Potsdam, 14476 Potsdam, Germany — [2]TU Berlin, Fakultät IV-MAR 4-2, Marchstraße 23, 10587 Berlin, Germany — [3]Centre for Systems Modelling and Quantitative Biomedicine, University of Birmingham, B15 2TT, United Kingdom

Experiments with active particles, e.g., motile microorganisms like bacteria or amebae, provide information about their position at discrete points in time. However, most active particle models, like active Ornstein-Uhlenbeck particles for example, are commonly described by first order stochastic differential equations for the velocity or force. This leads to a second order model in position posing challenges for parameter inference, because there is no general way to obtain a closed form expression for the likelihood of the parameters in terms of

those time-sampled trajectories. This would be needed to apply efficient Bayesian parameter estimation techniques. In this talk, we propose a filtering-like sequential method to address this problem. The likelihood is first expressed in terms of integrals over transition probabilities. Approximating the transition probability for small times makes these integrals analytically feasible, leading to a likelihood approximation that allows consistent parameter inference. Using a Bayesian approach, we furthermore show how to extend this framework to estimate the entire distribution of motility parameters in heterogeneous populations of particles efficiently.

Derivation and analysis of a phase field crystal model for a mixture of active and passive particles[*] — •Michael te Vrugt[1,2], Max Philipp Holl[1], Aron Koch[1], Raphael Wittkowski[1,2,3], and Uwe Thiele[1,3,4] — [1]Institut für Theoretische Physik, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany — [2]Center for Soft Nanoscience — [3]Center for Nonlinear Science — [4]Center for Multiscale Theory and Computation

We discuss an active phase field crystal (PFC) model that describes a mixture of active and passive particles [1]. First, a microscopic derivation from dynamical density functional theory is presented that includes a systematic treatment of the relevant orientational degrees of freedom. Of particular interest is the construction of the nonlinear and coupling terms. This allows for interesting insights into the microscopic justification of phenomenological constructions used in PFC models, the approximations required for obtaining them, and possible generalizations. Second, the derived model is investigated using linear stability analysis and nonlinear methods. It is found that the model allows for a rich nonlinear behavior with states ranging from steady periodic and localized states to various time-periodic states. The latter include standing, traveling, and modulated waves corresponding to spatially periodic and localized traveling, wiggling, and alternating peak patterns and their combinations.

Active Brownian Particles in a disordered motility environment — Gianni Jacucci[1], •Davide Breoni[2], Sandrine Heijnen[3], Hartmut Löwen[2], Giorgio Volpe[3], and Sylvain Gigan[1] — [1]Laboratoire Kastler-Brossel, Paris, France — [2]HHU Universität, Düsseldorf, Germany — [3]University College London, London, United Kingdom

The study of active matter, i.e. matter that consumes energy to perform actions, is fundamental to deepen the knowledge of living systems, as for example bacterial colonies or flocks of birds, and their collective behaviors. Complex environments, like the internal structure of a cell or a blood vessel, are of particular relevance in this field, as they provide a better description of the real-life settings typical of living matter.

In this work we study the effects of a disordered motility field on active Brownian particles, both in experiments and simulations. Experimentally, the motility field is generated by applying a speckle light field to thermophoretic Janus particles, in our case silica colloids half-coated with a carbon layer, suspended in a critical mixture of water and 2,6-lutidine. We focus on the differences between the effects of respectively a homogeneous and a disordered motility field on the dynamics of the particles.

DY 26.9 Wed 12:30 ZEU 160

Characterization of spatial heterogeneities as influencing factors on the dynamics of confluent endothelial cell migration — •Anselm Hohlstamm, Andreas Deussen, Stephan Speier, and Peter Dieterich — Institut für Physiologie, TU Dresden

Confluent endothelial cells are in perpetual movement. Their collective dynamics arises from the interplay of self-propelled motility and various distance-related cell interactions. However, an understanding of collective cell dynamics is complicated by large spatial heterogeneities and local cluster formations. It is the aim of this work to quantify and characterize their influence on the dynamics of cell migration. We used human umbilical vein endothelial cells, which were stained with a fluorescent dye and observed for 48 hours via time-lapse microscopy. With automated image segmentation we could track several 10.000 cells. Cell densities and mean squared velocities showed a heterogeneous spatial distribution with an inverse relation to each other. Higher cell densities also affected the strength of the velocity autocorrelation, whereas correlation times remained mostly stable during experiments. However, cell division increased the mean squared velocity without changing temporal correlations. In parallel, the mean squared displacement characterized regions with short superdiffusive phases in an aging, highly non-stationary system. In addition, local dynamics are coupled by long range spatial correlations. In summary, the dynamics of an entire endothelial layer is influenced by interactions of small heterogenous regions. Next, we will use this approach to compare different endothelial cells.

DY 26.10 Wed 12:45 ZEU 160

Exploiting the unknown - Smart nutrient collection surpassing the run and tumble strategy — •Mahdi Nasiri, Edwin Loran, and Benno Liebchen — Institut für Physik kondensierter Materie, Technische Universität Darmstadt, Hochschulstraße 8, D-64289 Darmstadt, Germany

Throughout evolution, microorganisms have developed efficient strategies for locating nutrients and avoiding toxins in complex environments. Understanding their adaptive policies can provide new key insights for the development of smart artificial active particles. In this talk, we will present a novel method that uses deep reinforcement learning (DRL) to develop smart nutrient collection strategies for chemotactic active particles. Our method is complementary to our previous work which used DRL to explore optimal navigation [1] and is able to devise efficient survival strategies inside unknown and complex environments while only having access to local sensory data. We were also able to extract an interpretable model from the learned strategies which resemble striking similarities with the classical run and tumble motion.

Evolution in changing environments and driven disordered systems — •Joachim Krug, Suman Das, and Muhittin Mungan — Institute for Biological Physics, University of Cologne, Köln, Germany

Biological evolution is governed by the fitness landscape, a map from the genetic sequence of an organism to its fitness. A fitness landscape depends on the organism's environment, and evolution in changing environments is still poorly understood. After introducing the concept of fitness landscapes and their mathematical description, the talk will focus on a particular model of antibiotic resistance evolution in bacteria [1]. Tradeoffs between adaptation to low and high concentration lead to a rugged landscape with an exponentially large number of fitness peaks. With evolutionary dynamics that follow fitness gradients, resistance evolution under slowly changing antibiotic concentration maps to the zero temperature dynamics of a disordered spin system [2]. Specifically, the set of genetic sequences that form a fitness peak at some concentration maps exactly to the metastable states in an equivalent Preisach system, a paradigmatic model of hysteresis in random magnets. Making use of the conceptual tool of state transition graphs developed in the context of driven disordered systems, we quantify the degree of genotypic and phenotypic reversibility in the response of the population to antibiotic concentration cycling.

DY 27.2 Wed 10:00 ZEU 250

Anomalous relaxation of density waves in a ring-exchange system — •Pranay Patil[1,2], Markus Heyl[1,3], and Fabien Alet[2] — [1]Max-Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Laboratoire de Physique Theorique, Universite de Toulouse, CNRS, UPS, France — [3]Theoretical Physics III, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, 86135 Augsburg, Germany

We present the analysis of the slowing down exhibited by stochastic dynamics of a ring-exchange model on a square lattice, by means of numerical simulations. We find the preservation of coarse-grained memory of initial state of density-wave types for unexpectedly long times. This behavior is inconsistent with the prediction from a low frequency continuum theory developed by assuming a mean field solution. Through a detailed analysis of correlation functions of the dynamically active regions, we exhibit an unconventional transient long ranged structure formation in a direction which is featureless for the initial condition, and argue that its slow melting plays a crucial role in the slowing-down mechanism. We expect our results to be relevant also for the dynamics of quantum ring-exchange dynamics of hard-core bosons.

DY 27.3 Wed 10:15 ZEU 250

Colloidal monolayers: bridging the gap between two and three spatial dimensions — Johannes Bleibel[2], •Alvaro Domínguez[1], and Martin Oettel[2] — [1]Univ. Sevilla, Spain — [2]Univ. Tübingen

It is well established that, unlike for a three-dimensional fluid, particle interactions prevent the hydrodynamic transport coefficients from being defined for a

two-dimensional fluid due to the notorious "long-time tail" feature of the velocity autocorrelation.

A colloidal monolayer formed at a fluid interface builds a bridge between these two limiting cases, and it provides insight on the transition from three down to two spatial dimensions: the particle positions are constrained to a plane and the colloid thus resembles a two-dimensional fluid. But the exchange of particle momentum takes place in three-dimensional space through hydrodynamic interactions in the ambient fluid.

Here we study the colloidal diffusivity starting from the Smoluchowski equation. We show that the diffusivity exhibits an intermediate behavior between purely two-dimensional and fully three-dimensional fluid: on the one hand, Fick's law, which pertains to *collective diffusion*, breaks down altogether, as confirmed experimentally. On the other hand, the coefficient of *self-diffusion* is finite, but the transitional nature of the monolayer shows up in a non-analytic dependence on the colloidal packing fraction, at odds with the case of a fully three-dimensional colloid.

DY 27.4   Wed 10:30   ZEU 250

Nonequilibrium mixture dynamics: A model for mobilities and its consequences — Maryam Akaberian, •Filipe Thewes, Peter Sollich, and Matthias Krüger — Institut für Theoretische Physik, Georg-August-Universität Göttingen, Göttingen, Germany

Extending the famous Model B for the time evolution of a liquid mixture, we develop an approximate approach for the mobility matrix that couples the different mixture components. This approach is based on a single component fluid with particles that are artificially grouped into colors and the relevant parameters can be determined from experiments or numerical simulations. We identify two distinct regimes, corresponding to collective motion and inter-diffusion, respectively, and show how they emerge from the microscopic properties of the fluid. As a test scenario, we study the dynamics after a thermal quench, providing a number insights from a Gaussian theory. Specifically, for systems with two or three components, analytical results for the time evolution of the equal time correlation function compare well to results of Monte Carlo simulations of a lattice gas. A rich behavior is observed, including the possibility of fractionation.

DY 27.5   Wed 10:45   ZEU 250

Dynamical Renormalization Group Theory for Driven Systems — •Nikos Papanikolaou and Thomas Speck — Institute of Theoretical Physics 4, University of Stuttgart, Stuttgart, Germany

Active matter describes nonequilibrium systems that are self-driven due to their microscopic dynamics. These systems pose a fundamental physics challenge by unveiling new phenomena, not present in equilibrium systems, such as the Motility Induced Phase Separation; formation of clusters in the absence of any attractive interactions. To study analytically nonequilibrium complex systems, the Renormalization Group (RG) theory has been successfully used to extract the phase diagram, to study its qualitative behavior, and to explore the critical properties in the different phases. In this project, we explore a variation of RG called Dynamical RG to study self-driven systems by directly applying the RG to dynamical field equations such as the KPZ equation or the Active Model B+ which describe the stochastic evolution of systems like the population of bacteria, interfaces, and neural networks.

DY 27.6   Wed 11:00   ZEU 250

Metastability as a Mechanism for Yielding in Amorphous Solids under Cyclic Shear — •Muhittin Mungan[1] and Srikanth Sastry[2] — [1]Institute of Biological Physics, University of Cologne, Cologne, Germany — [2]Jawaharlal Nehru Centre for Advanced Scientific Research, Bengaluru, India

We consider the yielding behavior of amorphous solids under cyclic shear deformation and show that it can be mapped into a random walk in a confining potential with an absorbing boundary. The resulting dynamics is governed by the first passage time into the absorbing state and suffices to capture the essential qualitative features recently observed in atomistic simulations of amorphous solids. Our results provide insight into the mechanism underlying yielding and its robustness. When the possibility of activated escape from absorbing states is added, it leads to a unique determination of a threshold energy and yield strain, suggesting thereby an appealing approach to understanding fatigue failure [1].

Tunable Brownian magneto heat pump — •Iman Abdoli[1], René Wittmann[2], Joseph Brader[3], Jens-Uwe Sommer[1], Hartmut Löwen[2], and Abhinav Sharma[1] — [1]Leibniz-Institut für Polymerforschung Dresden, 01069 Dresden, Germany — [2]Heinrich-Heine-Universität Düsseldorf, 40225 Düsseldorf, Germany — [3]Université de Fribourg, CH-1700 Fribourg, Switzerland

We propose a mesoscopic Brownian magneto heat pump made of a single charged Brownian particle that is steered by an external magnetic field. The particle is subjected to two thermal noises from two different heat sources. When confined, the particle performs gyrating motion around a potential energy minimum. We show that such a magneto-gyrator can be operated as both a heat engine and a refrigerator. The maximum power delivered by the engine and the performance of the refrigerator, namely the rate of heat transferred per unit external work, can be tuned and optimised by the applied magnetic field. Further tunability of the key properties of the engine, such as the direction of gyration and the torque exerted by the engine on the confining potential, is obtained by varying the strength and direction of the applied magnetic field. In principle, our predictions can be tested by experiments with colloidal particles and complex plasmas.

DY 27.8   Wed 11:45   ZEU 250

Work fluctuations in the harmonic Active Ornstein-Uhlenbeck particle model — •Giuseppe Gonnella — Università degli Studi di Bari, Bari, Italy — Istituto Nazionale di Fisica Nucleare, sezione di Bari

Over the past few years great interest arose in providing a thermodynamic description of Active Matter Systems and an important emphasis was put on the Active Work study. The distribution of such an observable has been object of recent research[1] as possible singularities signal the occurrence of Dynamical Phase Transitions (DPTs)[2,3], in turn related to peculiar trajectory realisations.

Here we focus on a single harmonically trapped Active Ornstein-Uhlenbeck Particle and provide the analytic expression for the scaled cumulant generating function (SCGF) of the Active Work. Interestingly, we find the SCGF to be non-steep in many physical situations and we provide insight on the effect of relevant system parameters, such as the Peclet number, on the SCGF steepness trough a phase diagram in the system parameter space. Through Legendre-Fenchel transform, the SCGF steepness is shown to lead to singular rate functions with linear tails, and ultimately to the occurrence of DPTs also in this system. We also investigate on the role of initial and final condition in producing the consequent anomalous trajectories.

DY 27.9   Wed 12:00   ZEU 250

Non-thermal fixed points of universal sine-Gordon coarsening dynamics — Philipp Heinen[1], Aleksandr N. Mikheev[1,2], Christian-Marcel Schmied[1], and •Thomas Gasenzer[1,2] — [1]Kirchhoff-Institut für Physik, Universität Heidelberg, Im Neuenheimer Feld 227, 69120 Heidelberg — [2]Institut für Theoretische Physik, Universität Heidelberg, Philosophenweg 16, 69120 Heidelberg

We examine coarsening of field-excitation patterns of the sine-Gordon (SG) model, in two and three spatial dimensions, identifying it as universal dynamics near non-thermal fixed points. The focus is set on the non-relativistic limit, governed by a Schrödinger-type equation with Bessel-function nonlinearity. The results of our classical statistical simulations suggest that, in contrast to wave turbulent cascades, in which the transport is local in momentum space, the coarsening is dominated by rather non-local processes corresponding to a spatial containment in position space. The scaling analysis of a kinetic equation obtained with path-integral techniques corroborates this numerical observation and suggests that the non-locality is directly related to the slowness of the scaling in space and time. Our methods, which we expect to be applicable to more general types of models, could open a long-sought path to analytically describing universality classes behind domain coarsening and phase-ordering kinetics from first principles, which are usually modelled in a near-equilibrium setting by a phenomenological diffusion-type equation in combination with conservation laws.

DY 27.10   Wed 12:15   ZEU 250

Nonequilibrium probability currents in optically-driven colloidal suspensions — •Samudrajit Thapa[1,2], Daniel Zaretzky[3], Grzegorz Gradziuk[4], Chase Broedersz[4,5], Yair Shokef[1,2,6], and Yael Roichman[3,6,7] — [1]School of Mechanical Engineering, Tel Aviv University, Tel Aviv 69978, Israel — [2]Sackler Center for Computational Molecular and Materials Science, Tel Aviv University, Tel Aviv 69978, Israel — [3]School of Chemistry, Tel Aviv University, Tel Aviv 69978, Israel — [4]Arnold Sommerfeld Center for Theoretical Physics, Ludwig Maximilians Universitaet Muenchen, Theresienstr. 37, 80333 Munich, Germany — [5]Department of Physics and Astronomy, Vrije Universiteit Amsterdam, 1081 HV Amsterdam, The Netherlands — [6]Center for the Physics and Chemistry of Living Systems, Tel Aviv University, 69978, Tel Aviv, Israel — [7]School of Physics & Astronomy, Tel Aviv University, Tel Aviv 69978, Israel

In the absence of visible currents and prior knowledge, it is often hard to recognize athermal fluctuations. Probability currents provide such a measure in terms of the rate at which they enclose area in phase space. We measure this area enclosing rate for trapped colloidal particles, where only one particle is driven, and they interact hydrodynamically. By combining experiment, theory and simulation, we identify an optimal measurement protocol in terms of the relations between the different time scales in the system. Furthermore, we find that hydrodynamic interactions render the effect of athermal agitation more local than that of elastic interactions. This may have significant implications for the interpretation of fluctuations in biological systems.

DY 27.11   Wed 12:30   ZEU 250

A nonlinear fluctuation-dissipation theorem for Markovian systems — •Benjamin Lindner[1,2], Kirsten Engbring[2], Dima Boriskovsky[3], and Yael Roichman[3] — [1]Bernstein Center for Computational Neuroscience Berlin, Philippstr.\ 13, Haus 2, 10115 Berlin, Germany — [2]Physics Department of Humboldt University Berlin, Newtonstr.\ 15, 12489 Berlin, Germany — [3]The Raymond and Beverley School of Physics \& Astronomy and The Raymond and Beverley School of Chemistry, Tel Aviv University, Tel Aviv 6997801, Israel

Fluctuation-Dissipation-Theorems (FDT) connect the internal spontaneous fluctuations of a system with its response to an external perturbation. In this work we propose a new nonlinear fluctuation-dissipation theorem as a test for Markovianity. Previously suggested FDTs are based on linear response and require a significant amount of measurements. However, the nonlinear relation holds for systems out of equilibrium, and for strong perturbations requiring significantly less data than the standard linear relation. We verify the nonlinear theorem for two theoretical model systems: a Brownian particle in a tilted periodic potential, and a harmonically bound particle. In addition, we apply our formalism and test for Markovianity in an inherently out of equilibrium experimental system, based on self-propelled agents.

DY 27.12   Wed 12:45   ZEU 250

Heat capacity for a driven array of semiclassical dots — •Pritha Dolai and Christian Maes — Instituut voor Theoretische Fysica, KU Leuven, Belgium

We analyze thermal properties for particle transport along an array of two-level systems. More specifically, we obtain analytic and numerical results for the heat capacity of a system of particles subject to mutual exclusion and to birth and death, driven around a ring by an external field. We find a zero-temperature phase transition as a function of the chemical potential of the environment, as shown by the divergence of the heat capacity at zero temperature. The non-vanishing of the heat capacity at absolute zero, violating the extended Third Law, is caused by a localization and corresponding delay in relaxation of excess heat. We also derive a regime of negative heat capacity indicating an anticorrelation between the temperature-dependence of the stationary occupation and the excess heat.

Crises and chaotic scattering in hydrodynamic pilot-wave experiments — George Choueiri[1,2], Balachandra Suri[1,3], Jack Merrin[1], Maksym Serbyn[1], Björn Hof[1], and •Nazmi Burak Budanur[1,4] — [1]Institute of Science and Technology Austria, 3400 Klosterneuburg, Austria — [2]MIME Department, University of Toledo, Toledo, Ohio 43606, USA — [3]Department of Mechanical Engineering, Indian Institute of Science, Bengaluru 560012, India — [4]Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany

Theoretical foundations of chaos have been predominantly laid out for finite-dimensional dynamical systems, such as the three-body problem in classical mechanics and the Lorenz model in dissipative systems. In contrast, many real-world chaotic phenomena, e.g., weather, arise in systems with many (formally infinite) degrees of freedom, which limits direct quantitative analysis of such systems using chaos theory. In the present work, we demonstrate that the hydrodynamic pilot-wave systems offer a bridge between low- and high-dimensional chaotic phenomena by allowing for a systematic study of how the former connects to the latter. Specifically, we present experimental results, which show the formation of low-dimensional chaotic attractors upon destabilization of regular dynamics and a final transition to high-dimensional chaos via the merging of distinct chaotic regions through a crisis bifurcation. Moreover, we show that the post-crisis dynamics of the system can be rationalized as consecutive scatterings from the nonattracting chaotic sets with lifetimes following exponential distributions.

DY 29.2   Wed 10:15   ZEU 147

Chemically Active Wetting — •Susanne Liese[1], Xueping Zhao[2], Frank Jülicher[3], and Christoph Weber[1] — [1]Universität Augsburg, Augsburg, Germany — [2]Xiamen University, Xiamen, China — [3]MPI/PKS, Dresden, Germany

In living cells, wetting of condensed phases on membrane surfaces provides a mechanism for positioning biomolecules. Biomolecules are also able to bind to such membrane surfaces. In living cells, this binding is often chemically active as it is kept out of equilibrium by the supply of energy and matter. Here, we investigate how active binding on membranes affects the wetting of condensates. To this end, we derive the non-equilibrium thermodynamic theory of active wetting. We find that active binding significantly alters the wetting behavior leading to non-equilibrium steady states with condensate shapes reminiscent of a fried egg or a mushroom. We further show that such condensate shapes are determined by the strength of active binding in the dense and dilute phases, respectively. Strikingly, such condensate shapes can be explained by an electrostatic analogy where binding sinks and sources correspond to electrostatic dipoles along the triple line. Through this analogy, we can understand how fluxes at the triple line control the three-dimensional shape of condensates.

DY 29.3   Wed 10:30   ZEU 147

Stimuli-responsive high aspect ratio surfaces for wetting studies — •Gissela Constante[1], Indra Apsite[1], Paul Auerbach[2], Sebastian Aland[2], Dennis Schönfeld[3], Thorsten Pretsch[3], Pavel Milkin[1], and Leonid Ionov[1,4] — [1]Uni Bayreuth, Bayreuth, Germany — [2]HTW Dresden, Dresden, Germany — [3]Fraunhofer IAP, Postdam, Germany — [4]Bavarian Polymer Institute, Bayreuth, Germany

The fabrication of switchable surfaces has been of interest in different fields such as biotechnology, industry, robotics, and others. The fabrication of these shape-changing bioinspired surfaces is a challenge due to the limited availability of materials and methods. In this research, an exceptional high aspect ratio lamellar surface topography was fabricated by melt-electrowriting of microfibers of a shape-memory thermo-responsive polyurethane. Two different types of stimuli: temperature and light exposition were applied to modify the mechanical properties and by it the deformation and recovery of the original surface. Wetting studies showed that the deformation of the high aspect ratio lamellar surface can be tunned not only manually, but as well by a liquid droplet. This behavior is controlled by variation of temperature conducted by direct heating/cooling or by exposure to light when the lamellae were stained with black ink. The liquid in combination with thermo-responsive topography presents a new type of wetting behavior. This feature opens the possibility to apply such topographies for the design of smart elements for microfluidic devices, for example, smart valves.

DY 29.4   Wed 10:45   ZEU 147

A Study about Shock-Induced Spallation in Mono- and Nanocrystalline High-Entropy Alloys — •Daniel Thürmer[1], Nina Merkert née Gunkelmann[1], Shiteng Zhao[2], Orlando Deluigi[3], Camelia Stan[4], Iyad Alhafez[5], Herbert Urbassek[5], Marc Meyers[6], and Eduardo Bringa[3,7] — [1]Institute of Applied Mechanics, Clausthal University of Applied Technology, Arnold-Sommerfeld-Stra*e, D-38678 Clausthal-Zellerfeld, Germany — [2]School of Material Science and Engineering, Beihang University, 37 Xueyuan Rd, Haidian District, Beijing, China, 100191 — [3]CONICET and Faculty of Engineering, University of Mendoza, Mendoza, 5500, Argentina — [4]Advanced Light Source Facility, Lawrence Berkeley National Laboratory, One Cyclotron Road, Berkeley, CA 94720, United States — [5]Physics Department and Research Center OPTIMAS, University Kaiserslautern, Erwin-Schr*odinger-Stra*e, D-67663 Kaiserslautern, Germany — [6]Mechanical and Aerospace Department, Univ. of California San Diego, La Jolla, CA 92093, United States — [7]Centro de Nanotecnología Aplicada, Universidad Mayor, Santiago, Chile

High-entropy alloys are highly attractive for future applications in the technical field thanks to their incredible potential regarding mechanical properties. Although they are increasingly sparking interest for future usage, their general understanding is not yet complete. To further understand high-entropy alloys and their capabilities, we studied the influence of shock-induced spallation on mono- and nanocrystalline high-entropy alloys with varying grain sizes.

Instability of Active Fluid Interfaces in Microfluidics — •KUNTAL PATEL and HOLGER STARK — Institut für Theoretische Physik, Technische Universität Berlin, Berlin, Germany

In recent years, microfluidic lab-on-a-chip devices have emerged as efficient miniaturized flow control platforms. Specifically, the advent of nonlinear microfluidics has opened a new avenue for chemical and biomedical applications such as droplet formation and cell sorting. In this work, we integrate ideas from active matter into a microfluidic setting and try to understand the mechanism and practical relevance of resulting microfluidic flows.

The present setup consists of two vertically stacked fluid layers with identical densities but different viscosities, sandwiched between the walls of a microfluidic channel. The interface separating both fluids is initialized with uniformly distributed active particles, which induce force dipoles that generate flows in the adjacent fluids.

Our hybrid lattice-Boltzmann finite-difference simulations reveal that when we perturb the fluid interface covered with extensile force dipoles $\updownarrow$, it eventually returns to its flat state irrespective of the strength of interfacial tension. In contrast, contractile force dipoles $\leftrightarrow$ lead to activity-driven interfacial instability. However, such instability emerges only above a critical value of the activity, which is proportional to the interfacial tension. We further examine the mechanism of instability and quantify the effect of viscosity contrast and perturbation wavelength. Lastly, we demonstrate the systematic formation of droplets using the present interfacial instability.

Optically controlled micro-transport with reduced heating impact — •ANTONIO MINOPOLI, ELENA ERBEN, SUSAN WAGNER, and MORITZ KREYSING — Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany

Recently it was demonstrated that thermoviscous flows can be used to move the cytoplasm of cells and developing embryos. These laser-induced intracellular flows (aka FLUCS), reach velocities comparable with those occurring during early stages of embryogenesis. As a side effect, the laser scanning may also cause temperature gradients across the sample (1-3 Kelvins) that could give rise to out-of-equilibrium phenomena. Here, we demonstrate that exploiting symmetry relations during the laser scan, we disentangle heating and flows. Specifically, since the flow speeds depend on the repetition frequency rather than on the beam velocity, it is possible to accelerate the scanning of the primary scan pattern, effectively compressing the scan signal to occupy only a fraction of the original period, and allowing to complement the flow stimuli by flow-invariant heat stimuli. We introduce strategies to complement even complex primary scan patterns by secondary heating stimuli thereby yielding a near isothermal temperature distribution and still generating significant net flows. As we experimentally show, the resulting temperature distributions are near homogenous across the sample (standard deviations 5-10 times lower than those measured with standard FLUCS) and can therefore be better compensated for by ambient cooling. In the next future, ISO-FLUCS may become the new standard for optofluidic manipulations within biological systems.

3D passive non-mechanical microfluidic valves fabricated using grayscale lithography — •SEBASTIAN BOHM[1,3], HAI BINH PHI[2,3], ERICH RUNGE[1], LARS DITTRICH[3], and STEFFEN STREHLE[2] — [1]TU Ilmenau, FG Theoretische Physik I — [2]TU Ilmenau, FG Mikrosystemtechnik — [3]5microns GmbH, 98693 Ilmenau

Passive non-mechanical valves represent a promising method for rectifying flows in micro- or nanofluidic systems [1]. They are very robust due to the absence of mechanical parts, easy to fabricate, and allow the implementation of efficient microfluidic systems such as micropumps [2,3]. However, with existing methods, the fabrication of fully three dimensional (3D) structured geometries is very hard to achieve. Here, a new and easy to implement method for the fabrication of three-dimensional valves is presented: Grayscale lithography followed by a proportional transfer with reactive ion etching is utilized to create 3D diffuser valves in silicon and glass substrates. We show that higher diodicities were achieved with 3D diffuser valves compared to conventional diffuser valves. These experimental findings correspond fit very well to the predictions of our numerical simulations. In combination with highly efficient optimization methods for two-dimensional Tesla valves, the fabrication of even more efficient 3D Tesla valves is hence now within reach.

Coalescence of nematic droplets in quasi 2D liquid crystal films — •CHRISTOPH KLOPP and RALF STANNARIUS — Otto von Guericke University, Institute of Physics

Coalescence of droplets is ubiquitous in nature and modern technology. Various experimental and theoretical studies explored droplet dynamics in three dimensions (3D) and on two-dimensional (2D) solid or liquid substrates, e.g. [1-4]. Here, we demonstrate coalescence experiments of isotropic and nematic droplets in quasi-2D liquids, viz. overheated smectic A freely suspended films. We investigated their dynamics experimentally and measured the shape deformation during the entire merging process using high-speed imaging and interferometry. This system is a unique example where the lubrication approximation can be directly applied, and the smectic membrane plays the role of a precursor film. Our studies reveal the scaling laws of the coalescence time depending on the droplet size and the material parameters. We also compared the dynamics of isotropic and nematic droplets and additionally analyzed the results based on an existing model for liquid lens coalescence on liquid and solid surfaces [4].

This study was supported by DLR with project 50WM2054 and by DFG with project STA 425/40.

effect of deposition method on the static contact angle of nanodroplets measured by AFM — •MOHAMMADALI HORMOZI and REGINE VON KLITZING — soft matter at interface, tu darmstadt, darmstadt, Germany

The wetting properties of substrates are often described by the static contact angle of a particular liquid. The contact angle depends on many parameters like substrate chemistry, liquid properties, and environment condition. In this study, we show that the method of depositing the liquid phase on the solid phase can play an important role for the static contact angle. For this purpose, microscale droplets of non-volatile liquids including Polyethylene Glycol (PEG200) and Squalane are deposited on the silanized substrate using four different methods. These methods are either based on nucleation (condensation and solvent exchange) or printing (inkjet and microcontact printing) of droplets. The contact angle of the microdroplets is scanned with an AFM and allows detailed analysis of the three phase contact line on a nm scale. The final static contact angle of the microdroplets is compared with the macroscopic contact angle determined by optical methods. Droplets formed via nucleation show smaller contact angle than printed ones. The latter ones were closer to the macroscopic contact angle. We will discuss this phenomenon.

DY 29.10 Wed 12:30 ZEU 147

Fingering contact propagation between a droplet and a thin liquid film — •KIRSTEN HARTH — Fachbereich Technik, TH Brandenburg — MRTM und MARS, Otto von Guericke Universität Magdeburg

When impacting droplets approach a hard plane substrate slowly, so that the Weber number is below approximately 5, a contact-less rebound will occur due to the entrainment of ambient gas. On slightly deformable and smooth spin-coated liquid films upon a rigid solid, this effect is more robust and may occur until slightly higher Weber numbers. Deformation of the thin film is usually ignored while it is proven to be present. The deformation amplitude depends on the impact dynamics as well as the thickness and viscosity of the surficial oil layer. At slightly higher impact velocities, i.e. slightly higher Weber numbers, delayed contact formation between the film liquid and the droplet occurs. Depending on the layer properties, interestingly, the contact line may be unstable displaying a fingering texture. Instability occurs independently of whether the drop and film liquid differ or not. We present and analyze this phenomenon.

DY 29.11 Wed 12:45 ZEU 147

Universality in One-Dimensional Breath Figures — •DANIEL DERNBACH, ADRIAN HÄUSSLER-MÖHRING, M MUHAMMAD, and JÜRGEN VOLLMER — Institut für Theoretische Physik, Universität Leipzig, Brüderstr. 16, D-04103 Leipzig, Germany

Patterns of droplets which condense upon substrates reveal self-similar features. They are described by a scaling theory with a non-trivial exponent that has been related to the fractal dimension of the scaling of the free area ("porosity") in between droplets. There is no agreement if this exponent is universal or affected by the dynamics. Here, we present numerical data that address the dependence of the asymptotic scaling of the porosity for hyper-spherical droplets growing on one-dimensional substrates. We vary the droplet dimension and interactions. For a given dimension the exponent is universal up to a critical range of interaction. For longer-ranged interactions the scaling depends on the dynamics.

Physics of gut motility governs digestion and bacterial growth — •Agnese Codutti[1], Jonas Cremer[2], and Karen Alim[1] — [1]School of Natural Sciences, Technical University of Munich, Germany — [2]Biology Department, Stanford University, USA

Malfunctioning of the small intestine contractility and the ensuing bacterial population therein are linked to a plethora of diseases. We, here, study how the small intestine's variety of contractility patterns impacts nutrient uptake and bacterial population [1]. Our analytical derivations in agreement with simulations identify flow velocity as the key control parameter of the nutrients uptake efficiency and bacterial growth, independently of the specifics of contractility patterns. Self-regulating flow velocity in response to the number of nutrients and bacteria in the gut allows for achieving 100% efficiency in nutrient uptake. Instead of the specifics of intestine contractility, our work points to the flow velocity and its variation in time within the intestine to prevent malfunctioning.

Turbulence induces clustering and arrested phase separation in polar active fluids — Vasco Worlitzer[1,2], Gil Ariel[2], Avraham Beer[3], Holger Stark[4], •Markus Bär[1,4], and Sebastian Heidenreich[1] — [1]Physikalisch-Technische Bundesanstalt, Berlin — [2]Bar-Ilan University, Ramat Gan, Israel — [3]Ben-Gurion University, Beer Sheva, Israel — [4]Technische Universität Berlin

We study a novel phase of active polar fluids, which is characterized by the continuous creation and destruction of dense clusters due to self-sustained turbulence. This state arises due to the interplay between self-advection of the aligned swimmers and their defect topology. The typical cluster size is determined by the characteristic vortex size. Our results are obtained by investigating a continuum model of compressible polar active fluids [1], which incorporates typical experimental observations in bacterial suspensions [2], in particular a non-monotone dependence of speed on density.

Bacterial spreading in complex environments — •Agniva Datta, Sönke Beier, Veronika Pfeifer, Robert Grossmann, and Carsten Beta — Institute of Physics and Astronomy, University of Potsdam, Potsdam, Germany

Elucidating the principles of bacterial motility and navigation is key to understand many important phenomena such as the spreading of infectious diseases and the formation of biofilms. A prime challenge of swimming bacteria is to navigate in their habitat purposefully and efficiently, e.g., in the soil, which is a complex, structured environment. In this talk, we address the question of how bacterial navigation at the microscale relates to their large-scale spreading in heterogeneous environments. We combine experiments with the soil bacterium *Pseudomonas putida* with active particle modeling. In particular, the motility pattern of these bacteria in agar will be discussed with a focus on anomalous transport properties in disordered environments. In contrast to *E. coli*, our analysis reveals transient subdiffusion of bacteria in agar due to intermittent trapping, giving rise to a hop-and-trap dynamics with power-law distributed trap times.

Minimum Entropy Production by Microswimmers with Internal Dissipation — •Andrej Vilfan, Abdallah Daddi-Moussa-Ider, Babak Nasouri, and Ramin Golestanian — Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany

Microswimmers are natural or artificial self-propelled microscale objects moving through a fluid at low Reynolds numbers. The entropy production of microswimmers, related to their dissipated power, consists of two contributions. The external dissipation takes place in the viscous fluid surrounding the microswimmer. Internal dissipation takes place in the propulsive layer on the swimmer's surface. We have previously shown that a lower bound on the external dissipation can be derived with the knowledge of drag coefficients of two bodies of the same shape, one with a no-slip and one with a perfect slip boundary condition [1]. Here, we show that our approach can be generalized to take into account the internal dissipation, which is often the dominant contribution. By combin-

ing the Helmholtz minimum dissipation theorem and the principle of linear superposition, we solve the combined minimum dissipation problem for different classes of swimmers including surface-driven viscous droplets, swimmers driven by tangential forces and swimmers driven by normal forces. We show that the minimum entropy production in suspensions of active microswimmers differs fundamentally from particles driven by external forces.

Synchronization of model cilia by time-dependent elasto-hydrodynamics — •Albert von Kenne[1], Holger Stark[2], and Markus Bär[1] — [1]Physikalisch-Technische Bundesanstalt (PTB), 10587 Berlin — [2]Technische Universität Berlin, 10623 Berlin

Collections of hair-like micro actuators known as cilia are employed in biology to pump extra cellular fluids at low Reynolds number conditions. Their collective dynamics exhibit synchronization and a large scale coordinated motion called metachronal waves. Typically, simple models that characterize the self-organization among hydrodynamically interacting cilia neglect the inertial forces in the fluid against the viscous forces. In this case, the mutual flows are determined instantaneously through the forces exerted by cilia. Consequentially synchronization requires a symmetry breaking external to hydrodynamics, that can come from elastic responses to flow perturbations (*T. Niedermayer et al., Chaos 2008*). Meanwhile, experiments show that inertial forces are significant in microscopic flow at the relevant scales (*D. Wei et al. Phys. Rev. Lett. 2019*). In this situation, the fluid response is explicitly time-dependent and hydrodynamic correlations can lead to synchronization (*M. Theers and R. Winkler, Phys. Rev. 2013*). We derived a simplified phase-oscillator model that describes the leading order coupling between cilia by elastic responses and hydrodynamic correlations. We show that its interrelations don't change the collective state qualitatively. However, the strength of coupling is always increased.

Microswimming near a wedge — •Alexander R. Sprenger and Andreas M. Menzel — Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Universitätsplatz 2, D-39106 Magdeburg, Germany

Artificial and living microswimmer encounter a large variety of geometric confinements and surfaces in the biological world which alter their motion when nearby. Here, we study the low-Reynolds-number dynamics of a microswimmer enclosed by a wedge-shaped free-slip interface. For various opening angles of the wedge, we derive an exact solution for flow and pressure fields using the method of images. The active swimmer is represented in terms of a superposition of Stokes singularities. In this way, the hydrodynamic interactions between the swimmer and the confining interfaces are examined. In particular, we find attraction or repulsion by the wedge depending on the propulsion mechanism (pusher- or puller-type swimming strokes) and the opening angle of the wedge. For the dynamics of a microswimmer inside the wedge, we present a minimal model in terms of coupled Langevin equations for position and orientation. Our analytic results are evaluated for parameters inspired by common self-propelling microorganisms like *Escherichia coli*.

Role of cohesion in the flow of active particles through bottlenecks — •Timo Knippenberg[1], Anton Lüders[1], Celia Lozano[2], Peter Nielaba[1], and Clemens Bechinger[1] — [1]Fachbereich Physik, Universität Konstanz, Germany — [2]Bosonit, AI Department, La Rioja, Spain

Recently, many studies examined the intermittent flow of granular particles through bottleneck-shaped apertures. A common framework which describes the occurring flow statistics was empirically found for a wide range of such systems reaching from microscopic colloids and macroscopic grains up to sheep herds. However, similar studies with active matter are scarce and do merely consider steric agent interactions. Here, we experimentally and numerically study the flow of programmable, colloidal active Janus swimmers through bottlenecks. Our results confirm the applicability of the above-mentioned statistical framework of granular intermittent flow also on complex-interacting active microswimmers. Moreover, upon increasing the strength of interparticle cohe-

sion, we find a transition from an arch-dominated clogging regime to a cohesion-dominated regime where droplets form at the outlet. The flow-rate only weakly depends on the cohesion strength in the arch-dominated regime, which suggests that cohesion needs not necessarily to hinder particle flow through geometric constrictions or pores.

Self-assembling meso-machines along liquid-air interfaces — •Nicolas Vandewalle, Megan Delens, and Ylona Collard — GRASP, University of Liege, B4000 Liege, Belgium

Magnetocapillary driven self-assembly allows us to create complex structures floating along a liquid-air interface. We show how these structures can be elaborated and how they can be triggered for locomotion. First, the pairwise capillary and magnetic interactions between floating objects are experimentally studied and rationalized through analogies with electrostatics. Then, the combination of capillary attraction and magnetic repulsion will lead to the spontaneous formation of a rich variety of floating structures. Placed in processing magnetic fields, those structures may behave like swimming ciliate organisms and start to move along the liquid-air interface. The conditions to obtain this magnetic powered locomotion are emphasized.

DY 31.9   Wed 17:15   MOL 213

Induced capillary dipoles in floating particle assemblies — •Megan Delens, Ylona Collard, and Nicolas Vandewalle — GRASP, Institut de Physique B5a, Université de Liège, Liège, BE

Capillary-driven self-assembly is a common fabrication method that consists in placing floating particles onto a liquid-air interface. The attractive capillary interaction between particles is due to the local deformations of the interface which can be described via so-called capillary charges. When the particles are spherical and far from each other, the menisci are planar circles and can be described by monopolar capillary charges. The capillary interaction is then approximately found by assuming that the charges carried by individual spheres may be linearly superposed. However, when particles are close together, we experimentally observed that the attraction is enhanced and becomes far more complex. Indeed, the contact lines start to tilt and the superposition principle no longer holds. For these situations, we propose to additionally consider induced capillary dipoles to describe the menisci, therefore, providing an extra attraction between particles at short distances. This effect is enhanced when particles have different sizes such that binary self-assemblies may reveal unusual local ordering.

A Versatile Swarm of Individually Controlled Microparticles for Object Manipulation and Transport — •Veit-Lorenz Heuthe[1], Emanuele Panizon[2], and Clemens Bechinger[1] — [1]Universität Konstanz, Konstanz, Germany — [2]International Centre for Theoretical Physics, Trieste, Italy

Some tasks for robotic systems require many robots to cooperate, similar to ants that join their forces to carry large objects. On a macroscopic scale, many examples for such collective tasks exist, like robot swarms that can assemble objects. However, future potential applications like minimally invasive medicine call for miniaturization of such concepts. On the microscopic scale, one major challenge is the strong thermal noise, that demands for much more robust control. We use a reinforcement learning algorithm to individually steer microswimmers

in a swarm that can manipulate and transport a large object. Due to decentralized control, our multi robot system is highly flexible, scalable and robust. With this demonstration we take micro-robot swarms one step further on their way to become tools for manipulating microscopic objects.

DY 31.11   Wed 17:45   MOL 213

New insights into the mechanism of self-phoresis — •Alvaro Domínguez[1], Mihail Popescu[1], and Siegfried Dietrich[2] — [1]Univ. Sevilla, Spain — [2]MPI für Intelligente Systeme, Stuttgart

Chemophoresis describes the displacement of a particle in an ambient fluid due to a gradient in chemical composition. Classic phoresis can be understood through linear–response theory: in the presence of a sufficiently small gradient $(\nabla n)_{\text{ext}}$ in concentration, the phoretic velocity of the particle is $\mathbf{V} = \mathscr{L}_{\text{lin}}(\nabla n)_{\text{ext}}$, in terms of the phoretic coefficient $\mathscr{L}_{\text{lin}}$ given by a Green–Kubo expression.

Self-phoretic particles induce a composition gradient $(\nabla n)_{\text{act}}$ through catalytic activity and provide a physical realization of artificial swimmers. Experimental observations are then customarily addressed as another instance of classic phoresis, $\mathbf{V} = \mathscr{L}_{\text{lin}}(\nabla n)_{\text{act}}$.

However, an additional role of the particle's chemical activity has been recently identified [1,2], namely, as responsible for a specific activity–induced response $\mathscr{L}_{\text{act}}$, so that one has to write

$$\mathbf{V} = \left(\mathscr{L}_{\text{lin}} + \mathscr{L}_{\text{act}}\right)\left[(\nabla n)_{\text{ext}} + (\nabla n)_{\text{act}}\right]$$

in the more general scenario. This would mean a change in paradigm as it disproves the claim that "self-phoresis is phoresis in a self-induced gradient".

DY 31.12   Wed 18:00   MOL 213

Orientational dynamics and rheology of active suspensions in viscoelastic media — •Akash Choudhary[1], Sankalp Nambiar[2], and Holger Stark[1] — [1]Institute of Theoretical Physics, Technische Universität Berlin, 10623 Berlin, Germany — [2]KTH Royal Institute of Technology and Stockholm University, Stockholm 10691, Sweden

Active suspensions are systems of motile organisms or active filaments that are driven out of equilibrium through self-propulsion. This localized energy-work conversion imparts rich phenomenology and anomalous macroscale properties that are in stark contrast to passive suspensions and polymeric fluids. Motivated by the ubiquitous microbial systems in biological fluids, we analyse the impact of non-Newtonian fluids on the rheological response of active suspensions to steady shear flows.

We first study the suspension at an individual level and show that elongated pushers (representative of *E. coli*) and pullers (*C. reinhardtii*) exhibit diverse orbital dynamics in a weakly viscoelastic shear flow. We find that the active stresses not only modify the Jeffery orbits well-known from Newtonian fluids, but microswimmers can exhibit alignment and shear-plane rotation states. To analyze the impact of such behavior on the bulk rheological response, we study an ensemble of a dilute suspension of such swimmers in the presence of stochastic noise from bacterial tumbling and rotary diffusion. In comparison to Newtonian media, the polymeric elastic stresses substantially amplify the swimmer-induced viscosity, in particular, the superfluid transition observed in pusher solutions.

DY 32: Focus Session: Physics of Fluctuating Paths (joint session DY/CPP)

State-of-the-art experiments probe physical observables, such as heat, work or entropy production, empirical densities and currents, on the level of individual, stochastic paths. Such experiments are typically analysed by averaging along a limited number of individual realisations, which leads to substantial uncertainties in estimates. The systematic sample-to-sample fluctuations of such path-observables encode important information about the underlying, microscopic dynamical processes and are therefore a frontier of experimental, theoretical, and computational physics. Recently there has been a surge in the development and applications of path-based concepts across many fields of physics. This focus session complements a symposium and contains contributed talks.

DY 32.1   Wed 15:00   ZEU 160

Towards a stochastic thermodynamics of fields and tracers — •Sarah A.M. Loos[1], Davide Venturelli[2], Benjamin Walter[3], Edgar Roldan[4], and Andrea Gambassi[2] — [1]DAMTP, University of Cambridge, Cambridge, UK — [2]SISSA, Trieste, Italy — [3]Imperial College London, UK — [4]ICTP, Trieste, Italy

Many results of stochastic thermodynamics, including the close connection between entropy production and stochastic heat dissipation, rely on physical assumptions, e.g., break down if there is no clear separation into "fast equilibrium bath degrees of freedom" and "slow nonequilibrium degrees of freedom". In this talk, I will discuss some insights into thermodynamic notions of nonequilibrium

systems that do not fall into the usual paradigm of stochastic thermodynamics. In particular, we develop a thermodynamic description for systems consisting of tracer particles coupled to correlated scalar fields with thermal fluctuations in terms of trajectory-wise energy flows of the particle and the field, as well as the joint entropy production rate measured by path-probability ratios. As an illustration, we consider the case in which the particle is dragged by a harmonic trap through a complex medium described by a fluctuating Gaussian field. Using a perturbative approach, we uncover three dynamical regimes with distinct scaling behavior of the power and discuss the heat dissipation occurring within the field.

DY 32.2   Wed 15:15   ZEU 160

Fluctuation theorem for time reversal markers — •Gabriel Knotz, Till M. Muenker, Timo Betz, and Matthias Krüger — Fakultät für Physik, Georg-August-Universität, Göttingen, Germany

The analysis of particle trajectories is of high theoretical and experimental interest. Especially if hidden degrees are present, detecting broken detailed balance is a challenging task. We introduce and analyze a class of observables with certain symmetry properties under time reversal of trajectories that detect the breakage of detailed balance. Further, these observables fulfill a new form of fluctuation theorem and, under certain conditions, this fluctuation theorem provides bounds and relations for the total change in entropy. These findings are not limited to Markov or overdamped dynamics.

DY 32.3   Wed 15:30   ZEU 160

Necessity for Coarse Graining Empirical Densities and Currents in Continuous Space — •Cai Dieball and Aljaz Godec — Max Planck Institute for Multidisciplinary Sciences, Goettingen, Germany

We present general results on fluctuations and spatial correlations of the coarse-grained empirical density and current of diffusion in equilibrium or non-equilibrium steady states on all time scales. The time averaging and coarse graining hardwired in the definition of the functionals under consideration give rise to experimentally relevant but highly non-trivial statistics. We unravel a deep connection between current fluctuations and generalized time-reversal symmetry. We highlight the essential role of coarse graining in space from mathematical, thermodynamical, and experimental points of view. Spatial coarse graining is required to uncover salient features of currents that break detailed balance, and a thermodynamically "optimal" coarse graining ensures the most precise inference of dissipation. Defined without coarse graining, the fluctuations of empirical density and current are proven to diverge on all time scales in dimensions higher than one, which has far-reaching consequences for large-deviation limits in continuous space and for continuum limits of Markov-jump processes. Our findings provide new intuition about time-averaged observables and allow for a more efficient analysis of single-molecule experiments.

DY 32.4   Wed 15:45   ZEU 160

How Stickiness Can Speed Up Diffusion in Confined Systems — Arthur Alexandre[1], Matthieu Mangeat[2], •Thomas Guérin[1], and David Dean[1] — [1]Laboratoire Ondes et matière d'Aquitaine, CNRS/University of Bordeaux, F-33400 Talence, France — [2]Center for Biophysics and Department for Theoretical Physics, Saarland University, D-66123 Saarbrücken, Germany

The paradigmatic model for heterogeneous media used in diffusion studies is built from reflecting obstacles and surfaces. It is well known that the crowding effect produced by these reflecting surfaces slows the dispersion of Brownian tracers. In this talk, using a general adsorption desorption model with surface diffusion, we present an analytical theory showing that making surfaces or obstacles attractive can accelerate dispersion. In particular, we show that this enhancement of diffusion can exist even when the surface diffusion constant is smaller than that in the bulk. Even more remarkably, this enhancement effect occurs when the effective diffusion constant, when restricted to surfaces only, is lower than the effective diffusivity with purely reflecting boundaries. We give analytical formulas for this intriguing effect in periodic arrays of spheres as well as undulating microchannels. Our results are confirmed by numerical calculations and Monte Carlo simulations. [Ref: How Stickiness Can Speed Up Diffusion in Confined Systems, Phys Rev Lett 128 210601 (2022)]

DY 32.5   Wed 16:00   ZEU 160

From trajectories to models: data-driven approaches to decipher the stochastic dynamics of living systems — •Pierre Ronceray — Turing Centre for Living Systems, CINaM, CNRS, Aix-Marseille University, France

Stochastic differential equations are often used to model the dynamics of living systems, from Brownian motion at the molecular scale to the dynamics of cells and animals. How does one learn such models from experimental data? This task faces multiple challenges, from information-theoretical limitations to practical considerations. I will present a recent and ongoing effort to develop new methods to reconstruct such stochastic dynamical models from experimental data, with a focus on robustness and data efficiency. This provides a generic means to quantify complex behavior and unfold the underlying mechanisms of an apparently erratic trajectory.

DY 32.6   Wed 16:15   ZEU 160

Entropons as vibrational excitations in active solids — •Lorenzo Caprini[1], Umberto Marini Bettolo Marconi[2], Andrea Puglisi[3], and Hartmut Löwen[1] — [1]Heinrich-Heine-Universität Düsseldorf — [2]Scuola di Scienze e Tecnologie, University of Camerino — [3]Istituto dei Sistemi Complessi, CNR

We study the vibrational properties of non-equilibrium active crystals, i.e. solids formed by active particles, that are intrinsically out of equilibrium and governed by entropy production. As known in solid-state physics, equilibrium crystals are characterized by basic collective excitations with thermal origins that are named phonons. In this talk, I will show that active crystals are described by additional vibrational excitations that we called 'entropons' because each of them represents a mode of spectral entropy production. Entropons coexist with phonons and dominate over them for large activity, i.e. when the solid is far from equilibrium, while they vanish in equilibrium conditions. Their existence can be verified in experiments on dense self-propelled colloidal Janus particles and granular active matter, as well as in living systems such as dense cell monolayers.

Inferring Fractional Processes Using Path Integrals — •Johannes A. Kassel[1], Benjamin Walter[2], and Holger Kantz[1] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Imperial College London, London, UK

We present a method for inferring overdamped nonlinear Langevin equations driven by multiplicative fractional Gaussian noise from single-trajectory time series. Constructing a maximum-likelihood estimator, we simultaneously infer the nonlinear deterministic force term and the space-dependent diffusion term. We illustrate our method using artificial time series. We observe that Markovian modeling of long-range correlated data leads to a substantial underestimation of the deterministic force term while for anti-correlated data it leads to an overestimation of the force term.

Kinetics of Imperfect Reactions for non-Markovian Random Walks — •Toni Vieira Mendes and Thomas Guérin — Laboratoire Ondes et Matière d'Aquitaine, Université de Bordeaux

Most transport influenced reactions between two random walkers are usually imperfect, i.e., they do not occur at first contact between the reactants. For such imperfect reactions, recent work has been made to determine the statistics of first reaction time for Markovian random walkers in confinement. However, a lot of physical random walks are actually non-Markovian, i.e., their movement in the future depend on the trajectory they have followed up to then, thus displaying memory effects. These memory effects can be seen, for example, for beads moving inside complex fluids where the force fields do not equilibrate instantly. In this contribution, we describe an analytical theory giving access to the mean reaction time for imperfect reactions for random walkers with memory in confinement. Our theory clearly shows that, contrary to the Markovian case, the reaction time is not the sum of the mean first passage time and the time to react once within reactive distance. We show that the results of our theory match the results of simulations for both one and two dimensions. Then, the equations are analytically solved in the limit of weakly non-Markovian processes. Remarkably, in the limit of weakly reactive targets for fractional Brownian Motion, we find that the mean reaction time displays a non-trivial scaling as a function of the reactivity.

DY 32.9   Wed 17:15   ZEU 160

Instantons and the Path to Intermittency in Turbulent Flows — •André Fuchs[1], Corentin Herbert[2], Joran Rolland[3], Matthias Wächter[1], Freddy Bouchet[2], and Joachim Peinke[1] — [1]Institute of Physics and ForWind, University of Oldenburg, Küpkersweg 70, 26129 Oldenburg, Germany — [2]Université de Lyon, Ens de Lyon, Université Claude Bernard, CNRS, Laboratoire de Physique, F-69364 Lyon, France — [3]Université de Lille, CNRS, ONERA, Arts et Métiers Institute of Technology, Centrale Lille, UMR 9014 - LMFL - Laboratoire de Mécanique des fluides de Lille - Kampé de Fériet, F-59000 Lille, France

Processes leading to anomalous fluctuations in turbulent flows, referred to as intermittency, are still challenging. We consider cascade trajectories through scales as realizations of a stochastic Langevin process for which multiplicative noise is an intrinsic feature of the turbulent state. The trajectories are conditioned on their entropy exchange. Such selected trajectories concentrate around an optimal path, called instanton, which is the minimum of an effective action. The action is derived from the Langevin equation, estimated from measured data. In particular instantons with negative entropy pinpoint the trajectories responsible for the emergence of non-Gaussian statistics at small-scales.

A nonadiabatic generalized-dividing-surface instanton rate theory — •Rhiannon A. Zarotiadis, Joseph E. Lawrence, and Jeremy O. Richardson — Lab. für Physikalische Chemie, ETH Zürich, Zürich, Switzerland.

The accurate prediction of quantum rate processes is fundamental to our understanding of chemical reactions, but exact calculations are extremely costly. To make them tractable many chemical processes are described within the Born-Oppenheimer (BO) approximation, which assumes strong coupling between the diabatic states, and BO instanton theory is known to capture nuclear quantum effects for these systems well [1]. Alternatively, some systems are better captured by Fermi's golden rule, which is appropriate in the opposite limit of weak coupling.

Nevertheless, many reactions are in neither of these two limits, and so a universal rate theory is desirable. We introduce a new nonadiabatic generalized-dividing-surface instanton approach rigorously derived from the flux-flux correlation function. Our new theory correctly recovers the weak- and strong-coupling limits and goes beyond existing, ad hoc attempts to describe general, nonadiabatic rate processes.

Instanton rate theories [1] have already resolved many longstanding discrepancies between experiment and theory [2] and this new rate theory will be key to address processes beyond their scope such as proton-coupled electron transfer reactions.

Sojourn probabilities for diffusive dynamics with state-dependent friction: Theory and experiment — Alice Thorneywork[1,2], Jannes Gladrow[2,3], Ulrich F. Keyser[2], Ronojoy Adhikari[4], and •Julian Kappler[4,5] — [1]Department of Chemistry, University of Oxford, Oxford, United Kingdom — [2]Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom — [3]Microsoft Research, Cambridge, United Kingdom — [4]Department of Applied Mathematics and Theoretical Physics, Cambridge University, Cambridge, United Kingdom — [5]Fakultät für Physik, Ludwig-Maximilians-Universität, München, Germany

The trajectories of diffusion processes are continuous but nondifferentiable, and each occurs with vanishing probability. This introduces a gap between theory, where path probabilities are used in many contexts, and experiment, where only events with nonzero probability are measurable. We bridge this gap by considering the sojourn probability, i.e. the probability for diffusive trajectories to remain within a tube of small but finite radius around a smooth path. For systems with state-dependent diffusivity, we show that the sojourn probability is characterized by a functional that is different from all previously reported multiplicative-noise stochastic actions. We corroborate our theoretical results by comparison to experimentally measured sojourn probabilities for a colloidal particle in a corrugated microchannel. Our work directly connects the discussion of path probabilities for diffusive dynamics with state-dependent friction to physical observables.

DY 32.12 Wed 18:00 ZEU 160

Optimality of non-conservative driving in discrete systems — •Jonas Fritz and Udo Seifert — II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany

A fundamental problem in stochastic thermodynamics is that of optimal driving. The goal is to drive a system from some specified initial state to a specified final state, while minimizing entropy production (or work performed) along the trajectory. As shown recently [1], the optimal protocol in a cyclical Markov network has a non-conservative force, i.e. non-zero cycle affinity, which is in contrast to continuous systems. However, the reduction in entropy production from such a non-conservative force has been numerically found to be at most on the order of 10^{-2} for the case of the three state cycle. We investigate why this is the case, by systematically varying step size and initial conditions numerically for the simple case of the three state cycle. Further, we try to maximize the improvement in entropy production through the non-conservative force. By increasing the number of states in the cycle, we find a possible improvement which is an order of magnitude larger than the previously known one. We attempt to find a lower bound for the possible improvement through non-conservative driving, by analyzing the scaling behavior of the underlying quantities.

Comparison of fitting strategies to extract the diffusion coefficient in microrheological experiments — •Sten Leipnitz, Christian Wagner, and Thomas John — Experimental Physics, Saarland University, Saarbrücken

Tracking of small particles undergoing a Brownian motion in liquids is a widespread method in passive microrheology to extract the diffusion coefficient D, the viscosity of the sample respectively. The mean-squared displacement (MSD) is determined from particle positions as a function of the timelag $MSD(\tau) = \sigma_0^2 + 2nD\tau + v_{drift}^2\tau^2$, where v_{drift} is a possible drift velocity and σ_0 is an offset due to position detection noise in experiments. We present: the extracted parameters depend strongly on the used number of fitting points in the MSD-relation. Surprisingly, considering only the beginning of the MSD-relation in the fitting procedure leads to the best expectation value of the diffusion coefficient. This is shown by numerical simulations of the Brownian motion as well as from experimental data.

DY 33.2 Wed 15:15 ZEU 250

Non-monotonic behavior of timescales of passage in heterogeneous media: Dependence on the nature of barriers — Moumita Dasgupta[1], •Sougata Guha[2], Leon Armbruster[1], Dibyendu Das[2], and Mithun K. Mitra[2] — [1]Department of Physics, Augsburg University, USA — [2]Department of Physics, IIT Bombay, India

Usually time of passage across a region may be expected to increase with the number of barriers along the path. Can this intuition fail depending on the special nature of the barrier? We study experimentally the transport of a robotic bug which navigates through a spatially patterned array of obstacles. Depending on the nature of the obstacles we call them either entropic or energetic barriers. For energetic barriers we find that the timescales of first passage vary non-monotonically with the number of barriers, while for entropic barriers first passage times increase monotonically. We perform an exact analytic calculation to derive closed form solutions for the mean first passage time for different theoretical models of diffusion. Our analytic results capture this counter-intuitive non-monotonic behaviour for energetic barriers. We also show non-monotonic effective diffusivity in the case of energetic barriers. Finally, using numerical simulations, we show this non-monotonic behaviour for energetic barriers continues to hold true for super-diffusive transport. These results may be relevant for timescales of intra-cellular biological processes.

DY 33.3 Wed 15:30 ZEU 250

Phase behavior and finite-size effects in biology — •Felix Herrmann, Burkhard Duenweg, and Martin Girard — Max-Planck Institut fuer Polymerforschung (MPI-P), Mainz, Germany

Phase behavior observed in biology remains puzzling. For instance, the plasma membrane of cells exhibits signs of criticality, as it is controlled to remain near a demixing point. This membrane contains thousand of components, and it is largely unclear how its composition is controlled. Beyond this, one can ask whether cells should obey the traditional thermodynamic picture, given their small size, large number of components and the presence of non-equilibrium processes.

Here, we study toy systems, lattice models containing many (>30) components. We show that these systems exhibit strong finite-size effects. These manifest as behavior that appears similar to traditional critical behavior, but vanish logarithmically with system size. We examine scaling laws, and whether traditional paradigms from macroscopic thermodynamics can be broken in such systems.

DY 33.4 Wed 15:45 ZEU 250

Hierarchical interactions in complex ecosystems — •Lyle Poley[1], Joseph W. Baron[3], and Tobias Galla[1,2] — [1]Theoretical Physics, Department of Physics and Astronomy, School of Natural Sciences, The University of Manchester, Manchester M13 9PL, UK — [2]Instituto de Física Interdisciplinar y Sistemas Complejos IFISC (CSIC-UIB), 07122 Palma de Mallorca, Spain — [3]Laboratoire de Physique Statistique, École Normale Supérieure (ENS), Paris Sciences et Lettres (PSL) Research University, Sorbonne Université, 75005 Paris, France

In the analysis of complex ecosystems it is common to use random interaction coefficients, often assumed to be such that all species are statistically equivalent. We relax this assumption by imposing hierarchical inter-species interactions, which we incorporate into a generalised Lotka-Volterra dynamical system. These interactions impose a hierarchy in the community. Species benefit more, on average, from interactions with species below them in the hierarchy than from interactions with those above.

Using analytical tools from the theory of disordered systems, most notably path-integrals and dynamic mean-field theory, we demonstrate that a stronger hierarchy stabilises the community by reducing the number of species in the surviving community. We will also show that the probability of survival for a given species is dependent on its position in the hierarchy.

DY 33.5 Wed 16:00 ZEU 250

Quantifying information content in continuous attractor networks — •Tobias Kühn[1,2] and Rémi Monasson[1] — [1]Laboratoire de Physique de l'Ecole Normale Supérieure, ENS, Université PSL, CNRS, Sorbonne Université, Université Paris Cité, F-75005 Paris — [2]Institut de la Vision, Sorbonne Université, INSERM, CNRS, F-75012 Paris

Attractor networks are a theme with long tradition to model information storage in the brain. Continuous attractor neural networks (CANN), in particular, have been employed to describe the storage of information about space and orienta-

tion. However, it stays controversial how useful this paradigm really is to explain actual processes, for example the representation of space in grid and place cells in the entorhinal cortex and the hippocampus, respectively.

A common criticism is that the disorder present in the connections might deteriorate the system's capability to reliably preserve the information of a certain pattern. In order to investigate if this criticism is valid, a measure is needed to objectively quantify the information content of a given neural network. Using the replica-trick, we compute the Fisher information for a network receiving space-dependent input whose connections are composed of a distance-dependent and a disordered component. We observe that the decay of the Fisher information is slow for not too large disorder strength, indicating that CANNs have a regime in which the advantageous effects of connectivity on information storage outweigh the detrimental ones.

DY 33.6   Wed 16:15   ZEU 250
Gift of gab: Probing the limits of dynamic concentration-sensing across a network of communicating cells — •Mohammadreza Bahadorian[1,2], Christoph Zechner[1,2,3], and Carl D. Modes[1,2,3] — [1]Max Planck Institut

for Molecular Cell Biology and Genetics (MPI-CBG), 01307 Dresden, Germany — [2]Center for Systems Biology Dresden (CSBD), 01307 Dresden, Germany — [3]Cluster of Excellence Physics of Life, TU Dresden, 01069 Dresden, Germany

Many systems in biology and other sciences employ collaborative, collective communication strategies for improved efficiency and adaptive benefit. One such paradigm of particular interest is the community estimation of a dynamic signal, when, for example, an epithelial tissue of cells must decide whether to react to a given dynamic external concentration of stress-signaling molecules. At the level of dynamic cellular communication, however, it remains unknown what effect, if any, arises from communication beyond the mean field level. What are the limits and benefits to communication across a network of neighbor interactions? What is the role of Poissonian versus super-Poissonian dynamics in such a setting? How does the particular topology of connections impact the collective estimation and that of the individual participating cells? In this article we construct a robust and general framework of signal estimation over continuous-time Markov chains in order to address and answer these questions.

Lane formation of colloidal particles driven by gravity — •Marc Isele, Kay Hofmann, and Peter Nielaba — Physics Department, University of Konstanz, Konstanz, Germany

Systems of particles that move with differing relative speeds as a counterpart to the movements of pedestrians and crowds have been shown to form a so-called lane structure. We simulate a quasi two dimensional system of two spherical particle types of different sizes driven by gravity. The particles are confined by hard walls orthogonal to the driving force and we employed Brownian Dynamics simulations (without hydrodynamic interactions). We found that the particles formed the well-known lane structure rather quickly. In this formation process the particles form slanted boundaries between the soon to be lanes which leads to regions of high and low densities. In the steady state we further found that the lanes closest to the hard walls were always occupied by the smaller particles (via something we call a funneling process). We also analyzed a wide variety of parameters giving us an optimized system for lane formation. Our work shows that the lane formation of driven particles is a phenomenon with a lot of different aspects that can depend heavily on the chosen system.

DY 34.2   Wed 17:00   ZEU 250
Time-reversal symmetries and equilibrium-like Langevin equations — •Lokrshi Prawar Dadhichi and Klaus Kroy — ITP, Leipzig University, Brüderstraße 15, 04103, Leipzig

Graham has shown in Z. Physik B 26, 397-405 (1977) that a fluctuation-dissipation relation can be imposed on a class of non-equilibrium Markovian Langevin equations that admit a stationary solution of the corresponding Fokker-Planck equation. Here we show that the resulting equilibrium form of the Langevin equation is associated with a nonequilibrium Hamiltonian and ask how precisely the broken equilibrium condition manifests itself therein. We find that this Hamiltonian need not be time reversal invariant and that the "reactive" and "dissipative" fluxes loose their distinct time reversal symmetries. The antisymmetric coupling matrix between forces and fluxes no longer originates from Poisson brackets and the "reactive" fluxes contribute to the ("housekeeping") entropy production, in the steady state. The time-reversal even and odd parts of the nonequilibrium Hamiltonian contribute in qualitatively different but physically instructive ways to the entropy. Finally, this structure gives rise to a new, physically pertinent instance of frenesy.

DY 34.3   Wed 17:15   ZEU 250
Quantum and classical contributions to entropy production in fermionic and bosonic Gaussian systems — •Krzysztof Ptaszyński[1,2] and Massimiliano Esposito[2] — [1]Institute of Molecular Physics, Polish Academy of Sciences, Mariana Smoluchowskiego 17, 60-179 Poznań, Poland — [2]Complex Systems and Statistical Mechanics, Physics and Materials Science Research Unit, University of Luxembourg, L-1511 Luxembourg, Luxembourg

As previously demonstrated, the entropy production – a key quantity characterizing the irreversibility of thermodynamic processes – is related to generation of correlations between degrees of freedom of the system and its thermal environment. The natural question appears whether such correlations are of a classical or a quantum nature, namely, whether they are accessible through measurements. We deal with this problem by investigating fermionic and bosonic Gaussian systems. It is shown that for fermions the entropy production is mostly quantum due to parity superselection rule which restricts the set of physically allowed

measurements to projections on the Fock states, which significantly limits the amount of classically accessible correlations. In contrast, in bosonic systems a much larger amount of correlations can be accessed through Gaussian measurements. Specifically, while quantum contribution may be important at low temperatures, in the high temperature limit the entropy production corresponds to purely classical position-momentum correlations.

DY 34.4   Wed 17:30   ZEU 250
Optimal power extraction from active particles with hidden states — •Luca Cocconi[1,2], Jacob Knight[2], and Connor Roberts[2] — [1]The Francis Crick Institute, London — [2]Imperial College, London

We identify generic protocols achieving optimal power extraction from a single active particle subject to continuous feedback control under the assumption that the instantaneous velocity, but not the fluctuating self-propulsion velocity, is accessible to direct observation. Our Bayesian approach draws on the Onsager-Machlup path integral formalism and is exemplified in the cases of free run-and-tumble and active Ornstein-Uhlenbeck dynamics in one dimension. Such optimal protocols extract positive work even in models characterised by time-symmetric positional trajectories and thus vanishing informational entropy production rates. We argue that the theoretical bounds derived in this work are those against which the performance of realistic active matter engines should be compared.

DY 34.5   Wed 17:45   ZEU 250
Driving a first-order phase transformation by quenching the density: Unleashing hidden states — •Miriam Klopotek[1], Martin Oettel[2], and Hans Joachim Schöpe[2] — [1]University of Stuttgart, SimTech Cluster of Excellence EXC 2075, Stuttgart, Germany — [2]University of Tübingen, Institute for Applied Physics, Tübingen, Germany

Abruptly increasing the number density, the primary order parameter of a many-particle system, is a basic mechanism to drive a first-order phase transition – elementary for athermal systems and thus for the solidification process from a fluid. A better-known experiment on thermal systems is quenching the temperature down to below the critical point, suddenly 'freezing out' the original degrees of freedom, whereafter the system densifies locally upon response. A density quench, in turn, intervenes directly and globally on the order parameter. A manifest example is thin film growth. As dynamical arrest is imminent, 'hidden' metastable states appear. We employ kinetic Monte Carlo simulations of a simple lattice model of sticky hard rods under quasi-2D confinement, gradually growing a full monolayer under different quench (growth) rates. The phenomenology is extremely rich: At least five distinct, non-classical phase transformation pathways are identified in this most simple model. They 'tile' a corresponding dynamical control diagram.

DY 34.6   Wed 18:00   ZEU 250
New phases and peculiar fluctuations in nonreciprocal systems — •Sarah Loos — DAMTP, University of Cambridge, UK

Nonreciprocal interactions, i.e., interactions that violate the *actio=reactio* principle, occur in various biological and artificial nonequilibrium systems on a wide range of scales. For example, a bird in a flock may react to the movements of the bird in front of it, while the reverse interaction is zero, simply due to missing visual information. Recent research shows that the occurrence of such nonreciprocal interactions can have a dramatic impact on the self-organization of many-body systems [1], and on their thermodynamic properties [2]. In this talk, we

will consider a nonequilibrium lattice model with vision cone interactions [3], and show how the presence of nonreciprocal interactions can lead to the emergence of new phases and peculiar fluctuations.

Reverse-engineering method for XPCS studies of non-equilibrium dynamics — •Anastasia Ragulskaya[1], Vladimir Starostin[1], Nafisa Begam[1], Anita Girelli[1], Hendrik Rahmann[2], Mario Reiser[2], Fabian Westermeier[3], Michael Sprung[3], Fajun Zhang[1], Christian Gutt[2], and Frank Schreiber[1] — [1]Universität Tübingen, Germany — [2]Universität Siegen, Germany — [3]DESY, Germany

X-ray photon correlation spectroscopy (XPCS) is a powerful tool for the investigation of dynamics covering broad time and length scales [1]. For nonequilibrium states, the resulting time-dependent dynamic behavior can be described using the two-time correlation function (TTC), which often contains more interesting features than only the component along the diagonal, and cannot be easily interpreted via classical simulation methods. Here, a reverse-engineering (RE) approach is proposed based on particle-based simulations [1]. This approach is applied to XPCS measurements on a protein solution undergoing liquid-liquid phase separation. We demonstrate that the rich features of experimental TTCs can be well connected with the key control parameters including size distribution, concentration, viscosity, and mobility of domains. The dynamic information obtained from this RE analysis goes beyond existing theory. The RE approach established in this work is applicable to other processes such as film growth, domain coarsening, or phase transformations.

Sensitivity of principal components to changes in the presence of non-stationarity — •Henrik Bette and Thomas Guhr — Fakultät für Physik, Universität Duisburg-Essen, Duisburg, Deutschland

Non-stationarity affects the sensitivity of change detection in correlated systems described by sets of measurable variables. We study this by projecting onto different principal components. Non-stationarity is modeled as multiple normal states that exist in the system even before a change occurs. The studied changes occur in mean values, standard deviations or correlations of the variables. Monte Carlo simulations are performed to test the sensitivity for change detection with and without knowledge about the non-stationarity for different system dimensions and numbers of normal states. A comparison clearly shows that the knowledge about the non-stationarity of the system greatly improves change detection sensitivity for all principal components. This improvement is largest for those components that already provide the greatest possibility for change detection in the stationary case.

DY 37.3   Thu 10:00   MOL 213

Inferring partial differential equations from molecular dynamics simulations — •Oliver Mai, Tim Kroll, Uwe Thiele, and Oliver Kamps — Institute of Theoretical Physics and Center for Nonlinear Science, University of Münster

Although integral to scientific or engineering applications, deriving partial differential equations (PDEs) solely from experimental data proves quite challenging and in most cases relies on physical principles in addition to qualitative behaviour of the system. In the last decade various efforts based on empirical data have been put forth to supplement first-principle derivations in theoretical sciences. That is in place of or in addition to typical conservation laws or phenomenological observations, time series data has been used to yield analytic expressions to describe the spatio-temporal evolution of a given dynamical system. While there have been various improvements in the sparsity and interpretability of the results, we provide another approach to optimization using the predictive power of the estimation when integrating it. Additionally aggregated small scale

behaviour in macro- or mesoscopic experiments may exhibit unknown governing laws and as such a way for comparing data more directly to models derived in statistical physics may prove critical in furthering our understanding. To this end we study the application of system identification methods on molecular dynamics (MD) simulations.

DY 37.4   Thu 10:15   MOL 213

Reproducibility of analysis workflows in biomedical physics — •Alexander Schlemmer[1,4], Inga Kottlarz[1,2], Baltasar Rüchardt[1,3,4], Ulrich Parlitz[1,2,4], and Stefan Luther[1,2,3,4] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, Georg-August-Universität Göttingen, Germany — [3]Institute of Pharmacology and Toxicology, University Medical Center Göttingen, Germany — [4]German Center for Cardiovascular Research (DZHK), Partner Site Göttingen, Germany

Sustainable and well-documented data analysis workflows are essential for effectiveness and reproducibility in data-intensive research. In our terminology, documentation includes method and algorithm descriptions as well as human- and machine-readable representations of parameters, initial conditions and data, versions and dependencies and a well-defined software execution environment.

In practice, many software frameworks for reproducibility fail to achieve a widespread adoption. Using examples from data analysis in cardiac research, we illustrate typical challenges and show, how simple guidelines - when implemented in a pragmatic way - can already lead to a high degree of documentation and reproducibility. Furthermore, we discuss the employment of containers and semantic data management which simplify reproducibility, findability and interoperability.

DY 37.5   Thu 10:30   MOL 213

Bayesian approach to anticipate critical transitions in complex systems — •Martin Hessler[1,2] and Oliver Kamps[2] — [1]Westfälische Wilhelms-Universität Münster, 48149 Münster — [2]Center for Nonlinear Science, Westfälische Wilhelms-Universität Münster, 48149 Münster

Complex systems in nature, technology and society can undergo sudden transitions between system states with very different behaviour. In order to avoid undesired consequences of these tipping events, statistical measures have been proposed as leading indicators. They can give a hint of an ongoing bifurcation-induced (B-tipping) destabilization process. However, we present an alternative approach that is open-source available and more robust under numerous aspects. It assumes the dynamical system to be described by a Langevin equation. Starting from this stochastic description, we combine MCMC sampling, rolling window methods and Bayesian reasoning to derive the drift slope as an alternative early warning sign including credibility bands which make it easier to distinguish significant leading indicator trends prior to B-tipping. Furthermore, our approach provides information about an increasing noise level in a multi-stable system. This is an important information related to the Kramers escape rate of a noise-induced tipping (N-tipping) event. We show some results and discuss the method's potential to be applied in N-tipping scenarios and under more complex conditions like correlated non-Markovian or multiplicative noise. Finally, possible limitations and tasks of future research are mentioned.

15 min. break

Invited Talk   DY 37.6   Thu 11:00   MOL 213
Power law error growth rates – a dynamical mechanism for a strictly finite prediction horizon in weather forecasts — Hynek Bednar[1,2], Jonathan Brisch[1], Burak Budanur[1], and •Holger Kantz[1] — [1]Max Planck Insstiute for the Physics of Complex Systems, Dresden, Germany — [2]Dept. of Atmospheric Physics, Charles University, Prague, Czech Republic

While conventional chaotic systems have a finite positive Lyapunov exponent, physical arguments and observations suggest that the maximal Lyapunov exponent of the model equations of the atmosphere is the larger the smaller are the resolved spatial scales. Specifically, a power law divergence of the scale dependent error growth rate would translate into a strictly finite prediction horizon, since due to the divergence, additional accuracy of initial conditions is not translated into longer prediction times. We present conceptual toy models with such behavior, we show its presence in a more realistic spatially extended system with advective transport, and we present numerical results from turbulence simulations where the largest Lyapunov exponent scales as an inverse power of spatial resolution. The idea of a power law scale dependence of error growth rates and of a finite prediction horizon is also supported by re-analysis of numerical error growth experiments performed with an operational weather model. Altogether, this suggests that the prediction horizon of numerical weather prediction is strictly finite.

DY 37.7   Thu 11:30   MOL 213
Wave Digital Optimization of a Modified Compact Models of 1T-1R Random Resistive Access Memory Cells — •Bakr Al Beattie[1], Max Uhlmann[2], Gerhard Kahmen[2], and Karlheinz Ochs[1] — [1]Ruhr-Universität Bochum, Lehrstuhl für digitale Kommunikationssysteme, Bochum, Deutschland — [2]Leibniz-Institut für innovative Mikroelektronik, Frankfurt (Oder), Deutschland

Random Resistive Access Memory (RRAM) cells are popular memristive devices that are commonly used in neuromorphic applications. In this context,

RRAM cells are usually utilized to embed synaptic plasticity, a property that is exhibited by biological synapses, into analog-based artificial neural networks. However, since RRAM-based technology has yet to reach a state of maturity, circuit designers are usually forced to make use of compact models to avoid dealing with device-to-device variabilities. The Stanford PKU model is a well-established compact model that has been developed to capture the dynamics of 1T-1R RRAM cells. In this contribution, we present a modified compact model, based on the Stanford PKU model, that takes more properties of real RRAM cells into account, such as the RESET voltage shift in multilevel devices. To demonstrate the capabilities of our model, we exploit the wave digital concept to apply a live parameter optimization, which fits the model parameters to a technologically reproducible device from the Leibniz Institute for High Performance Microelectronics (IHP).

DY 37.8   Thu 11:45   MOL 213
Discovering Causality and Coupling in high dimensional nonlinear dynamical systems — •Tim Kroll[1,2] and Oliver Kamps[2] — [1]Westfälische Wilhelms-Universität Münster, 48149 Münster — [2]Center for Nonlinear Science, Westfälische Wilhelms-Universität Münster, 48149 Münster

In this talk we present a method to infer causal relationships between observables from data of systems where the underlying dynamics are not known a priori. The method is based on the hypothesis that the system of interest can in principle be described by a set of coupled nonlinear ordinary differential equations. Following the work of Prusseit and Lehnertz in 2008 we can then determine the couplings between observables by integrating out all other observables. Since the estimation of the underlying dynamical system invokes the efficient representation in terms of polynomials the method can be applied also to hight dimensional systems. We demonstrate the capabilities of the method by inferring the network structure of coupled Rössler-Attractors.

Acoustically propelled nano- and microparticles: From fundamentals to applications — •Raphael Wittkowski — Institut für Theoretische Physik, Center for Soft Nanoscience, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany

Among the existing types of artificial active colloidal particles, acoustically propelled nano- and microparticles have a particularly high potential for future applications in fields like medicine and materials science. However, despite intensive research on this type of motile particles in recent years, the understanding of their properties is still very limited. A reason for the limited understanding is that the previous research has mostly been experimental and that it is difficult to study the dependence of certain system parameters on the propulsion of the particles in experiments since the parameters can often not be varied independently of the other parameters and in ranges of reasonable size. In this talk, I will give an overview about our theoretical investigation of the properties of acoustically propelled nano- and microparticles and the challenges that remain for future research.

DY 38.2   Thu 10:00   ZEU 160
Force on probe in a confined active fluid — Shuvojit Paul[1], •Ashreya Jayaram[2], N Narinder[1], Thomas Speck[2], and Clemens Bechinger[1] — [1]Fachbereich Physik, Universität Konstanz, 78464 Konstanz, Germany — [2]Institut für Physik, Johannes Gutenberg-Universität Mainz, 55128 Mainz, Germany

When immersed in a dispersion of smaller "depletants", a colloidal particle experiences depletion forces in the presence of another colloidal particle or under confinement. While the nature of these forces is well-established for passive systems, much less is known about the consequence of making the depletants self-propelled or "active". In this work, we consider a large, optically trapped probe under circular confinement surrounded by smaller active Janus particles. We find that the force experienced by the probe varies non-monotonically as the distance between the colloid and the confinement is increased. To rationalize this observation, we relate the measured force to the active stress and, subsequently, to the microstructure of the surrounding active fluid. Going beyond synthetic active matter, our work could shed light on the organization of intracellular entities in biological systems.

DY 38.3   Thu 10:15   ZEU 160
Symmetry-breaking refractive index profiles as a propulsion mechanism for active Brownian particles — •Julian Jeggle[1], Matthias Rüschenbaum[2], Cornelia Denz[2], and Raphael Wittkowski[1] — [1]Institut für Theoretische Physik, Center for Soft Nanoscience, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany — [2]Institut für Angewandte Physik, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany

Active Brownian particles (ABPs) have been realized with various propulsion mechanisms such as self-diffusiophoresis, self-electrophoresis or acoustic scattering. Typically, these mechanisms induce flow fields around the particles that represent a deviation from the "pure" ABP model. Here, we present a novel implementation of ABPs in the form of transparent microswimmers with a symmetry-breaking refractive index gradient. Utilizing the momentum transfer associated with light refraction as the driving force induces no flow fields beyond Stokes flow. Unlike optothermally driven particles, this archetype of ABPs also allows for sensitivity to the phase and polarization of the driving light field thus improving the spatio-temporal control of light-based propulsion mechanisms. Using non-light-absorbing particles enables bulk volume systems and allows the introduction of feedback loops, therefore making this approach a promising foundation for adaptive matter systems.

DY 38.4   Thu 10:30   ZEU 160
The interaction-expansion method: a systematic derivation strategy for active field theories[*] — •Michael te Vrugt[1,2], Jens Bickmann[1,2], Stephan Bröker[1,2], Tobias Frohoff-Hülsmann[1], Eyal Heifetz[3], Michael E. Cates[4], Uwe Thiele[1,5,6], and Raphael Wittkowski[1,2,5] — [1]Institut für Theoretische Physik, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany — [2]SoN, Westfälische Wilhelms-Universität Münster — [3]Porter School of the Environment and Earth Sciences, Tel Aviv University, 69978 Tel Aviv, Israel — [4]DAMTP, Centre for Mathematical Sciences, University of Cambridge, Cambridge CB3 0WA, United Kingdom — [5]CeNoS, Westfälische Wilhelms-Universität Münster — [6]CMTC, Westfälische Wilhelms-Universität Münster

Field-theoretical models have made enormous contributions to our understanding of the collective dynamics of active matter. In this contribution, we introduce the interaction-expansion method (IEM) [1], which allows for a systematic derivation of active field theories from the microscopic dynamics of individual particles. We then discuss some recent applications of the IEM to particles with orientation-dependent propulsion speed [2] and particles with inertia [3].

DY 38.5   Thu 10:45   ZEU 160

Entropy production in active turbulence — •Byjesh Nalini Radhakrishnan, Thomas Schmidt, and Etienne Fodor — Department of physics and material science, University of Luxembourg

Active particles like bacteria and sperm cells sustain a continuous intake and dissipation of energy. Consequently, they are intrinsically out of equilibrium which leads to a non-vanishing entropy production rate (EPR) even in steady states. Quantifying how the EPR varies in different collective phases is crucial in developing a thermodynamic framework for active matter. In this work, we look at the EPR in active turbulence. We use Active Model H, a continuum model for active particles in a momentum-conserving fluid, to study turbulence in contractile scalar active systems. We measure the local EPR in numerical simulations, which unveils the role of the noise and activity parameters on the EPR in active turbulent systems.

DY 38.6   Thu 11:15   ZEU 160

Phase transitions in multicomponent active matter: a quantitative kinetic theory — •Jakob Mihatsch[1], Thomas Ihle[1], Rüdiger Kürsten[2], and Horst-Holger Boltz[1] — [1]Institute for Physics, University of Greifswald, Greifswald, Germany — [2]Departament de Física de la Matèria Condensada, University of Barcelona, Barcelona, Spain

We consider a multicomponent model of self-propelled particles with Kuramoto-type alignment interactions. Starting from the N-particle Fokker-Planck equation we observe that the usual factorization Ansatz of the probability density, often called Molecular Chaos approximation, predicts a relaxation behavior which qualitatively disagrees with agent-based simulations. Therefore, we develop a kinetic theory which takes the time-evolution of the two-particle correlation function explicitly into account, i.e. goes beyond the mean-field approximation. We show that this theory predicts the relaxation behavior of the system as well as the order-disorder transition with high precision in certain parameter ranges. In particular, the dependence of the transition threshold on the particle speed is predicted correctly.

DY 38.7   Thu 11:30   ZEU 160

Emergent collective behaviour due to virtual interactions between robotic swimmers — •Samudrajit Thapa[1,2], Bat-El Pinchasik[1,3], and Yair Shokef[1,2,3] — [1]School of Mechanical Engineering, Tel Aviv University, Tel Aviv 69978, Israel — [2]Sackler Center for Computational Molecular and Materials Science, Tel Aviv University, Tel Aviv 69978, Israel — [3]Center for the Physics and Chemistry of Living Systems, Tel Aviv University, 69978, Tel Aviv, Israel

Many organisms in nature use local interactions to realize global collective behaviour. Here we study how simple two body distance-based interactions between active Brownian particles results in collective motion. The interactions are not physical but virtual, wherein each particle senses the presence of other particles nearby and changes its behaviour accordingly. We study the radial distribution function to quantify the emergent interactions for both social and anti-social behaviour. Using Langevin dynamics simulations, we discover that under certain conditions positive correlations of the motion can emerge even in the case of anti-social behaviour. Our results might be potentially useful for designing robotic swimmers that can swim collectively just based on sensing the distance to their neighbours.

DY 38.8   Thu 11:45   ZEU 160

Kinetic Event-Chain Algorithm for Active Matter — •Nico Schaffrath, Thevashangar Sathiyanesan, Tobias Kampmann, and Jan Kierfeld — Physics Department, TU Dortmund University, 44221 Dortmund, Germany

We present a cluster kinetic Monte-Carlo algorithm for active matter systems of self-propelled hard particles. The kinetic event-chain algorithm is based on the event-chain Monte-Carlo method and is applied to active hard disks in two dimensions. The algorithm assigns Monte-Carlo moves of active disks a mean time based on the mean and variance of the move length in force direction. This time is used to perform diffusional rotation of their propulsion force. We show that the algorithm reproduces the motility induced phase separated region in the phase diagram of hard disks correctly and efficiently.

DY 38.9   Thu 12:00   ZEU 160

Emergent pattern formation in communicating active matter — •Robert Grossmann[1], Zahra Mokhtari[2], Robert I.A. Patterson[3], and Felix Höfling[2,4] — [1]Institut für Physik und Astronomie, Universität Potsdam — [2]Institut für Mathematik, Freie Universität Berlin — [3]WIAS Berlin — [4]Zuse Institut Berlin

Inspired by trail formation as observed in colonies of driver ants, for example, we study ensembles of agent particles that communicate via deposition and sensing of pheromones. These chemical traces are produced by the agents themselves and encode their current position and walking direction. Other agents passing by will then tend to align with the orientation inscribed in the pheromone traces. In the limit of short pheromone lifetime, the dynamics of this system reduces to the seminal Vicsek model and, thus, yields the formation of transversally moving bands. In the opposite limit, the effective agent-agent interaction represents a form of delayed feedback and yields the spontaneous formation of macroscopic, persistent trails, which are followed and reinforced by the agents [New J. Phys. **24** 013012 (2022)]. In this talk, we present large-scale simulations of the agent model and establish the phase diagram as function of the lifetime of pheromones. We rationalize our findings by analyzing mean-field equations that are systematically derived from the stochastic particle model. Combining numerical solutions of these order parameter equations and a linear stability analysis, we show how transversal bands, common in the Vicsek model, are destabilized, giving rise to the formation of "longitudinal" trails, pointing in the mean direction of motion.

DY 38.10   Thu 12:15   ZEU 160

Binary Mixture of Deforming Particles — •Yiwei Zhang, Alessandro Manacorda, and Etienne Fodor — DPhyMS, University of Luxembourg, Luxembourg, Luxembourg

Phase separation occurs in miscible liquids where components have distinct properties. In reactors, components undergo stochastic change in their properties which affect the liquid composition. While phase separation and reaction-diffusion have already been studied extensively as separate ingredients, how they combine in non-ideal reactors remains poorly understood. To bridge this gap, we consider repulsive particles with fluctuating size subject to one-body landscape and nonequilibrium synchronisation. The landscape features minima which, regarding size as reaction coordinate, distinguish three states: Particles with finite size, either A- or B-type, and point particles. In this context, synchronisation penalizes A particles in B-rich phases, and vice versa, so that the system eventually accommodates a uniform state. We report the phase diagram depending on the stability of each state and the corresponding particle sizes. Combining hydrodynamic and phenomenological arguments, we recapitulate how metastability regulates the interplay between synchronisation and repulsion. Our results reveal the role of nonequilibrium kinetic factors at play in non-ideal reaction-diffusion systems.

DY 38.11   Thu 12:30   ZEU 160

Self-organization of model catalytic cycles — •Vincent Ouazan-Reboul[1], Jaime Agudo-Canalejo[1], and Ramin Golestanian[1,2] — [1]Max Planck Institute for Dynamics and Self-Organization, Am Fassberg 17, D-37077, Göttingen, Germany — [2]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, OX1 3PU, Oxford, UK

We study analytically and numerically a model metabolic cycle composed of an arbitrary number of species of catalytically active particles. Each species converts a substrate into a product, the latter being used as the substrate by the next species in the cycle. Through a combination of catalytic activity and chemotactic mobility, the catalytic particles develop effective interactions with particles belonging to neighbouring species in the cycle. These interactions, being fully out-of-equilibrium, show some unusual features, in particular being non-reciprocal. We find that such model metabolic cycles are able to self-organize through a macroscopic instability, with a strong dependence on the characteristics of the cycle. For instance, cycles containing an even number of species are able to minimize repulsion between their component particles by aggregating all even-numbered species in one cluster, and all odd-numbered species in another. Such a grouping is not possible if the cycle contains an odd number of species, which can lead to oscillatory steady states in the case of chasing interactions.

DY 38.12   Thu 12:45   ZEU 160

Reentrant condensation transition in a model of driven scalar active matter with diffusivity edge — Berx Jonas[2], •Bose Aritra[1], Mahault Benoit[1], and Golestanian Ramin[1,3] — [1]Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany — [2]Institute for Theoretical Physics, KU Leuven, B-3001 Leuven, Belgium — [3]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford OX1 3PU, United Kingdom

A class of scalar active matter for which the effective diffusivity vanishes beyond a certain density threshold, hereby referred to as diffusivity edge, triggers the formation of a condensate when confined in a harmonic potential. The condensation transition exhibits remarkable similarities with a Bose-Einstein Condensation (BEC). Here we study the effect of a diffusivity edge in a system of scalar active matter confined by a periodic potential and driven by an external force.

We find that this system shows qualitatively distinct stationary regimes depending on the amplitude of the driving force with respect to the potential barrier. For small driving, the diffusivity edge induces a condensation analogous to

the BEC-like transition reported for the nondriven case, which is characterised by a density-independent steady state current. Conversely, large external forces lead to a qualitatively different phase diagram where condensation is not possible below a density threshold and the associated transition at moderate densities above the threshold the transition is reentrant due to the existence of a subsequent evaporation transition at low effective temperatures.

Optimized Work Protocols for the Higgs RNA-Model — •PETER WERNER and ALEXANDER K. HARTMANN — Institute of Physics, University of Oldenburg, Germany

When a system is driven from one state to another in a *finite* amount of time $t \in [0, \ldots, \tau]$ by changing an external control parameter according to a protocol $\lambda(t)$, some work W is performed. Here $\langle W \rangle \geq \Delta F$ holds, where ΔF is the equilibrium free energy difference between initial and final states. The protocol $\lambda^*(t)$ minimizing the average amount of work is of interest, since it tightens the upper bound to ΔF. The optimum protocols of simple Brownian-particle systems exhibit distinct jumps especially at the beginning and end of the process [1,2] and it was speculated that these are a generic feature for arbitrary systems.

Here the *many-particle* Higgs RNA model [3] is considered, where work is performed by stretching the RNA through changing an external force. For this model, an exact calculation of the free-energy differences ΔF and the sampling of the equilibrium initial state can be performed in polynomial time. The work processes are realized by means of non-equilibrium Monte-Carlo simulations [4]. The optimum protocols are obtained numerically with the parallel-tempering approach. Also for this complex system, the optimum protocols exhibit distinct jumps at the beginning and end.

Coherence of oscillations in the weak-noise limit — •BENEDIKT REMLEIN, VOLKER WEISSMANN, and UDO SEIFERT — II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany

In a noisy environment, oscillations lose their coherence, which can be characterized by a quality factor. We determine this quality factor for oscillations arising from a driven Fokker-Planck dynamics along a periodic one-dimensional potential analytically in the weak-noise limit. With this expression, we can prove for this continuum model the analog of an upper bound that has been conjectured for the coherence of oscillations in discrete Markov network models. We show that our approach can also be adapted to motion along a noisy two-dimensional limit cycle. Specifically, we apply our scheme to the noisy Stuart-Landau oscillator and the thermodynamically consistent Brusselator as a simple model for a chemical clock. Our approach thus complements the fairly sophisticated extant general framework based on techniques from Hamilton-Jacobi theory with which we compare our results numerically [1].

DY 40.3   Thu 10:30   ZEU 250
Work extraction potential for a single spin in equilibrium with a non-isotropic environment — •FELIX HARTMANN[1] and JANET ANDERS[1,2] — [1]Institut für Physik und Astronomie, University of Potsdam, 14476 Potsdam, Germany — [2]Department of Physics and Astronomy, University of Exeter, Stocker Road, Exeter EX4 4QL, UK

Thermal equilibrium properties of nanoscale systems deviate from standard macroscopic predictions due to a non-negligible coupling to the environment. For non-isotropic three-dimensional materials, we derive the mean force corrections to the equilibrium state of a single classical spin vector. The result is valid at arbitrary coupling strength.

Specifically, we consider cubic, orthorhombic, and monoclinic symmetries, and compare differences in their spin expectation values as a function of temperature. We underpin the correctness of the mean force state by evidencing its match to the steady state of the simulated non-Markovian spin dynamics. Our results show an explicit dependence on the symmetry of the material in which the spin is confined.

Further, we quantify how the mean force-generated inhomogeneities in the energy shells lead to a work extraction potential. Such inhomogeneities constitute a classical equivalent to quantum coherences.

DY 40.4   Thu 10:45   ZEU 250
Time-resolved statistics of snippets as general framework for model-free entropy estimators — •JANN VAN DER MEER, JULIUS DEGÜNTHER, and UDO SEIFERT — II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart

Irreversibility is commonly quantified by entropy production. An external observer can estimate it through measuring an observable that is antisymmetric under time-reversal like a current. We introduce a general framework that, inter alia, allows us to infer a lower bound on entropy production through measuring the time-resolved statistics of events with any symmetry under time-reversal, in particular, time-symmetric instantaneous events. We emphasize Markovianity as a property of certain events rather than of the full system and introduce an operationally accessible criterion for this weakened Markov property. Conceptually, the approach is based on snippets as particular sections of trajectories, for which a generalized detailed balance relation is discussed.

DY 40.5   Thu 11:00   ZEU 250
Anomalous relaxation from a non-equilibrium steady state: An isothermal analog of the Mpemba effect — •JULIUS DEGÜNTHER and UDO SEIFERT — II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany

The Mpemba effect denotes an anomalous relaxation phenomenon where a system initially at a hot temperature cools faster than a system that starts at a less elevated temperature. We introduce an isothermal analog of this effect for a system prepared in a non-equilibrium steady state that then relaxes towards equilibrium. Here, the driving strength, which determines the initial non-equilibrium steady state, takes the role of the temperature in the original version. As a paradigm, we consider a particle initially driven by a non-conservative force along a one-dimensional periodic potential. We show that for an asymmetric potential relaxation from a strongly driven initial state is faster than from a more weakly driven one at least for one of the two possible directions of driving. These results are first obtained through perturbation theory in the strength of the potential and then extended to potentials of arbitrary strength through topological arguments.

DY 40.6   Thu 11:30   ZEU 250
Measurement phase transitions in the no-click limit as quantum phase transitions of a non-hermitean vacuum. — •CATERINA ZERBA[1,2,3] and ALESSANDRO SILVA[2] — [1]Technical University of Munich, 85748 Garching, Germany — [2]International School for Advanced Studies (SISSA), via Bonomea 265, 34136 Trieste, Italy — [3]Università degli Studi di Trieste, via Alfonso Valerio 2, 34127 Trieste, Italy

We study dynamical phase transitions occurring in the stationary state of the dynamics of integrable many-body non-hermitian Hamiltonians, which can be either realized as a no-click limit of a stochastic Schrödinger equation or using spacetime duality of quantum circuits. In two specific models, the Transverse Field Ising Chain and the Long Range Kitaev Chain, we observe that the entanglement phase transitions occurring in the stationary state have the same nature as that occurring in the vacuum of the non-hermitian Hamiltonian: an area law phase when the imaginary part of the quasi-particle spectrum is gapped and a logarithmic growth for gapless imaginary spectrum. This observation suggests the possibility to generalize the area-law theorem to non-Hermitian Hamiltonians

DY 40.7   Thu 11:45   ZEU 250
Thermodynamics of growth in chemical reaction networks — •SHESHA GOPAL MAREHALLI SRINIVAS, FRANCESCO AVANZINI, and MASSIMILIANO ESPOSITO — Complex Systems and Statistical Mechanics, Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg

Open chemical reaction networks show a variety of complex dynamical behaviour such as chemical waves, oscillations, chaotic dynamics, multistability,

and so on. Progress in stochastic thermodynamics has enabled us to identify the energetic costs of these phenomena. However, very little attention has been paid to chemical growth. We will identify the necessary conditions under which open homogeneous CRNs evolving with mass action kinetics show asymptotic growth. Our main results show that growth with nonequilibrium abundances requires nonlinear CRNs with the influx of at least one species from the surrounding. Linear CRNs, on the other hand, can only grow with equilibrium abundances. Our results illustrate the important interplay between topology and the chemostatting procedure in determining the asymptotic dynamics of CRNs.

DY 40.8   Thu 12:00   ZEU 250

Irreversible fluctuations herald dynamical phases in non-Hermitian phase-field models — •Thomas Suchanek[1], Klaus Kroy[1], and Sarah Loos[2] — [1]Institut für Theoretische Physik, Universität Leipzig, Leipzig, Germany — [2]DAMTP, University of Cambridge, Cambridge, United Kingdom

We study the time-reversal symmetry (TRS) breaking of fluctuations in phase-field models that exhibit dynamical phases. We focus on two typical scenarios in which dynamical phases can be born, namely, oscillatory instabilities and the recently uncovered $\mathcal{PT}$-symmetry breaking transitions in non-Hermitian systems [1] that are accompanied by Exceptional Points. Quantifying the TRS breaking by the informatic entropy production rate [2] and analytically investigating the zero noise limit, we find divergent behavior at both transitions. We discuss an example model of two nonreciprocally coupled Chan-Hilliard fields, and offer interpretations of the TRS breaking in terms of interface dynamics, the $\mathcal{PT}$-symmetry breaking and the amplification of dissipative noise near Exceptional Point transitions.

Large deviations theory for noisy non-linear electronics — •Ashwin Gopal, Massimiliano Esposito, and Nahuel Freitas — University of Luxembourg, L-1511 Luxembourg, Luxembourg

The latest generations of transistors are nanoscale devices whose performance and reliability are limited by thermal noise in low-power applications. Therefore, developing efficient methods to compute the voltage and current fluctuations in such non-linear electronic circuits is essential. In this presentation, I will describe the large deviations approach to compute these fluctuations using the stochastic thermodynamic description of CMOS-based electronics (Phys. Rev. B 106, 155303). Starting from the thermodynamically consistent description of the charge transfer at a single electron level, I will then consider the macroscopic limit. This corresponds to scaling up the transistor's physical dimensions, resulting in an increase in the number of electrons on the conductors. In this limit, the thermal fluctuations satisfy a Large Deviations Principle which I will show is also remarkably precise in settings involving only a few tens of electrons, by comparing our results with Gillespie simulations and spectral methods. Traditional approaches, using the stationary Gaussian white noise, are recovered by resorting to an ad hoc diffusive approximation revealing their inconsistencies. To illustrate these findings, I will use the case study of the low-power CMOS inverter, or NOT gate, which is a basic primitive in electronic design. Finally, I will briefly comment on thermodynamic uncertainty (TUR) relations and information processing, in the context of such electronic circuits.

Transition to mesoscale turbulence in an active fluid — •Henning Reinken[1], Sebastian Heidenreich[2], Markus Bär[2], and Sabine H.L. Klapp[1] — [1]Technische Universität Berlin — [2]Physikalisch-Technische Bundesanstalt

Microswimmer suspensions, a paradigmatic example of an active fluid, self-organize into complex spatio-temporal flow patterns, including regular vortex lattices and mesoscale turbulence, a highly dynamical state that exhibits a characteristic length scale. This work investigates the transition to this turbulent state using a continuum-theoretical approach for the effective microswimmer velocity field [1], where the dynamics is governed by the competition between relaxation to a regular vortex lattice and destabilization by nonlinear advection. For the unconstrained bulk flow, we show how to identify the onset of mesoscale turbulence analytically. To this end, we determine the linear stability of the vortex lattice state by explicitly taking into account the coupling between multiple modes via the nonlinear terms. Recent experiments [2] have also demonstrated how vortex lattices can be stabilized by small obstacles [3]. Using the continuum-theoretical approach, we further show numerically that the formation of these patterns exhibits features of a continuous second-order equilibrium phase transition in the 2D Ising universality class [4].

Dynamics and clustering of active run-and-tumble particles on two-dimensional lattices — •Lars Torbjørn Stutzer and Peter Sollich — Institut für Theoretische Physik, Georg-August Universität Göttingen

We study the dynamics of run-and-tumble particles on two-dimensional lattices, focusing on the effects of lattice geometry (square, triangular and hexagonal) and maximum occupation number n_{max} per lattice site. We identify three phases in the stationary state: a cluster (C) phase with extensive clusters formed by motility-induced phase separation, which appears only for $n_{max} \geq 2$; a gas (G) phase consisting of finite-sized clusters; and a new sponge (S) phase where small fluctuating clusters percolate. The nature of the transitions between these phases depend on lattice type and density. C-G transitions are mostly, but not always, first order, while C-S transitions are continuous. Single particle displacement

distributions become non-Gaussian at higher densities, with intermediate exponential tails. Considering finally the transient dynamics from a random initial condition, the time it takes for clustering to appear in the system is independent of the tumble rate α but grows with the lattice coordination number and (exponentially or stronger) with n_{max}.

DY 42.3   Thu 13:00   P1

Pressure in inertial active particle systems with frictional contacts — •Kay-Robert Dormann, Lukas Hecht, and Benno Liebchen — Institut für Physik kondensierter Materie, Technische Universität Darmstadt, Hochschulstr. 8, 64289 Darmstadt, Germany

In systems of isotropic overdamped active Brownian particles (ABPs), the pressure is a state function [1]. It can be shown, that an equation of state (EOS) also exists, if the ABPs are inertial [2]. Here, we explore inertial active Brownian particles [3,4] with additional frictional contacts and find that no EOS exists. We attribute this to the fact that the rotational diffusion depends on density in the presence of frictional contacts.

The breakdown of the EOS due to frictional contacts has interesting implications: for example, when embedding a passive Janus-sphere, whose two hemispheres show a different stiffness, into an active bath, the sphere shows active Brownian motion. In addition, we find that frictional contacts and the associated breakdown of the EOS also have interesting implications for motility-induced phase separation as we will specify on the poster.

Advanced Sampling Methods for Non-Equilibrium Particles — •Thomas Kiechl, Michele Caraglio, and Thomas Franosch — Institute for Theoretical Physics, Universität Innsbruck, Innsbruck, Austria.

Active particles or microswimmers are capable of converting energy into directed motion - which is why they are classified as out-of-equilibrium systems. Microswimmers, such as bacteria or spermatozoa often find themselves in a *target search* situation, where the microswimmers have to make a transition from an initial area to a target area crossing complex environments. Transition Path

Theory, a rigorous statistical mechanics description of transition processes, can be generalized to characterize the target search problem. A simple way of modeling a complex environment for the microswimmer is via an external potential, in which the metastable initial position is separated from the target by an energy barrier. This makes the target search a *rare event*, in which the timescales of the fluctuations in the metastable states and the transition process are separated. Brute force simulations solving the equations of motion are inefficient due to this gap in timescales. The main result is that a more efficient sampling method, Transition Path Sampling (TPS), originally developed for rare transitions of passive systems, can be generalized to Run-and-Tumble systems. TPS is a Monte Carlo simulation of successful trajectories where the new trajectory is accepted according to a metropolis rule based on a path integral formulation.

DY 42.5 Thu 13:00 P1

Markov state modelling of self-assembling active triblock Janus particles — •Salman Fariz Navas, Juri Schubert, and Sabine H.L. Klapp — ITP, Technische Universität Berlin, Germany

Active triblock Janus particles have been shown to form open-cell colloidal lattices in both experiments as well as simulations. Such structures are of particular interest owing to their novel optical and mechanical properties. However, the self-assembly of open-cell lattices is a multistep process involving the formation of many intermediate competing structures resulting in long time-scales.

Here, we develop a Markov State Model for a self-assembling active triblock Janus particle system [1] from particle resolved Brownian Dynamics simulations by reducing the continuous many particle dynamics into a discrete set of states [2],[3]. We use the local order parameters introduced in [4] to develop the discrete states. The transition probability matrix between these states can then be constructed using which, information regarding the metastable states, the relaxation times and the pathways relevant to the aggregation process can be extracted.

DY 42.6 Thu 13:00 P1

Dynamics of an active agent subject to orientational resetting — •Yanis Baouche and Christina Kurzthaler — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

We study the dynamics of an active particle whose swimming direction is subject to rotational diffusion and a stochastic resetting mechanism. The latter allows for taking into account the particle's response to external stimuli.

We use renewal processes to model the reorientation mechanism of the active agent and provide analytical expressions for the characteristic function of the stochastic process and its low-order moments.

Finally, the interplay between rotational diffusion and resetting of the particle's orientation is quantified for different resetting distributions.

DY 42.7 Thu 13:00 P1

Adaptive microvascular remodeling under flow — Fatemeh Mirzapour-Shafiyi, •Leonie Karr, and Karen Alim — School of Natural Sciences, Technische Universität München

Vessel morphology is adapted to minimise energetic costs of dissipation and homogenize flow transport in the network. Resource-deprived tissues produce chemotactic agents to induce vessel formation during development and in tissue homeostasis. The primitive, mesh-like vascular network formed initially through neovascularisation is highly ramified. Later, vascular network is normalised into a hemodynamically preferred tree-like structure. The normalisation process, termed vessel remodeling, leads to an organ-specific network architecture which better meets the metabolic needs of its surrounding tissue. As vessel growth and remodeling is found impaired in various disease states, several factors regulating vessel formation and branching morphology were identified over the past decades. However, while some of these factors have been undergoing clinical trials, their effects on transport properties of the altered vessel morphology are not fully elucidated yet. Establishing a perfusable human vasculature-on-a-chip (hVoC) model system, here we aim to investigate how vascular morphology correlates with flow field. Our hVoC model allows extensive quantitative analyses of network morphology and adaptive remodeling under fluid flow applied by a low-pressure syringe pump. Results of our analyses will contribute to the next generation therapeutics targeting vessel development.

DY 42.8 Thu 13:00 P1

Thermodynamics of active matter systems under coarse graining — •Robin Bebon and Thomas Speck — Institute for Theoretical Physics 4, University of Stuttgart, Heisenbergstraße 3, 70569 Stuttgart, Germany

Over the last decade, dynamic field theories have proven useful in the description of collective behavior and large-scale dynamics of active matter systems. However, despite their popularity, surprisingly little is known about how to capture thermodynamics on the level of such hydrodynamic descriptions. This is partially due to the fact that common approaches, based on symmetry arguments and conservation laws, typically neglect degrees of freedom that play a crucial role in quantifying the system's energetics, e.g., the self-propulsion mechanism. To advance, we propose a bottom-up approach that starts with a thermodynamically consistent microscopic model of catalytic particles driven by a constant affinity and derive effective hydrodynamic equations via explicit coarse graining. To ensure that information of the self-propulsion mechanism and its energy consumption is preserved on the macro-scale, we introduce an additional field, which for the considered model tracks the local rate of successful chemical events. We find that, near equilibrium, particle current and chemical field couple linearly through their respective thermodynamic forces, closely resembling linear irreversible thermodynamics. This provides an access point to investigate the thermodynamic properties of our field theory and compare the results with their microscopic counterparts.

DY 42.9 Thu 13:00 P1

The Liquid-Glass-Jamming Rheology of Soft Active Particles — •Roland Wiese[1], Klaus Kroy[1], and Demian Levis[2,3] — [1]Institute for Theoretical Physics, Leipzig University, 04103 Leipzig, Germany — [2]Departement de Fisica de la Materia Condensada, Facultat de Fisica, Universitat de Barcelona, Marti i Franquès 1, 08028 Barcelona, Spain — [3]University of Barcelona Institute of Complex Systems (UBICS), Facultat de Fisica, Universitat de Barcelona, Marti i Franquès 1, 08028 Barcelona, Spain

We study the linear and nonlinear rheology of an active Brownian particle suspension at different densities. In the low density and low shear limits the flow is Newtonian. In this regime its linear response viscosity can be calculated via the Green-Kubo autocorrelation method and is found to scale with an effective temperature. In the nonlinear regime of high shearing rates shear thinning is observed universally for all parameters considered in our study. Above the critical density of the glass transition the dynamics becomes arrested, marked by the appearance of a finite yield stress. Increasing the self-propulsion of the active particles shifts the glass transition to higher densities by melting the amorphous solid. The yield stress enables us to construct a phase diagram in the spirit of jamming phase diagrams, but exchanging temperature with activity. For sufficently high activities glassy physics becomes suppressed and the yield stress scales with a power law in the density, known from jammed granular materials.

DY 42.10 Thu 13:00 P1

Wetting of reflecting plates by an Active Brownian fluid — •Matthieu Mangeat, Shauri Chakraborty, Adam Wysocki, and Heiko Rieger — Universität des Saarlandes, Saarbrücken, Germany

We study, using interacting active Brownian particles (ABP), the wall-wetting mechanism of active sedimenting fluid. We consider a minimal model of active particles under gravitational field, inside a two-dimensional rectangular box. An accumulation of particles near the bottom wall is observed, as well as the wetting of vertical plates by the rise of active particles against the gravity, even without any attractive force within the system. We characterize this wall-wetting by the meniscus height, calculated from stationary density profile and depending on the inter-particle repulsion. The maximum wetting height depends superlinearly on active sedimentation length for interacting ABP, and linearly for non-interacting ABP. We also observe two large vortices concentrated close to the meniscus, due to the persistence motion of ABP against the gravity. Moreover, with non-interacting ABP, a current flow is present near the boundaries for which we propose a coarse-grained description.

DY 42.11 Thu 13:00 P1

Force-free Ratcheting in Static Activity Landscapes — •Constantin Rein[1], Martin Kolár[2], Klaus Kroy[1], and Viktor Holubec[2] — [1]Leipzig University, Faculty of Physics and Earth Sciences, Institute for Theoretical Physics, Brüderstraße 16, 04081 Leipzig — [2]Charles University, Faculty of Mathematics and Physics, Department of Macromolecular Physics, V Holešovičkách 2, CZ-180 00 Praha

We study the possibility of rectifying active Brownian motion solely using time-independent activity landscapes. We argue that, in one dimension, spatially asymmetric activity does not suffice to induce directed transport, unless the activity is modulated in time or an additional potential is used, whereas, in higher dimensions, static activity landscapes alone can induce ratcheting. The underlying principle is similar to the ratcheting induced by asymmetric obstacles in microswimmer baths: swimmers with suitable orientations get channeled, while the others get trapped in low-activity regions until they lost their orientation. For landscapes with wedge-shaped low-activity regions, we numerically found an average transport velocity of the order of 1% of the particle's swim speed.

DY 42.12 Thu 13:00 P1

The nature of non-phononic excitations in disordered systems — •Walter Schirmacher[1,2], Matteo Paoluzzi[3], and Giancarlo Ruocco[2,4] — [1]Universität Mainz, Mainz, Germany — [2]Istituto Italiano di Tecnologia, Roma, Italy — [3]Universitat de Barcelona, Barcelona, Spain — [4]Universita di Roma "La Sapienza", Roma, Italy

We theoretically and numerically investigate the nature of the non-phononic excitations appearing in the vibrational spectrum of disordered materials of small systems, which do not allow for low-frequency waves (phonons). Using heterogeneous-elasticity theory and a new generalization, we are able to distinguish between two types of non-phononic vibrational excitations of disordered materials (glasses). A first type (Type-I) arises beyond the boson peak due to strong scattering from the structural disorder. These excitations are similar to the eigenvectors of random matrices. In very small systems, in the absence of low-frequency waves, the spectrum exhibits a gap, which, in a marginal-stable situation, may extend to zero frequency and features a DOS proportional to the square of the frequency. In such small systems, in a more stable situation, a second type of non-phononic excitations (Type-II) appears, which involve rotational oscillations around local frozen-in stresses. The frequency spectrum of these Type-II excitations is related to the interaction potential in the regime, where the potential contributions are small, rendering the frequency dependence non-universal. The frequently observed frequency scaling with the fourth power is shown to be an artifact due to the smooth tapering of the potential cutoff in the simulations.

DY 42.13 Thu 13:00 P1
Glass Transition in Modulated Liquids — •Abolfazl Ahmadirahmat[1], Michele Caraglio[1], Vincent Krakoviack[2], and Thomas Franosch[1] — [1]Institut für Theoretische Physik, Universität Innsbruck, Technikerstraße 21A, A-6020 Innsbruck, Austria — [2]Laboratoire de chimie, École normale supérieure de Lyon, 46 Allée d'Italie 69364 Lyon, Cedex 07, France
We have developed a theoretical description for the structural and dynamical properties of quasi-two-dimensional colloidal suspensions subject to periodic potentials using mode-coupling theory (MCT). We solve the MCT equations numerically for monodisperse hard disks modulated by a periodic external potential and, we show that the theory reduces to the conventional MCT equations of the glass transition for bulk systems if the external modulation vanishes. To do so, we elaborate numerical results for the long-time limits of suitably generalized intermediate scattering functions. We compare the nonergodicity parameter of a two-dimensional modulated liquid in zero modulation with the corresponding nonergodicity parameter for the bulk system in two dimensions.

DY 42.14 Thu 13:00 P1
Assembly of iron oxide nanocuboids directed by surface, ligand, and magnetic interactions — •Sindy J. Rodríguez Sotelo[1,2], Mario C.G. Paseggi Jr.[1,2], Carlos García[3], and Igor Stanković[4] — [1]Instituto de Física del Litoral IFIS-CONICET, Santa Fe, Argentina — [2]Facultad de Ingeniería Química, Universidad Nacional del Litoral UNL, Santa Fe, Argentina — [3]Departamento de Física y Centro Científico Tecnológico de Valparaíso-CCTVal, Universidad Técnica Federico Santa María, Valparaíso, Chile — [4]Scientific Computing Laboratory, Center for the Study of Complex Systems, Institute of Physics Belgrade, University of Belgrade, Serbia
The direction of the dipole moment in the magnetite spherical nanoparticles is unrelated to the morphology particle. For non-spherical particles, a coupling between particle form and magnetic moment direction might result in unexpected behaviours, especially when the moment is not aligned along a particle symmetry axis [1,2]. We introduce energy models accounting for the directionality and magnitude of the van der Waals and dipolar interactions as a function of the shape of the nanocubes, illustrating the importance of the directional dipolar forces for the formation of the nanocube clusters, the dominance of the van der Waals multi-body interactions and exclusion forces of ligands. We illustrate how minimal energy structures depend on the assembly size, shape of the particles, and the balance of surface and magnetic dipolar coupling.

DY 42.15 Thu 13:00 P1
Phase Behaviour of a Minimal Lattice Model with Chiral Interactions — •Boyi Wang[1,2], Patrick Pietzonka[1], and Frank Jülicher[1,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Institute of Physics, Chinese Academy of Sciences, Beijing, China — [3]Cluster of Excellence, Physics of Life, TU Dresden, Dresden, Germany
We introduce chiral interactions to a minimal lattice model based on the Ising model, adding second neighbour interactions that favour an L-shaped structure. We run Monte-Carlo simulations in equilibrium at low temperatures, and find two new ground states which exhibit chiral periodic tiling. We also study the phase behabiour analytically as a function of the strength of the chiral interaction and the external magnetic field. With number conservation, we observe the coexistence of chiral and achiral phases and the formation of droplets. Furthermore, we consider the role of chirality in this minimal lattice model with active driving forces.

DY 42.16 Thu 13:00 P1
Static and dynamical magnetic properties ferrofluid with ellipsoid-like nanoparticles — •Vladimir Zverev, Alla Dobroserdova, Ekaterina Ekaterina, Elena Pyanzina, and Alexey Ivanov — Ekaterinburg, Russia
A system of magnetic ellipsoids with a point dipole at the particle center is considered. We take into account different shape's anisotropy and different positions of the magnetic moment inside the particle (parallel and perpendicular to the main axis of the ellipsoid). In order to study this system, molecular dynamics simulations are used. The ratio of the main semi-axis to the additional one was used as a measure of the particle anisotropy. In particular, we have studied the system in which the particles have magnetic moments, but there is no dipole-dipole interaction between them. As a result, the initial magnetic susceptibility (magnetic characteristic) and the radial distribution function (structural characteristic) were calculated. For the initial susceptibility, the data obtained in computer simulations differ from the Langevin magnetization (theoretical ideal case) within the statistical error. The data for the Radial Distribution Function (RDF) also match within the calculation error. The next stage of research was to take into account dipole-dipole interparticle interactions and also will be presented.

DY 42.17 Thu 13:00 P1
Hopping conduction in networks with site energy disorder — •Quinn Emilia Fischer, Marco Bosi, and Philipp Maass — Fachbereich Physik, Universität Osnabrück, Barabarastraße 7, D-49076 Osnabrück, Germany
Understanding conductivities due to hopping motion in disordered systems is an important problem with various applications ranging from electron transport in amorphous semiconductors to ion transport in glasses [1,2]. A prominent model is that of particle hopping on a lattice with random site energies, where each lattice site can be occupied by at most one particle. For this model, a theory has been proposed, where transport properties are determined by a mapping onto a random resistor network [3]. By comparison with extensive kinetic Monte Carlo simulations for different types of site energy distributions, we show that this theory gives good predictions for small and high particle concentrations but is less accurate for intermediate concentrations. We present a refined theory which takes into account nearest neighbour correlations between occupation numbers in current carrying nonequilibrium steady states. This theory yields an improved prediction of conductivities and their activation energies in very good agreement with the Monte Carlo results.

DY 43: Poster: Quantum Dynamics and Many-Body Systems

Time: Thursday 13:00–16:00   Location: P1

DY 43.1 Thu 13:00 P1
applications of generalized coherent states in bosonic systems — •Yulong Qiao[1], Frank Grossman[2], and Joonsuk Huh[3] — [1]Institute for theoretical physics, TU Dresden, 01062 Dresden, Germany — [2]Institute for theoretical physics, TU Dresden, 01062 Dresden, Germany — [3]Department of Chemistry, Sungkyunkwan University, Suwon 16419, Republic of Korea
Generalized coherent states (GCS) are found to be very useful for studying bosonic systems with a fixed number of particles, such as the Bose-Hubbard model and boson sampling. Firstly, we present the non-equilibrium dynamics of the Bose-Hubbard model based on the time-dependent variational principle [1]. Increasing the multiplicity of GCS leads to converged results quickly for weak interaction strength, which indicates that GCS are a well-suited basis in the superfuild phase. Secondly, we investigate the boson sampling problem whose input state is a Fock state. Using an exact expansion of the Fock state in terms of GCS,

we obtain the output state by means of a unitary rotation. By this process the total information is contained in a finite number of GCS. The specific structure of the GCS allows us to split the whole system into two parts easily and to study the entanglement entropy of the output state in detail [2].

Coupling in Optical Microcavity-Arrays — •Tom Rodemund and Martina Hentschel — Department of Physics, University of Applied Sciences Chemnitz, Chemnitz, Germany

Optical microcavities capture light by total internal reflection in so-called whispering-gallery modes. Deformed disk-shaped microcavities, for example of Limaçon shape, allow one to keep high Q-factors while manipulating the far-field emission via the resonator geometry, thereby allowing for a wide range of applications from microlasers to sensors.

Coupling of several microdisk resonators enhances the possibilities to tame light considerably [1]. Depending on the number and distance of the coupled cavities, the far-field characteristics vary tremendously and can even be reversed [1]. Here, we investigate the underlying mechanisms. To this end we use phase-space methods and analyze the resonance wave functions in real space as well as the corresponding Husimi functions to characterize the coupling behavior. We employ ideas from ray-wave correspondence to deepen our insight by establishing a relation to the nonlinear light ray dynamics and its fingerprint in the Poincaré surface of section.

DY 43.3 Thu 13:00 P1

From Dual Unitarity to Generic Quantum Operator Spreading — •Michael A. Rampp, Roderich Moessner, and Pieter W. Claeys — Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany

Dual-unitary circuits are paradigmatic examples of exactly solvable yet chaotic quantum many-body systems, but solvability naturally goes along with a degree of non-generic behaviour. By investigating the effect of weakly broken dual-unitarity on the spreading of local operators we study whether, and how, small deviations from dual-unitarity recover fully generic many-body dynamics. We present a discrete path-integral formula for the out-of-time-order correlator and use it to recover a butterfly velocity smaller than the light-cone velocity, $v_B < v_{LC}$, and a diffusively broadening operator front, two generic features of ergodic quantum spin chains absent in dual-unitary circuit dynamics. We find that the butterfly velocity and diffusion constant are determined by a small set of microscopic quantities and that the operator entanglement of the gates plays a crucial role.

DY 43.4 Thu 13:00 P1

Transmission of a single electron through a Berry ring — •Kenmoe Maseim Bassis — Universitätsstraße 31, 93053, Regensburg — Prüfeningerstraße 121, 93049, Regensburg

A theoretical model of transmission and reflection of an electron with spin is proposed for a mesoscopic ring with rotating localized magnetic moment. This model may be realized in a pair of domain walls connecting two ferromagnetic domains with opposite magnetization. If the localized magnetic moment and the traveling spin is ferromagnetically coupled and if the localized moment rotates with opposite chirality in the double path, our system is formulated in the model of an emergent spin-orbit interaction in a ring. The scattering problem for the transmission spectrum of the traveling spin is solved both in a single-path and a double-path model. In the double path, the quantum-path interference changes dramatically the transmission spectrum due to the effect of the Berry phase. Specifically, the spin-flip transmission and reflection are both strictly forbidden.

DY 43.5 Thu 13:00 P1

Optimal route to quantum chaos in the Bose-Hubbard model — Lukas Pausch[1,2], Edoardo Carnio[2,3], Andreas Buchleitner[2,3], and •Alberto Rodríguez[4] — [1]Département de Physique, Université de Liège, Belgium — [2]Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Hermann-Herder-Straße 3, D-79104, Freiburg, Germany — [3]EUCOR Centre for Quantum Science and Quantum Computing, Albert-Ludwigs-Universität Freiburg, Freiburg, Germany — [4]Departamento de Física Fundamental, Universidad de Salamanca, E-37008 Salamanca, Spain

The dependence of the chaotic phase of the Bose-Hubbard Hamiltonian [1,2] on particle number N, system size L and particle density is investigated in terms of spectral and eigenstate features. We analyze the development of the chaotic phase as the limit of infinite Hilbert space dimension is approached along different directions, and show that the fastest route to chaos is the path at fixed density $n \lesssim 1$ [3]. The limit $N \to \infty$ at constant L leads to a slower convergence of the chaotic phase towards the random matrix theory benchmarks. In this case, from the distribution of the eigenstate generalized fractal dimensions, the ergodic phase becomes more distinguishable from random matrix theory for larger N, in a similar way as along trajectories at fixed density.

Chaotic resonance modes in optical microcavities — •Florian Lorenz and Roland Ketzmerick — TU Dresden, Institut für Theoretische Physik, Dresden, Germany

Following a recently proposed conjecture, we show that resonance modes in dielectric cavities are a product of a conditionally invariant measure from classical dynamics and universal fluctuations [1]. The first factor describes the average of

modes with similar lifetime and has a multifractal structure which we resolve on very fine scales. It is approximately described by conditionally invariant measures from classical dynamics [1]. However, increasing the openness of a dielectric cavity (i.e. by investigating TE modes or a small refractive index) is a challenge to the construction of appropriate classical measures.

[1] R. Ketzmerick, K. Clauß, F. Fritzsch, and A. Bäcker, Chaotic resonance modes in dielectric cavities: Product of conditionally invariant measure and universal fluctuations, Phys. Rev. Lett. **129**, 193901 (2022).

DY 43.7 Thu 13:00 P1

Classical and quantum escape dynamics in the vicinity of hyperbolic fixed points — •Alexander Hempel, Jonas Stöber, and Arnd Bäcker — TU Dresden, Institut für Theoretische Physik, Dresden, Germany

For an ensemble of orbits started in the vicinity of an inverse hyperbolic fixed point in the area-preserving standard map we find a slow, non-exponential decay of the survival probability. It turns out that this is governed by the geometry of the stable and unstable manifolds which form a partial barrier enclosing a resonance zone. An analysis of transit times through the resonance zone using the lobe dynamics of the partial barrier, including re-entrance of orbits, explains the non-exponential decay. Quantum mechanically, coherent states follow the classical behavior for remarkably long times.

DY 43.8 Thu 13:00 P1

Many-body localization in disordered Heisenberg-type spin chain models — •Yilun Gao and Rudolf A. Römer — Department of Physics, University of Warwick, Coventry, CV4 7AL, UK

Disordered quantum systems have become an important research topic in modern condensed matter physics ever since the discovery of Anderson localization. The investigation of many-body localization in quantum interacting systems has received much recent attention following the increase of computational power and improvement in numerical methods. One of the standard models that has been studied is the disordered spin-1/2 Heisenberg chain. It was shown that there exists a phase transition from ergodic states to many-body localized states as the disorder is increased. Here, we focus on a variant of the model where the exchange couplings between neighboring spins are taken to be disordered. We calculate the consecutive-spectral-gap ratio and its probability distribution for different system sizes and disorders. The result is compared with the case when the disorder is onsite. We average over many disorder realizations. We also plot the sample-to-sample variance against disorder and system size as a further characteristic of the phases across the MBL transition.

DY 43.9 Thu 13:00 P1

Nonlinear magnetoelectric effects in class AIII 3D topological insulators — •Nithin Thomas, Jan Wilhlem, and Ferdinand Evers — Institute of Theoretical Physics, Regensburg University, D-93053 Regensburg, Germany

We investigate nonlinear magnetoelectric effects in class AIII 3D topological insulators[1]. Within the framework of a tight-binding model, we numerically observe a quadratic scaling of wrapping currents with the electric field strength. Starting with the theory of nonlinear Hall effect induced by Berry curvature dipole[2], we develop an analytic description of our numerical findings.

Shinsei Ryu et al 2010 New J. Phys. 12 065010 (2010) Inti Sodemann and Liang Fu, Phys. Rev. Lett. 115, 216806 (2015)

DY 43.10 Thu 13:00 P1

Flat band physics for dispersive bands — •Jie Liu[1], Carlo Danieli[2], and Rudolf A. Römer[3] — [1]School of Physics and Optoelectronics, Xiangtan University, Xiangtan 411105, China — [2]Department of Physics, University of Sapienza, Piazzale Aldo Moro 5, 00185 Rome, Italy — [3]Department of Physics, University of Warwick, Coventry, CV4 7AL, United Kingdom

Lieb models provide a convenient test bed for the characterization of compactly localized states (CLS) in "flat" energy bands. The CLS have been discussed as potential candidates for information storage applications. However, they are typically sensitive to perturbations. Uncorrelated onsite disorder in most cases lifts the existence of CLS irrespective of the disorder strength and induces wave localization in flat band lattices. In certain cases, however, local symmetries within flat band lattices suggest local correlations in the onsite disorder which result in anomalous localization features. Here we make use of these ideas to proposed an engineered "disorder" that allows to keep the compactness of the CLS while it at the same time changes half of the dispersive states to become more CLS-like. The work has potential applications for the many situations where flat-band physics has been shown to be relevant, effectively stabilizing the CLS.

DY 43.11 Thu 13:00 P1

Electron cavity optics in bilayer graphene billiards — •Lukas Seemann[1], Angelika Knothe[2], Klaus Richter[2], and Martina Hentschel[1] — [1]Technische Universität Chemnitz, D-09107 Chemnitz, Germany — [2]Institut für Theoretische Physik, Universität Regensburg, 93040 Regensburg, Germany

Rapid developments in the field of 2D materials and their nanostructures make it possible to trap charge carriers with different dispersions in various confinement

geometries with a high degree of control. This progress now allows studying 2D electron optics phenomena enriched by the charge carriers' different electronic and topological properties compared to the photonic. Here, we demonstrate the differences induced by deviating from an isotropic dispersion relation by theoretically investigating cavities in gapped bilayer graphene characterized by the presence of a trigonally warped band structure [1]. We employ an approach based on ray-wave correspondence [2] and find dramatic deviations from the optical-case behavior with clear signatures in phase space. We show that the fermion optics characteristics can be conveniently tuned by gate voltages and illustrate the experimentally relevant consequences.

Quantum many-body dynamics in two dimensions using tree tensor networks — •Wladislaw Krinitsin[1], Niklas Tausendpfund[1,2], Matteo Rizzi[1,2], and Markus Schmitt[1] — [1]Forschungszentrum, Jülich, Deutschland — [2]Institut der Theoretischen Physik, Köln, Deutschland

Many body systems out of equilibrium are notoriously difficult to solve due to the rapid growth of entanglement with time. In particular the rapidly expanding possibilities to address 2-dimensional systems in quantum simulation turn a spotlight on the lack of reliable numerical methods in this regime. We explore an approach to solve the time dependence of 2-dimensional systems by applying the time-dependent variational principle (TDVP) to Tree Tensor Networks (TTNs). More specifically, this method is used to study non-ergodic dynamics in the quantum Ising model.

DY 43.13   Thu 13:00   P1

Numeric investigation of the Kibble-Zurek mechanism in 2D — •Seyedeh Parya Katoorani, Ralf Schützhold, Naser Ahmadiniaz, Gernot Schaller, and Friedemann Queisser — Theoretical Physics (FWZ), HZDR, Dresden, Germany

The two-dimensional classical Ising model can be approximately implemented on a Si(100) surface, where the dimers are anisotropically coupled. In particular, the setup allows for time-dependent temperatures, where the Kibble-Zurek mechanism predicts topological defect formation while traversing the critical point at a finite rate. We numerically investigate the corresponding relaxation dynamics of a two-dimensional extended Ising model with diagonal couplings and time-dependent temperature.

DY 43.14   Thu 13:00   P1

Explicit expressions for stationary states of the Lindblad equation for a finite state space — •Bernd Michael Fernengel — TU Darmstadt, Darmstadt, Germany

The Gorini-Kossakowski-Sudarshan-Lindblad Equation is a quantum master equation describing the time evolution of quantum mechanical states. It is used to model open quantum systems. We give explicit expressions of stationary solutions of the Lindblad equation in the case of a finite state space, using the concept of state transition networks of Markov chains. Our treatment is based on the so-called quantum-jump unravelling, which is an ensembles of stochastic quantum trajectories, compatible with the Lindblad equation. A single such trajectory is a piecewise deterministic process, which is interrupted by stochastic jumps. We discuss differences to the classical case and conditions, under which the Lindblad equation is asymptotically stable.

DY 43.15   Thu 13:00   P1

Generic partial barriers to chaotic transport in 4D symplectic maps — •Benjamin Hertzsch, Arnd Bäcker, and Roland Ketzmerick — TU Dresden, Institut für Theoretische Physik, Dresden, Germany

Chaotic transport in Hamiltonian systems is often restricted due to the presence of partial barriers, leading to a limited flux between different regions in phase phase. Typically, the most restrictive partial barrier in a 2D symplectic map is based on a cantorus, the Cantor set remnants of a broken 1D torus. Recently, for a weakly coupled 4D symplectic map, a partial barrier based on a normally hyperbolic invariant manifold with the structure of a cantorus has been established. We investigate how this can be extended to a generic 4D map, where the most restrictive partial barriers are expected to lie on the most irrational slopes between resonance channels in frequency space.

Stability analysis of a periodically driven ultra-cold Bose gas — •Larissa Schwarz, Simon B. Jäger, Dimo Claude, Imke Schneider, and Sebastian Eggert — Physics Department and Research Center OPTIMAS, Technische Universität Kaiserslautern, D-67663, Kaiserslautern, Germany

We theoretically study the dynamics of a Bose-Einstein condensate under periodic driving of the s-wave scattering length. In this setup, we first determine the stability of the condensate using Bogoliubov theory with time-periodic modulation. We find an exponential gain in the resonant k-modes due to a parametric

amplification which leads to a rapid condensate depletion. These findings are compared with the simulation of the Gross-Pitaevskii equation which shows the formation of a density-wave pattern with the predicted k-wavevector. We extend the Bogoliubov theory by including non-linearities which result in an effective damping of the k-modes. This enables the creation of stable density-wave pattern below a critical driving strength. Moreover, above this critical driving strength we analyze simple non-quadratic models and find macroscopic and stable occupation of the resonant k-mode.

DY 43.17   Thu 13:00   P1

Energy-conserving adaptive partitioning QM/MM simulations — •Marvin Nyenhuis[1,2] and Nikos Doltsinis[1,2] — [1]Institute for Solid State Theory, University of Münster, Wilhelm-Klemm-Straße 10, 48149 Münster, Germany — [2]Center for Multiscale Theory and Computation,, University of Münster, Wilhelm-Klemm-Straße 10, 48149 Münster, Germany

Bachmann and Doltsinis have recently proposed an energy-conserving adaptive partitioning method between two different atomistic representations based on an extended Hamiltonian, which switches the system from a potential energy surface V_1 to another potential V_2. In this work, we develop this method further and implement it into the QM/MM molecular dynamics framework of the CP2K software package, enabling atoms travelling out of (or into) the QM region to adopt an MM (or QM) representation. For a test system consisting of a solvated sodium ion, we analyse the degree to which energy is conserved over a large number of switching events depending on the value chosen for the mass of the fictitious lambda particle. In addition, we investigate how this choice affects the switching speed and we seek the optimum mass that simultaneously ensures rapid switching and good energy conservation.

DY 43.18   Thu 13:00   P1

Classification of noisy spectra using machine learning — Aritra Mishra and •Alexander Eisfeld — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

A general problem in quantum mechanics is to obtain information of the eigenstates from the experimentally measured data which consists inherent noises. For an example, in the case of molecular aggregates, the information about excitonic eigenstates is vitally important to understand their optical and transport properties [1,2].

We show that it is possible to reconstruct the underlying delocalised aggregate eigenfunctions from near-field spectra using convolution neural networks [3]. We also investigate convolution neural networks for an eigenstate based classification of the spectra, in the presence of noise. Each aggregate eigenstate, corresponds to a distinctly looking spectrum. Therefore, we can assign a class to each of the eigenstate. We find that the network is also able to classify the spectra of different noise strengths along with the one it has been trained for.

DY 43.19   Thu 13:00   P1

Exact time local equations of quantum dissipation with minimal state space — •Meng Xu[1], Vasilii Vadimov[2], Malte Krug[1], Jürgen T. Stockburger[1], and Joachim Ankerhold[1] — [1]Institute for Complex Quantum Systems and IQST, Ulm University — [2]QCD Labs, QTF Centre of Excellence, Aalto University, Finland

We present a minimal state space approach to unravel the Feynman path integral influence functional for open quantum system dynamics. The resulting time local evolution equation for the density in minimally extended state space is exact and in combination with tensor network methods, can be very efficiently propagated with very high precision also for long times [1]. It is capable to treat the full non-Markovian dynamics, regardless of low temperature, structured reservoir, and strong system-bath coupling. On a formal level, its intriguing structure allows to demonstrate that the new equation is closely related to an entire family of representations (Lindblad-type, Fokker-Planck-type). Alternative perturbative and non-perturbative formulations of quantum dissipation can be derived from it, with our new approach being favorable through a comparably low dimension of auxiliary dimensions. With the new platform at hand, lab-based high-precision simulations in parallel to actual experiments with, for example, superconducting qubits are within reach.

Training Restricted Boltzmann Machines for Spin-1 Quantum Magnets — •Abhiroop Lahiri and Michele Casula — IMPMC, Sorbonne Université, Paris, France

Neural Network Quantum states (NQS) have gained popularity in recent times for their ability to study quantum many-body systems. Restricted Boltzmann Machines (RBMs) have been quite successful in providing an accurate representation of the ground states of spin-1/2 quantum systems both in one and two dimensions. Based on recent studies of the spin-1 representation of RBMs using one-hot encoding and a quadratic energy function, we aim to test these ansatze

for spin-1 models in various configurations. We train the network parameters and investigate their behaviour to resolve the ground state of these systems.

DY 43.21 Thu 13:00 P1
Enhancement and suppression of charge transport in organic semiconductors under strong light-matter coupling — •SEBASTIAN STUMPER and JUNICHI OKAMOTO — University of Freiburg, Institute of Physics
We study a model of an organic semiconductor coupled to a cavity with variable disorder and electronic filling factors as well as dissipative effects. It represents a fermionic generalization of the Dicke model such that charges can move between lattice sites.

Different mechanisms are explored to explain experimentally observed conductivity enhancements in the strong coupling regime. These are either based on an increase of the charge mobility or of the charge density. Mobilities and the generalized inverse participation ratio, which characterizes localization, are accessible from various two- and four-point correlators that we obtain by a Lanczos technique. In agreement with several previous studies, we find that excitons are indeed delocalized under strong light-matter coupling and show an enormously increased mobility. The same is not true for electrons and holes.

Charge densities are increased by excitation of electrons to the upper band

through counter-rotating light-matter interaction terms. However, this is counteracted by the cavity-mediated formation of bound electron-hole states. We analyze the relative strengths of these processes under finite size scaling, and how the formation of bound states is affected by disorder and dephasing. In certain limits for an undoped system, the Dicke model is recovered.

DY 43.22 Thu 13:00 P1
Investigation of two-dimensional quantum billiards with mixed dynamics in microwave resonators — •LENNART ANDERSON and ANDREAS WIECK — Angewandte Festkörperphysik, Ruhr-Universität Bochum
Based on the analogy of the stationary Schrödinger equation and the Helmholtz equation for a flat electromagnetic resonator, two-dimensional quantum mushroom billiards are studied in the microwave regime. We give a practical approach, ranging from the construction process of the resonator to the eigenvalue statistics. I.e. the frequency spectrum is measured for different stem widths. The obtained nearest neighbour spacings are fitted with respect to three different distribution functions for systems with mixed dynamics respectively. The degrees of chaoticity are determined analytically, dependent on the stem width, and compared with the fitted data. The presented approach is of both conceptual and educational interest.

Understanding probability and irreversibility in the Mori-Zwanzig projection operator formalism — •MICHAEL TE VRUGT — Institut für Theoretische Physik, Westfälische Wilhelms-Universität Münster, Center for Soft Nanoscience, Philosophisches Seminar, 48149 Münster, Germany
Explaining the emergence of stochastic irreversible macroscopic dynamics from time-reversible deterministic microscopic dynamics is one of the key problems in philosophy of physics. The Mori-Zwanzig (MZ) projection operator formalism, which is one of the most important methods of modern nonequilibrium statistical mechanics, allows for a systematic derivation of irreversible transport equations from reversible microdynamics and thus provides a useful framework for understanding this issue. However, discussions of the MZ formalism in philosophy of physics tend to focus on simple variants rather than on the more sophisticated ones used in modern physical research. In this work [1], I will close this gap by studying the problems of probability and irreversibility using the example of Grabert's time-dependent projection operator formalism. This allows to better understand how general proposals for understanding probability in statistical mechanics, namely (a) quantum approaches and (b) almost-objective probabilities, can be accomodated in the MZ formalism.

Finite-temperature absorption spectrum of Al_2O_3 from first principles — •ANGELA F. HARPER[1], BARTOMEU MONSERRAT[2], and ANDREW J. MORRIS[3] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]University of Cambridge, UK — [3]University of Birmingham, UK
Advancing the next generation of materials for solid-state devices requires an understanding of their underlying electronic structure. One such material is alumina (Al_2O_3), which is used to enhance performance in electronic devices from Li-ion batteries to perovskite solar cells and field effect transistors. By including phonon-assisted transitions within plane-wave DFT methods for calculating the X-ray absorption spectrum (XAS) we obtain the Al K-edge XAS at 300 K for two crystalline Al_2O_3 phases. The 300 K XAS reproduces the pre-edge peak for α-Al_2O_3, which is not visible at the static-lattice level of approximation. The 300 K XAS for γ-Al_2O_3 correctly describes two out of the three experimental peaks. We show that the second peak arises from 1s to mixed s-p transitions and is absent in the 0 K XAS. The method presented here is generalizable to any element and absorption edge, and is a feasible way to calculate finite temperature spectroscopy for any crystalline material.

DY 44.3 Thu 13:00 P1
Potts model with invisible states on a scale-free network — •MARIANA KRASNYTSKA[1,2,3] and PETRO SARKANYCH[1,2] — [1]ICMP, NAS of Ukraine, Lviv, Ukraine — [2]L4 Collaboration Leipzig-Lorraine-Lviv-Coventry — [3]Université de Lorraine, Nancy, France
Different models are proposed to understand magnetic phase transitions through the prism of competition between the energy and the entropy. One of such models is a (q+r)-state Potts model with invisible states. This model introduces r invisible states such that if spin lies in one of them, it does not interact with the rest. We consider such a model using the mean-field approximation on an annealed scale-free network where the probability of a randomly chosen vertex having a given degree is governed by the power law with decay exponent

λ. Our results confirm that q, r and λ play a role of global parameters that influence the critical behaviour of the system. Depending on their values the phase diagram is divided into three regions with different critical behaviour. However, the topological influence, presented by the marginal value of $\lambda c(q)$, has proven to be dominant over the entropic one, governed by the number of invisible states r [arXiv:2211.14048].

DY 44.4 Thu 13:00 P1
Thermodynamics of $su(n)$-symmetric integrable models and their continuum limit — •INGRYD PASSOS and ANDREAS KLÜMPER — Bergische Universität Wuppertal, Wuppertal, Germany
Traditionally the computation of the partition function of integrable quantum chains is achieved by means of the thermodynamic Bethe ansatz (TBA). On the other hand, an alternative formulation which relies on finite sets of nonlinear integral equations has been developed and successfully applied to seminal cases like for example the spin-1/2 Heisenberg chain, the supersymmetric t-J model and quantum chains with $su(3)$ and $su(4)$ invariance. This approach, known as the Quantum Transfer Matrix (QTM) method, allows for faster numerical computations and calculation of finite temperature correlation lengths. However, the derivation of these alternative equations was done in case by case studies in which by trial and error suitable auxiliary functions were identified. Another shortcoming of the QTM method is its applicability in the case of continuum integrable models. A way to circumvent this issue is to identify the proper lattice model from which the continuum model follows after a suitable scaling limit. This way, it is possible, for example, to determine the thermodynamics of multicomponent Bose gases from anisotropic spin chains. In this work we present a way to derive systematically finite sets of nonlinear integral equations for $su(n)$-symmetric integrable lattice models and discuss a scaling limit of these equations in the case of the $su(3)$-invariant anisotropic spin chain.

Simple-to-complex phase transition for longest increasing subsequences (Ulam's problem) — •TAMMO LENTSCH and ALEXANDER K. HARTMANN — Institute of Physics, University of Oldenburg, Germany
It is possible to calculate the LIS length L by efficient algorithms in polynomial time. Finding and analyzing LIS was first considered numerically in the 1950s by Stanislav Ulam. The LIS problem has applications in bioinformatics and data analysis but is also studied in mathematics and statistical physics [1].

Recently, an algorithm to count the number of LIS [2] was extended to directly sample LIS [3]. The phase space where σ are random permutations was studied by calculating the distribution $P(q)$ of overlaps, revealing a complex structure similar to Replica Symmetry Breaking.

Here we consider the effect of randomly partially presorting σ with $O(n^\alpha)$ sorting steps. For sequences up to length $n = 8192$, we analyzed the LIS length L and $P(q)$. The results indicate a phase transition at a critical value α_c from $O(n)$ to $O(\sqrt{n})$ LIS length scaling and from simple to complex phase-space structure.

Nonergodicity of scaled fractional Brownian motion with nonliner time and space clocks — •Yingjie Liang[1,2], Wei Wang[2], Andrey G. Cherstvy[2], and Ralf Metzler[2,3] — [1]Hohai University — [2]University of Potsdam — [3]Asia Pacific Center for Theoretical Physics

Experimental evidences show that diffusion processes are not always Brownian motion. It is anomalous diffusion with the mean squared displacement (MSD) being a power law in time, ultraslow diffusion with a logarithmic law, and superfast diffusion with an exponential law. To describe different types of non-Brownion motion in heterogeneous media, this study provides scaled fractional Brownian motion (SFBM) with nonliner time and space clocks. In the Langevin system for the FBM runnning with a nonliner time clock, i.e., the time scaled FBM, the real time is a temporal function of the original times in FBM. For the FBM runnning with a nonliner space clock, i.e., the space scaled FBM, the real position is a nonlinear spatial function of the orginial positions in FBM. The nonergodicity properties of SFBM are quantified based on single particle trajectories of the fractional Brownian motion running with time and space clocks. The simulations are consistent with the general analytical results in specific values of the dominated parameters for the behaviors of the MSD, time averaged mean squared displacement (TAMSD) and aging. Potential applications of these results are encountered in diverse scientific fields, such as biophysical, soft matter and hydrology systems.

DY 44.7   Thu 13:00   P1

The Griffiths Phase: A Large Deviations Study — •Lambert Münster[1], Martin Weigel[1], and Alexander K. Hartmann[2] — [1]Institut für Physik, TU Chemnitz, 09107 Chemnitz, Germany — [2]Institut für Physik, Carl von Ossietzky Universität Oldenburg, 26129 Oldenburg, Germany

For spin systems with quenched disorder, the Griffiths phase is the thermal region between the phase transition in the pure system and the corresponding transition in the disordered system. The standard example is a dilute ferromagnet, where a certain fraction of bonds is missing [1]. The physical behavior of this phase is characterized by large fluctuations in the order parameter which are visible in the tails of the distribution of the magnetic susceptibility. To directly investigate this property, we combine a large-deviation Monte Carlo sampling algorithm [2,3] with a Gaussian modified ensemble [4], thus allowing us to study the distribution of physical quantities on a much larger range of the support as compared to previous studies [5], i.e., in the region of exponential small probabilities. In addition to considering the susceptibility distribution we also study other observables such as the specific heat, thus shedding new light on this intriguing physical phenomenon.

Transport Properties of Brownian Particles: Analytical Results and Computer Simulations — •Regina Rusch[1], Gerhard Jung[2], and Thomas Franosch[1] — [1]Institute for Theoretical Physics, Universität Innsbruck, Innsbruck, Austria. — [2]Laboratoire Charles Coulomb (L2C), Université de Montpellier, CNRS, 34095 Montpellier, France.

The results of computer simulations for Brownian particles can be improved by using a novel noise cancellation algorithm, with which the velocity autocorrelation function (VACF) can be measured more precisely. The algorithm is based on the fact that the Brownian noise can be stored in computer simulations and thus the noise can be subtracted from a simulated trajectory. Doing this, a reduced motion of the particle due to interactions or an external force is obtained. It could be shown that the VACF of the reduced motion is connected with the original VACF up to a cross-correlation term, which is shown to be sufficiently small. For the system of a Brownian particle in a periodic step potential the noise cancellation algorithm decreases the error of the VACF by about one order of magnitude. A power-law decay in the VACF is found by employing Monte-Carlo simulations. We also present analytical results for the probability distribution of the particle position using the Bloch theorem. This enables us to compute further correlation functions such as the intermediate scattering function which is in quantitative agreement with simulations.

DY 44.9   Thu 13:00   P1

First passage time as thermodynamical parameter — •Vasiliy Ryazanov — Institute for nuclear research NANU, Kiev, Ukraine

The first-passage time is proposed as an independent thermodynamic parameter of the statistical distribution that generalizes the Gibbs distribution. The thermodynamic parameter conjugated to the first-passage time is the same as the Laplace transform parameter of the first-passage time distribution in the partition function. The thermodynamic parameter conjugated to the first-passage time can be expressed in terms of the deviation of the entropy from the equilibrium value. Thus, all the moments of the distribution of the first passage time

expressed in terms of the deviation of the entropy from its equilibrium value and the external forces acting on the system. By changing the thermodynamic forces, you can change of the first passage time.

An analogy is drawn between version of non-equilibrium thermodynamics a distribution-based containing an additional thermodynamic first-passage time parameter, nonequilibrium statistical operator method and extended irreversible thermodynamics with flows as an additional thermodynamic parameter. Various conditions for the dependence of the distribution parameters of the first-passage time on the random value of energy, the first thermodynamic parameter, are considered. Expressions are obtained for the thermodynamic parameter, the conjugate of the first passage time through the entropy change, and for the average first passage time through the flows.

Stochastic dynamics with multiplicative noise under resetting — •Trifce Sandev[1,2,3], Ljupco Kocarev[1,3], Ralf Metzler[2,4], and Aleksei Chechkin[2,5,6] — [1]Macedonian Academy of Sciences and Arts, Skopje, Macedonia — [2]University of Potsdam, Germany — [3]Ss. Cyril and Methodius University in Skopje, Macedonia — [4]Asia Pacific Center for Theoretical Physics, Pohang, Republic of Korea — [5]Wroclaw University of Science and Technology, Poland — [6]Akhiezer Institute for Theoretical Physic, Kharkiv, Ukraine

We analyze different stochastic processes with multiplicative noise under resetting in non-homogeneous media. We use the subordination approach, which is a powerful technique for solving various diffusion and Fokker-Planck equations, to analyze the probability density functions and the mean squared displacements. Additionally, we show that such systems under stochastic resetting reach non-equilibrium stationary states. The transition to the non-equilibrium stationary states is analyzed in terms of the large deviation function, by employing the Laplace approximation of the integral in the renewal equation for the probability density of the process with resetting events.

Quench-Probe Setup as an Analyzer of Fractionalized Entanglement Spreading — •Nicolas P. Bauer[1], Jan Carl Budich[2], Björn Trauzettel[1], and Alessio Calzona[3] — [1]Julius Maximilians Universität Würzburg, Würzburg, Germany — [2]TU Dresden, Dresden, Germany — [3]IQM Quantum Computers, München, Germany

We propose a novel spatially inhomogeneous setup for revealing quench-induced fractionalized excitations in entanglement dynamics. In this quench-probe setting, the region undergoing a quantum quench is tunnel-coupled to a static region, the probe. Subsequently, the time-dependent entanglement signatures of a tunable subset of excitations propagating to the probe are monitored. We exemplify the power of this generic approach by identifying a unique dynamical signature associated with the presence of an isolated Majorana zero mode in the post-quench Hamiltonian. In this case excitations emitted from the topological part of the system give rise to a fractionalized jump of log(2)/2 in the entanglement entropy of the probe. This dynamical effect is highly sensitive to the localized nature of the Majorana zero mode, but does not require the preparation of a topological initial state.

DY 44.12   Thu 13:00   P1

Exploiting Skyrmion motion for computing — •Alessandro Pignedoli, Björn Dörschel, and Karin Everschor-Sitte — University of Duisburg-Essen, Duisburg, Germany

Brownian motion is a natural phenomenon that can be exploited for energy efficient computing. Here, an assemblage of simple parts evolves in an energetic labyrinth to a low energy state which is isomorphic to the desired solution of a computation [1]. Magnetic Skyrmions [2] are topologically stable magnetic whirls that have been shown to behave like interacting Brownian particles [3,4]. We use a Langevin model to describe and investigate the motion of Skyrmions by means of correlations and statistical observables to carry out Brownian computation. We show that besides the Brownian motion of individual Skyrmions, their interactions and external driving forces break ergodicity. This allows for a rapid convergence to the low-energy state of the system and thus solves the calculation faster.

DY 44.13   Thu 13:00   P1

A generalised rotational diffusion approach to modeling of the dielectric relaxation processes with resetting — •Irina Petreska[1], Ljupco Pejov[1,2], Trifce Sandev[1,3,4], Ljupco Kocarev[1,3], and Ralf Metzler[4] — [1]Ss. Cyril and Methodius University in Skopje, Macedonia — [2]University of Stavanger,

Norway — [3]Macedonian Academy of Sciences and Arts, Skopje, Macedonia — [4]University of Potsdam, Germany

We consider the rotational diffusion equation with a generalised memory kernel in the context of dielectric relaxation processes in a medium composed of polar molecules. We give an overview of existing models on non-exponential relaxation and introduce an exponential resetting dynamic in the corresponding process, providing a detailed analysis of the autocorrelation function and complex susceptibility. It is shown that stochastic resetting leads to a saturation of the autocorrelation function to a constant value, in contrast to the case without resetting, for which it decays to zero. The behaviour of the autocorrelation function, as well as the complex susceptibility in the presence of resetting, confirms that the dielectric relaxation dynamics can be tuned by an appropriate choice of the resetting rate.

Dividing Active Brownian Particles — •TILL WELKER and HOLGER STARK — Institut für Theoretische Physik, Technische Universität Berlin, Germany.
We aim to combine active motion with cell division to answer questions like: Does nutrient input induce clustering? How does a non-uniform nutrient distribution effects population dynamics?

To include cell division and death in the model of active Brownian particles, we propose a simple rule: *in a time interval dt, each particle has a probability $dt \cdot g(s)$ to divide and $dt \cdot d$ to die.* The growth rate g depends on the nutrient concentration s at the position of the bacterium and is described by the Monod function. The nutrient diffuses with the diffusion coefficient D_N. We add a source with steady input rate S_0, in addition, each particle takes up nutrient with a rate $\gamma g(s)$.

The population dynamics strongly depends on nutrient diffusion: For large D_N, the population oscillates before reaching a steady population number N^*. For small D_N, the population is stronger damped and equilibrates quickly. N^* is independent of D_N, but the population fluctuation decreases for lower D_N due to the damping. The collective behavior is also influenced by the nutrient: First, for large D_N the swarm has a strongly asymmetric shape during the transient phase which then becomes symmetric in the steady state. Second, the swarm is less dense for larger D_N, but the relationship between spread of nutrient and bacteria is not linear.

We show that combining two key aspects of microbial life, mobility and growth, gives rise to interesting population and spatial dynamics.

DY 44.15 **Thu 13:00** **P1**
Ornstein-Uhlenbeck process and generalizations: influence of comb geometry and stochastic resetting on the particle dynamics — •PETAR JOLAKOSKI[1], PECE TRAJANOVSKI[1], KIRIL ZELENKOVSKI[1], ALEXANDER IOMIN[2], LJUPCO KOCAREV[1,4], and TRIFCE SANDEV[1,3,4] — [1]Macedonian Academy of Sciences and Arts, Skopje, Macedonia — [2]Department of Physics, Technion, Haifa, Israel — [3]University of Potsdam, Germany — [4]Ss. Cyril and Methodius University in Skopje, Macedonia

The Ornstein-Uhlenbeck (O-U) process can be interpreted as a Brownian motion in a harmonic potential. The process is an established Gauss-Markov process that has a bounded variance and admits a stationary probability distribution, in contrast to the standard Brownian motion. Over time, the process tends to drift towards its mean function: such a process is called mean-reverting. Here, we study the effects of stochastic resetting on the O-U process and its generalizations which were hitherto unexplored. In particular, we investigate the dynamics with and without resetting on comb-like structures. For the studied specific 2D comb geometry, we compute the first moment, the non-equilibrium stationary state and the mean squared displacement, and find that the global resetting hinders the particle's transport in the two dimensions. Moreover, the two divergent forces, namely the resetting and the drift towards the mean, lead to compelling results both in the case of O-U process with resetting and its generalization on a 2D comb structure.

Theoretical design of Geometric Brownian Information Engine: Analysis of output work — •SYED YUNUS ALI, RAFNA RAFEEK, and DEBASISH MONDAL — IIT Tirupati, Yerpedu, Andhrapradesh, India
We design a geometric Brownian information engine by considering overdamped Brownian particles inside a 2-D monolobal confinement with irregular width along the transport direction. Under such conditions, particles experience an effective entropic potential. We employ a feedback control protocol as an outcome of error-free position measurement.The protocol comprises three stages: measurement, feedback, and relaxation. We show that the upper bound of the achievable work shows a cross-over from $(5/3 - 2 \ln 2)k_B T$ to $k_B T/2$ when the system changes from an entropy-dominated regime to energy dominated one. Next, we determine the benchmarks for utilizing the available information in an output work and the optimum operating requisites for best work extraction in asymmetric feedback protocol. Transverse bias force (G) tunes the entropic con-

tribution in the effective potential and hence the equilibrium marginal probability distribution standard deviation(σ).We recognize that the amount of extracted work reaches a global maximum when $x_f = 2x_m$ with $x_m = 0.6\sigma$, irrespective of the extent of the entropic limitation.

Diffusion and order in mixed lattice gas of hard squares — NIKLAS RAAKE[1], •PIOTR NOWAKOWSKI[2], and ANA-SUNČANA SMITH[1,2] — [1]Friedrich–Alexander–Universität Erlangen–Nürnberg, Erlangen, Germany — [2]Institut Ruđer Bošković, Zagreb, Croatia
We study a lattice gas composed of hard square particles of 1×1 and 2×2 size (measured in lattice constant) undergoing Brownian motion on a two–dimensional square lattice. For different concentrations of both types of particles we determine numerically the diffusion coefficients and compare them with predictions of a model based on a persistent random walk with one or two step memory. Good agreement is observed only for very low and very high concentration of particles. The deviations present in between these regimes suggest that the correlations play an important role in the dynamics of the system.

Additionally, we introduce a configurational order parameter that characterizes clustering of bigger squares. This allows us to study the continuous transition between unordered liquid and ordered crystal phases.

DY 44.18 **Thu 13:00** **P1**
Non-Markovian modeling of non-equilibrium fluctuations and dissipation in active viscoelastic biomatter — •AMIR ABBASI[1], ROLAND R. NETZ[1], and ALI NAJI[2] — [1]Freie University of Berlin, Berlin, Germany — [2]Institute for Research in Fundamental Sciences (IPM), Tehran, Iran
Viscoelastic gels such as permanently or transiently cross-linked networks of semiflexible polymers are important soft biological materials. The polymeric nature of such gels is responsible for their salient rheological properties, including their frequency-dependent response to external forces.

Here, based on a Hamiltonian that incorporates the elastic coupling between a tracer and active particles, we derive a generalized Langevin model for the non-equilibrium mechanical response of active viscoelastic biomatter. Our model accounts for the power-law viscoelastic response of the embedding polymeric network as well as for the non-equilibrium energy transfer between active and tracer particles. Our analytical expressions for the frequency-dependent response function and the positional autocorrelation function agree nicely with experimental data for red blood cells and actomyosin networks with and without ATP. The fitted effective active-particle temperature, elastic constants and effective friction coefficients of our model allow straightforward physical interpretation.

Ornstein-Uhlenbeck process on three dimensional comb structure under stochastic resetting — •PECE TRAJANOVSKI[1], PETAR JOLAKOSKI[1], KIRIL ZELENKOVSKI[1], ALEXANDER IOMIN[2], LJUPCO KOCAREV[1,4], and TRIFCE SANDEV[1,3,4] — [1]Macedonian Academy of Sciences and Arts, Skopje, Macedonia — [2]Department of Physics, Technion, Haifa, Israel — [3]University of Potsdam, Germany — [4]Ss. Cyril and Methodius University in Skopje, Macedonia
The Ornstein-Uhlenbeck (O-U) process is a generalised diffusion process, introduced as a model for the velocity of a particle undergoing a Brownian motion confined in harmonic potential. The process is a stationary, meaning that over time, it tends to drift towards its long-time mean function: such a process is called mean-reverting. Here, we investigate the influence of the three dimensional comb structure and the stochastic resetting on the particle dynamics governed by O-U processes along the backbone (x-direction) and the main fingers (y-direction) and standard Wiener process along the secondary fingers of the comb (z-direction). The explicit analytical expressions for the first moment and mean squared displacement along all three directions are calculated and confirmed numerically. The marginal probability density functions along all directions are simulated by using coupled Langevin equations for comb geometry.

Generalized molecular Stokes-Einstein and Stokes-Einstein-Debye relations including temperature-dependent slip and effective radius — •SINA ZENDEHROUD, JAN O. DALDROP, YANN VON HANSEN, and ROLAND R. NETZ — Freie Universität Berlin, Department of Physics, Arnimallee 14, 14195 Berlin, Germany
We perform molecular dynamics simulations of water at different temperatures and calculate the viscosities as well as the rotational and translational self-diffusion constants of water molecules in the lab frame and in the comoving coordinate frame of the molecules. Instead of interpreting the results as deviations from the Stokes-Einstein and Stokes-Einstein-Debye relations, we simultaneously determine the slip length and the effective hydrodynamic radius from the simulation data. We show that the viscosity dependence of the diffusion constants of water can be understood in terms of an almost constant effective radius and a pronounced temperature dependence of the slip length.
