Energy transfer between the librational and the inter- and intramolecular vibrational modes of liquid water — •Louis Lehmann and Roland Netz — Fachbereich Physik, Freie Universität Berlin

The molecular dynamics of liquid water can be split into librational and inter- and intramolecular vibrational modes. By applying the Eckart decomposition scheme, the infrared absorption spectrum can be exactly decomposed into contributions from these different modes. The complete energy transfer network of the librational and inter- and intramolecular vibrational modes in liquid water is established based on the energy transfer rates determined from equilibrium molecular dynamics simulations with conventional and many-body force fields. The results are validated by comparison with non-equilibrium molecular dynamics simulations that mimic pump-probe experiments.

Domain Drift and Diffusion in Cell-Polarization Processes — •Johannes Ewald and Jürgen Vollmer — Institute of Theoretical Physics, Universität Leipzig, Brüderstr. 16, D-04103 Leipzig, Germany

Cell polarization can be driven by the formation of signaling patterns on cell membranes. They can be modeled by two species of membrane proteins that can bind to cytosolic enzymes. The enzymes drive the conversion between cell membranes. These chemical reactions drive the coarsening of domains on the cell surface. Polarization amounts to the situation where the cell surface is covered by only two domains on opposing sides of the cell. Certain aspects of the domain coarsening are reminiscent to ripening of spin-up and spin-down domains in ferromagnets. In this analogy the conversion of membrane proteins takes the role of spin flips of the magnetic system. However, there are also distinct differences in the dynamics because the conversion is driven by a dissipative chemical reaction, while spin-flips arise due to thermal fluctuations. Based on the analytical solutions for domain drift and diffusion in the two models we will discuss differences and communalities of the processes.

A systematic approximation scheme mapping systems with time delays to sets of ordinary differential equations — •Daniel Henrik Nevermann and Claudius Gros — Institut für Theoretische Physik, Goethe-Universität Frankfurt, Deutschland

Mathematically, delayed differential equations evolve in infinite dimensional state spaces. It is hence conceivable that time-delayed systems can be approximated by a set of $N+1$ ordinary differential equations, with the trajectory of the primary variable converging to the solution of the original time-delayed system when $N \to \infty$. We show that this program can be carried out using sequences of time-delay kernels related to discrete gamma distributions.

We present several analytical and numerical results for the proposed approximation scheme, finding that the instability of fixed points due to increasing time delays is captured accurately already for $N \sim 10$. For the Mackey-Glass system we find that the locus of a limit-cycle doubling are recovered in good approximation only for substantially larger $N \sim 10^2 - 10^3$, with the transition to chaos requiring an even larger state space. In general, we find that relative approximation errors scale as $1/N$. In addition, we discuss how the approximation proposed can be applied to the case of distributed time delays.

It is in general an approximation to model a given experimental protocol by a dynamical system characterized by a single time delay T. Using a distribution of time delays peaked at T, with width $\sim 1/N$, can hence be argued to provide a more accurate description of real-world non-Markovian processes.

Preprocessing algorithms for the estimation of ordinary differential equation models with polynomial nonlinearities — •Oliver Strebel — Angelstr. 17, 75392 Deckenpfronn

The data analysis task of determining a model for an ordinary differential equation (ODE) system from given noisy solution data is addressed. Based on a previously published parameter estimation method for ODE models [1] four related model estimation algorithms were developed. The algorithms are tested for over 20 different polynomial ordinary equation systems comprising 60 equations at various noise levels. Two algorithms frequently compute the correct model [2]. They are compared to the prominent SINDy-family for those SINDy-algorithms that have simple default hyperparameters [3]. A novel and successful method for determining the parameter of Tikhonov regularization when calculating numerical differentials is also presented.

Testing Jump-Diffusion in Epileptic Brain Dynamics: Impact of Daily Rhythms — •Jutta G. Kurth[1,2], Klaus Lehnertz[2], and Thorsten Rings[2] — [1]Georg-August-Universität Göttingen — [2]Rheinische Friedrich-Wilhelms-Universität Bonn

Stochastic approaches to complex dynamical systems have recently provided broader insights into spatial-temporal aspects of epileptic brain dynamics. Stochastic qualifiers based on higher-order Kramers-Moyal coefficients derived directly from time series data indicate improved differentiability between physiological and pathophysiological brain dynamics. It remains unclear, however, to what extent stochastic qualifiers of brain dynamics are affected by other endogenous and/or exogenous influencing factors. Addressing this issue, we investigate multi-day, multi-channel electroencephalographic recordings from a subject with epilepsy. We apply a recently proposed criterion to differentiate between Langevin-type and jump-diffusion processes and observe the type of process most qualified to describe brain dynamics to change with time. Stochastic qualifiers of brain dynamics are strongly affected by endogenous and exogenous rhythms acting on various time scales*ranging from hours to days. Such influences would need to be taken into account when constructing evolution equations for the epileptic brain or other complex dynamical systems subject to external forcings.

Keywords: diffusion process; jump-diffusion process; time series analysis; brain; epilepsy; biological rhythms

Temporal localized states and square waves in semiconductor microresonators with strong time delayed feedback — •Elias R. Koch[1,2], Thomas Seidel[1], Julien Javaloyes[2], and Svetlana V. Gurevich[1] — [1]Institute for Theoretical Physics, University of Münster, Wilhelm-Klemm-Str. 9, 48149 Münster, Germany — [2]Departament de Física & IAC-3, Universitat de les Illes Balears, C/ Valldemossa km 7.5, 07122 Mallorca, Spain

Recent works demonstrated the promising potential of injected microresonators enclosed into external cavities as high-power, tunable sources of Frequency Combs in the near infra-red. It was shown that the natural modeling approach consists in using singularly perturbed time delayed systems. Departing from former studies that considered a single intensity dependent refractive index (i.e. Kerr nonlinearity) we explore in this contribution the impact of a semiconductor Quantum-Well as the nonlinear element. A first principle model for the optical response is employed which allows to explore the influence of the detuning with respect to the band-gap. We show that this extended model predicts the existence of a bistable set of bright and dark temporally localized states as well as square-waves, with a periodic of twice the delay in the case of antiresonant optical feedback.

Finally, in order to clarify the influence of the second and third order chromatic dispersion and of the frequency dependence of the quantum-well response, we perform a multiple time-scale analysis in the so-called good cavity limit. The resulting normal form PDE shows a good agreement with the original, first principle, time delayed model.

Antipersistent random walks in time-delayed systems — •Tony Albers[1], David Müller-Bender[1], and Günter Radons[1,2] — [1]Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany — [2]Institute for Mechanical and Industrial Engineering, Chemnitz, Germany

In this contribution, we show that the occurrence of chaotic diffusion in a typical class of time-delayed systems with linear instantaneous and nonlinear delayed term can be well described by an antipersistent random walk. We numerically investigate the dependence of all relevant quantities characterizing the random walk on the strength of the nonlinearity and on the delay. With the help of analytical considerations [1], we show that for a decreasing nonlinearity parameter the resulting dependence of the diffusion coefficient is well described by Markov processes of increasing order.

DY 45.6   Thu 13:00   P1

Advection dependent pulse dynamics — •Adrian Misselwitz[1], Susanne Lafon[2], Jean-Daniel Julien[2], and Karen Alim[1,2] — [1]School of Natural Sciences, Technische Universität München — [2]Max-Planck-Institut für Dynamik und Selbstorganisation, Göttingen

Models of pulse formation in nerve conduction have provided manifold insight not only into neuronal dynamics but also the non-linear dynamics of pulse formation in general. Recent observation of neuronal electro-chemical pulses also driving mechanical deformation of the tubular neuronal wall and thereby generating ensuing cytoplasmic flow now question the impact of flow on the electrochemical dynamics of pulse formation. We, here, theoretically investigate the classical Fitzhugh-Nagumo model now accounting for advective coupling between the pulse propagator typically describing membrane potential and here triggering mechanical deformations and, thus, governing flow magnitude, and the pulse controller, a chemical species advected with the ensuing fluid flow. Employing analytical calculations and numerical simulations we find, that advective coupling allows for a linear control of pulse width while leaving pulse velocity unchanged. We therefore uncover an independent control of pulse width by fluid flow coupling.

DY 45.7   Thu 13:00   P1

(Broken) gradient-dynamics description of reactive thin liquid films — •Florian Voss, Fenna Stegemerten, and Uwe Thiele — Institut für Theoretische Physik, Westfälische Wilhelms-Universität Münster, Wilhelm-Klemm-Str. 9, 48149 Münster, Germany

After reviewing the gradient dynamics formulation of chemical reactions, applied e.g. in [1] to reacting phase-separating systems, we apply the concept to thin liquid films and shallow drops that are either covered by reactive surfactants [2] or react with the solid substrate [3]. Next we discuss how the breaking of the variational form by imposed fluxes results in intricate spatio-temporal dynamics of the film/drop and reactant density profiles. As an example we consider a simple model for oscillatory behaviour in droplets of slime mould.

Coupling short-range signaling and tissue mechanics for biological pattern formation — •Valèria Ribelles Pérez, Stephan Kremser, Mareike Bojer, Sabina Orazov, and Ulrich Gerland — Physics Department, Technical University of Munich

Pattern formation phenomena are ubiquitous in natural and synthetic multicellular systems. Both mechanical forces and biochemical interactions between cells play key roles in tissue dynamics. While much is known about these physical and biochemical processes separately, their interplay is still poorly understood. Here, we focus on short-range signaling between cells, modelled by cellular automata, coupled to a vertex model incorporating mechanical interactions, to investigate patterning principles during tissue homeostasis and growth. We test the modelling framework in the context of salt-and-pepper-like patterns that arise for instance in epithelial tissues.

DY 45.9   Thu 13:00   P1

Robust, precise, and modular solutions to the French flag problem in two dimensions without global signaling — •Lukas Zett, Stephan Kremser, Gabriel Vercelli, and Ulrich Gerland — Technical University of Munich

The formation of axial patterns with broad regions in multicellular systems has been conceptualized by Wolpert in his famous French flag problem. Both of Wolpert's proposed solutions, the balancing and gradient model, utilize long-range signaling between cells. Models relying on short-range signaling, based on cellular automata (CA) rules as modeling tool, have also computationally been shown to successfully solve the French flag problem in one dimension (1D). Here, we extend these models to two spatial dimensions (2D) to investigate whether the 1D solutions can be generalized to the 2D case and to search for novel solutions existing only in 2D. We dissect the 2D problem into two coupled, 1D pattern formation processes along and perpendicular to the axis of the French flag. Using evolutionary algorithms and consensus procedures as well as engineering approaches, CA dynamics which solve the French flag problem are found. We show that these solutions form more precise patterns and are in general more robust than their 1D counterparts, while still being able to scale with system size. Depending on the desired robustness and precision of the solution, different patterning modules along the two axes can be combined. Using the regulatory logics of these underlying modules could therefore serve as a basis for the design of synthetic patterning systems with a range of different specifications.

DY 45.10   Thu 13:00   P1

Kinetic Monte Carlo Model for Computing Functionalities in Nanoparticle Networks — •Jonas Mensing[1] and Andreas Heuer[2] — [1]Institut für Physikalische Chemie, WWU Münster — [2]Institut für Physikalische Chemie, WWU Münster

We want to achieve reconfigurable computational unctionality in a nanoparticle network for energy efficient machine learning applications. Previous research has shown that disordered networks of functionalized gold nanoparticles can be configured to behave like Boolean logic gates and binary classifiers. In this regard, gold nanoparticles serve as switchable single-electron transistors, while organic molecules connecting the nanoparticles act as tunable tunnel barriers. The resulting network is then placed within an array of electrodes that manipulate the charge and potential landscape of the network to evolve the system into its desired emergent functionality. In total, the network is able to mimic the mechanism of a brain-like neural network. The theoretical underpinning of these networks is investigated with a highly optimized physical model and subsequent simulations. The model is able to simulate the charge transport within the network stochastically, i.e. with a kinetic Monte Carlo approach. Requirements for various computing functionalities such as Boolean logic are examined. Besides graph theory and data-driven tools allow mapping network and electrode properties to the appearance of computational functionalities. The simulations are carried out in close comparison with corresponding experiments.

Randomised mixed labyrinth fractals — •Janett Prehl[1], Ligia Loretta Cristea[2], and Daniel Dick[1] — [1]Technische Universität Chemnitz, Chemitz, Germany — [2]Technische Universität Graz, Graz, Austria

Fractals, introduced by Benoit Mandelbrot in the early 1980s, allow the analysis of physical properties of natural geometries and structures in non-integer dimensions. It has been shown recently, that utilizing fractals structures, for instance for gas sensors made of carbon nanotubes increase their efficiency or give new insights to complex quantum phenomena. Here, we are interested how the effect of randomness, as observed in real materials, alter the topology and thus dynamics of the resulting fractal structures in comparison to the pure cases. We focus on a special class of Sierpinski carpets, i.e., the labyrinth fractals [1], that can be used for dendritic networks or porous materials. Therefore, we mix to fractal patterns, with different properties, i.e., shortest path and random walk dimension, randomly together at different mixing ratios. Surprisingly we found that even in cases where the initial patterns exhibit the same non-integer dimensions the resulting randomised fractals give a different property [2].

How Can Cell-Like Inflated Shells Control Their Shape? —A Stability Analysis — •Paul Nemec and Ulrich Gerland — Physics Department, Technical University of Munich

This work follows a long history of studying how biological organisms arrive at and maintain their shape [1]. Inspired by the question of how E. coli maintain their cylindrical shape during growth [2], we study the growth of pressurised cell-like structures. The model is this: a cell is an inflated elastic shell, where internal and fine grained details are neglected. Growth is the time evolution of the reference or undeformed configuration of the cell, which may depend on geometric and mechanical properties like curvature and stress. Growth must be local and invariant under translations and rotations of the entire cell. Under these constraints, how can cells robustly achieve simple target geometries like a sphere given arbitrarily perturbed initial conditions? This poster presents some initial insights.

Stimulating self-optimisation of flow networks for transport — •Swarnavo Basu and Karen Alim — School of Natural Sciences, Technical University of Munich, Germany

Flow transport in networks is ubiquitous in biology (e.g. blood vasculature) and engineering (e.g. porous media). Many biological networks are adaptive and can self-organise in response to external stimuli. They homogenise flow to achieve optimal perfusion and a uniform flow of chemicals across the network. In contrast, engineered networks of random media have heterogeneous flow velocity distributions across the network. Self-organising engineered networks that can homogenise flow will have many applications, ranging from microfluidic networks for cooling batteries and chemical reactors to *in vitro* vasculature for perfusing tissues and implants. We propose a model of a network whose tube radii can be controlled using periodic inflows of pulses of an eroding agent that erodes the network's walls. We observe that such networks self-organise in response to the eroding agent, leading to a homogenised flow. This provides a framework for engineering networks that can self-organise to achieve optimal perfusion.

Fixation probabilities in network structured meta-populations — •Sedigheh Yagoobi[1] and Arne Traulsen[2] — [1]Max-Planck institute for evolutionary biology — [2]Max-Planck Institute for Evolutionary Biology
The effect of population structure on evolutionary dynamics is a long-lasting research topic in evolutionary ecology and population genetics. Evolutionary graph theory is a popular approach to this problem, where individuals are located on the nodes of a network and can replace each other via the links. We study the effect of complex network structure on the fixation probability, but instead of networks of individuals, we model a network of sub-populations with a probability of migration between them. We ask how the structure of such a meta-population and the rate of migration affect the fixation probability. Many of the known results for networks of individuals carry over to meta-populations, in particular for regular networks or low symmetric migration probabilities. However, when patch sizes differ we find interesting deviations between structured meta-populations and networks of individuals. For example, a two patch structure with unequal population size suppresses selection for low migration probabilities.

Ising model with variable spin/agent strengths on graphs — Mariana Krasnytska[1,2,3], Yurij Holovatch[1,2,4], •Bertrand Berche[2,3], and Ralph Kenna[2,4] — [1]ICMP, NAS of Ukraine, Lviv, Ukraine — [2]L4 Collaboration Leipzig-Lorraine-Lviv-Coventry — [3]Université de Lorraine, Nancy, France — [4]Coventry University, UK
We consider a generalization of the Ising model in which individual spin strengths can vary [1]. The model describes the ordering in systems comprised of agents which, although matching in their binarity (i.e., maintaining the iconic Ising features of spin 'up'/'down', 'yes'/'no'), differ in their strengths. With inhomogeneous physical systems in mind, but also anticipating interdisciplinary applications, we present the model on graph structures of varying degrees of complexity: complete graph, Erdös-Rényi graph, and on a scale-free network. This allows us to explore the interplay of two types of randomness: individual strengths of spins or agents and collective connectivity between them. We find the delicate interplay between variable properties of nodes and interactions between them leads to new universality classes.

Homeostatic plasticity in a minimal model for brain criticality — •Marco Schmidt and Stefan Bornholdt — Institut für Theoretische Physik, Universität Bremen
The 'criticality hypothesis' asserts that real-world neural networks operate near a critical phase transition. Experimental evidence exists and numerous models studying the possible underlying mechanisms accumulated during the last 20 years.

Early models based on simple threshold networks tune to a critical connectivity $K = 2$, which is not a realistic value when compared to real-world neural networks.

However, a phase transition in high degree threshold networks using the inhibition to excitation ratio as a control parameter does exist [1], as well as a corresponding self-organized critical toy model [2]. It features an adaptive threshold network, self-tuning to the critical inhibition to excitation ratio by using an activity based rewiring process that results in a highly clustered network and reaches criticality independent of K.

Here we present a new version of the model, incorporating a simple homeostatic plasticity mechanism as it appears in biological systems.

Time series analysis of loudness fluctuations in musical performances and psychophysical experiments — •Benjamin Schulz[1,2], Corentin Nelias[1,2], and Theo Geisel[1,2,3] — [1]MPI for Dynamics and Self-Organization, Göttingen, Germany — [2]Physics Dept., Georg-August University, Göttingen, Germany — [3]Bernstein Center for Computational Neuroscience, Göttingen, Germany
Over the last decades, the study of fluctuations in musical time series showed power spectral densities that exhibit a $1/f^\beta$-shape across certain frequency regions, indicating long range correlations. So far time series of pitch, rhythm, or timing were investigated across different musical epochs, composers and styles, showing a variety of β-values between 0 and 2. Whether the fluctuations of musical dynamics, or in other words loudness fluctuations, have similar spectral properties, is an open question, however. We have carried out in-depth studies of manually recorded data sets in different musical settings. A first set results from psychophysical tapping experiments. A second one consists of drum performances recorded in a musical environment. All participating musicians were professionals. The tapping and drumming data consistently show the clear occurrence of a $1/f^\beta$-shape in the power spectral density. Furthermore, the presence of a metronome click in the tapping experiment leads to the strengthening of specific periodic structures in the loudness fluctuations and also seems to have an impact on the coefficient β.

Battery modeling: Fusing equivalent circuit models with data-driven surrogate modelling — •Limei Jin[1,2], Franz P. Bereck[2], Josef Granwehr[2], Rüdiger-A. Eichel[2], Karsten Reuter[1], and Christoph Scheurer[1] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]IEK-9, Forschungszentrum Jülich, Jülich, Germany
Electrochemical impedance spectroscopy (EIS) is widely used to characterize electrochemical energy conversion systems. The traditional analysis with equivalent circuit models (ECM) has recently been augmented by a transform based distribution of relaxation times (DRT) analysis which allows one to reduce the ambiguity in the construction of ECMs and thus overfitting. Experimentally determined ECM parameters vary depending on operating conditions and the lifetime history of battery usage. Here we focus on State of Health (SOH) and State of Charge (SOC) as a basis for operando diagnosis and functionality optimization in the setting of fast-charging. Within pure ECM approaches, aging effects can only be represented to a limited extent, as aging is related to a variety of different factors whose impact on cell impedance are not sufficiently understood, yet. The highly complex interplay of factors motivates the development of data-driven Machine Learning (ML) models as a basis for future battery management systems. We present ML enabled ECMs based on experimental impedance analyses and a data-driven ML approach that computationally samples an abstract target space for classification and recognition of cells at vastly different SOC/SOH combinations.

Machine learning categorization of the Anderson model — •Quangminh Bui-Le and Rudolf Römer — Department of Physics, University of Warwick, Coventry, CV4 7AL
Machine learning (ML) methods have been used to identify phase transitions of physical systems by categorizing systems based on the Ψ^2 values of their wavefunctions into extended and localized states, which a model is then trained on in order to identify between the extended and localized states. Here we want to see if ML is powerful enough to categorize systems into even more specific groups by attempting to categorize Anderson model data into categories based on the disorder of the wave-function. We are using a PyTorch model to create a convolutional neural network using a ResNet18 model. This model will be trained on 3D Anderson model Ψ^2 values from 17 disorder values spanning a range of 15 to 18.

DY 46.4   Thu 13:00   P1

Neural-network based Monte Carlo Markov chain simulation of spin glasses — •Michael Engbers and Alexander K. Hartmann — Carl von Ossietzky University, Oldenburg, Germany
Spin glasses exhibit a complex equilibrium and non-equilibrium behavior at low temperatures. The reason is the existence of an energy landscape with many local minima and high barriers. In computer simulations, this leads to long correlation times when investigating large systems. Due to this numerical hardness, the model has motivated the development of many new algorithmic approaches like generalized Wolff cluster algorithms, parallel tempering or genetic algorithms.

Recently, it has been shown that the application of generative neural networks can accelerate Monte Carlo simulations, also for simple spin models with apparently promising results.

Here, we use an autoregressive distribution estimator (NADE) to perform a Monte Carlo simulation of spin glasses [1]. We embedded the NADE into a Metropolis-Hastings Markov-chain approach, therefore ensuring detailed balance. We confirm previous results that the acceptance rates of the NADE approach surprisingly increase with decreasing temperature. Nevertheless, we show that crucial observables, such as the distribution of spin overlaps, indicate that this neural-network approach suffers from the lack of effective ergodicity.

Influence of mode-coupling on the information processing rate of Spin-VCSEL reservoir computer — •LUKAS MÜHLNICKEL, LINA JAURIGUE, and KATHY LÜDGE — Institut f. Physik, Technische Universität Ilmenau, Weimarer Str. 25, 98684 Ilmenau, Germany

The relative simplicity of reservoir computing, when comparing it to other machine learning methods, makes it suitable for efficient hardware implementation. The needed high dimensional reservoir dynamics can be provided by adding feedback to only one single nonlinear node, while driving the system with time multiplexed inputs. One promising realization utilizes the fast polarization dynamics of power efficient Spin-VCSELs. These fast field interactions are related to birefringence, dichroism and electron transition rates in the cavity material and occur on shorter time scales than the relaxation oscillations. Thus, compared to typical semiconductor lasers, much higher cutoff frequencies in the system response are observed for the Spin-VCSELs. We investigate the influence of these fast polarization oscillation dynamics on the reservoir performance when increasing data processing rates.

DY 46.6 Thu 13:00 P1

Deep learning-based clogging prediction in outflow of hard and soft grains — •SEDDIGHEH NIKIPAR, DMITRY PUZYREV, JING WANG, and RALF STANNARIUS — Institute of Physics and MARS, Otto von Guericke University Magdeburg, Universitätsplatz 2, D- 39106 Magdeburg, Germany

Studying the outflow of granular materials has been recognized as a challenging topic in physics due to their unexpected behavior, such as segregation, blockage, and other dynamical events [1]. In particular, the early detection of clogging during discharge of granular materials through narrow orifice in silo has significant challenges. In this work, the possibility of early prediction of clogging was investigated through implementation of image-based deep learning approach, which turns out to be a promising strategy to predict the time until the next clog [2]. For this purpose, experiments on discharge of mixtures of hard and soft spheres from a quasi-two dimensional (2D) silo have been conducted [3]. The image dataset of flowing particles was used to train the Convolutional Neural Networks of various architectures and to CNN-LSMT architecture specifically designed for time series analysis. The trained networks demonstrate considerable accuracy in clogging prediction.

This study is supported by DLR projects VICKI and EVA (50WM2252 and 50WM2048)

DY 46.7 Thu 13:00 P1

Optical reservoir computing with incoherent optical memory — •MINGWEI YANG[1,2], ELIZABETH ROBERTSON[1,2], LEON MESSNER[1,3], NORMAN VINCENZ EWALD[1], LUISA ESGUERRA[1,2], and JANIK WOLTERS[1,2] — [1]Deutsches Zentrum für Luft- und Raumfahrt, Institute of Optical Sensor Systems, Berlin, Germany. — [2]Technische Universität Berlin, Berlin, Germany. — [3]Humboldt-Universität zu Berlin, Berlin, Germany.

Reservoir computing is a machine learning method that is particularly suited for dynamic data processing. A fixed reservoir projects the input information to a high-dimensional feature space, and only the readout weights need to be trained, allowing fast data processing with low energy consumption [1,2]. In this work, we demonstrate an optical reservoir computing using incoherent memory in a cesium vapor cell to predict time-series data. The information is stored in the reservoir by controlling the pump and probe process on the Cs D2 transitions. The coupling between the reservoir and both the input and output data is realized by acousto-optic modulators.

Metadynamics Simulations of Chemical Reactions in Solution — •AZAD KIRSAN, SAGARMOY MANDAL, and BERND MEYER — Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg, Germany

For four important chemical reactions we have benchmarked two different method for reconstructing the free energy surface (FES) and for estimating the free energy barrier from *ab initio* molecular dynamics (AIMD) simulations: standard metadynamics (MTD) and the recently introduced well-sliced metadynamics (WS-MTD) approach [1], which is a combination of umbrella sampling and MTD. The chosen reactions are a Diels-Alder reaction, an aromatic decarboxylation, an aromatic Claisen rearrangement, and the base-catalyzed hydrolysis of formamide. This selection includes a cycloaddition, an elimination, an intermolecular rearrangement, and an OH^- addition, thus covering a wide range of different reaction types and mechanisms. By utilizing our recently improved version of the CPMD code [2] it was possible to obtain many ns long trajectories of the reactions in the gas phase as well as in an explicitly included solvent.

Analyzing Extreme Fluctuations of the Randomly Forced Nonlinear Schrödinger Equation via Large Deviation Theory — •SUMEJA BUREKOVIĆ[1], TOBIAS SCHÄFER[2], and RAINER GRAUER[1] — [1]Institute for Theoretical Physics I, Ruhr-University Bochum, Germany — [2]Department of Mathematics, College of Staten Island, Staten Island, United States of America

Recently, the focusing nonlinear Schrödinger equation with additive noise has been proposed as a model for finite-time singularity mediated turbulence [1]. Among other findings, the authors of [1] show through direct numerical simulations that the statistics of quantities such as the energy dissipation rate and structure functions are intermittent. Here, in order to explain these observations and to quantify the effect of extreme fluctuations on the turbulence statistics, we employ methods from large deviation theory or instanton calculus [2]. In the first step, the probability density function or expectation for the quantities of interest is approximated by the Freidlin-Wentzell action of the large deviation minimizer or instanton. Additionally, our aim is to improve this approximation by taking into account Gaussian fluctuations around the instanton, harnessing the techniques of [3].

DY 46.10 Thu 13:00 P1

Light propagation in media with electric and magnetic disorder: 3D Anderson localization — •WALTER SCHIRMACHER[1,2], THOMAS FRANOSCH[3], MARCO LEONETTI[1,4], and GIANCARLO RUOCCO[1,5] — [1]Istituto Italiano di Tecnologia, Roma, Italy — [2]Universität Mainz, Mainz, Germany — [3]Universität Innsbruck, Innsbruck, Austria — [4]SLML, Consiglio Nazionale delle Richerche, Roma, Italy — [5]Universita "La Sapienza", Roma Italy

We consider Maxwell's equations in a 3-dimensional material, in which both, the electric permittivity, as well as the magnetic permeability, fluctuate in space. Differently from all previous treatments, we transform the fields in such a way that the linear operator in the equations is manifestly Hermitian, in order to deal with a proper eigenvalue problem. We use an appropriate version of the Coherent-Potential approximation (CPA) to calculate the density of states and scattering-mean-free path. We find that in the presence of both electric and magnetic disorder the spectral range of Anderson localization appears to be much larger than in the case of electric (or magnetic) disorder only.

Imperfect Many-Body Localization in Exchange-Disordered Isotropic Spin Chains — •JULIAN SIEGL and JOHN SCHLIEMANN — University of Regensburg
We study many-body localization in isotropic Heisenberg spin chains with the local exchange parameters being subject to quenched disorder. The Hamiltonian is invariant under global SU(2)- rotations and incorporates therefore a non-abelian symmetry. Systems of common spin length 1/2 and 1 are studied numerically using random matrix techniques. In both cases we find a transition from an ergodic phase at small disorder strength to an incompletely localized phase at stronger disorder. The transition is signaled by a maximum of the sample-to-sample variance of the averaged consecutive-gap ratio. The incompletely localized phase found here is distinguished from a fully localized system by the scaling behavior of the sample-to-sample variance.

Magnetic Dipole Clusters - Resurrection of Catastrophe Machines — •INGO REHBERG and SIMEON VÖLKEL — Experimental Physics, University of Bayreuth
Hysteretic transitions between stable configurations of a hexagonal magnetic dipole cluster [1] are set in a broader context by revealing the nature of the corresponding instabilities [2]. Following the animation of this bifurcation scenario [3], we present an experimental setup where the height of the centre dipole serves as the bifurcation parameter. This catastrophe machine demonstrates the two instabilities forming the hysteresis loop, and it might provide a hint to the unresolved puzzle of the slowing down of one of the eigenmodes [4].

Signatures of the interplay between chaos and local criticality on the dynamics of scrambling in many-body systems — FELIX MEIER[1], •MATHIAS STEINHUBER[2], JUAN DIEGO URBINA[2], DANIEL WALTNER[1], and THOMAS GUHR[1] — [1]University of Duisburg-Essen, Lotharstr. 1, 47048 Duisburg, Germany — [2]University of Regensburg, Universitätsstr. 31, 93040 Regensburg, Germany
Fast scrambling, quantified by the exponential initial growth of Out-of-Time-Ordered-Correlators (OTOCs), is the ability to efficiently spread quantum correlations among the degrees of freedom of interacting systems, and constitutes a characteristic signature of local unstable dynamics. As such, it may equally manifest both in systems displaying chaos or even in integrable systems around criticality. We discuss the results from our recent publication [1], where we go beyond these two well-studied regimes with an exhaustive study of the interplay between local criticality and chaos. We address many-body systems with a well-defined classical (mean-field) limit, as coupled large spins and Bose-Hubbard chains, thus allowing for semiclassical analysis. Our aim is to investigate the dependence of the exponential growth of the OTOCs, defining the quantum Lyapunov exponent λ_q on quantities derived from the classical system with mixed phase space, specifically the local stability exponent of a fixed point λ_{loc} as well as the maximal Lyapunov exponent λ_L of the chaotic region around it.

Characterizing quantum chaoticity of kicked spin chains — •TABEA HERRMANN, MAXIMILIAN F. I. KIELER, and ARND BÄCKER — TU Dresden, Institut für Theoretische Physik, Dresden, Germany
Quantum many body systems are commonly considered as quantum chaotic if their spectral statistics, such as the level spacing distribution, agree with those of random matrix theory. Using the example of the kicked Ising chain we demonstrate that even if both level spacing distribution and eigenvector statistics agree well with random matrix predictions, the entanglement entropy deviates from the expected Page curve. We propose a new measure of the effective spin interactions and obtain the corresponding random matrix result. By this the deviations of the entanglement entropy can be understood.

DY 48.5   Thu 16:00   MOL 213

Entanglement Characterization of Measurement-Induced Phase Transition in Fermionic Chains — •JIANGTIAN YAO[1,2], SEBASTIAN DIEHL[1], and MICHAEL BUCHHOLD[1] — [1]Institute for Theoretical Physics, University of Cologne, D-50937 Cologne, Germany — [2]Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany
We report characterization of measurement-induced phase transition in Gaussian fermionic chains. We use various entanglement measures to characterize the two phases as well as the nature of the transition. Through a numerical study on the entanglement spectra, we observe closure of the entanglement gap in the

critical phase and relate the scaling of the closure to the effective central charge of the system. In addition, we numerically extract the effective Luttinger liquid parameter of the system and use it to characterize the critical phase. Lastly, we use the scaling behavior of the effective Luttinger liquid parameter as well as the Schmidt gap to estimate the critical point for the phase transition.

Dynamical characterization of the chaotic phase in the Bose-Hubbard model — DAVID PEÑA MURILLO and •ALBERTO RODRÍGUEZ — Departamento de Física Fundamental, Universidad de Salamanca, E-37008 Salamanca, Spain
We study the dynamical manifestation of the Bose-Hubbard model's chaotic phase [1] by analysing the temporal behaviour of connected two-point density correlations on experimentally accessible time scales up to a few hundred tunneling times. The time evolution of initial Mott states with unit density in systems including up to 17 bosons (Hilbert space dimension $\approx 10^9$) reveals that the chaotic phase can be unambiguously identified from the early time fluctuations of the considered observable around its equilibrium value [2]. The emergence of the chaotic phase is also seen to leave an imprint in the initial growth of the time signals. The possibility to discern specific features of this many-body chaotic phase, on top of the universal prediction of random-matrix theory, from these experimentally accessible measures is explored.

Universal Eigenvalue Distribution for Locally Interacting Quantum Systems — •TOBIAS HELBIG, TOBIAS HOFMANN, RONNY THOMALE, and MARTIN GREITER — Institut für Theoretische Physik und Astrophysik, Universität Würzburg, D-97074 Würzburg, Germany
Wigner has shown [1] that the eigenvalue distribution of a Gaussian orthogonal or unitary ensemble of random matrices approaches a semicircle in the thermodynamic limit. Here, we show that the joint eigenvalue distribution of locally interacting quantum systems, that is, ensembles of finite dimensional subsystems with local interactions between them, approaches a Gaussian distribution as the number of subsystems is taken to infinity [2]. In the talk, we present our analytical results supported by numerical data and discuss possible implications of a Gaussian density of states for physical problems.

DY 48.8   Thu 17:00   MOL 213

Power-law decay of correlations after a global quench in the massive XXZ chain — •FLÁVIA BRAGA RAMOS[1], ANDREW URICHUK[2,3], IMKE SCHNEIDER[1], and JESKO SIRKER[3] — [1]Fachbereich Physik and Research Center OPTIMAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany — [2]University of Manitoba, Winnipeg, Canada — [3]Bergische Universität Wuppertal, Wuppertal, Germany
While there have been great advances in understanding the final equilibration of integrable systems after a quantum quench, relatively little is known about their precise relaxation towards the steady state. In this context, the XXZ chain provides a playground for the investigation of interaction effects in out-of-equilibrium properties of quantum many-body systems. We investigate the relaxation dynamics of equal-time correlations in the antiferromagnetic phase of the XXZ spin-1/2 chain following a global quantum quench of the anisotropy parameter. In particular, we focus on the relaxation dynamics starting from an initial Néel state. Using the exact solution of an effective free-fermion model, state-of-art density matrix renormalization group simulations, and the quench-action approach, we show that the late-time relaxation is characterized by a power-law decay $\sim t^{-3/2}$ independent of anisotropy. Overall, we find remarkable agreement in the results obtained from the distinct approaches.

DY 48.9   Thu 17:15   MOL 213

Universal correlations in chaotic many-body quantum states: lifting Berry's Random Wave Model into Fock space — RÉMY DUBERTRAND[1], JUAN-DIEGO URBINA[2], KLAUS RICHTER[2], and •FLORIAN SCHÖPPL[2] — [1]Department of Mathematics, Physics and Electrical Engineering, Northumbria University, NE1 8ST Newcastle upon Tyne, United Kingdom — [2]Institut für Theoretische Physik, Universität Regensburg, 93040 Regensburg, Germany
Using a semiclassical analysis based on Berry's ansatz [1] we investigate the universal statistical features of eigenstate correlations in chaotic mesoscopic many-body quantum systems, focusing on Bose-Hubbard lattices, where the existence

of a classical (mean-field) limit allows for the use of many-body semiclassical methods [2]

For this, we first have to lift Berry's ansatz into the many-body space by expanding the microscopic correlations and the conjectured multivariant Gaussian distribution of expansion coefficients into the Fock space of quantum fields. Together with numerical evidence, which supports the extension to multi-point correlations of the known Gaussian distribution for a single expansion coeffi-

cient, the universality of eigenstate correlations can be extended well beyond random matrix theory, where these correlations are absent. Our results bring the correlation backbone of eigenfunctions into a precise signature of quantum chaos in many-body mesoscopic systems.

Metastate analysis for two-dimensional Ising spin glasses — •Alexander K. Hartmann[1] and A. Peter Young[2] — [1]University of Oldenburg, Germany — [2]University of California, Santa Cruz, USA
Spin glasses (SGs) are disordered magnetic systems which provide prototypical models for complex systems, including systems outside physics such as neural networks and machine-learning problems. For the two-dimensional (2d) case, exact numerical ground states (GSs) of large sizes can be obtained by polynomial-time graph-matching algorithms. Using these methods it was shown that 2d SGs exhibit a spin-glass ordered phase only at zero temperature, see e.g. [1]. Results from applying a modified version of the GS algorithm indicate that this phase is well described [2] by the so-called "droplet" theory, i.e., it has a simple structure. Here, we consider the *metastate* approach, which was introduced [3] to deal with the chaotic size-dependence of the spin-glass state. By studying a large range of sizes, we show convincingly that, in the thermodynamic limit, spin correlations in a local region are unaffected by the bonds far away, which is one of the main assumptions of the droplet picture.

On the criticality of structurally disordered magnets — Maxym Dudka[1,2], Mariana Krasnytska[1,2,3], Juan Ruiz-Lorenzo[4,5], and •Yurij Holovatch[1,2,6] — [1]ICMP, NAS of Ukraine, Lviv, Ukraine — [2]L4 Collaboration Leipzig-Lorraine-Lviv-Coventry, Europe — [3]Université de Lorraine, Nancy, France — [4]Universidad de Extremadura, Badajoz, Spain — [5]BIFI, Zaragoza, Spain — [6]Coventry University, Coventry, UK
We discuss the problem of influence of structural disorder on criticality. As a case study, we consider an impact of a weak quenched disorder on a magnetic phase transition. Usually, such an impact is analyzed for a two-component mixture (e.g. a solid solution of a magnet with its non-magnetic counterpart). A distinct feature of our analysis is consideration of changes in the magnetic phase transition when both components are magnets. To this end, we make use of a generalized Ising model suggested recently [M. Krasnytska et al., J.Phys.: Complexity 1 (2020) 035008] in a context of complex systems. We apply the field theoretical renormalization group approach to analyze its effective and asymptotic critical behaviour. We show that this is the structural disorder itself that causes changes in the universal critical behaviour, regardless of whether it has a form of a random mixture of magnetic and non-magnetic constituents or of two different magnetic compounds [M. Dudka et al., arXiv:2207.13655].

Non-Hermitian PT-symmetric Ising spin chains: novel quantum phases and quantum phase transitions — •Grigory Starkov, Mikhail Fistul, and Ilya Eremin — Ruhr-Universität Bochum, Bochum, Germany
A theoretical study of quantum phases and quantum phase transitions occurring in non-Hermitian PT-symmetric transverse-field Ising spin model. A non-Hermitian part of the Hamiltonian is implemented via imaginary staggered longitudinal magnetic field corresponding to a local staggered gain and loss terms, γ.

Using a numerical diagonalization of the Hamiltonian for spin chains of a finite size N accompanied by a scaling procedure for the coherence length ξ, a complete quantum phase diagram γ-J (J is an adjacent spins interaction strength) is established. We obtain two quantum phases for J < 0, i.e., PT-symmetry broken antiferromagnetic state and PT-symmetry preserved paramagnetic state, and the quantum phase transition line is the line of exception points. For J > 0 the PT-symmetry of the ground state is retained in a whole region of parameter space of J and γ, and a system shows two intriguing quantum phase transitions between ferromagnetic and paramagnetic states for a fixed parameter $\gamma > 1$.

The qualitative quantum phase diagram is derived in the frame- work of the Bethe-Peierls approximation that is in a good accord with numerically obtained results. The quantum phase diagram can be verified in the microwave transmission experiments allowing to identify the transitions between the first excited and the ground states.

Predictive percolation: assessing fire connectivity in California — Olivia Hemond[1], •Diego Rybski[1,2,3], Ariani C. Wartenberg[1,4], Katherine J. Siegel[5], and Van Butsic[1] — [1]Department of Environmental Science, Policy, and Management, University of California, Berkeley, Berkeley, CA, United States — [2]Potsdam Institute for Climate Impact Research - PIK, Member of Leibniz Association, P.O. Box 601203, 14412 Potsdam, Germany — [3]Complexity Science Hub Vienna, Josefstädterstrasse 39, A-1090 Vienna, Austria — [4]Leibniz Centre for Agricultural Landscape Research, Eberswalder Str. 84, 15374 Müncheberg, Germany — [5]Department of Ecology & Evolutionary Biology, University of Colorado, Boulder, CO, USA
Damages from wildfire are increasing globally. Analyzing historical California fire data from 1950-2019, we propose a new method to estimate the percolation threshold, which represents statewide connectivity of fire-affected habitats. We create grid realizations of burnt areas over various time spans, measure the critical distances, and explore analogies with continuum percolation to predict the percolation threshold. Fires within our study period trend towards but do not yet reach percolation. We calculate the percolation threshold to be 45.8% of the state?s burnable area. Assuming fire patterns similar to the past seventy years, it would take 146.5 years, starting from 1950, to reach percolation across California. Within time periods shorter than 146 years, wildfire-affected areas are fragmented.

Determination of the nearest-neighbor interaction strength in VO2 via fractal dimension analysis — •Jacob Holder, Daniel Kazenwadel, Peter Nielaba, and Peter Baum — Universität Konstanz, Konstanz, Deutschland
The Ising model is one of the simplest and well-established models to simulate phase transformations in complex materials. However, its most central constant, the interaction strength J between two nearest neighbors, is not directly related to any macroscopic material property and is therefore hard to obtain. Here we report how to obtain this basic constant by a fractal dimension analysis of measured domain structures. In the example of VO_2, a strongly correlated material with first-order metal-to-insulator transition close to room temperature, we obtain an interaction strength of 11 meV. In a two dimensional simplification, we find an effective value of 17 meV due to the reduced number of nearest neighbors. These results link the fundamental constants in the Ising model to measured quantities of bulk materials.

Global Speed Limit for Finite-Time Dynamical Phase Transition in Nonequilibrium Relaxation — •Kristian Blom and Aljaz Godec — Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany
The nearest-neighbor interacting Ising model is a paradigm for classical many-body physics. Recent works unraveled an intriguing finite-time dynamical phase transition in the thermal relaxation of a mean field Curie-Weiss Ising model. This phase transition reflects a sudden switch in the dynamics, and manifests as a cusp in the probability density of magnetization. Its existence in systems with a finite range of interaction, however, remained unclear.

Employing the Bethe-Guggenheim approximation, which is exact on Bethe lattices, we demonstrate the finite-time dynamical phase transition in nearest-neighbor Ising systems for arbitrary quenches, including those within the two-phase coexisting region. Strikingly, for any given initial condition we prove and explain the existence of non-trivial speed limits for the dynamical phase transition and the relaxation of magnetization, which are absent in the mean field setting. Pair correlations, which are neglected in mean field theory, and trivial in the Curie-Weiss model, account for kinetic constraints due to frustrated local configurations, that give rise to a global speed limit.

Our findings may be relevant for optimizing ultrafast optical-switching ferromagnetic materials.

DY 49.7 Thu 16:45 ZEU 160

Crossover in the phase-coexistence between models with discrete and continuous variables — •Florian Kischel, Nils Caci, and Stefan Wessel — RWTH Aachen University, Aachen, Germany

The relative weight of the distinct phases that coexist at a first-order phase transition in systems with discrete degrees of freedom is well understood. For example, in the q-state Potts model, it is characterized by a ratio $R = 1 : q$ of the disordered vs. ordered regions. In models with continuous variables on the other hand, this ratio is generally unknown. Several recent instances however suggest that it equals $R = 1 : I_O$, where I_O denotes the integral measure of the space of extremal states of the ordered phase. In order to explore the emergence of this integral measure, we examine a system that realizes a crossover from discrete to continuous variables and study the behavior of R at its phase-coexistence points. In particular, we consider a generalized n-state clock-model on a three-dimensional simple cubic lattice with both bilinear and biquadratic exchange interactions. In the large-n (XY) limit, this model is known to harbor a first-order thermal phase transition, as does the 3-state Potts model, to which the model reduces in the limit of $n = 3$. Here, we explore the phase-coexistence over the range of intermediate values of n using large-scale Monte Carlo simulations.

DY 49.8 Thu 17:00 ZEU 160

Partition function zeros in the 3D Blume-Capel model — •Leïla Moueddene — Laboratoire de Physique et Chimie Théoriques, Université de Lorraine, Vandoeuvre-lès-Nancy, France

The phase diagram of the three-dimensionnal Blume Capel model shows an ordered ferromagnetic phase and a disordered paramagnetic phase, separated by a transition line from second order to first order at the tricritical point (TCP). The universality class of the second-order line is the Ising class, while the tricritical universality class governs the behaviour of the critical exponents at the tricritical point. It is well known that the upper critical dimension is $d_{uc} = 3$ at the TCP, thus Mean Field exponents are expected, modified by logarithmic correction factor. We determine analytically the logarithmic-correction exponents - also universal - using RG for ϕ_6 model. The knowledge of the partition function zeros is a quite fundamental and powerful approach to study a phase transition. While the Fisher zeros and Lee-Yang zeros are well known to study the thermal exponent y_t and magnetic exponent y_h, we build a new type of zeros from the complex plane of the crystal field which leads to the crystal exponent y_2: the crystal field zeros. We study the leading and logarithmic-corrections exponents numerically from the partition function zeros and compare with the analytical results, and check if the scaling relations are verified.

DY 49.9 Thu 17:15 ZEU 160

Boundary critical behavior of the three-dimensional O(N) universality class — •Francesco Parisen Toldin[1] and Max A. Metlitski[2] — [1]Institut für Theoretische Physik und Astrophysik, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany — [2]Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

It was recently realized that the three-dimensional O(N) model exhibits an extraordinary surface universality class for a finite range of $N \geq 2$. We investigate the boundary critical behavior by means of high-precision Monte Carlo simulations of an improved model, where leading scaling corrections are suppressed. Contrary to simplified arguments on the bulk-surface phase diagram, and in line with a recent field-theoretical analysis, we find a special surface transition for $N = 3$, with unusual exponents, and an extraordinary phase with logarithmically decaying correlations. For a general N, the existence and universal properties of extraordinary phase are predicted to be controlled by certain amplitudes of the normal universality class, where one applies an explicit symmetry breaking field to the boundary. We extract these universal amplitudes by Monte Carlo simulations for $N = 2, 3$. Our results are in good agreement with direct Monte Carlo studies of the extraordinary universality class serving as a nontrivial quantitative check of the connection between the normal and extraordinary classes.

Critical phenomena in the two-dimensional dilute Baxter-Wu model — •Alexandros Vasilopoulos[1], Nikolaos G. Fytas[1], Michail Akritidis[1], and Martin Weigel[2] — [1]Centre for Fluid and Complex Systems, Coventry University, Coventry CV1 5FB, United Kingdom — [2]Institut für Physik, TU Chemnitz, 09107 Chemnitz, Germany

We study the question of universality in the two-dimensional spin-1 Baxter-Wu model in the presence of a crystal field Δ. We employ extensive numerical simulations consisting of various types, providing us with complementary results: Wang-Landau sampling at fixed values of Δ and a parallelized variant of the multicanonical approach performed at constant temperature T. A detailed finite-size scaling analysis in the regime of second-order phase transitions in the (Δ, T) phase diagram indicates that the transition belongs to the universality class of the four-state Potts model. Previous controversies with respect to the nature of the transition are discussed and attributed to the presence of strong finite-size effects, especially as one approaches the pentacritical point of the model. Lastly, to facilitate the study of $\Delta > 0$, where the two previous methods become increasingly inhibitory, a hybrid algorithm consisting of both a cluster and a single-spin-flip update was implemented and tested.

Spectral Response of Disorder-Free Localized Lattice Gauge Theories — •Nilotpal Chakraborty[1], Markus Heyl[1,2], Petr Karpov[1], and Roderich Moessner[1] — [1]Max Planck Institute for Physics of Complex Systems, Dresden — [2]University of Augsburg

We show that certain lattice gauge theories exhibiting disorder-free localization have a characteristic response in spatially averaged spectral functions: a few sharp peaks combined with vanishing response in the zero frequency limit. This reflects the discrete spectra of small clusters of kinetically active regions formed in such gauge theories when they fragment into spatially finite clusters in the localized phase due to the presence of static charges. We obtain the transverse component of the dynamic structure factor, which is probed by neutron scattering experiments, deep in this phase from a combination of analytical estimates and a numerical cluster expansion. We also show that local spectral functions of large finite clusters host discrete peaks whose positions agree with our analytical estimates. Further, information spreading, diagnosed by an unequal time commutator, halts due to real space fragmentation. Our results can be used to distinguish the disorder-free localized phase from conventional paramagnetic counterparts in those frustrated magnets which might realize such an emergent gauge theory.

DY 55.3 Fri 10:00 MOL 213

Chaos in the three-site Bose-Hubbard model - classical vs quantum — •Goran Nakerst[1] and Masudul Haque[1,2] — [1]Institut für Theoretische Physik, Technische Universität Dresden, D-01062 Dresden, Germany — [2]Max-Planck-Institut für Physik komplexer Systeme, D-01187 Dresden, Germany

We consider a quantum many-body system - the Bose-Hubbard system on three sites - which has a classical limit, and which is neither strongly chaotic nor integrable but rather shows a mixture of the two types of behavior. We compare quantum measures of chaos (eigenvalue statistics and eigenvector structure) in the quantum system, with classical measures of chaos (Lyapunov exponents) in the corresponding classical system. As a function of energy and interaction strength, we demonstrate a strong overall correspondence between the two cases. In contrast to both strongly chaotic and integrable systems, the largest Lyapunov exponent is shown to be a multi-valued function of energy.

DY 55.4 Fri 10:15 MOL 213

Many-Body Dwell-time and Density of States — •Georg Maier, Carolyn Echter, Juan-Diego Urbina, and Klaus Richter — Universität Regensburg, Regensburg, Germany

Many body systems with a large number of degrees of freedom are usually described by statistical physics on the theoretical side while experiments usually relay on scattering (e.g. particle physics). Is it possible to relate scattering and statistical physics, or to measure scattering-related observables which directly relate to quantities of statistical physics? At least for single particle systems a close relation exists between the well known Wigner-Smith delay time in scattering theory and the density of states of the scattering system.

I will present a novel ansatz relating a many-body version of dwell-/Wigner-Smith delay time and many body density of states based on the famous Birman-Krein-Friedel-Loyd formula connecting scattering theory and statistical observales in the many-body context. This formalism could provide answers to a wide variety of interesting questions, e.g. can we observe the effect of interactions (or even the emergence of chaos) through the lens of the dwell-time? Another interesting point is the roll of particle statistics on dwell-time meaning e.g. does it take longer for a particle to leave a fermionic or bosonic system?. I will present our analytical and numerical results on these questions.

DY 55.5 Fri 10:30 MOL 213

Dynamical correlations and domain wall relocalisation in transverse field Ising chains — •Philippe Suchsland[1], Benoît Douçot[2], Vedika Khemani[3], and Roderich Moessner[1] — [1]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Str. 38, 01187 Dresden, Germany — [2]LPTHE, UMR 7589, CNRS and Sorbonne Université, 75252 Paris Cedex 05, France — [3]Department of Physics, Stanford University, Stanford, California 94305, USA

We study order parameters and out-of-time-ordered correlators (OTOCs) for a wide variety of transverse field Ising chains: classical and quantum, clean and disordered, integrable and generic. The setting we consider is that of a quantum quench. We find a remarkably rich phenomenology, ranging from stable periodic to signals decaying with varying rates. This variety is due to a complex interplay of dynamical constraints (imposed by integrability and symmetry) which thermalisation is subject to. In particular, a process we term dynamical domain wall relocalisation provides a long-lived signal in the clean, integrable case, which can be degraded by the addition of disorder even without interactions. Our results shed light on a proposal to use an OTOC specifically as a local dynamical diagnostic of a quantum phase transition even when evaluated in a state with an energy density corresponding to the paramagnetic phase.

Time evolution at the quantum-critical point of the sawtooth chain — •Jannis Eckseler, Florian Johannesmann, and Jürgen Schnack — Fakultät für Physik, Universität Bielefeld, Postfach 100131, D-33501 Bielefeld, Germany

It is known for the antiferromagnetic sawtooth chain with Heisenberg interactions to develop a flat band at the quantum-critical point of $J_1 = 2J_2$, where J_1 is the exchange interaction between nearest neighbors and J_2 the interaction at the base of the triangles [1]. We investigate the time evolution of several observables of the sawtooth chain, especially near that point and in particular in view of their equilibration properties. [1] J. Schulenburg, A. Honecker, J. Schnack, J. Richter, H.-J. Schmidt, Phys. Rev. Lett. 88 (2002) 167207

DY 55.7 Fri 11:15 MOL 213

Quantum Noise as a Symmetry-Breaking Field — •Paul McClarty[1], Beatriz Dias[2], Domagoj Perkovic[3], Masudul Haque[4], and Pedro Ribeiro[5] — [1]MPI PKS, Dresden, Germany — [2]TU Munich, Garching, Germany — [3]Cavendish Lab, University of Cambridge, UK — [4]TU Dresden, Germany — [5]IST, Lisbon, Portugal

We investigate the effect of quantum noise on the measurement-induced quantum phase transition in monitored random quantum circuits. Using the efficient simulability of random Clifford circuits, we find that the transition is broadened into a crossover and that the phase diagram as a function of projective measurements and noise exhibits several distinct regimes. We show that a mapping to a classical statistical mechanics problem accounts for the main features of the random circuit phase diagram. The bulk noise maps to an explicit permutation symmetry breaking coupling; this symmetry is spontaneously broken when the noise is switched off. These results have implications for the realization of entanglement transitions in noisy quantum circuits.

DY 55.8 Fri 11:30 MOL 213

Finite-size prethermal behavior at the chaos-to-integrable transition — •Johannes Dieplinger[1] and Soumya Bera[2] — [1]Institute of Theoretical Physics, University of Regensburg, D-93040 Germany — [2]Department of Physics, Indian Institute of Technology Bombay, Mumbai 400076, India

We investigate the dynamics of the complex Sachdev-Ye-Kitaev model complemented with a single particle hopping term, leading to a chaos-to-integrable transition of the eigenstates. We determine the dynamics close to the transition via the density-density correlator, where we observe a prethermal plateau in the ergodic phase. This indicates a finite time localised behavior up to an interaction-dependent thermalization time scale. This time scale is quantified as $t_{th} \propto 2^{\alpha/\sqrt{\lambda}}$ as a function of the relative interaction strength λ. The results are validated by investigating the time-dependent structure of the time-evolved wave functions in the Fock space.

DY 55.9 Fri 11:45 MOL 213

Quasiparticle Description of Entanglement Growth — •Molly Gibbins, Bruno Bertini, and Adam Smith — University of Nottingham

The quasiparticle picture of entanglement is a novel way to describe a feature unique to quantum many-body systems. Recent research has found excellent agreement of this description with numeric results: a description that had been shown to hold for the general family of Rényi entanglement entropies, for different classes of quench and different geometries of the boundary across which entanglement develops.

The aim of this project is to develop a quasiparticle description of the entanglement growth in free-fermionic systems with translational invariance in both 1D and 2D. The propagation of quasiparticles across this cut will respect this translational invariance and it is expected that the entanglement generated between these particles will be in very good agreement with the exact solution for these systems.

Excitation Transport in Molecular Aggregates with Thermal Motion — •Ritesh Pant and Sebastian Wüster — Indian institute of science education and research, Bhopal, India

Molecular aggregates can under certain conditions transport electronic excitation energy over large distances due to the long range dipole-dipole interactions. These interactions are also the characteristics of Rydberg aggregates which have been proved as the quantum simulators for molecular aggregates. An idea that naturally arises in Rydberg aggregates, is adiabatic excitation transport through atomic motion, where slow motion of the atoms combined with excitation transport can result in efficient and guided transport of the excitation from one end of an atomic chain to the other. Based on the analogy between Rydberg and Molecular aggregates, in ref. [1] we explore whether the adiabatic excitation transport can play a functional role in molecular aggregates in the absence of intra-molecular vibrations. But because the transport is partially adiabatic and because it involves transitions between non-eigenstates, it is challenging to estimate the adiabaticity of transport in molecular aggregates. Hence, in ref [2] we established a measure to quantify the adiabatic character of quantum transitions in general. Next, the effect of intramolecular vibrations is included by extending our calculation for excitation transport to an open-quantum- system technique [3].

Tailoring the Phonon Environment of Embedded Rydberg Aggregates — •Sidharth Rammohan[1], Sebastian Wüster[1], and Alexander Eisfeld[2] — [1]IISER Bhopal, Madhya Pradesh, India — [2]MPIPKS, Dresden, Germany

State-of-the-art experiments can controllably create Rydberg atoms inside a Bose-Einstein condensate (BEC) such that the Rydberg electron orbital volume contains many neutral atoms, which can be tuned, resulting in electron-atom scattering events [1]. In my talk, I will discuss the physics of the interaction and corresponding dynamics of a single or multiple Rydberg atoms in two internal electronic states embedded inside a BEC, to assess their utility for controlled studies of decoherence and quantum simulations of excitation transport similar to photosynthetic light-harvesting. We initially developed a theoretical framework to calculate the open quantum system input parameters for a single Rydberg atom, possibly in two internal states, in BEC and then for a chain of Rydberg atoms, forming an aggregate [2]. The electron-atom interactions lead to Rydberg-BEC coupling, creating phonons in the BEC. Using the spin-boson model with the calculated parameters, we then examine the decoherence and the Non-Markovian features of a Rydberg atom in a superposition, resulting from the interaction with the environment [3]. The scenario with a single Rydberg atom is then extended to the aggregate case, allowing us to set up dynamics similar to those found in light-harvesting complexes. Ref:1. J. B. Balewski, et.al; Nature 502 664 (2013).2. S. Rammohan, et.al; PRA 103, 063307 (2021).3. S. Rammohan, et.al; PRA 104, L060202 (2021).

DY 56: Brownian Motion and Anomalous Diffusion

Time: Friday 9:30–12:45 Location: ZEU 160

DY 56.1 Fri 9:30 ZEU 160

Odd Diffusion of Interacting Particles — •Erik Kalz[1], Hidde Derk Vuijk[2], Iman Abdoli[2], Jens-Uwe Sommer[2,3], Hartmut Löwen[4], Ralf Metzler[1], and Abhinav Sharma[2,3] — [1]Universität Potsdam, Institut für Physik und Astronomie — [2]Leibniz-Institut für Polymerforschung Dresden, Institut Theorie der Polymere — [3]Technische Universität Dresden, Institut für Theoretische Physik — [4]Heinrich Heine-Universität Düsseldorf, Institut für Theoretische Physik II: Weiche Materie

It is generally believed that collisions of particles reduce the self-diffusion coefficient, closely related to autocorrelation functions, which are assumed to decay monotonously in the overdamped limit. We show that these beliefs are only limiting cases in odd-diffusive systems, which are characterized by diffusion tensors with antisymmetric offdiagonal elements. We show that in the dilute limit, particle interactions can reduce, unalter and even enhance the self-diffusion. The underlying particle dynamics thereby can be captured by the force autocorrelation function. We show that this autocorrelation function exhibits a variety of behaviour: (a) even in the dilute limit where collisions are rare, the correlation can become negative, (b) despite the overdamped dynamics, the force autocorrelation can exhibit temporal oscillations and (c) the long-time power-law decay of the force autocorrelation depends on the odd-diffusion parameter. Odd diffusivity, therefore, shines new light on fundamental beliefs in overdamped systems.

Kalz, Erik, et al. Collisions enhance self-diffusion in odd-diffusive systems. Physical Review Letters 129.9 (2022): 090601.

DY 56.2 Fri 9:45 ZEU 160

Bounding Uncertainty of Empirical First-Passage Times of Reversible Markov Processes — •Rick Bebon and Aljaz Godec — Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany

First-passage phenomena are ubiquitous in nature and are at the heart of, e.g. reaction kinetics, cell signaling, gene regulation, foraging behavior of animals, and stock option dynamics. Whereas theoretical studies typically focus on predicting statistics for a given process, practical applications often aim at inferring, e.g. mean first-passage times (i.e. inverse kinetic rates) from experimental or simulation data. The inference of mean first-passage times is challenging because only a small number of realizations is usually available, in turn leading to high uncertainties and non-Gaussian errors. We derive universal concentration inequalities for first-passage times of ergodic reversible Markov processes on discrete and continuous-state spaces. For a sample of $n \geq 1$ independent realizations of the first-passage process, we prove a Cramér-Chernoff-type bound on the probability that the inferred sample mean deviates from the true mean first-passage time by more than any given amount. We further construct reliable non-asymptotic estimation guarantees, such as confidence intervals valid for all sample sizes n. Our findings allow for a rigorous uncertainty quantification of inferred first-passage times and lay grounds for a systematic understanding of finite-sample effects avoiding asymptotic approximations or biases due to prior-distribution assumptions.

DY 56.3 Fri 10:00 ZEU 160

Single-trajectory spectral analysis as a criterion of anomalous diffusion — •Vittoria Sposini — University of Vienna, Austria

The departure of the spreading dynamics of diffusing particles from the traditional law of Brownian-motion is a signature feature of a large number of complex soft-matter and biological systems. This anomalous diffusion can emerge due to a variety of physical mechanisms, e.g., trapping interactions or the viscoelasticity of the environment. Demonstrating that a system exhibits normal- or anomalous-diffusion is highly desirable for a vast host of applications. In this talk I will present a criterion for anomalous-diffusion based on the method of power-spectral analysis of single trajectories. The robustness of this criterion is studied for trajectories of fractional-Brownian-motion, a ubiquitous stochastic process for the description of anomalous-diffusion, in the presence of two types of measurement errors. In particular, I will report results from various tests on surrogate data in absence or presence of additional positional noise demonstrating the efficacy of this method in practical contexts.

DY 56.4 Fri 10:15 ZEU 160

Apparent anomalous diffusion and non-Gaussian distributions in a simple mobile-immobile transport model with poissonian switching — •Timo J. Doerries[1], Aleksei V. Chechkin[1,2,3], and Ralf Metzler[1] — [1]Institute of Physics & Astronomy, University of Potsdam, Germany — [2]Faculty of Pure and Applied Mathematics, Hugo Steinhaus Center, Wrocław University of Science and Technology, Wrocław, Poland — [3]Akhiezer Institute for Theoretical Physics National Science Center "Kharkiv Institute of Physics and Technology", Kharkiv, Ukraine

We analyse mobile-immobile transport of particles that switch between mobile and immobile states with finite rates. Despite this seemingly simple assumption of Poissonian switching we unveil rich transport dynamics including significant transient anomalous diffusion and non-Gaussian displacement distributions. Our discussion is based on experimental parameters for tau proteins in neuronal cells, but the results obtained here are expected to be of relevance for a broad class of processes in complex systems. Concretely, we obtain that when the mean binding time is significantly longer than the mean mobile time, transient anomalous diffusion is observed at short and intermediate time scales, with a strong dependence on the fraction of initially mobile and immobile particles. We unveil a Laplace distribution of particle displacements at relevant intermediate time scales and the mean squared displacement of mobile tracers displays a plateau. Adding advection to the mobile phase, corresponding to a biosensor with flow, generates a cubic regime of the MSD for high Péclet numbers.

Invited Talk DY 56.5 Fri 10:30 ZEU 160

Transport and self-organization in living fluids — •Matthias Weiss — Experimental Physics I, University of Bayreuth, Bayreuth, Germany

Intracellular fluids, e.g. the eukaryotic cytoplasm, are crowded with a plethora of macromolecules, bearing similarities to semidilute polymer solutions. Since

many of the macromolecules are actively driven by ATP hydrolysis, these crowded living fluids are also equipped with genuine non-equilibrium properties. Using model systems from culture cells to extracts, we have explored fluctuation-driven transport and the self-organized formation of compartments in living fluids. As a result, we have observed via extensive single-particle tracking experiments that the generic mode of motion in the cytoplasm appears to be a driven, anti-persistent, and partially intermittent fractional Brownian motion process. On larger length scales, we have observed that a spontaneous, ATP-driven compartmentalization in cell extracts without priming template structures, features geometric properties and a dynamic coarse-graining like two-dimensional foams. Altogether, our experimental observations suggest that fluctuation-driven transport and self-organized space compartmentalization in living biofluids are well captured by few but robust physico-chemical principles.

Brownian solitons in periodic structures — •Alexander P. Antonov[1], Artem Ryabov[2], and Philipp Maass[1] — [1]Fachbereich Physik, Universität Osnabrück, Osnabrück, Germany — [2]Charles University, Faculty of Mathematics and Physics, Department of Macromolecular Physics, Prague, Czech Republic

Solitons are known in systems with inertia as waves propagating without dispersion due to nonlinear effects. We show that solitons can occur in the absence of inertia for fully overdamped Brownian dynamics of hard spheres in periodic potentials at high particle densities [1,2]. The solitons manifest themselves as periodic sequences of different particle assemblies moving even in the zero-noise limit, where transport of single particles is not possible. To uncover the hard sphere dynamics at zero noise, a new simulation technique has been developed that can be applied for arbitrary external force fields [3]. At low temperature, the solitons give rise to particle currents appearing in band-like structures around certain particle diameters. At high temperatures, currents occur for all particle diameters. The variation of the current magnitudes with particle diameter and driving force reflects the inherent soliton formation.

Large beam X-ray Photon Correlation Spectroscopy — •Fabian Westermeier, Nimmi Das A, Vijay Kartik, Zhe Ren, Wojciech Roseker, Rustam Rysov, Daniel Weschke, Han Xu, and Michael Sprung — Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

The Coherence Applications Beamline P10 at PETRA III is dedicated to coherent X-ray scattering experiments such as X-ray Photon Correlation Spectroscopy (XPCS) and Coherent Diffraction Imaging (CDI). In an XPCS experiment, either the speckle visibility or the temporal changes of a series of scattering patterns are used to measure the dynamics of a sample.

At beamline P10, two 12 m long experimental hutches (EH1 and EH2) house various experimental setups. Among them, two setups are optimized to perform XPCS experiments. One of them is a SAXS/WAXS instrument, where the detector can be translated between 0° and 30° at a sample to detector distance of 5 m. This setup also offers the possibility to use a range of different focal sizes to adjust to the needs of the experiment. The other configuration is an ultra-small angle X-ray scattering (USAXS) setup, where the detector is positioned at a sample to detector distance of around 21 m. This long pathway allows it to use a large fraction of the coherent flux in an unfocused X-ray beam, while providing a fairly strong speckle visibility. Exemplary experimental results obtained at both setups will be shown illustrating the possibilities of XPCS at the beamline.

DY 56.8 Fri 11:45 ZEU 160

Dynamic finite size correction reveals the long-time hydrodynamic tail of liquid water from molecular dynamics simulations — •Laura Scalfi, Domenico Vitali, and Roland R. Netz — Fachbereich Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany

Finite-size effects in molecular dynamics simulations with periodic boundary conditions have significant effects on computed static and dynamic properties. We study the effect of periodic boundary conditions on the friction memory function and on velocity autocorrelation functions of a particle in a liquid using hydrodynamic theory and molecular dynamics simulations. We show that

for liquid water, the long-time decay of these functions is significantly affected by hydrodynamic finite-size effects so that the long-time power law tails are not visible for standard simulation box sizes. We develop an analytical correction scheme that corrects for hydrodynamic finite-size effects. Using this correction scheme, the long-time power-law tails of the friction memory and the velocity autocorrelation functions are clearly revealed even for relatively small simulation box sizes. Our developed method generally allows the accurate determination of the long-time behavior of time-dependent response functions from molecular dynamics simulations.

DY 56.9 Fri 12:00 ZEU 160

Fractional anomalous diffusion and Non-Darcian flow in geological system — •Qing Wei — Institute for Physics and Astronomy, University of Potsdam, 14476 Potsdam-Golm,Germany

With the non-Darcian flow and anomalous diffusion in low-permeability porous media as research subjects, the analytical models of non-Darcian flow as well as diffusive transport in low-permeability porous media was in- vestigated by invoking the fractional calculus theory. Using the fractional derivatives with different kernel, fractional diffusion models are proposed to describe radionuclide anomalous transport in geological repository sys- tems. On the basis of Darcy*s law, the memory effectiveness deduced by solid-fluid interaction is depicted by fractional derivative approach, and a fractional Swartzendruber model is proposed for the description of low velocity non-Darcian flow in porous media.

DY 56.10 Fri 12:15 ZEU 160

Universal hyper-scaling relations, power-law tails, and data analysis for strong anomalous diffusion — •Jürgen Vollmer[1], Lamberto Rondoni[2], Claudio Giberti[3], and Carlos Mejía-Monasterio[4] — [1]Inst. Theor. Physik, Univ. Leipzig, 04103 Leipzig, Germany — [2]Dept. Math. Sc., Politecnico di Torino, 10129 Torino, Italy — [3]Dept. Scienze e Metodi dell Ingegneria, Univ. Modena e Reggio E., 42100 Reggio E., Italy — [4]School of Agric. Food and Biosys. Eng., Techn. Univ. Madrid, 28040 Madrid, Spain

Strong anomalous diffusion is often characterized by a piecewise-linear spectrum of the moments of displacement. The spectrum is characterized by slopes ξ and ζ for small and large moments, respectively, and by the critical moment α of the crossover. Higher moments are asymptotically dominated by ballistic excursions; lower moments correspond to weak anomalous diffusion. We argue that ξ and ζ characterize the asymptotic scaling of the bulk and the tails of the distribution, respectively. Asymptotic theory is adopted to match the behaviors at intermediate scales. The resulting constraint entails that strong anomalous diffusion emerges if the distribution has algebraic tails, and it relates α to the corresponding power law. Our theory provides the leading-order corrections to the asymptotic power-law behavior. This insight allows us to point out sources of (at times) severe systematic errors in numerical estimates of the moments of displacement. Rather than fitting exponents we devise a robust scheme to determine ξ, ζ and α. The findings are supported by numerical and analytical results on different models exhibiting strong anomalous diffusion.

DY 56.11 Fri 12:30 ZEU 160

Bio-hybrid colloidal transport of beads on cell monolayers — Lara Bort, Setareh Sharifi Panah, •Robert Grossmann, and Carsten Beta — Institute of Physics and Astronomy, University of Potsdam, Potsdam, Germany

The erratic motion of Brownian particles at the mesoscale, driven by collisions with the surrounding fluid particles, is the paradigm of random colloidal transport within a passive environment. In this work, we describe the transport of polystyrene micro-beads whose motion is driven by a monolayer of motile cells. We use cells of the social amoeba *Dictyostelium discoideum*, which is a widely used model organism for actin-driven motility of adherent eukaryotic cells, including neutrophils and cancer cells. Given the non-specific adhesion of our model organism, the binding of such micro-cargo to the cell membrane does not require any surface-functionalization – the physical link between cargo and carrier is established spontaneously. As a particle gets in contact with a cell, it adheres to the cell membrane and is then subjected to active forces exerted by cells. The dynamics of micro-beads reveals linear scaling of the ensemble-averaged mean-square displacement and, notably, non-Gaussian displacement distributions. We rationalize these findings by assuming that each colloidal particle effectively performs normal Brownian motion, but the diffusion coefficients vary within the ensemble due to cell-to-cell variability. This superstatistics allows to reproduce the statistical features of the long-time dynamics of colloids, subject to the active cellular forces. It serves as a first step to better understand the targeted transport of foreign objects in dense tissues.

DY 57: Networks: From Topology to Dynamics IV (joint session DY/SOE)

Time: Friday 9:30–11:45 Location: ZEU 250

DY 57.1 Fri 9:30 ZEU 250

Efficient integration of short-range models on complex networks — •Jeffrey Kelling[1,2], Géza Ódor[3], Lilla Barancsuk[3], Shengfeng Deng[3], Bálint Hartmann[3], and Sibylle Gemming[2] — [1]Chemnitz University of Technology, Chemnitz, Germany — [2]Helmholtz-Zentrum Dresden - Rossendorf, Dresden, Germany — [3]Centre for Energy Research, Budapest, Hunguary

Complex, hierarchical or random network topolgies can give rise to unique behavior in many physical models. We study dynamical synchronization behavior in Kuramoto models on power grids and brain connectomes with millons of connections and $\mathcal{O}(100k)$ nodes. At these scales it is crucial to use the sparsity when computing derivatives, which, due to the random network structure, makes employing modern parallel hardware tricky. Here, we present our approach to numerically solving large systems ordinary differential equations on random directed graphs, where we focus on the computationally expensive task of computing derivatives and leave the common integration step to the `boost::odeint` library. Our application can utilize both parallel CPUs and GPUs. We also provide an overview of our results on human and fly brain connectomes as well as failure cascades in power grids and provide a measure of the advantage gained from our computational optimization efforts.

DY 57.2 Fri 9:45 ZEU 250

Discovering hidden layers in quantum graphs — Łukasz Gajewski, •Julian Sienkiewicz, and Janusz Hołyst — Faculty of Physics, Warsaw University of Technology, Warsaw, Poland

Finding hidden layers in complex networks is an important and nontrivial problem in modern science. We explore the framework of quantum graphs to determine whether concealed parts of a multilayer system exist and, if so, their extent, i.e., how many unknown layers are there. Assuming that the only information available is the time evolution of wave propagation on a single layer of a network, it is indeed possible to uncover that which is hidden by merely observing the dynamics. We present evidence on both synthetic and real-world networks that the frequency spectrum of the wave dynamics can express distinct features in the form of additional frequency peaks. These peaks exhibit dependence on the number of layers taking part in the propagation and thus allowing for the extraction of said number. We show that, in fact, with sufficient observation time, one can fully reconstruct the row-normalized adjacency matrix spectrum. We compare our propositions to a machine learning approach using a wave packet signature method modified for the purposes of multilayer systems.

DY 57.3 Fri 10:00 ZEU 250

Dynamic network modelling of tumor disease and sepsis — •Eckehard Schöll[1,2,3], Jakub Sawicki[1,2], Rico Berner[1,4], Fenja Drauschke[1], Moritz Alkofer[1], Eckhardt Schneider[5], and Thomas Löser[5] — [1]Institut für Theoretische Physik, TU Berlin — [2]Potsdam Institute for Climate Impact Research — [3]Bernstein Center for Computational Neuroscience Berlin — [4]Institut für Physik, HU Berlin — [5]Institut LOESER, Wettiner Straße 6, 04105 Leipzig

We introduce a novel functional model for tumor disease and sepsis within the framework of complex networks [1,2]. Both diseases are treated in a unified way centered on their effect on the innate immune system. We propose an adaptively coupled two-layer network model of phase oscillators based upon the interaction of parenchymal cells (organ tissue) and immune cells, respectively, and the co-evolutional dynamics of parenchymal, immune cells, and cytokines. The interaction and information exchange via cytokines between the cells of the parenchyma and the innate immune system is modeled by adaptive coupling weights. The emergent complex collective dynamics is represented with a few fundamental control parameters. Concepts and methods of nonlinear dynamical systems and networks theory, such as partial synchronization and clustering, as well as numerical and statistical methods are applied to describe physiological and pathological states. [1] Sawicki, J., Berner, R., Löser, T., and Schöll, E., Front. Netw. Physiol. 1, 730385 (2022). [2] Berner, R., Sawicki, J., Thiele, M., Löser, T. and Schöll, E., Front. Netw. DY 57.4 Fri 10:15 ZEU 250

Automated chemical reaction network discovery for the simulation of long-timescale degradation of materials — •Joe Gilkes[1], Mark Storr[2], Reinhard J. Maurer[1], and Scott Habershon[1] — [1]University of Warwick, United Kingdom — [2]AWE plc, United Kingdom

Degradation of organic materials such as polymers occurs over time scales of years and involves rare reaction events over an expansive network of elementary processes. Building such networks in order to predict the degradation pathways of these materials requires tackling combinatorially large chemical spaces, and propagating these networks in time becomes considerably more difficult as network size increases. Predicting overall rates by which materials break down requires accurate calculations of the energetic barriers of thousands of elementary reaction steps, which also comes with a substantial computational cost. We

present a software framework written in the Julia language for automatically traversing chemical reaction space with an approach that iteratively expands the reaction network through successive re-evaluation of degradation products. We couple this with a machine learning model to predict activation energies. The result is a workflow that can swiftly sample reaction space to create computationally efficient molecular breakdown networks, and then run simulations to predict the long-term stability of these species under a range of environmental conditions. We demonstrate this approach for the example of polyethylene degradation.

Exact statistical mechanics of spin models on networks — •Konstantin Klemm — IFISC (CSIC-UIB), Mallorca, Spain

Biological, social, and technical systems are modeled as discrete entities interacting through a network. Predicting these systems' behaviour thus involves the computationally difficult task of solving dynamics on a given complex network. Although networks of interest typically have an abundance of short cycles influencing dynamics, existing computational methods build on the assumption that short cycles are small structural corrections, thus making a *locally tree-like* approximation. Here we show that exact and efficient prediction, exemplified by the Ising and spin glass models, is possible for many networks. We exploit *globally tree-like* structure in the sense of small tree-width. The full manuscript is available at https://arxiv.org/abs/2111.04766 .

DY 57.6 Fri 11:00 ZEU 250

Network meta-analysis: A statistical physics perpective — Annabel L. Davies[1] and •Tobias Galla[2] — [1]Bristol Medical School, University of Bristol, Bristol BS8 2PS, UK — [2]IFISC, Instituto de Física Interdisciplinar y Sistemas Complejos (CSIC-UIB), Campus Universitat de les Illes Balears, 07122 Palma de Mallorca, Spain

Network meta-analysis (NMA) is a technique used in medical statis- tics to combine evidence from multiple medical trials. In particular it allows one to compare treatments that have not been tested directly against each other in a trial. NMA defines an inference and information processing problem on a network of treatment options and trials connecting the treatments. In this talk I will briefly outline the 'NMA problem', and I will then describe how statistical physics can offer useful ideas and tools for this area, including from the theory of complex networks, stochastic modelling and simulation techniques [1]. In particular I will present an analogy we recently established between NMA and random walks on networks [2], and which improves existing algorithms for the estimation of 'proportion contributions' – that is the importance of any one element in the network for the comparison of any two given treatment options. One main aim of the talk is to attract physicists to this timely, interesting and worthwhile area of research.

Controlling the coarsening dynamics of ferrogranular networks by means of a vertical magnetic field — •Oksana Bilous[1], Pedro Sánchez[1], Matthias Biersack[2], Ali Lakkis[2], Reinhard Richter[2], and Sofia Kantorovich[1] — [1]University of Vienna — [2]University of Bayreuth

In nature, phase transitions of various nature are significant and often lead to abrupt changes in the macroscopic properties of the material. Here, we address the question if a viscoelastic phase separation (VPS), proposed in 2000 by Hajime Tanaka for dynamically asymmetric mixtures, scales up for a shaken mixture of steel and glass spheres, i.e. for a so-called ferrogranulate when an external magnetic field is applied perpendicular to the plane in which the system is confined. In this contribution we focus on computer simulation. We calculated magnetization, dipolar and steric energies, radial distribution functions, the average number of neighbours and the efficiency of the emerging networks as functions of the simulation time and the values of the external vertical magnetic fields. Our results demonstrate that the network formation can be inhibited by the field perpendicular to the sample via dipole-dipole repulsion the field. These results are qualitatively confirmed by the experimental data.

Overview of Invited Talks and Sessions
(Lecture halls POT 6, POT 81, POT 112, POT 151, POT 251, and POT 361; Poster P1 and P2/EG)

Plenary Talks of the Semiconductor Physics Division

PLV I	Mon	8:30– 9:15	HSZ 01	**Spin-Photon Interfaces and Their Applications** — •Mete Atatuere
PLV VIII	Thu	8:30– 9:15	HSZ 01	**Nanomechanics: Tunes of the nanoguitar** — •Eva Weig
PLV IX	Thu	14:00–14:45	HSZ 01	**Metal Halide Perovskites for Photovoltaic Applications** — •Laura Herz

Invited Talks

HL 3.1	Mon	9:30–10:00	POT 151	**Schrödinger cat states of a 16-microgram mechanical oscillator** — •Yiwen Chu, Marius Bild, Matteo Fadel, Yu Yang, Uwe von Lüpke, Phillip Martin, Alessandro Bruno
HL 3.2	Mon	10:00–10:30	POT 151	**High-fidelity quantum information processing with spins and phonons** — •Peter Rabl
HL 3.5	Mon	11:30–12:00	POT 151	**Control of spin centers in silicon carbide using acoustic fields** — •Alberto Hernández-Mínguez
HL 8.9	Mon	17:30–18:00	POT 81	**Time-resolved optical spectroscopy of 3R-stacked MoS$_2$** — •Swarup Deb, Michael Kempf, Rico Schwartz, Tobias Korn
HL 9.1	Mon	15:00–15:30	POT 361	**Spin and valley lifetime in graphene quantum dots** — •Guido Burkard
HL 9.2	Mon	15:30–16:00	POT 361	**Microscopic modelling of electrostatically induced bilayer graphene quantum dots** — •Angelika Knothe
HL 9.4	Mon	16:45–17:15	POT 361	**Single-shot spin and valley Pauli blockade read-out in bilayer graphene quantum dots** — •Chuyao Tong, Rebekka Garreis, Wister Wei Huang, Annika Kurzmann, Jocelyn Terle, Samuel Jele, Kenji Watanabe, Takashi Taniguchi, Thomas Ihn, Klaus Ensslin
HL 9.5	Mon	17:15–17:45	POT 361	**Particle-hole symmetry protects spin-valley blockade in graphene quantum dots** — •Christian Volk, Luca Banszerus, Samuel Möller, Katrin Hecker, Eike Icking, Kenji Watanabe, Takashi Taniguchi, Fabian Hassler, Christoph Stampfer
HL 10.1	Mon	15:00–15:30	POT 151	**Surface Acoustic Wave Cavity Optomechanics with 2D Materials** — •Galan Moody
HL 10.2	Mon	15:30–16:00	POT 151	**Phononic Microresonators Coupled by Surface Acoustic Waves** — •Sarah Benchabane, Maciej Baranski, Feng Gao, Olivier Gaiffe, Valérie Soumann, Roland Salut, Abdelkrim Khelif
HL 23.1	Wed	9:30–10:00	POT 361	**Vertical-cavity surface-emitting lasers – this is the way** — •Å. Haglund, G. Cardinali, L. Persson, F. Hjort, J. Enslin, E. Torres, C. Kuhn, S. Graupeter, M. Grigoletto, M. A. Bergmann, N. Prokop, M. Guttmann, L. Sulmoni, N. Lobo Ploch, M. Cobet, T. Kolbe, J. Gustavsson, F. Nippert, I. Häusler, M. R. Wagner, J. Ciers, T. Wernicke, M. Kneisl
HL 23.2	Wed	10:00–10:30	POT 361	**Towards GaN-based diode lasers with narrow linewidth and high reliability** — •Sven Einfeldt, Erik Freier, Ji-Hye Kang, Hans Wenzel, Anna Mogilatenko, Johannes Glaab, Asmaa Abou-Shewarib, Veit Hoffmann, Johannes Enslin, Martin Guttmann, Saad Makhladi, Jörg Fricke, Olaf Brox, Mathias Matalla, Maria Norman-Reiner, Christoph Stölmacker, Markus Weyers, Luca Sulmoni, Michael Kneissl, Lukas Uhlig, Ulrich T. Schwarz

HL 23.3	Wed	10:30–11:00	POT 361	**Use of wafer patterning for new functionalities of InGaN light emitters** — •Anna Kafar, Ryota Ishii, Atsushi Sakaki, Kiran Saba, Conny Becht, Szymon Grzanka, Ulrich Schwarz, Mitsuru Funato, Yoichi Kawakami, Piotr Perlin
HL 25.1	Wed	9:30–10:00	POT 251	**Interfaces in perovskite optoelectronics: role of energy level alignment and interface chemistry** — •Selina Olthof
HL 27.1	Wed	15:00–15:30	POT 81	**experimentamus! Forschendes Lernen von Physik und Chemie in der Grundschule** — •Sebastian Schlücker
HL 27.4	Wed	16:00–16:30	POT 81	**Under the Microscope – spotlighting materials and nano science** — •Svenja Lohmann, Pranoti Kshirsagar
HL 27.5	Wed	17:00–17:30	POT 81	**Phyphox – A pocketful of physics** — •Christoph Stampfer
HL 27.8	Wed	18:00–18:30	POT 81	**Physics for school and the public at the LMU** — •Dr. Cecilia Scorza-Lesch
HL 28.1	Wed	15:00–15:30	POT 361	**Fabrication of AlGaN-based UV-B laser diodes on lattice-relaxed high-quality AlGaN** — •Motoaki Iwaya, Sho Iwayama, Tetsuya Takeuchi, Satoshi Kamiyama, Hideto Miyake
HL 28.2	Wed	15:30–16:00	POT 361	**Breakthrough technologies to realize room-temperature continuous-wave deep-ultraviolet laser diodes** — •Maki Kushimoto
HL 35.1	Thu	9:30–10:00	POT 361	**Quantum Dynamics of Polarons in Doped Semiconductor Monolayers** — •Xiaoqin Elaine Li, Di Huang
HL 35.2	Thu	10:00–10:30	POT 361	**Impact of phonons on time-resolved optical signals from excitons** — •Doris E. Reiter
HL 35.3	Thu	10:30–11:00	POT 361	**Hot-Exciton Quantum Dynamics in Zero-Dimensional Structures** — •Alfred Leitenstorfer
HL 35.6	Thu	12:00–12:30	POT 361	**Ultrafast dynamics and wave mixing at excitonic resonances in atomically thin semiconductors** — •Andreas Knorr, Dominik Christiansen, Florian Katsch, Manuel Katzer, Malte Selig
HL 35.7	Thu	12:30–13:00	POT 361	**Spontaneous parametric down-conversion in semiconductor metasurfaces** — •Maria Chekhova
HL 43.1	Thu	15:00–15:30	POT 251	**Superradiance as a witness to multipartite entanglement** — •Frederik Lohof, Christopher Gies

Invited Talks of the joint Symposium SKM Dissertation Prize 2023 (SYSD)
See SYSD for the full program of the symposium.

SYSD 1.1	Mon	9:30–10:00	HSZ 04	**Diffusion of antibodies in solution: from individual proteins to phase separation domains** — •Anita Girelli
SYSD 1.2	Mon	10:00–10:30	HSZ 04	**Intermediate Filament Mechanics Across Scales** — •Anna V. Schepers
SYSD 1.3	Mon	10:30–11:00	HSZ 04	**Ultrafast Probing and Coherent Vibrational Control of a Surface Structural Phase Transition** — •Jan Gerrit Horstmann
SYSD 1.4	Mon	11:00–11:30	HSZ 04	**Electro-active metasurfaces employing metal-to-insulator phase transitions** — •Julian Karst
SYSD 1.5	Mon	11:30–12:00	HSZ 04	**The role of unconventional symmetries in the dynamics of many-body systems** — •Pablo Sala

Invited Talks of the joint Symposium Real-Time Measurements of Quantum Dynamics (SYQD)
See SYQD for the full program of the symposium.

SYQD 1.1	Thu	9:30–10:00	HSZ 01	**Real-time measurement and control of spin dynamics in quantum dots** — •Seigo Tarucha
SYQD 1.2	Thu	10:00–10:30	HSZ 01	**Quantum Dot arrays for Quantum Information Transfer** — •Gloria Platero, David Fernandez-Fernandez, Juan Zurita
SYQD 1.3	Thu	10:30–11:00	HSZ 01	**Optical Detection of Real-Time Quantum Dynamics in Quantum Dots** — •Martin Geller, Jens Kerski, Eric Kleinherbers, Jürgen König, Annika Kurzmann, Pia Lochner, Axel Lorke, Arne Ludwig, Hendrik Mannel, Philipp Stegmann, Andreas Wieck, Marcel Zöllner
SYQD 1.4	Thu	11:30–12:00	HSZ 01	**Cooper Pair Splitting in Real-Time** — •Christian Flindt
SYQD 1.5	Thu	12:00–12:30	HSZ 01	**Trajectory-based detection in stochastic and quantum thermodynamics** — •Jukka Pekola

Invited Talks of the joint Symposium Physics of van der Waals 2D Heterostructures (SYHS)

See SYHS for the full program of the symposium.

SYHS 1.1	Fri	9:30–10:00	HSZ 01	**Novel moiré excitons and ultrafast optical dynamics in van der Waals 2D heterostructures** — •Steven G. Louie
SYHS 1.2	Fri	10:00–10:30	HSZ 01	**Interaction induced magnetism in 2D semiconductor moiré superlattices** — •Xiaodong Xu
SYHS 1.3	Fri	10:30–11:00	HSZ 01	**Ions in tight places: intercalation and transport of ions in van der Waals heterostructures** — •Irina Grigorieva
SYHS 1.4	Fri	11:15–11:45	HSZ 01	**Spin-orbit proximity in van der Waals heterostructures** — •Felix Casanova
SYHS 1.5	Fri	11:45–12:15	HSZ 01	**Plethora of many-body ground states in magic angle twisted bilayer graphene** — •Dmitri Efetov

Sessions

HL 1.1–1.10	Mon	9:30–12:30	POT 81	**2D Materials I (joint session HL/CPP)**
HL 2.1–2.6	Mon	9:30–11:15	POT 361	**Organic Semiconductors (joint session HL/CPP)**

HL 1: 2D Materials I (joint session HL/CPP)

Time: Monday 9:30–12:30   Location: POT 81

HL 1.1   Mon 9:30   POT 81

Spin-valley physics in strained transition metal dichalcogenides monolayers — •Paulo E. Faria Junior[1], Klaus Zollner[1], Tomasz Woźniak[2], Marcin Kurpas[3], Martin Gmitra[4], and Jaroslav Fabian[1] — [1]University of Regensburg, Regensburg, Germany — [2]Wroclaw University of Science and Technology, Wroclaw, Poland — [3]University of Silesia, Chorzów, Poland — [4]Pavol Jozef Šafárik University in Košice, Košice, Slovakia

Transition metal dichalcogenides (TMDCs) are ideal candidates to explore the manifestation of spin-valley physics under external stimuli. Here, we investigate the influence of strain on the spin, orbital angular momenta and g-factors of monolayer TMDCs within first principles[1]. Our calculations reveal the behavior of direct exciton g-factors under the isolated impact of strain: tensile (compressive) strain increases (decreases) the absolute value of g-factors. Strain variations of 1% modify the bright (A and B) exciton g-factors by 0.3 (0.2) for W (Mo) based compounds and the dark exciton g-factors by 0.5 (0.3) for W (Mo) compounds, suggesting that strain can be responsible for g-factor fluctuations observed experimentally. We complete our analysis for the Gamma and Q valleys, revealing that the spin degree of freedom dominates. This fundamental microscopic insight into the role of strain in the spin-valley physics of TMDCs is crucial to understand recent experiments[2,3]. [1] Faria Junior et al., NJP 24, 083004 (2022). HL 1.2   Mon 9:45   POT 81

A bright single-photon source based on a WSe$_2$ monolayer in an open cavity — •Victor Mitryakhin[1], Hangyong Shan[1], Jens-Christian Drawer[1], Sven Stephan[1], Martin Silies[2], Falk Eilenberger[3], Carlos Antón-Solanas[1], Martin Esmann[1], and Christian Schneider[1] — [1]Carl von Ossietzky Universität Oldenburg, 26129 Oldenburg, Germany — [2]Hochschule Emden/Leer, 26723 Emden, Germany — [3]Friedrich-Schiller-Universität Jena, 07745 Jena, Germany

Single photon sources based on crystalline defects present in transition-metal dichalcogenide monolayers, 2D atomically thin direct-bandgap semiconductors, have recently emerged as a promising platform for realization of and use in quantum communication and information processing.

In this work, we investigate the properties of single photon emission from a single exciton in a WSe$_2$ monolayer weakly coupled to an asymmetric plano-concave microcavity consisting of freely movable mirrors in 3 directions. In this regard, it enables us for an in-situ control of the properties of the emission and the extraction efficiency of single photons in the device.

We report a highly bright and linearly polarized single photon source with source brightness exceeding 70 % under saturation conditions, polarization degree of 98.4±1.3 % and high photon purity noted by the second-order correlation $g^{(2)}(0)$ value of 0.047±0.007, measured in Hanbury-Brown-Twist type of a setup.

HL 1.3   Mon 10:00   POT 81

Strong coupling of excitons in a WS2-monolayer coupled to a silver nanogroove array — •Yuhao Zhang[1], Hans-Joachim Schill[1,2], Stephan Irsen[2], and Stefan Linden[1] — [1]Physikalisches Institut, Universität Bonn — [2]Center of Advanced European Studies and Research (caesar)

In this work, we report on room-temperature interaction of a WS2 monolayer with a tapered nanogroove array milled into monocrystalline silver flake. The bare nanogroove array features three polariton branches resulting from the coupling of localized surface plasmon modes (LSPR) in the nanogrooves and propagation surface plasmon modes (SPP). The linewidth of the lower plasmon polariton branch critically depends on the geometry of the nanogrooves. When a WS2 monolayer is deposited on the nanogroove array with optimized damping, the reflection spectra show an avoided crossing of the exciton mode and the lower plasmon polariton branch with a Rabi splitting of 38.7 meV indicating strong exciton-plasmon polariton coupling.

HL 1.4   Mon 10:15   POT 81

Theory of exciton localization in TMDCs using metal nanoparticles — •Robert Salzwedel[1], Lara Greten[1], Stefan Schmidt[1], Chelsea Carlson[2], Stephen Hughes[2], Malte Selig[1], and Andreas Knorr[1] — [1]Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Berlin, Germany — [2]Department of Physics, Queen's University, Kingston, Ontario, Canada

In recent years, monolayers of transition metal dichalcogenides (TMDCs) have attracted considerable attention due to their strong Coulomb and light-matter interactions, leading to tightly bound excitons with large optical oscillator strength. Due to the finite thickness of the monolayers, these excitons are very sensitive to the environment, which allows their properties to be tailored, e.g., by functionalization with molecules or metal nanoparticles (MNPs) [1,2].

We present a theory based on a self-consistent solution of Maxwell's and Bloch equations to analytically study a coupled system of MNP plasmons and TMDC excitons. For the combined system, we identify an effective eigenvalue equation that governs the center of mass motion of the dressed excitons in a plasmon-induced potential. Examination of the ensuing plexcitonic equation reveals the existence of bound states, which we interpret as excitons localized in the external potential. The appearance of these bound states in this potential is an indicator of strong coupling between excitons and plasmons.

HL 1.5   Mon 10:45   POT 81

Electronic effects of non-uniformly strained 2D TMDCs — •Mohammadreza Daqiqshirazi and Thomas Brumme — Chair of Theoretical Chemistry, Technische Universität Dresden, Bergstraße 66c, 01069 Dresden, Germany

Strain plays an important role in most 2D materials since there is a strong influence of the strain state on the relative band alignment of different valleys in the electronic band structure. The effects of non-uniform strain on the properties of 2D materials are scarcely studied theoretically, even if in experiments a lot of different structures can be found in which a spatial varying strain state is present such as wrinkles or folds. Here, we are investigating how such non-uniform strain influences the electronic properties of the prototypical 2D materials WSe2 and MoS2.We study nanoscale wrinkles and nanotubes in detail and discuss important differences in the strain distribution and magnitude, also to understand if nanotubes could be used as a model system for non-uniformly strained systems. Using Density Functional Theory we find that the inclusion of spin-orbit interaction is crucial to correctly predict the changes in the band structure of wrinkled 2D materials as the non-uniform strain changes the symmetry compared to a flat layer. This introduces a strong Rashba-like splitting of the valence-band maximum near the Γ point. The situation complicates even more with the addition of an extra layer forming a bilayer or a hetrobilayer. The spatial varying band alignments in wrinkled multilayers can lead to new interlayer excitons which are confined to certain regions of the system.

HL 1.6   Mon 11:00   POT 81

Optical properties of monolayer ReSe$_2$ and ReS$_2$ — •Thorsten Deilmann — Institute of Solid State Theory, University of Münster, Germany

Rhenium-based transition metal dichalcogenides unite the fascinating characteristics of the confined in-plane physics with their reduced crystal symmetry. This paves the way for polarization-sensitive applications, such as optical logic circuits operating in the infrared spectral region.

Here, we investigate the doping-dependent optical properties of ReSe$_2$ and ReS$_2$ from first principles. Besides strong excitonic effects, recent experimental studies have reported three-particle states (i.e. trions) with trion binding energies of more than 100 meV [1,2]. Using our ab initio methods we are able to predict neutral and charged properties and find much smaller binding energies compared to experiment.

HL 1.7   Mon 11:15   POT 81

Evaluating Atomically Thin Single-Photon Sources for Quantum Key Distribution — •Timm Gao[1], Martin v. Helversen[1], Carlos Anton-Solanas[2], Christian Schneider[2], and Tobias Heindel[1] — [1]Institut für Festkörperphysik, Technische Universität Berlin, 10623 Berlin, Germany — [2]Institut für Physik, Carl von Ossietzky Universität Oldenburg, 26111 Oldenburg, Germany

Quantum light sources are considered key building blocks for future quantum communication networks. In recent years, atomic monolayers of transition metal dichalcogenides (TMDCs) emerged as a promising material platform for the development of compact quantum light sources. In this work, we evaluate for

the first time the performance of a single-photon source (SPS) based on a strain engineered WSe_2 monolayer [1] for applications in quantum key distribution (QKD) [2]. Employed in a QKD-testbed emulating the BB84 protocol, an anti-bunching of $g^{(2)}(0) = 0.127 \pm 0.001$ and a raw key rate of up to (66.95 ± 0.10)kHz make this source competitive with previous SPS based QKD experiments using quantum dot based SPSs. Furthermore, we exploit routines for the performance optimization previously applied to quantum dot based single-photon sources [2]. Our work represents an important step towards the application of TMDC-based devices in quantum technologies.

Theory of Thermalization of Excitons at Elevated Densities in Atomically Thin Semiconductors — •Manuel Katzer, Andreas Knorr, and Malte Selig — Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

Atomically thin semiconductors exhibit tightly bound electron-hole pairs which stimulated exciton research in recent years [1]. So far, many studies focused on the understanding of exciton dynamics in the limit of very dilute systems. Recent experimental findings [2] raised the question of the excitonic thermalization behaviour for densities above this dilute, classical limit. Due to the co-bosonic nature of excitons [3], we find both bosonic but also fermionic contributions to the thermalization, with the fermionic Pauli blocking effects being dominant for a broad range of parameters. Based on a Heisenberg equation of motion ansatz [4], we discuss the first order of non-linear exciton-phonon interaction exceeding the classical Boltzmann scattering limit, in order to analyze the character of the exciton thermalization at elevated excitation densities.

Strong exciton-plasmon coupling in hybrids of 2D semiconductors and plasmonic crystals — •Lara Greten[1], Robert Salzwedel[1], Stephen Hughes[2], Malte Selig[1], and Andreas Knorr[1] — [1]Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Germany — [2]Department of Physics, Queen's University, Kingston, Canada

Monolayers of transition metal dichalcogenides (TMDCs) are direct-gap semiconductors that exhibit tightly bound excitons with pronounced optical amplitudes. Thus, they are promising for various optoelectronic applications and an excellent material to investigate excitons. Another material with a large optical amplitude is a plasmonic crystal - arrays of metal nanoparticles - which supports collective plasmon modes, and yields amplification of the electric fields on the nano-scale.

Here, we theoretically consider exciton-plasmon coupling in a hybrid structure of a TMDC layer interacting with a plasmonic crystal with a 2d lattice. Our study reveals a hybridization of plasmons and initially momentum dark excitons. In addition, we find an excitonic mode with negligible coupling to the plasmonic near field, emitting undisturbed radiation into the far field. To connect to related experiments, we compute the scattered light in the near- and far-field explicitly and identify signatures of strong exciton-plasmon coupling with a Rabi splitting of more than 100 meV. We also find that the uncoupled exciton mode results in a third peak at the undisturbed exciton energy.

Enhancement of Light Emission in Hexagonal Boron Nitride Structures — •Felix Schaumburg, Marcel Zöllner, Vasilis Dergianlis, Stephan Sleziona, Marika Schleberger, Axel Lorke, Martin Geller, and Günther Prinz — Faculty of Physics and CENIDE, University Duisburg-Essen, Germany

Optical spectroscopy, especially Raman- and photoluminescence (PL)-spectroscopy, is commonly used to study the optical properties of 2D materials. In order to obtain the highest Raman/PL-signals, it is important to reduce the reflection of the excitation laser.

We studied a number of exfoliated hexagonal Boron Nitride (hBN) flakes with different thicknesses on a Si substrate with a 300 nm SiO_2 top layer. By changing the hBN layer thickness, we found a specific thickness, where all Raman signals (from Si, SiO_2 and hBN) showed maximum intensity, whereas the backscattered laser light was suppressed. To explain the increased intensities, we calculated the reflectivity and transmissivity of the full layer system (air, hBN, SiO_2, Si) for different hBN layer thicknesses and for different excitation wavelengths (457 nm, 532 nm, 633 nm), using the transfer-matrix-algorithm. To compare theory with experiment, we performed Raman measurements with the 3 different wavelengths on different flakes and determined their thicknesses with AFM-measurements.

Our results are in good agreement with theory and show that it is possible to choose the best flakes for spectroscopy, just by looking at their color in an optical microscope. This also allows us to easily find good flakes for observation of efficient single defect emission.

Field-induced Seebeck voltage in disordered semiconductors — •Anton Kompatscher and Martijn Kemerink — IMSEAM, University Heidelberg

For disordered semiconductors it is theorized that finite electric fields can heat up the charge carrier distribution to effective temperatures that can significantly exceed the lattice temperature. Here, we argue that this effective temperature should be able to efficiently drive a thermoelectric generator (TEG) based on the Seebeck effect.(1) Utilizing kinetic Monte-Carlo simulations we were able to show similar results when driving a TEG with temperature or field. As a model system we choose the Seebeck ratchet introduced by Büttiker, replacing temperature- with field-driven effective temperature modulation. This allowed us to compare the current predicted by theory with the simulation currents resulting in good functional agreement. Effective temperature drive offers interesting advantages. Since only the electron distribution but not the lattice itself is heated, one of the mayor loss channels in TEG, lattice thermal conductivity, can be suppressed. Additionally, there is no need for n- and p-type materials (nor for heat exchangers) and a single material is sufficient. The main issue for concrete realization lies in the very high necessary field strengths at which effective temperature becomes relevant and that somehow need to be coupled into the TEG.

Momentum dependent investigation of electronic excitations in β-metal-phthalocyanines — •Louis Philip Doctor and Martin Knupfer — Leibniz-Institut für Festkörper- und Werkstoffforschung Dresden, Helmholtzstraße 20, 01069 Dresden

This work presents an investigation of the electronic excitations of β-metal-phthalocyanines. We prepared 120 nm thick thin films by physical vapour deposition, which afterwards underwent an annealing process. Infrared spectroscopy

revealed that the annealed films were in the β-phase. The films were further characterised in the visible regime. The prominent feature in this regime is the Q-band, which consists of four peaks arising from the HOMO to LUMO transition split by solid state effects. Furthermore the dispersion of the Q-band was measured using electron energy loss spectroscopy. We found a complex momentum dependent behaviour. Most interesting is the negative dispersion of the lowest lying excitation, which also has a tremendous effect on the performance of optoelectronic devices. This redshift partially correlates with the intermolecular distance and the charge carrier transfer integrals. The latter were determined by a theoretical model, which describes the interaction of Frenkel and charge transfer excitons in metal-phthalocyanines. Our results clearly indicate a prominent influence of charge transfer excitons to the lowest electronic excitations.

HL 2.3 Mon 10:00 POT 361

Photovoltaic and nonlinear optical properties of complex self-assembled liquid crystal structures — •Ahmad Murad[1], Alexey Eremin[1], Martin Feneberg[1], Maximilian Baumann[2], Matthias Lehmann[2], and Mohamed Alaasar[3] — [1]Otto-von-guericke-Universität, Magdeburg,Deutchland — [2]Julius- Maximilians -Universität Würzburg — [3]Martin Luther University Halle-Wittenberg, Halle (Saale),

We explore conducting and photovoltaic properties in a series of two classes of semiconducting liquid crystals. BTBT-derived polycatenary mesogens doped with fullerenes show helical network phases exhibiting a strong photovoltaic effect in a broad range of light spectrum from UV to VIS. The second class is star-shaped mesogens with subphthalocyanine core that forms self-assembled ferro-electric columnar phases. We characterise the polar order using polarisation-resolved measurements of Second Harmonic Generation (SHG). Dynamical SHG studies provide information about the switching rates and the stability of the ferroelectric states. The photovoltaic effect is demonstrated under UV exposure.

What's special about Y6; working mechanism of Neat Y6 organic solar cell — •Elifnaz Saglamkaya[1], Artem Musiienko[2], Mohammad Saeed Shadabrooa[1], Bowen Sun[1], Sreelakshmi Chandrabose[3], Giulia Lo Gerfo M.[4], Niek F. van Hulst[4], Dieter Neher[3], and Safa Shoaee[1] — [1]University of Potsdam Disordered Semiconductor Optoelectronics Karl-Liebknecht-Strasse 24-25 14476 Potsdam-Golm — [2]Department Novel Materials and Interfaces for Photovoltaic Solar Cells, Helmholtz-Zentrum Berlin für Materialien und Energie, Kekuléstraße 5, 12489 Berlin, Germany — [3]University of Potsdam Physik und Optoelektronik weicher Materie Karl-Liebknecht-Straße 24-25 14476 Potsdam-Golm — [4]Institut de Ciencies Fotoniques, The Barcelona Institute of Science and Technology, 08860 Castelldefels, Barcelona, Spain

In this study, we analyse the working mechanism of single component small molecule acceptor Y6 solar cells with power conversion efficiencies reaching up to 4.5% and short circuit currents up to 8.4 mAcm-2.Using Hall effect, photo-Hall, and photoinduced absorption (PIA) measurements, we show that the charge photo-generation occurs in the bulk of Y6. With the aid of space charge limited current (SCLC) measurements we show that Y6 has an ambipolar charge carrier mobility. Our data shows that the limiting factor for the power conversion efficiency is fast charge recombination, which can be suppressed in presence of the transport layers, or modifying the morphology with a solvent additive.

Ultrastrong light-matter coupling of J-aggregated squaraine in a room temperature open cavity — •Christoph Bennenhei[1], Lukas Lackner[1], Moritz Gittinger[1], Heiko Knopf[2], Falk Eilenberger[2], Jennifer Zablocki[3], Arne Lützen[3], Martin Silies[1], Christoph Lienau[1], Martin Esmann[1], and Christian Schneider[1] — [1]Institute of Physics, University of Oldenburg — [2]Fraunhofer-Institute for Applied Optics and Precision Engineering IOF, Jena — [3]Kekulé Institute of Organic Chemistry and Biochemistry, University of Bonn

Organic molecule exciton-polaritons in artificial lattices are an emerging platform to emulate complex electronic Hamiltonians at ambient conditions. We present J-aggregated squaraine dye (SQ) thin films [1] as a promising candidate for exciton-polaritons in optical cavities due to the high oscillator strength and tunable resonance. Using white light reflection spectroscopy, we demonstrate tunable ultrastrong coupling of light to the SQ thin film in an open cavity at room temperature [2] which we support by transfer matrix calculations. In ongoing experiments, we introduce structured photonic lattices to the open cavity to investigate the coupling of the polaritons to tailored potential landscapes. [1] M. Schulz, et al., Nat Commun 9, 2413 (2018). [2] L. Lackner, et al., Nat Commun 12, 4933 (2021).

Room-temperature polariton lasing in anisotropic optical microcavities — •Christoph Bennenhei[1], Nils Kunte[1], Marti Struve[1], Heiko Knopf[2], Falk Eilenberger[2], Jürgen Ohmer[3], Utz Fischer[3], Martin Esmann[1], and Christian Schneider[1] — [1]Institute for Physics, Universität Oldenburg, Germany — [2]Fraunhofer-Institute for Applied Optics and Precision Engineering IOF, Jena, Germany — [3]Department of Biochemistry, Universität Würzburg, Germany

Organic molecule exciton-polaritons in artificial photonic potentials are an emerging platform to emulate electronic Hamiltonians at ambient conditions and for realizing low-threshold microlasers. In this work, we probe the polarization of polariton lasing in microcavities composed of dielectric Bragg reflectors with anisotropic indentations, enclosing the fluorescent protein mCherry. This material has been previously presented as a promising material for room-temperature polariton condensation [1,2]. Here, we experimentally show that lasing above the threshold differs distinctly for the two linearly polarized, energetically non-degenerate cavity eigenmodes. This effect leads to a drastic increase in the degree of linear polarization for the coherent photoluminescence emitted from the cavity. Our devices have relevant applications both for new types of polarized coherent light sources on chip and for accessing additional degrees of freedom in the emulation of topological electronic lattice Hamiltonians at room temperature.

HL 3: Focus Session: Progress in Hybrid Phononic Quantum Technologies I

Phonons, the quanta of lattice vibrations, are the fundamental excitations in a crystal and couple to literally any type of excitation in a solid. This universal coupling makes them ideally suited for hybrid quantum architectures which synergistically harness the strengths of its components and at the same time mitigate individual shortcomings. For chip-based hybrid quantum devices, phonons are particularly attractive because they can be routed in integrated circuits with very little dissipation over macroscopic distances in the solid state or confined in small mode volume phononic cavities. Although the research of phonons has a long-lasting history, only recently important breakthroughs were made that will unleash the full potential of acoustic waves in quantum technologies. For example, the rapid progress in the development of surface acoustic wave resonators now allows to generate desired phonon quantum states which promotes the field of quantum acoustics.

Schrödinger cat states of a 16-microgram mechanical oscillator — •Yiwen Chu[1,2], Marius Bild[1,2], Matteo Fadel[1,2], Yu Yang[1,2], Uwe von Lüpke[1,2], Phillip Martin[1,2], and Alessandro Bruno[1,2] — [1]Department of Physics, ETH Zürich — [2]Quantum Center, ETH Zürich

While the principle of superposition in quantum physics is routinely validated for microscopic systems, it is still unclear why we do not observe macroscopic objects to be in superpositions of states that can be distinguished by some classical property. I will present our experiments that harness the resonant Jaynes-Cummings interaction between a high overtone resonator mode of a bulk acoustic wave resonator and a superconducting qubit to demonstrate the preparation of Schrödinger cat states of motion. In such a state, the constituent atoms oscillate in a superposition of two opposite phases with an effective oscillating mass of 16 micrograms. Making use of the circuit quantum acoustodynamics toolbox we have developed, we furthermore show control over amplitudes and phases of the created Schrödinger cat states, and investigate their decoherence dynamics by observing the disappearance of Wigner negativities. Our results can find applications in continuous variable quantum information processing and in fundamental investigations of quantum mechanics in massive systems.

Invited Talk   HL 3.2   Mon 10:00   POT 151

High-fidelity quantum information processing with spins and phonons — •Peter Rabl — Atominstitut, TU Wien, Stadionallee 2, 1020 Wien, Austria — Physik-Department, Technische Universität München, 85748 Garching, Germany — Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany

Phonons in solids are usually uncontrolled and therefore represent one of the main sources of decoherence for many solid-state quantum systems. However, when appropriately designed, isolated mechanical modes offer fascinating new opportunities for engineering coherent interactions between systems that cannot be coupled efficiently otherwise. In this talk, I will discuss the prospects of this approach for engineering phonon-mediated quantum gate operations between spin qubits associated with SiV defect centers in a diamond phononic crystal. Specifically, I will show how the application of continuous spin-echo techniques can substantially boost the coherence times in this system and suppress gate errors below 10^{-4} for experimentally realistic noise parameters. Therefore, although the field is still in its infancy, this analysis outlines a realistic path toward moderate- and large-scale quantum devices with spins and phonons, at a level of control that is comparable to other leading quantum-technology platforms.

HL 3.3   Mon 10:30   POT 151

Acoustically-induced pseudo-gauge fields and anomalous transport phenomena in graphene — •PAI ZHAO[1], LARS TIEMANN[1], LEV MOUROKH[2], VADIM M. KOVALEV[3], and ROBERT H. BLICK[1] — [1]University of Hamburg, Germany — [2]Department of Physics, Queens College, New York, USA — [3]Novosibirsk, Russia

One of many remarkable consequences of the low-energy Dirac description of graphene is the emergence of synthetic gauge fields under lattice deformation that affect the carrier dynamics. We show that acoustically stimulated carrier transport in graphene at 4 Kelvin signals the presence of artificial gauge fields through the build-up of a transversal voltage at zero magnetic field. We fabricated a gate-tunable, large-scale CVD graphene Hall bar on a hybrid piezo-electric LiNbO$_3$ on insulator substrate. An interdigitated transducer launches a surface acoustic wave (SAW) that acoustically accelerates the carriers in the graphene. At zero magnetic field, we observe large anomalous acoustically-induced synthetic Hall voltages up to 200 μV, depending on the carrier type, concentration and SAW power. The synthetic Hall voltage can modulate a conventional Hall voltage arising in a large external magnetic field [1]. Our observation is consistent with studies of strain-induced pseudo-gauge fields [2-4].

On-chip waveguides for hypersound with planar semiconductor optical microcavities — ANTONIO CRESPO-POVEDA, •ALEXANDER KUZNETSOV, ALBERTO HERNÁNDEZ-MÍNGUEZ, ABBES TAHRAOUI, KLAUS BIERMANN, and PAULO SANTOS — Paul Drude Institute for Solid State Electronics, Berlin, Germany

In solid-state systems, coherent oscillations of the atomic lattice (phonons) couple to the majority of elementary excitations. This motivates studies that aim at creating phonon-based interfaces between photons and quantum systems. In this work, we show piezoelectric excitation of 6 GHz hypersound in a buried (Al,Ga)As planar waveguide. Acoustic echo spectroscopy reveals that phonons propagate over mm-long distances. Furthermore, the waveguide contains quantum wells and is embedded into an optical microcavity. The strong-coupling between nIR photons and excitons leads to the formation of light-matter quasi-particles – polaritons. Due to the excitonic component, polaritons act as a sensitive local optical probe for gAPs. Thus, we demonstrated a conversion of microwave signals to guided hypersound with the subsequent polariton-mediated transduction to photons. In a broad context, the results are important for the remote coherent control of optoelectronic resonances and the realization of the on-chip phonon circuitry and a microwave-to-optical interface.

Control of spin centers in silicon carbide using acoustic fields — •ALBERTO HERNÁNDEZ-MÍNGUEZ — Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany

Atom-like color centers in solids are attractive for applications in quantum technologies because their spin states exhibit long coherence times and can be controlled by optical, microwave and acoustic fields. In this contribution, we report on acoustically driven spin transitions in silicon vacancy centers in SiC. Specifically, we use the dynamic strain of surface acoustic waves to selectively excite room-temperature spin transitions with magnetic quantum number differences of ±1 and ±2 in the absence of external microwave fields [1]. Compared to the ground states, spin levels in the optically accessible excited states possess even stronger interaction with acoustic vibrations, thus giving rise to novel and, so far, largely unexploited physical phenomena. A remarkable example is the acoustically induced coherent spin trapping [2], which consists in the quenching of the optically detected spin resonance due to the precession of the spin around the same axis in both ground and excited states. Our findings provide new opportunities for the coherent control of spin qubits with dynamic strain fields that can lead towards the realization of future spin-acoustic quantum devices.

Storage and retrieval of telecom single photons from a semiconductor quantum dot in a rubidium ORCA memory — •LUKAS WAGNER[1], SARAH THOMAS[2], CORNELIUS NAWRATH[1], SIMONE LUCA PORTALUPI[1], PATRICK LEDINGHAM[3], IAN WALMSLEY[2], and PETER MICHLER[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart, Germany — [2]Faculty of Natural Sciences, Department of Physics, Imperial College London, Imperial College Rd, South Kensington Campus, London SW7 2AZ, United Kingdom — [3]Department of Physics and Astronomy, University of Southampton, Southampton SO17 1BJ, United Kingdom

Photons are highly attractive as carriers of information thanks to their propagation at the speed of light and their low interaction with matter. Furthermore, various implementations of photonic quantum technologies will strongly benefit from the possibility of storing quantum information. Indeed, quantum memories would allow synchronizing the arrival time of multiple photons. Semiconductor quantum dots (QDs) are highly attractive as sources of quantum light. Atomic vapors are known as a very powerful platform to realize on-demand storage and retrieval of light. For these reasons a hybrid quantum system combining these two elements was for long sought after. Here, we will report on our progress to interface single photons from an In(Ga)As QD emitting at telecom wavelength with a rubidium off-resonance cascaded absorption (ORCA) quantum memory.

Excitation and read-out of macroscopic mechanical motion by phase-modulated optical driving of a single-photon emitter — •THILO HAHN[1], JACEK KASPRZAK[2], ORTWIN HESS[3], TILMANN KUHN[1], and DANIEL WIGGER[3] — [1]Institute of Solid State Theory, University of Münster, Germany — [2]Université Grenoble Alpes, CNRS, France — [3]School of Physics, Trinity College Dublin, Ireland

Resonance phenomena provide an access to drive inert systems out of equilibrium by applying a periodic force. In this contribution we will investigate a hybrid quantum system consisting of a single photon emitter (SPE) that is on the one hand coupled to a single phonon mode, e.g., in the form of a mechanic resonator, and on the other hand driven by a laser field. To convert a series of laser pulses into a measurable displacement of the phonon mode, originally a synchronization between the pulse repetition and the mode frequency was suggested [2] and demonstrated. Here, we discuss a different excitation scheme that is adapted from the heterodyne four-wave mixing (FWM) technique: We consider a series of pulse pairs which drives the phonons into a far displaced quasi-coherent state by tuning the harmonically oscillating phase relation within the pulse pairs in resonance with the phonons. Conversely, the optical properties of the SPE are dynamically affected by the phonon motion. Conveniently this can directly be measured by the FWM signal emitted by the SPE in order to detect the mechanical motion. Consequently, we combine resonant driving and read-out in a single method. HL 3.8   Mon 12:30   POT 151

Imaging surface acoustic waves on 2D materials using atomic force microscopy — •MINGYUN YUAN[1], ALBERTO HERNÁNDEZ-MÍNGUEZ[1], IGOR AHARONOVICH[2], and PAULO V. SANTOS[1] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany — [2]School of Mathematical and Physical Sciences, University of Technology Sydney, Ultimo, Australia

There is an increasing interest in coupling the dynamic strain of surface acoustic waves (SAWs) to electronic excitations in 2D-material-based nanostructures to acoustically manipulate their optoelectronic properties. While optical phenomena in 2D nanostructures can be conveniently mapped by photoluminescence, local probing of mechanical properties remains challenging. This task can, nevertheless, be assisted by high-frequency (GHz) SAWs, which are particularly suitable for probing very thin objects due to their micron-size wavelengths and their confinement near the surface. Here, we use atomic force microscopy (AFM) to image SAWs propagating along a LiNbO3 acoustic resonator containing a multilayer hexagonal Boron Nitride (hBN) flake irradiated with Ar ions to create color centers. The high spatial resolution of AFM enables us to investigate the SAW strain transferred to the flake. We observe spatial inhomogeneities, revealing that the strain transferred to 2D materials can exhibit large spatial fluctuations. Possible mechanisms that affect the coupling will be discussed. Our method demonstrates a straight-forward way to characterize dynamic strain fields in hybrid SAW/2D-material systems.

HL 3.9   Mon 12:45   POT 151

Effect of helium ion implantation on nanomechanical resonators in 3C-SiC — •NAGESH SHAMRAO JAGTAP[1,2], YANNICK KLASS[3], FELIX DAVID[3], PHILIPP BREDOL[3], EVA WEIG[3], MANFRED HELM[1,2], GEORGY ASTAKHOV[1], and ARTUR ERBE[1,2] — [1]Helmholtz-Zentrum Dresden - Rossendorf, Institute of Ion Beam Physics and Materials Research, Dresden — [2]TU Dresden — [3]Technical University of Munich, Chair of Nano and Quantum Sensors, Munich

Silicon carbide (SiC) is a suitable candidate for nanoelectromechanical systems due to its superior mechanical properties. It is also an interesting material platform to study the coupling of mechanical modes with localized spins associated with irradiation-induced defects. Such a spin-mechanical system can be used for quantum sensing applications [1]. The nanomechanical resonators in 3C-SiC are fabricated by standard semiconductor processing techniques such as electron beam lithography and reactive ion etching. They are characterized using Fabry-Pérot interferometer. In the preliminary experiments, we focus on the material modification by helium ion broad beam implantation on strained 3C-SiC resonators. The effect of varying fluence on resonance frequencies and quality factors is studied (see contribution of Philipp Bredol).

Bandgap engineering of two-step processed perovskite top cells for application in perovskite-based tandem photovoltaics — •Ronja Pappenberger[1,2], Alexander Diercks[2], Ahmed Farag[1,2], Paul Fassl[1,2], and Ulrich W. Paetzold[1,2] — [1]Institut für Mikrostrukturtechnologie, KIT, Germany — [2]Lichttechnisches Institut, KIT, Germany

Tandem solar cells offer a promising concept of raising the efficiency of silicon solar cells above the theoretical limit of 29%. In this context, silicon is supplemented by a wide-bandgap perovskite top solar cell to make better use of the solar spectrum. Perovskite solar cells come into play given their favorable optoelectronic quality and tunable bandgap. Textured-front perovskite silicon tandem solar cells currently promise the highest energy yield for modules in the field. To avoid shunting, ensure high efficiency and economic production of the perovskite on the μm-sized pyramids, a conformal growth of the perovskite layer as well as a sufficient layer thickness are necessary. A two-step method - containing a separate deposition of the PbI_2 and the organic cations - enables high film quality, flexibility in choice of component/solution and the possibility of upscaling. Here, we investigate different strategies of increasing the bandgap of the perovskite. Thereby the location of the added bromine - cation solution and/or PbI_2 solution - is critical. With our approach, the device performance - PCE of 17.2%, FF of 76% and V_{oc} of 1.156 V ($E_g \approx 1.64$ eV) - and film quality can be maintained. Furthermore, the effect of an increasing bandgap in combination with planar/textured silicon bottom cells is studied.

HL 4.2   Mon 9:45   POT 251

Application of plasma enhanced atomic layer deposition process of alumina on perovskite film boosts efficiency of solar cells — •Małgorzata Kot[1], Mayank Kedia[2], Paul Plate[3], Ludwig Marth[3], Karsten Henkel[1], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, BTU Cottbus-Senftenberg, Konrad-Zuse-Strasse 1, 03046 Cottbus, Germany — [2]Institut fuer Photovoltaik Universitaet Stuttgart, Pfaffenwaldring 47, 70569 Stuttgart, Germany — [3]SENTECH Instruments GmbH, Schwarzschildstraße 2, 12489 Berlin, Germany

It is assumed that plasma-enhanced atomic layer deposition (PEALD) cannot be used to prepare thin films on sensitive organic-inorganic perovskites because the plasma destroys the perovskite film and thus deteriorates its photophysical properties. Here, we prove that using an appropriate geometry of the ALD system (SENTECH SI PEALD system) and suitable process parameters it is possible to coat perovskites with alumina by PEALD. Spectromicroscopy followed by electrical characterisation reveal that as long as the PEALD process is not optimized (too long plasma pulses) one gets degradation of the perovskite as well as dissociation of the created iodine pentoxide (during PEALD) under light that causes a valence band maximum (VBM) shift to the Fermi level and thus significantly decreases the solar cell efficiency. However, once the PEALD process parameters are optimized, no VBM shift is observed. Moreover, the solar cell efficiency depends inversely on process temperature and layer thickness.

HL 4.3   Mon 10:00   POT 251

Tuning Crystallization for Highly Efficient Perovskite Silicon Tandem Solar Cells — •Mohamed Mahmoud[1,2], Oussama Er-Raji[1,2], Patricia Schulze[1], Anna Juliane Borchert[1,2], and Andreas W. Bett[1,2] — [1]Fraunhofer ISE — [2]University of Freiburg

Perovskite solar cells have the advantages of a strong absorption edge, defect tolerance, and potential cheap production due to easy production methods such as spin coating or slot-die coating as a highly scalable production method. In the industry, double-sided textured (micro-meter sized pyramid) silicon is commonly produced to decrease reflection losses and improve light trapping. Solution-based processing methods of perovskite on top of the textured Si showed low conformality, which resulted in shunts and non-working solar cells. To overcome this issue, the hybrid route was developed, in which inorganic precursors are co-evaporated using the thermal vapor deposition technique and then organic precursors are spin-coated followed by a thermal annealing. By doing that, high conformality of perovskite thin films on top of the textured silicon is achieved. However, the resulting perovskite grain size is rather low, which can lower the bulk quality. In this work, various additives were used to increase the grain size, and their working mechanisms were studied. In addition, we study the consequences of different grain sizes at the tandem level with respect to device efficiency as well as stability. Moreover, using the thermodynamics fundamentals of crystallization, we hypothesize for the first time a common general explanation for the working mechanism of all the different additives used.

Efficient Modeling Workflow for Accurate Electronic Structures of Hybrid Perovskites — Julian Gebhardt[1,2], •Wei Wei[1,2], and Christian Elsässer[1,2,3] — [1]Fraunhofer IWM, 79108 Freiburg — [2]Cluster of Excellence livMatS, University of Freiburg — [3]Freiburg Materials Research Center, University of Freiburg

Hybrid organic-inorganic halide perovskites are the most promising photovoltaic absorber materials to substitute or complement silicon in high-efficiency solar cells. These hybrid materials are often constrained by their low stability and critical elements like lead. Computational high-throughput screening studies, based on solid-state electronic-structure theory, are useful to identify promising substitute materials with targeted properties. In this work, we present an efficient computational approach based on density-functional theory, which is suitable to predict band gaps for arbitrary compounds reliably and in good quantitative agreement with experimental band gap data for known compounds. This approach is described and demonstrated for the building blocks of one of the most promising hybrid perovskites, namely, $(HC(NH_2)_2)_x Cs_{1-x} Pb(I_y Br_{1-y})_3$, with x and y varied between zero and one.

Photon Management for Ultrathin Solar Cells: Enabling Waveguide Modes by Structured Back Contact — •Merve Demir, Thomas Schneider, Torsten Hölscher, Heiko Kempa, and Roland Scheer — Martin-Luther-Universität Halle-Wittenberg, Germany

The recent research based on Cu(In,Ga)Se2 (CIGSe) solar cells is focused on thinning down the absorber layer to enable less material consumption and cost effective large scale production. However, having ultra-thin CIGSe solar cells with absorber layer thickness in sub-micron level brings the cost of limited absorption of solar spectra and hence leads to lower energy conversion efficiencies. This problem can be overcome by the cell architecture including functional back contact elements for the enhancement of optical absorption. In this contribution, ultrathin CIGSe solar cells with 500 nm thick absorber layer were combined with nano-textured SiO2 back contacts together with aluminum back mirror. With this cell design, it is aimed to have increased power conversion efficiency for ultra-thin CIGSe solar cells due to enhanced absorption of long wavelength region photons. The solar cell parameters were extracted and compared with the conventional CIGSe back contact, flat molybdenum, to reveal the effects of functional back contact. The experimental findings on quantum efficiency measurements prove the positive effects of having highly reflective and textured back contact. Furthermore, the growth of CIGSe on textured substrates was examined throughout cross section cuts by scanning electron microscopy and energy dispersive X-ray diffraction.

HL 4.6   Mon 11:15   POT 251

Employing three-dimension structure analysis: digital twin for studying grain boundary effects in thin film solar cells — •Chang-Yun Song[1], Matthias Maiberg[1], Heiko Kempa[1], Ali Gholinia[2], Wolfram Witte[3], Dimitrios Hariskos[3], Daniel Abou-ras[4], and Roland Scheer[1] — [1]Martin-Luther-University Halle-Wittenberg, Halle, D — [2]University of Manchester, Manchester, UK — [3]Zentrum für Sonnenenergie- und Wasserstoff-Forschung, Stuttgart, D — [4]Helmholtz-Zentrum Berlin, Berlin, D

Grain boundaries (GBs) in polycrystalline Cu(In,Ga)Se2 (CIGSe), are believed to be one of the performance limiting factors of current record efficiency CIGSe solar cells. Numerous simulation studies have been conducted to unveil their effects. Most simulations, however, have been done within two-dimensions (2D), thereby presumably using the simplified GBs shapes. In this study, we thus present a realistic three-dimensional (3D) GB model for a high-efficiency CIGSe layer. To this end, a combination of electron backscatter diffraction and focused ion beam was applied to obtain 3D data of the CIGSe layer, which then allowed the reconstruction of the 3D grain structure into a computer model. By using the computer model as input for 3D optoelectronic simulations, we study the electronic effects of GBs on the high-efficiency solar cell under investigation bulk parameter values for the simulations were obtained through a combination of simulation and experiments, such that the solar cell is consistently described. As an outcome, the 3D simulations confirm that the effect of GB was indeed underestimated in earlier conventional 2D simulations.

HL 4.7   Mon 11:30   POT 251

Interface Engineering to reduce non-radiative recombination losses at the perovskite/C60 interface in monolithic perovskite silicon tandem solar cells — •Johanna Modes, Patricia S. C. Schulze, Kaitlyn Mc Mullin, Maryamsadat Heydarian, Christoph Messmer, Juliane Borchert, and Andreas Bett — Fraunhofer ISE

Metal halide perovskites have emerged in recent years as a promising absorber material for solar cells with the potential to combine high power conversion efficiency with low production costs. However, significant non-radiative charge carrier recombination occurs at the perovskite interface to the contacts, thus preventing the full potential of the solar cell from being exploited. Photoluminescence quantum yield measurements clearly show that the Quasi-Fermi level splitting is reduced by evaporation of the electron contact C60 onto perovskites, leading to limited open-circuit voltage in devices. In recent literature, as well as in our investigations, different passivation layers are deposited between perovskite and the electron contact to reduce non-radiative recombination and to improve the open-circuit voltage. This is on the one hand pursued by increasing the selectivity at the contacts through field effects and band alignment and secondly by reducing defects at the interface through chemical passivation.

HL 4.8   Mon 11:45   POT 251

Spontaneous Polarization in NaNbO$_3$ — •Kisung Kang[1], Saud Bin Anooz[2], Jutta Schwarzkopf[2], Matthias Scheffler[1], and Christian Carbogno[1] — [1]The NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft and IRIS-Adlershof of the Humboldt-Universität zu Berlin — [2]Leibniz-Institut fur Kristallzüchtung (IKZ)

The perovskite NaNbO$_3$ is regarded as a promising lead-free piezoelectric material, also because its polarization properties can be further tailored via strain engineering. [1] In thin films, lattice strain can be incorporated by the heteroepitaxial growth on lattice mismatch. By tuning the epitaxial strain in the films, different polymorphs with distinctively different polarization strength and orientation can be realized [2, 3]. We investigate this question by using density-functional theory at the semi-local level of theory, which we carefully validate with hybrid-functional calculations. By this means, we compute the spontaneous polarization for ten phases of NaNbO$_3$ as a function of stress and strain. In line with experiments, we confirm that the monoclinic *Pm* phase features a non-vanishing in-plane polarization, the orientation of which is independent of the strain. Conversely, the polarization direction of the orthorhombic *Pmc2*$_1$ phase depends on the applied tensile strain. We analyze the underlying electronic and atomistic mechanism and discuss how the relevant properties are influenced by phase transformations.

HL 4.9   Mon 12:00   POT 251

Peculiar bond length dependence and its impact on the band gap bowing in (Ag,Cu)(In,Ga)Se$_2$ thin film alloys — •Hans H. Falk[1], Stefanie Eckner[1], Konrad Ritter[1], Sergiu Levcenko[1], Timo Pfeiffelmann[1], Edmund Welter[2], Jes Larsen[3], William N. Shafarman[4], and Claudia S. Schnohr[1] — [1]Felix Bloch Institute for Solid State Physics, Leipzig University, Germany — [2]Deutsches Elektronen-Synchrotron DESY, Germany — [3]Department of Materials Science and Engineering, Uppsala University, Sweden — [4]Department of Materials Science and Engineering, University of Delaware, USA

Incorporation of Ag into Cu(In,Ga)Se$_2$ thin film solar cells improves several of their properties. However, with increasing Ag content, the band gap of (Ag,Cu)GaSe$_2$ increases even though the lattice expands and the Ga-Se bond length is predicted to decrease. This is counterintuitive, since in other chalcopyrite alloys all bond lengths increase and the band gap decreases as the lattice expands. Therefore, we studied the element-specific average bond lengths of (Ag,Cu)GaSe$_2$, (Ag,Cu)InSe$_2$ and Ag(In,Ga)Se$_2$ using X-ray absorption spectroscopy for thin films grown on Mo-coated soda lime glass by a single stage co-evaporation process. As predicted, the Ga-Se bond length decreases with increasing Ag content in (Ag,Cu)GaSe$_2$. While the In-Se bond length of (Ag,Cu)InSe$_2$ shows the same behavior, Ag(In,Ga)Se$_2$ exhibits a dependence similar to that of Cu(In,Ga)Se$_2$, demonstrating that the peculiar behavior is related to mixing the group-I lattice site. Using the bond lengths we model the anion positions and estimate their effect on the band gap bowing.

HL 4.10   Mon 12:15   POT 251

Fast diffusion of spin polarized excitons in bulk lead halide perovskites — •Sergiu Anghel[1], Dmitri R. Yakovlev[1], Dmitry N. Dirin[2], Maksym V. Kovalenko[2], Manfred Bayer[1], and Markus Betz[1] — [1]Experimentelle Physik 2, Technische Universität Dortmund, Otto-Hahn-Straße 4a, D-44227 Dortmund, Germany — [2]Laboratory of Inorganic Chemistry, Department of Chemistry and Applied Biosciences, ETH Zürich, Zürich CH-8093, Switzerland

We investigate the spin diffusion of the free "hot" excitons in FA0.9Cs0.1PbI2.8Br0.2 bulk lead halide perovskite crystal at cryogenic temperatures by employing ultrafast time- and spatial-resolved magneto-optical Kerr microscopy. We measure the spin diffusion coefficient (D_s) of the free excitons of D_s~50 cm^2/s , which is a very surprising outcome, especially in the light of the recent results obtained on bulk or two-dimensional perovskites [1,2], where D_s is at least two orders of magnitude lower. D_s shows a roughly linear dependence on pump energy whereas the dependence on pump power is much more intricate - after a certain pump power threshold we observe an anomalous, nonlinear spatial dependence of D_s. We discuss our findings in view of efficient exciton-phonon coupling and Auger processes.

Time-resolved analysis of propagating exciton-polariton condensates in photonic potential landscapes. — •Christian G. Mayer, Philipp Gagel, Simon Betzold, Tristan H. Harder, Monika Emmerling, Adriana Wolf, Fauzia Jabeen, Sven Höfling, and Sebastian Klembt — Technische Physik, RCCM and Würzburg-Dresden Cluster of Excellence ct.qmat, University of Würzburg, Germany

Confining photons in a Fabry-Perot microcavity and coupling them strongly to excitons leads to the formation of hybrid matter-light particles named exciton-polaritons (polaritons). Owing to their bosonic statistics, they undergo a phase transition above a critical density to a dynamic condensate via stimulated scattering. Polaritons have quite long diffusion length compared to excitons because of their lower effective mass inherited by their photonic fraction. Propagation effects of a polariton condensate take place on a time scale of a few picoseconds and are caused by the repulsive potential facilitated by the matter fraction due to polariton-exciton and polariton-polariton interactions. By varying the light-matter composition of the polariton condensate, we investigate changes in the propagation properties such as velocity and length.

Using electron beam lithography, we spatially confine propagating polaritons in waveguides, as well as in resonator lattices supporting quantum valley Hall modes. Using a streak camera, the propagation of the polariton condensate is measured in a variety of confined structures and systems.

HL 5.2   Mon 10:15   POT 112

Tackling the band ordering problem for transport calculations in strained semiconductors: A k × p perspective — •Daniel Fritsch[1], Costanza L. Manganelli[2], Christian Merdon[1], and Patricio Farrell[1] — [1]Weierstrass Institute for Applied Analysis and Stochastics, Mohrenstr. 39, 10117 Berlin, Germany — [2]IHP Leibniz-Institute for High Performance Microelectronics, Im Technologiepark 25, 15236 Frankfurt (Oder), Germany

A reliable determination of band energies in strained semiconductor heterostructures is indispensable for subsequent transport calculations. However, one crucial problem is presently hidden within the change in valence band ordering due to intrinsically occurring strain in semiconductor heterostructures, nanowires, or quantum dots.

In order to tackle this problem, we present a numerical algorithm based on the Bir-Pikus **k × p** Hamiltonian, that takes into account additional wavevector dependent properties, e.g. the effective mass tensor, to identify the nature of the valence bands. It provides the necessary connection between arbitrary strain profiles for semiconductor nanostructures calculated by means of a finite element method [1] and transport calculations employing a drift diffusion model [2].

The new algorithm is applied to example strain profiles, e.g. biaxial and uniaxial strain, and results are compared to earlier theoretical and experimental findings.

Improved growth of unstrained HgTe quantum well on InAs — •Mahitosh Biswas[1,2], Hartmut Buhmann[1,2], and Laurens W. Molenkamp[1,2] — [1]Institute for Topological Insulators, Universität Würzburg, 97074 Würzburg, Germany — [2]Physikalisches Institut (EP3), Universität Würzburg, 97074 Würzburg, Germany

HgTe turned out to be a prototype material for investigations of transport properties in topological insulator materials. The material system also demonstrated its versatility when compressive strain is applied, resulting in Weyl and Kane semimetal states. It has been shown that the strain can be controlled sufficiently by the period of a CdZnTe/CdTe superlattices grown on a doped GaAs substrate. However, these strained and/ or strained layers exhibit a rather high surface roughness which makes them unsuitable for sub-micrometer device fabrication or local probe measurement techniques. Here we show that CdZnTe/CdTe superlattices grown on doped InAs improve the situation significantly. Surface roughness is about three times lower compared with GaAs. These observations are confirmed by TEM measurements which monitor dislocations originating at the III-V/II-VI semiconductor interface. Magneto-transport measurements reveal that the doped substrate can be used as a highly efficient back gate. Carrier variations between $2 \times 10^{11} \, cm^{-2}$ (electron) and $-2 \times 10^{11} \, cm^{-2}$ (hole) are observed for a medium ± 10 V gate range. These results manifest a (big) step forward toward the fabrication of functional top and back gated devices on topological materials.

HL 5.4   Mon 10:45   POT 112

Band alignment of thin strontium germanate layer on silicon from *ab initio* — •Tomáš Rauch[1,2], Pavel Marton[3,4], Silvana Botti[1,2], and Jiří Hlinka[3] — [1]Institut für Festkörpertheorie und -optik, Friedrich-Schiller-Universität Jena, Germany — [2]European Theoretical Spectroscopy Facility — [3]Institute of Physics of the Czech Academy of Sciences, Praha, Czech Republic — [4]Institute of Mechatronics and Computer Engineering, Technical University of Liberec, Czech Republic

Silicon is one of the most used materials for optoelectronic applications. In photo-catalytic cells for hydrogen evolution reaction, Si must be capped by a protective layer, additionally allowing the photo-excited electrons to travel to the device surface. It has been demonstrated, that $SrTiO_3$ (STO) can fulfill these two functions [1].

In this work, we studied $SrGeO_3$ (SGO) as an alternative to STO, using density-functional theory. We calculated the structural properties of a chosen prototypical SGO/Si(001) interface and studied its electronic structure, focusing on the band offsets between Si and SGO. We found a metallic type-III interface with occupied conduction bands of SGO and a charge transfer from Si to SGO. Aligning the local band edges of the thin SGO layer with the redox potentials allows us to conclude that the SGO/Si interface should be suitable for water reduction.

We acknowledge funding by the Czech Science Foundation (project no. 21-20110K) and by the Volkswagen Foundation (project "dandelion").

Evolution of vacancy like defects in heavily doped GaAs — •Maciej Oskar Liedke[1], Slawomir Prucnal[2], Maik Butterling[1], Juanmei Duan[2], Eric Hirschmann[1], Mao Wang[2], Manfred Helm[2], Shengqiang Zhou[2], and Andreas Wagner[1] — [1]Institute for Radiation Physics, Helmholtz-Zentrum Dresden - Rossendorf, Dresden, Germany — [2]Institute for Ion Beam Physics, Helmholtz-Zentrum Dresden - Rossendorf, Dresden, Germany

The effect of intense pulsed laser melting and flash lamp annealing on defects distribution and activation efficiency in chalcogenide-implanted GaAs was investigated by means of positron annihilation spectroscopy and transport measurements. Using positrons as a sensitive probe of open volumes and dedicated DFT calculations, we will highlight the capability of nanosecond pulsed laser melting to control the type and density of defect complexes, e.g. S or Te substituting As atoms associated to Ga vacancy, playing a crucial role for donor deactivation. The distribution of defects and carriers will be discussed regarding the depth distribution of implanted elements and the solidification velocity during recrystallization.

HL 6: Focus Session: Frontiers of Electronic-Structure Theory III (joint session O/HL)

Electronic-structure calculations, based on density-functional theory (DFT) and methodology beyond, are getting increasingly involved as they face the following challenges: First, investigations of modern materials typically require large unit cells, owing to complex crystal structures, mixed compositions, internal interfaces, etc. Second, at the same time, they often require advanced methods, including hybrid functionals of DFT, Green-function techniques from many-body perturbation theory (MBPT), high-level wavefunction-based methods like coupled-cluster (CC) theory, or quantum Monte-Carlo simulations. All these methods should ideally be implemented in scientific software that is running efficiently on modern supercomputers. With both methodology and computer architectures exhibiting increasing complexity, collaborative development and shared tools, including ready-to-use libraries and codes, are becoming indispensable. This interdisciplinary symposium covers recent progress in the broad area of electron-structure methods and highly-sophisticated tools that enable the entire community to explore most exciting materials from different perspectives to either predict peculiar features or get insight into measured counterparts.

Testing the hell out of DFT codes with virtual oxides — Emanuele Bosoni[1], •Stefaan Cottenier[2], and Giovanni Pizzi[3] — [1]ICMAB-CSIC, Spain — [2]Ghent University, Belgium — [3]EPFL, Switzerland

If you use DFT to predict a property of a crystal, how confident can you be that the prediction is computed in a bug-free way? And if your DFT-code uses pseudopotentials, can you trust that the pseudopotential does not modify your predictions? Answering such questions has been the goal of a study a few years ago, in which 71 unary crystals were examined in exactly the same way by 40 different DFT methods and codes [DOI 10.1126/science.aad3000]. In a next step, a consortium of 41 scientists (*) has done a similar exercise for a much larger pool of crystals: all elements of the periodic table up to Z=96, each in 10 different crystal structures, 6 of them being (virtual) oxides that sample a range of chemical bond types and 4 being unary crystals that sample low to high coordination environments. In this presentation, we will discuss the reasons to choose these crystals, the different quality criteria by which results can be compared, we will demonstrate how this exercise leads to more precise and more trustworthy pseudopotential libraries, and we will show how this data set is shared with the community in order to foster better-tested codes and pseudopotentials for all.

(*) Unfortunately the size of this abstract does not allow to mention them all.

High-throughput absorption spectra obtained by beyond-DFT workflows — •Fabian Peschel, Alexander Buccheri, and Claudia Draxl — Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany

Fully converging *ab initio* calculations can be a challenging task, in particular when it comes to excited states, which require multiple ground-state calculations for different physical quantities. In this work, we aim at computing highly precise absorption spectra by employing the Bethe-Salpeter equation of many-body perturbation theory, as implemented in the all-electron full-potential package `exciting` [1,2]. To obtain benchmark data for a wide range of material classes, we have developed workflows where Python tools automatically create input files, start calculations, and evaluate results. For each material, all relevant input parameters, such as the number of k-points for the Brillouin-zone sampling, basis-set basis cutoff and the number of unoccupied states, are varied until the targeted convergence criteria are reached. With the help of a workflow manager, the calculations can be executed in a high-throughput fashion on a high-performance computing cluster. We demonstrate our approach with core-level spectra of elemental and binary solids, and provide an in-depth analysis of the obtained data. This work is carried out in the framework of the NOMAD Center of Excellence [3] and the CRC FONDA [4].

Topical Talk HL 6.3 Mon 11:00 TRE Ma
Large-scale machine-learning assisted discovery and characterization of materials — •Miguel Alexandre Lopes Marques — Institut für Physik Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany
In this talk we discuss our recent attempts to discover, characterize, and understand inorganic compounds using ab initio approaches accelerated by machine learning. We start by motivating why the search for new materials is nowadays one of the most pressing technological problems. Then we summarize our recent work in using crystal-graph attention neural networks for the prediction of materials properties. To train these networks, we curated a dataset of over 2 million density-functional calculations with consistent calculation parameters. Combining the data and the newly developed networks we have already scanned more than two thousand prototypes spanning a space of more than one billion materials and identified tens of thousands of theoretically stable compounds. We then discuss how simple, interpretable machine learning approaches can be used to understand complex material properties, such as the transition temperature of superconductors. Finally, we speculate which role machine learning will have in the future of materials science.

HL 6.4 Mon 11:45 TRE Ma
Predicting the electronic structure at any length scale with machine learning — •Attila Cangi — Helmholtz-Zentrum Dresden-Rossendorf, Görlitz, Germany
The properties of electrons in matter are of fundamental importance. They give rise to virtually all molecular and material properties and determine the physics at play in objects ranging from semiconductor devices to the interior of giant gas planets. Calculations rely primarily on density functional theory (DFT), which has become the principal method for predicting the electronic structure of matter. While DFT calculations have proven to be very useful, their computational scaling limits them to small systems. We have developed a scalable machine learning framework for predicting the electronic structure on any length scale [1,2,3]. It shows up to three orders of magnitude speedup on systems where DFT is tractable and, more importantly, enables predictions on scales where DFT calculations are infeasible. Our work demonstrates how machine learning circumvents a long-standing computational bottleneck and advances science to frontiers intractable with any current solutions.

HL 6.5 Mon 12:00 TRE Ma
Demonstrating temperature transferability of neural network models replacing modern density functional theory — •Lenz Fiedler and Attila Cangi — Helmholtz-Zentrum Dresden-Rossendorf / CASUS
Due to its balance between accuracy and computational cost, Density Functional Theory (DFT) is one of the most important computational methods within materials science and chemistry. However, current research efforts such as the modeling of matter under extreme conditions demand the application of DFT to larger length scales as well as higher temperatures. Such investigations are currently prohibited due to the computational scaling of DFT.
We have recently introduced a machine-learning workflow that replaces modern DFT calculations [1,2,3]. This workflow uses neural networks to predict the electronic structure locally. We show that by employing such an approach, models can be trained to predict the electronic structure of matter across temperature ranges. This paves the way for large-scale simulations of thermodynamically

sampled observables relevant to modeling technologically important phenomena such as radiation damage in fusion reactor walls.

Pure non-local machine-learned density functional theory for electron correlation — •Johannes T. Margraf — Fritz-Haber-Institut der MPG, Berlin, Germany
Density-functional theory (DFT) is a rigorous and (in principle) exact framework for the description of the ground state properties of atoms, molecules and solids based on their electron density. While computationally efficient density-functional approximations (DFAs) have become essential tools in computational chemistry, their (semi-)local treatment of electron correlation has a number of well-known pathologies, e.g. related to electron self-interaction. Here, we present a type of machine-learning (ML) based DFA (termed Kernel Density Functional Approximation, KDFA) that is pure, non-local and transferable, and can be efficiently trained with fully quantitative reference methods. The functionals retain the mean-field computational cost of common DFAs and are shown to be applicable to non-covalent, ionic and covalent interactions, as well as across different system sizes.

HL 6.7 Mon 12:30 TRE Ma
Predicting the response of the electron density to electric field using machine learning — •Alan Lewis and Mariana Rossi — MPI for Structure and Dynamics of Materials, Hamburg, Germany
The response of the electron density of a molecule or material to a homogeneous electric field defines its dielectric constant, along with its Raman and sum-frequency spectrum. We present a local and transferable machine learning approach capable of predicting the density response of molecules and periodic system on the same footing. This uses a very similar framework to that of the SALTED method recently introduced by these authors,[1,2] requiring only a small modification to the $\lambda-$SOAP descriptors used to represent the atomic environments. This allows us to predict the density response of liquid water to a field applied in each Cartesian direction from a single machine learning model. The tensorial dielectric constant can then be derived from this predicted density response, dramatically reducing the computational cost of calculating these properties relative to the standard approach of using density functional perturbation theory. We discuss the transferability of the model to different phases, and demonstrate the extrapolative power of this approach.

Analysis of Batching Methods in Graph Neural Network Models for Materials Science — •Daniel Speckhard, Tim Bechtel, Jonathan Godwin, and Claudia Draxl — Humboldt-Universität zu Berlin, Physics Department and IRIS Adlershof, Berlin, Germany
Graph neural network (GNN) based models have shown promising results for materials science [1]. These models often contain millions of parameters, and like other big-data based models, require only a portion of the entire training dataset to be fed as a mini-batch to update model parameters. The effect of batching on the computational requirements of training and model performance has been thoroughly explored for neural networks [2] but not yet for GNNs. We explore two different types of mini-batching methods for graph based models, static batching and dynamic batching. We use the Jraph library built on JAX to perform our experiments where we compare the two batching processes for two data-sets, the QM9 dataset of small molecules and the AFLOW materials database [3]. We show that dynamic batching offers significant improvements in terms of computational requirements for training. We also present results on the effect of the batch size and batching method on model performance.

Investigation of the P-line in indium doped silicon with low temperature photoluminescence by applying an illumination and annealing cycle — •Dominik Bratek, Katharina Peh, Kevin Lauer, Dirk Schulze, Stefan Krischok, Aaron Flötotto, and Robin Müller — Institut für Physik, Technische Universität Ilmenau, Weimarer Str. 32, 98693 Ilmenau, Germany

In recent years a photoluminescent feature called P-line is of rising interest for the current research [1,2,3] and, in combination with the so called ASiSii-defect model, may lead to an explanation of the infamous light induced degradation (LID) process in indium doped silicon [2,3]. In this contribution we show studies of indium implanted silicon by using low temperature photoluminescence (LTPL) spectroscopy. We investigate the LID cycle and it*s influence on the P-line and show a possibility to explained the observed behavior by the proposed energy diagram of the ASiSii-defect. In addition we present activation energies, determined during these investigations, which can be associated to ASiSii-defect transitions. [1] K. Terashima und T. Matsuda, Japanese Journal of Applied Physics 41 Part 1, No. 3A (2002). [2] K. Lauer, C. Möller, D. Schulze, and C. Ahrens, AIP Advances 5, 017101 (2015). [3] K. Lauer, C. Möller, C. Teßmann, D. HL 7.2 Mon 13:00 P2/EG

Investigation of the influence of light-induced degradation on boron-doped silicon — •Robin Lars Benedikt Müller, Katharina Peh, Kevin Lauer, Dirk Schulze, Stefan Krischok, Dominik Bratek, and Aaron Flötotto — TU Ilmenau

For Si-based devices like solar cells or radiation detectors, the light-induced-degradation (LID) in doped Czochralski Si is a profound issue. A reasonable explanation for the appearing LID process is the so-called ASi-Sii defect model [1,2], whose possible defect configuration manifests itself in indium-doped silicon by the appearance of the so-called P-line in the spectrum of low-temperature photoluminescence (LTPL) [3]. Comparatively, boron-doped Si does not exhibit a equivalent line, instead showing near the associated energy only the well-known electron-hole liquid (EHL) luminescence [4]. Therefore we investigate the influence of various treatments such as illumination, annealing or quenching on the LTPL spectrum of different boron-doped Si samples with emphasis on the behavior of the EHL. Additionally we present EPR studies on the impact of these treatments. [1]: Möller, C. et.al, (2013), Light-induced degradation in indium-doped silicon. Phys. Status Solidi RRL, 7: 461-464 [2]: Möller, C. et.al. , ASi-Sii-defect Model of Light-induced Degradation in Silicon, Energy Procedia, Volume 55, 2014, Pages 559-563 [3]: Lauer, K. et.al., "Identification of photoluminescence P line in indium doped silicon as InSi-Sii defect", AIP Advances 5, 017101 (2015) [4]: Peh, K. et.al., Low-Temperature Photoluminescence Investigation of Light-Induced Degradation in Boron-Doped CZ Silicon. HL 7.3 Mon 13:00 P2/EG

Atomic layer deposition of iron titanate for use as a photoanode — •Nina Miller[1,2], Ryan Kisslinger[1,2], and Ian Sharp[1,2] — [1]Walter Schottky Institut Technical University of Munich — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich, Garching, Germany

TiO_2 is of significant importance in the field of energy research. However, to develop it for artificial photosynthesis, the band gap of TiO_2, which is 3.2 eV and consequently absorbs only ultraviolet light, must be paired with a material capable of absorbing visible light. Here, we experimentally explore the effect of depositing thin films of hematite (α - Fe_2O_3) on nanostructured TiO_2 using atomic layer deposition, with a further high-temperature annealing step to produce visible-light absorbing iron titanate (Fe_2TiO_5). Iron titanate may allow enhance charge transfer at the photoanode surface, and serve as a visible light absorbing layer. Furthermore, the TiO_2 nanotube arrays used as the substrate during atomic layer deposition can orthogonalize light absorption with respect to charge separation, leading to enhanced photocatalytic conversion during solar water splitting.

HL 7.4 Mon 13:00 P2/EG

Polaron Transport in $BiVO_4$ — •Sven Doll, Tim Rieth, David Vogl, Viktoria F. Kunzelmann, Ian D. Sharp, and Martin S. Brandt — Walter Schottky Institut and School of Natural Sciences, Technische Universität München, 85748 Garching

Bismuth vanadate ($BiVO_4$) is a promising photoelectrode material for solar-to-fuel conversion. This semiconductor is particularly interesting considering its strong visible light absorption, efficient charge carrier separation, and favorable quasi-Fermi-level alignment with relevant redox potentials. However, temperature-dependent photoconductivity measurements indicate thermally-activated hopping transport of small polarons, with transport barriers of several hundred meV. To gain further insight into charge carrier transport and the nature of these polaronic states, we explore whether the hopping of the small polarons in $BiVO_4$ is spin-dependent using electrically detected magnetic resonance. Since such spin-dependent signals are known (e.g., from similar experiments on doped crystalline silicon) to critically depend on the charge carrier density, we evaluate the possibility to use the persistent photoconductivity of $BiVO_4$ to tune the polaron density. This technique may provide valuable insights into the microscopic transport processes in modern photoelectrodes used for energy conversion. This work was supported by the DFG under Germany's Excellence Strategy - EXC 2089/1 - 390776260.

HL 7.5 Mon 13:00 P2/EG

In silico tuning the properties of inorganic-organic hybrid systems — •Mohammed El Amine Miloudi and Oliver Kühn — Institute of Physics, Rostock University, Albert-Einstein-Str. 23-24 18059 Rostock

Two-dimensional (2D) materials are expanding the range of processes that can be studied in two dimensions as well as in van der Waals (vdW) heterostructures. Integrating organic molecules into these systems has enormous potential because nature offers a finite number of 2D materials. Still, an almost unlimited range of molecules can be tailored and synthesized with predictable properties. Organic compounds are widely known for their high absorption with low mobility and charge stability, whereas inorganic compounds have comparatively low absorption with excellent charge transport properties. Thus, the formation of vdW heterostructures that combines an inorganic compound with organic molecules potentially offers the advantages of both. Molybdenum disulfide (MoS2), one of the transition-metal dichalcogenides (TMDs), is one of the most exciting 2D semiconductors holding promises for potential applications in transistors, optoelectronics, and catalysis. Perylenes are widely used dyes whose optical properties can be tuned by chemical modification of the perylene core. Here we report on a systematic study of the structural, electronic, and optical properties of MoS2/perylene hybrid systems by means of density functional theory. Using different perylenes (perylene orange, perylene diimide, and perylene red) highlights the extent to which property tuning can be achieved in the hybrid system.

HL 7.6 Mon 13:00 P2/EG

Epitaxial growth of GaN buffer layers on Si(111) by reactive magnetron sputtering — •Ralf Borgmann, Florian Hörich, Jürgen Bläsing, Anja Dempewolf, Frank Bertram, Jürgen Christen, Gordon Schmidt, Peter Veit, André Strittmatter, and Armin Dadgar — Otto-von-Guericke-Universität Magdeburg, FNW-IfP, Universitätsplatz 2, 39106 Magdeburg

GaN is a key material typically grown by MOVPE for high-voltage electronic devices. Reactive sputter epitaxy is an alternative to MOVPE, potentially offering much lower growth cost. Recently, we achieved high quality AlN layers on Si(111) [1] on which (Al,Ga)N layers can be grown. We present study on the effects of ammonia flow and growth temperature on GaN layer quality using MOVPE-grown GaN templates, high purity gases and targets. At Tgrowth ~705 °C and an ammonia flow of ~20 sccm, GaN shows a smooth surface and XRD (0002) ω-FWHMs around 340 arcsec. AlGaN layers can be grown in a large composition range by Al- and Ga- co-sputtering resulting in very smooth surfaces. A sputtered 1.4 mum thick AlN/AlGaN/GaN layer stack on Si(111) shows high resistivity and a vertical breakdown field strength >2.5 MV/cm, ideal as buffer for transistor devices. [1] F. Hörich et al., Journal of Crystal Growth 571, 126250 (2021)

HL 7.7   Mon 13:00   P2/EG

Molybdenum disulfide/diselenide deposition by radio frequency sputtering towards facile integration as heterojunction — •Oscar Alberto Lopez Galan[1,2], Manuel Ramos[3], and Torben Boll[1] — [1]Institute of Applied Materials (IAM-WK), Karlsruhe Institute of Technology (KIT), Eggenstein-Leopolshafen, Germany — [2]Institute of Nanotechnology (INT), Karlsruhe Institute of Technology (KIT), Eggenstein-Leopolshafen, Germany — [3]Instituto de Ingenieria y Tecnologia, Universidad Autonoma de Ciudad Juarez (UACJ), Ciudad Juarez, Mexico

The fabrication of heterojunctions using transition metal dichalcogenides remains a fundamental challenge in solid-state technology. In this work, we studied vertical MoS2/MoSe2 heterojunctions deposited by radio frequency sputtering at 3 thicknesses, 300 nm, 500 nm, and 600 nm. We found a dependency between thickness and crystal structure; the sample with a total thickness of 500 nm presents a crystal size of 64 nm while the thinner and thicker samples appear amorphous. Scanning electron microscopy and Raman spectroscopy reveal the presence of MoS2 and MoSe2 distinctly. Measurements by atom probe tomography indicate that MoS2 and MoSe2 are not having a sharp interface. This may influence the electrical performance of the device since dangling bonds and lattice mismatch between MoS2 and MoSe2 limit the charge carriers flow. Density functional calculations reveal a type-I heterojunction, with a reduced band gap of ~1.0 eV and a potential alignment of 0.5 eV.

HL 7.8   Mon 13:00   P2/EG

Atomic structure of As-modified Si(100) surfaces prepared in CVD ambience — Manali Nandy[1], Agnieszka Paszuk[1], Oleksandr Romanyuk[2], •Chris Yannic Bohlemann[1], Aaron Flötotto[3], Aaron Giess[1], Peter Kleinschmidt[1], Ivan Gordeev[2], Jana Houdkova[2], Erich Runge[3], and Thomas Hannappel[1] — [1]Fundamentals of Energy Materials, Institute of Physics, Ilmenau University of Technology, Ilmenau, Germany — [2]Institute of Physics, Academy of Sciences of the Czech Republic, Prague, Czech Republic — [3]Theoretical Physics 1, Institute of Physics, Ilmenau University of Technology, Ilmenau, Germany

For highly efficient III-V-on-Si devices, a low-defect III-V nucleation and a sharp interface are prerequisites. Stabilization of Si surfaces by arsenic is a promising technological step allowing to grow As-based III-V epitaxial layers in consecutive process steps. Here, we study the atomic structure of Si(100) surfaces prepared in As-rich ambiance utilizing MOCVD. Arsenic was supplied either directly via the precursor (TBAs) or indirectly as background As_4. The Si(100):As surfaces were analysed with a multitude of techniques such as STM, LEED, AR-XPS and FTIR after contamination-free transfer to ultra-high vacuum. The experimental results are supported by *ab initio* density functional theory (DFT) calculations. STM scans provide atomic-scale details of As-stabilized Si(100) surface structure consisting of rows of predominately asymmetric dimers. DFT simulations revealed a new stable structure with asymmetric As-Si-H dimers. The presence of hydrogen on the surface was confirmed by FTIR.

HL 7.9   Mon 13:00   P2/EG

Preparation of P- and III-rich GaInP (100) with subsequential water & oxygen exposure — •David Ostheimer, Mohammad Amin Zare Pour, Sahar Shekerabi, Agnieszka Paszuk, and Thomas Hannappel — Technische Universität Ilmenau, Ilmenau, Deutschland

III/V semiconductor multi-junction photoelectrochemical cells enable, either direct or indirect solar-to-fuel conversion with highest efficiencies to date, as their tunable bandgap enables optimal use of the solar spectrum. In tandem devices, GaInP has an appropriate bandgap for a top photoabsorber or a transparent, charge selective contact (window layer). A detailed understanding of the reactions at the semiconductor/electrolyte heterointerface is crucial to tailor the semiconductor surface appropriately to avoid trapping of the photogenerated charge carriers and reduce corrosion. Here, we study interaction of oxygen and water with the mixed-dimer, group-III-rich and phosphorus-rich GaInP (100) surface by combining in situ optical spectroscopy and in system photoelectron spectroscopy. The GaInP(100) surfaces were prepared by metal-organic chemical vapor deposition. The surface reconstruction of the as-prepared samples and after exposure was investigated by low energy electron diffraction. We find that the surface reconstruction of the GaInP(100) significantly affects its interaction with water. P-rich GaInP(100) surface shows much higher stability compared to the group-III-rich.

HL 7.10   Mon 13:00   P2/EG

Band energy diagrams of n-GaInP/n-AlInP(100) surfaces and heterointerfaces — •Mohammad Amin Zare Pour[1], Oleksandr Romanyuk[2], Dominik C. Moritz[3], Agnieszka Paszuk[1], Clément Maheu[3], Sahar Shekerabi[1], Kai Daniel Hanke[1], David Ostheimer[1], Thomas Mayer[3], Jan P. Hofmann[3], Wolfram Jaegermann[3], and Thomas Hannappel[1] — [1]Technische Universität Ilmenau, Ilmenau, Germany — [2]Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic — [3]Technical University of Darmstadt, Darmstadt, Germany

n-AlInP(100) charge selective contacts are commonly grown on n-p GaInP(100) top absorbers in high-efficiency III-V multijunction solar or photoelectrochemi-

cal cells. Understanding the atomic and electronic properties of the GaInP/AlInP heterointerface is crucial for the reduction of photocurrent losses in multijunction devices. We investigated chemical composition and electronic properties of n-GaInP/n-AlInP heterostructures by X-ray photoelectron spectroscopy (XPS). 1-50 nm thick n-AlInP(100) epitaxial layers were grown on n-GaInP(100) buffer layer on n-GaAs(100) substrates by metal organic vapor phase epitaxy. We observed (2x2)/c(4x2) low-energy electron diffraction patterns on both AlInP(100) and GaInP(100) as-prepared surfaces. An upward surface band bending probably caused by localized mid-gap electronic states was observed. Pinning of the Fermi level by localized electronic states remained in n-GaInP/n-AlInP heterostructures. A valence band offset of +0.2 eV was derived by XPS and band diagram models for the n-n junctions were suggested.

HL 7.11   Mon 13:00   P2/EG

GaAs/PEDOT:PSS Hybrid Solar Cell Improvement by the Incorporation of Ternary Quantum Dots — •Alexander Ehm[1], Oleksandr Selyshchev[1], Serhiy Kondratenko[2], and Dietrich R. T. Zahn[1] — [1]Semiconductor Physics, TU Chemnitz, Chemnitz D-09107, Germany — [2]Taras Shevchenko National University of Kyiv, 01601 Kyiv, Ukraine

Colloidal quantum dots (QD) have gained much interest over recent years due to their absorption and photoluminescence properties, which can be tuned by varying the particle size. Among these, ternary In-based chalcogenide QDs possess the advantage of low toxicity, making them more environmentally friendly candidates for the application in solar harvesting devices for green energy production.

As a prove of concept, colloidal AgInS and CuInS QDs [1] are deposited on n-GaAs(100) substrates in order to incorporate them in hybrid GaAs/PEDOT:PSS solar cells. The deposition is verified and analysed by X-ray photoemission and optical spectroscopy methods as well as atomic force microscopy. A significantly enhanced power conversion efficiency of such solar cells modified by colloidal QDs compared to the devices without QDs is shown by current density-voltage measurements under AM1.5 equivalent illumination.

One-dimensional topological interface states: a novel approach for optical pressure sensors — •Jakob Lindenthal[1,2], Anton Widulla[1], Johannes Benduhn[1], and Karl Leo[1,2] — [1]Dresden Integrated Center for Applied Physics and Photonic Materials, Technische Universität Dresden — [2]ct.qmat - Würzburg-Dresden Cluster of Excellence

The research field of nano-optics in connection with topological photonics has quickly evolved over the past decade. Topological considerations in the design of photonic systems open a wide range of possibilities for disorder protection and electric field alignment optimisation. Different material systems and topological setups are discussed in the context of pressure-sensitive nano-optical resonators, demonstrating a novel, highly versatile pressure sensor concept. The demonstrated system combines a compressible optical microcavity with an organic absorber material, which allows highly sensitive pressure-dependent tuning of the mode intensity. The contribution features modelling and characterisation results for systems with different topologies, showing pathways to significant topology-induced sensitivity enhancement. The use of coupled cavities is shown to provide additional sensing information with potential for industrial implementation.

HL 7.13   Mon 13:00   P2/EG

Electric-field-induced second harmonic generation in amorphous materials for hybrid photonic structures — •Laurids Wardenberg, Benito Bunk, and Jörg Schilling — Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany

We investigate electric-field-induced second harmonic generation (EFISH) on different amorphous materials, e.g a-Si and As_2S_3 films. These materials have sizeable $\chi^{(3)}$ values but a vanishing $\chi^{(2)}$ due to their amorphous structure. Applying a dc-voltage we gain the ability to create a quasi-$\chi^{(2)}$ and perform second order nonlinear optical processes. The possibility to manipulate value and polarity of the created quasi-$\chi^{(2)}$ allows an unprecedented control over these second order wavelength conversion processes. Introducing a way to electrically modulate and switch this nonlinearity, is of high practical interest for the realization of nonlinear active hybrid photonic structures.

Since EFISH is strongly associated with the $\chi^{(3)}$, we use the z-scan technique to determine the real and the imaginary parts of the $\chi^{(3)}$ of the investigated films. Subsequently chromium contacts were deposited on the films and electric fields up to 10^5 V/m were applied. Our voltage and intensity dependent SHG measurements show a quadratic dependence on input intensity and applied DC field, which is a clear indicator for EFISH. The nonlinear optical measurements are mainly performed at a wavelength of 1030 nm using a femtosecond laser system supplying 200 fs pulses at a repetition rate of 1 kHz. Additional measurements at wavelengths above 1200 nm, which are of interest for silicon photonics, will be demonstrated as well.

HL 7.14   Mon 13:00   P2/EG

Excitons in lithium niobate and their impact on non-linear optical proper-
ties — •Agnieszka Kozub, Wolf Gero Schmidt, and Uwe Gerstmann —
Universität Paderborn, Department Physik, 33095 Paderborn, Germany

The influence of self-trapped and vacancy-trapped excitons on the lithium nio-
bate (LiNbO$_3$, LN) dielectric function and nonlinear susceptibility is calculated
based on density-functional theory. The PBE0 hybrid functional is used for the
description of electron exchange and correlation. The dielectric function it ob-
tained by solving the Bethe-Salpeter equation. This yields an absorption peak at
2.6 eV, in perfect agreement with experiment [1]. The second- and third order-
nonlinear susceptibility tensors are obtained from a Berry-phase formulation
of the dynamical polarization. A strong enhancement of the susceptibilities for
photon energies in the band gap region is noted to arise from localized excitons.

Structured Gradient Index Silicon (Oxy)Nitride Layers for Antireflection
in Silicon Solar Cells — •Florian Damerau[1], Maria Gaudig[1], Ralf
Wehrspohn[1], Prerak Dhawan[2], Carsten Rockstuhl[2], and Alexander
Sprafke[1] — [1]Institute of Physics, Martin Luther University Halle-Wittenberg,
Heinrich-Damerow-Str. 4, 06120 Halle (Saale), Germany — [2]Institute of Theo-
retical Solid State Physics, Karlsruhe Institute of Technology, 76131 Karlsruhe,
Germany

The frontside of crystalline silicon (c-Si) solar cells oftentimes is micro- or nan-
otextured to increase light in-coupling, and thus conversion efficiency. Current
state-of-the-art textures comprise micron sized pyramidal structures, whereas
future ultrathin c-Si solar cells demand new approaches such as submicron
nanophotonic structures. However, directly nanotexturing the Si surface de-
grades its electronic properties strongly, such that a possible gain in absorption
does not necessarily translate into an increased conversion efficiency. In this
work, we aim to maintain the electronic properties of a planar c-Si interface by
leaving it intact but place a nanophotonic structure on top. This structure con-
sists of a nanstructured SiOxNy layer. Moreover, changing the stoichiometry
(x,y) during deposition enables us to smoothly vary its refractive index between
$n \approx 1.5 - 3.0$. Inspired by transformation optics, we aim to mimic the optical
properties of strongly non-planar textures such as black silicon by a planar layer
of smoothly varying spatial-dependant refractive index. In this contribution we
will present experimental results on the microstructure as well as on the optical
properties of our fabricated structures.

HL 7.16   Mon 13:00   P2/EG

Exciton-polariton emission in copper halides — •E. Krüger[1], S. Merker[2],
S. Blaurock[2], R. Hildebrandt[1], A.L. Pereira[1], L. Käferstein[1], H.
Krautscheid[2], M. Grundmann[1], and C. Sturm[1] — [1]Universität Leipzig,
Felix-Bloch-Institut für Festkörperphysik, Germany — [2]Universität Leipzig, In-
stitut für Anorganische Chemie, Germany

Copper halides (CuI, CuBr, and CuCl) have recently attracted research interest
since they combine intrinsic p-type conductivity with large bandgaps (3.1 eV -
3.4 eV) and high exciton binding energies (62 meV - 190 meV), making them
promising candidates for applications in transparent optoelectronics [1].

Here, we present an overview of the optical properties of solution grown Cu-
halide bulk single crystals, focusing especially on spectral- and time-resolved
measurements of the near-band-edge luminescence for temperatures between
10 K and room temperature. The line shape of the emission lines at low tem-
peratures is interpreted in terms of exciton-polaritons and their dispersion re-
lation [2]. The different decay characteristics of free and localized states are ex-
plained by their coupled interaction. In addition to observation of an anomalous
temperature-dependent bandgap shift to higher energies with increasing tem-
perature we present in detail the temperature-dependent decay characteristics of
the polariton emission and discuss the corresponding relaxation mechanisms.

Persistent spectral holeburning of the donor-bound exciton transition in
ultra-pure ^{28}Si:P — •Nico Eggeling[1], Michael Oestreich[1], Eduard
Sauter[1], Jens Huebner[1], and N. V. Abrosimov[2] — [1]Leibniz Universität Han-
nover, Germany — [2]IKZ Berlin, Germany

We utilize persistent spectral hole burning to determine the origin of dynamic
and static spectral broadening of the donor-bound exciton transition in ultra-
pure ^{28}Si:P with 99.995% isotopic enrichment [1]. From time-dependent mea-
surements of the spectral hole width and frequency shift we try to determine
the impact of donor-acceptor interaction on the spectral transition broadening.
The donor-acceptor pair recombination is on the order of seconds in the inves-
tigated sample with a donor concentration of $1.2 \times 10^{15} cm^{-3}$ and an acceptor
concentration of estimately $4.6(10) \times 10^{13} cm^{-3}$. We expect to observe an impact
of the recombination dynamics on the measured frequency and width of spectral
holes. These results could lead to a better understanding of spin initialization for

donors in ^{28}Si:P, which are a promising candidate for quantum computation [2].

HL 7.18   Mon 13:00   P2/EG

Manipulating the luminescence of a rare-earth doped spacer — •Sören
Lerner[1], Francesco Vitale[1], Thomas Siefke[2], Uwe Zeitner[2,3], and
Carsten Ronning[1] — [1]Institute of Solid State Physics, Friedrich-Schiller Uni-
versität, Helmholtzweg 3, 07743 Jena, Germany — [2]Institute of Applied Physics,
Friedrich Schiller Universität, Albert-Einstein-Straße 15, 07745 Jena, Germany
— [3]Fraunhofer Institute for Applied Optics and Precision Engineering IOF,
Albert-Einstein-Straße 7, 07745 Jena, Germany

The coupling of rare-earth elements with surface plasmon polaritons can lead
to a change of their emission properties. We implant rare-earth elements in a
nanometric silica spacer on top of an aluminum layer by ion beam implanta-
tion. The luminescence properties of such systems were examined by photo-
and cathodoluminescence measurements. Placing zinc oxide nanowires on top
of this two-layer system allows for additional coupling with surface plasmon po-
laritons, which generate a high electric field density in the spacer layer. The re-
spective effects and the possibilities of tailoring the emission will be discussed.

HL 7.19   Mon 13:00   P2/EG

Coupling of Excitons and Plasmons with Phonons in Raman scatter-
ing for CuI — •R. Hildebrandt[1], S. Blaurock[2], H. Krautscheid[2], M.
Grundmann[1], and C. Sturm[1] — [1]Universität Leipzig, Felix Bloch Institute
for Solid State Physics, Germany — [2]Universität Leipzig, Institute of Inorganic
Chemistry, Germany

CuI is an intrinsic p-type with potential for opto-electronic applications. Via
resonance effects, various of its fundamental properties may be accessed. For
CuI we investigate phonon-exciton- and phonon-plasmon-interactions by Ra-
man spectroscopy.

We present Raman spectra with excitation wavelength of 532 nm, 355 nm and
325 nm for single crystals and thin films. Each excitation wavelength indicates
different fundamental Raman scattering processes. With 532 nm fundamental
modes as well as second order Raman singals are observed and analyzed [1].
For doped samples with $p = 10^{18} cm^{-3}$, phonon-plasmon coupling is observed
which is compared with Hall measurements. By 355 nm excitation, slightly above
the bandgap, a phonon damped-plasmon mode coupling modifies the Raman
spectra [2]. Finally with a 325 nm a transition close to $E_g + \Delta_0$, indicates a cas-
cade exciton scattering process. This is dominated by the Fröhlich interaction
and n-LO overtones up to $n = 7$ are observed [3]. For each excitation wave-
length, an overview of possible applications and possible limits for CuI is shown.

HL 7.20   Mon 13:00   P2/EG

Raman spectra of CuI alloys with Ag and Br — •A.L. Pereira[1], R.
Hildebrandt[1], J. Bredow[1], C. Dethloff[1], V. Gottschalch[2], S. Vogt[1], H.
Krautscheid[2], M. Grundmann[1], and C. Sturm[1] — [1]Universität Leipzig, Felix
Bloch Institute for Solid State Physics, 04103 Leipzig, Germany — [2]Universität
Leipzig, Institute of Inorganic Chemistry, 04103 Leipzig, Germany

CuI is a p-type semiconductor with a wide band gap of 3.1 eV that has potential
for (opto-) electronic applications [1]. By alloying CuI with isoelectronic Ag or
Br its properties such as e.g. the charge carrier concentration, lattice constant or
band gap can be tuned.

We present our investigations on CuI alloys and their phonon properties with
Raman spectroscopy. $Ag_xCu_{1-x}I$ and $CuBr_xI_{1-x}$ (both $0 \leq x \leq 1$) thin films
were produced with various deposition techniques such as solid-state reaction,
close distance sublimation, sputter deposition and pulsed laser deposition. Ra-
man spectroscopy measurements were conducted at low temperatures and the
phonon modes were analyzed regarding their energetic position, broadening and
intensity. This was supported by an oscillator strength model [2]. The Cu(Br,I)
alloy revealed a nonlinear dependence of the Raman shift on the composition.
In the (Ag,Cu)I alloy an apparent three-mode behavior due to a defect mode was
observed and characterized.

Excited-state properties of PbWO4 from ab initio calculations — •Ather Ah-
mad and Kai-Thomas Brinkmann — II. Phys. Inst. Gießen

Fast response, high density and radiation hardness make lead tungstate (PbWO4
or PWO) a well suited scintillator for an electromagnetic calorimeter. Lead
tungstate crystals are already used as working material in various experiments,
e.g. the CMS at the LHC in CERN. New generation crystals (PWO-II) with
improved properties were developed for the PANDA experiment at FAIR in
Darmstadt. To reduce absorption of the scintillation light within the crystals,

the lead tungstate is doped with Lanthanum and Yttrium. This results in a change of the electronic and optical properties.

In order to assess the functionality of the calorimeter, we first need to analyse these electronic and optical properties of lead tungstate. In our work, we investigate these properties of lead tungstate containing different impurities and defects with ab initio calculations to derive its radiation hardness and scintillation mechanism.

This project is supported by HFHF and HGS-hire

Multiphoton absorption induced photoluminescence in CuI — •Andreas Müller[1], Sebastian Henn[1], Evgeny Krüger[1], Steffen Blaurock[2], Harald Krautscheid[2], Marius Grundmann[1], and Chris Sturm[1] — [1]Felix-Bloch-Institut für Festkörperphysik, Universität Leipzig, Linnéstr. 5, 04103 Leipzig, Germany — [2]Institut für Anorganische Chemie, Universität Leipzig, Johannisallee 29, 04103 Leipzig, Germany

Two- and three-photon absorption induced photoluminescence (2PAPL, 3PAPL) are nonlinear optical processes useful for energy upconversion or, in contrast to near-to-the-surface single-photon absorption, excitation within the bulk material.

In this work, we report on low temperature (30 K) 2PAPL and 3PAPL in transparent conducting CuI crystals (E_g = 3.1 eV), analyzed employing excitation energy and density-dependent, steady-state, and time-resolved photoluminescence. Using an excitation energy that corresponds to half of the bandgap energy, the observed intensity dependence on the excitation power shows an almost parabolic behavior. By a further reduction of the photon energy, the cubic contribution of the excitation power on the intensity increases, and for low excitation energies, an almost cubic behavior is obtained. We describe the experimental findings, taking into account the sum of the two- and three-photon transition rates and including the Gaussian spectral intensity distribution of the laser. Through this analysis, the ratio of the cross-sections for the two- and three-photon absorption is estimated to be 10^{-5} cm^2/s.

Optical properties of the organic semiconductor Dimethylanthradithiophene (DMADT) — •Anncharlott Kusber and Martin Knupfer — IFW Dresden, Helmholtz Straße 20, D-01069 Dresden, Germany

This work presents an analysis of the optical properties of anti- and syn-dimethylanthradithiophene. We have produced 120 nm thick thin films by physical vapour deposition. Using optical spectroscopy, we were able to characterize the films in the visible range. Davydov splitting, due to the existence of two molecules in the unit cell, was observed. Besides that, we measured the exciton dispersion by using electron energy-loss spectroscopy. There we found a positive dispersion of the lowest lying excitation. Comparing the measured values and the calculated coupling strengths, we came to the conclusion that both materials are very weak J-aggregates and that charge transfer exciton coupling is the dominant process and determines the delocalization of the lowest lying excitations.

HL 7.24   Mon 13:00   P2/EG

Highly dipolar molecule on single crystals: Impact of chemical affinity on the interface formation — •Baris Öcal and Selina Olthof — Department of Chemistry, University of Cologne, Greinstraße 4-6, 50939 Cologne, Germany

Merocyanines are functional dyes with interesting electronic properties due to their resonant structure between charged and uncharged states. Their bandgap can be widely tuned via the donor and acceptor strength, which makes them interesting as active material in organic-based solar cells, especially since they show very strong absorption. Their physical properties can be further improved by ordering them. The ordering of the molecules is closely related to initial growth on the substrate underneath and interaction between this substrate and molecule. In my work, I investigate the effect of substrate/molecule and molecule/molecule interactions on the electronic structure by photoelectron spectroscopy methods. Highly dipolar HB238 merocyanine has been chosen to observe the chemical interaction and its effect of the charge states of the molecule easier. Surfaces such as SiC/graphene, Au(100), Ag(100) and Cu(100) are used as templating substrates due to their different chemical affinity and ordered structure. Thickness dependent X-ray Photoelectron spectroscopy (XPS) measurements helps us to understand the chemical effect of substrate on the charge states, while Ultraviolet Photoelectron Spectroscopy (UPS) measurement gives information on the molecular phase changes such as dimerization, orientation change. We find that chemical interaction of the substrate significantly affects molecule/molecule interaction.

HL 7.25   Mon 13:00   P2/EG

Spontaneous orientation polarization in phosphine oxides and how to control it — •Albin Cakaj, Markus Schmid, Alexander Hofmann, and Wolfgang Brütting — Institut für Physik, Universität Augsburg, Germany

The orientation of small organic molecules in amorphous thin films prepared by vapor-deposition is an important aspect in further improvement of organic semiconductor devices. This feature can influence the optical and electrical properties of organic light emitting diodes (OLEDs) drastically. Due to their asymmetric molecular structure, microscopic properties like the permanent dipole moment (PDM) can show preferential alignment and lead to a macroscopic film polarization in the organic layer. This so-called spontaneous orientation polarization (SOP) affects the charge injection and accumulation behaviour in a device. In our studies, we investigated the electrical and optical orientation of a group of organic molecules, characterized by P=O double bonds, and how to control it by their design and the film-growth conditions. Many of these phosphine oxides have a large PDM, due to a strong electronegative oxygen. However, the magnitude of their SOP is often affected by the presence of multiple molecular conformers. Thus, using less polar species with only one P=O bond yields superior performance with record-high SOP of up to 160mV/nm, even though optical measurements hint to almost no preferred orientation on average.

HL 7.26   Mon 13:00   P2/EG

Impact of solution processing on the photophysical properties of TADF emitters — •Konstantin Rausch, Rishabh Saxena, and Anna Köhler — Soft matter Optoelectronics, University of Bayreuth, Germany

Continuous innovation of thermally activated delayed fluorescence (TADF) compounds has led to the rapid development of these materials as emitters in efficient vacuum-deposited organic light emitting diodes (OLEDs). However, the cost of device fabrication, inefficient use of materials and limitation on pixel size are some detracting features of vacuum-deposition. An alternative cost- and materials-efficient fabrication technique is solution processing. In this regard, it is important to understand the impact of different processing conditions, such as varying solvents and host materials, on the photophysical properties of TADF emitters. In general, a donor-acceptor (D-A) strategy is adopted for the chemical design of TADF emitters. Recent studies suggest that conformational flexibility associated with the D-A dihedral angle leads to a distribution of reverse intersystem crossing rates (k_RISC); a parameter that determines the efficiency of the TADF process. In this study, we perform inverse Laplace transform fitting of emission decay, obtained using time-resolved photoluminescence measurements, to extract this distribution. Furthermore, we investigate the impact of different film-preparation methods (spin-coating and evaporation), matrix polarity and conformational rigidity of TADF emitter on the RISC rate distribution with an aim to optimize the performance of solution-processed TADF OLEDs.

HL 7.27   Mon 13:00   P2/EG

single molecule spectroscopy of emitters in hexagonal boron nitride(hBN) — •osama farooqui and klas lindfors — department of chemistry, university of cologne

Efficient interaction of light with atoms or molecules has been found crucial in the study of materials that can be used in the development of high-speed communication devices [1]. The central goal of this project is to observe and investigate the light emission and absorption processes in heterostructures of two- and one-dimensional materials and single emitter molecules.

Previously, single terrylene diimide (TDI) molecules on glass substrate have been investigated using single molecule spectroscopy. In order to address the problem of stability of the molecules, hBN is used to encapsulate emitter molecules to avoid chemical reactions with the ambient environment. The preliminary data of time traces of triisopropylsilyl pentacene (TIPS-pentacene) molecules encapsulated in hBN flakes shows that the molecules do not get photobleached over 1 hour at room temperature. However, fast photoblinking was observed in the time traces of the molecules. The cause of fast photoblinking could be the interaction of the molecules with close-by two-level systems, which appears to be related to hBN flakes.

Electronic and optical properties of p-type delafossite transparent conducting oxides: Density Functional Theory calculations — •Moufdi Hadjab[1,2] and Olga Guskova[2] — [1]Mohamed Boudiaf University of Msila, Msila, Algeria — [2]IPF Dresden, Germany

Transparent conducting oxides (TCO) possessing high optical transparency and electrical conductivity have been studied widely due to their applications in optoelectronics. Delafossite materials with chemical formula AIBIIIO2 are among the promising p-type TCOs. In this study, we have investigated physical properties of three novel semiconductors to address some problems related to the photovoltaic industry. The structural, electronic and optical properties of delafossite transparent conducting oxides CuMO2 have been studied using the Full-Potential Linearized Augmented Plan Wave method based on DFT as implemented in Wien2k computational code. The LDA and PBE generalized gradient approximation have been utilized as the exchange-correlation term for calculating the structural and electronic parameters. Moreover, Tran-Blaha modified Beck-Johnson potential has been used to achieve better degree of accuracy in calculations of the electronic and optical properties. The observations have been compared with published theoretical and experimental data. The ternary de-

lafossite transparent conducting oxide compounds can be considered as an alternative material in photovoltaic applications.

HL 7.29　Mon 13:00　P2/EG

Simulating multi-component target ablation: A new pulsed laser deposition technique — •Arne Jörns, Holger von Wenckstern, and Marius Grundmann — University of Leipzig, Felix Bloch Institute for Solid State Physics, Semiconductor Physics Group

Laterally and radially segmented targets allow the fabrication of functional thin films with lateral and vertical composition spreads, respectively [1]. The latter also enables the creation of material libraries consisting of homogeneous thin films with discrete material composition. However, fabrication of such targets is technically demanding with respect to powder blending, insufficient hardening or thermic decomposition due to deviating sintering temperatures of the source powders for the respective segments.

In this work we present a new target design and deposition technique for pulsed laser deposition in order to create vertical composition spreads as well as discrete composition material libraries but bypassing the above mentioned drawbacks. Simulations for the expected material contents will be presented. Then, experimentally determined elemental distributions and growth rates are compared to calculated values. Electrical and optical properties of samples obtained by such techniques will be reported.

Wide bandgap aeromaterials and prospects for their applications — •Vladimir Ciobanu, Tudor Braniste, Eduard Monaico, and Ion Tiginyanu — National Center for Materials Study and Testing, Technical University of Moldova, Chisinau, Moldova

We report on the fabrication of aeromaterials based on GaN, Ga2O3, TiO2 and Zn2TiO4 using hydride vapor phase epitaxy (HVPE) or Atomic Layer Deposition (ALD) approaches. The fabrication process is based on growth of the preferred material on sacrificial templates consisting of interconnected ZnO microtetrapods. During the epitaxial growth of GaN at high temperatures and corrosive environment, the ZnO is etched away and, consequently, hollow microtetrapods with the wall thickness of the tubes in the range of 20 - 100 nm are obtained. Further, GaN can be transformed into Ga2O3 through an annealing process at temperature as high as 800 ˚C. Alternatively, ALD approach is used to fabricate aero-TiO2 or aero-Zn2TiO4 materials using sacrificial ZnO templates.

The fabricated materials demonstrated new interesting properties: aero-GaN exhibits good electromagnetic shielding in X-band and THz region, on the other hand aero-Ga2O3 is completely transparent at GHz and THz frequencies, up to 3 THz. We also established that aero-GaN is characterized by dual hydrophilic-hydrophobic behavior. This phenomenon enabled one to demonstrate novel liquid marbles. Due to high active surface area of developed aero-Ga2O3 decorated with noble metal nanodots, aero-TiO2 and aero-Zn2TiO4, these materials are shown to be promising for photocatalytic applications.

HL 7.31　Mon 13:00　P2/EG

Graded $Zn_xMg_{1-x}O$ layers as building blocks for ultra-compact wavemeters — Philipp Firme, •Christoph Brunhuber, Lukas Trefflich, Peter Schlupp, Daniel Splith, Holger von Wenckstern, Chris Sturm, and Marius Grundmann — Universität Leipzig, Felix Bloch Institute for Solid State Physics, 04103 Leipzig, Germany

Recently, a new design for a monolithic, ultra-compact wavemeter was proposed, which can be used in a wide spectral range [1]. The building blocks of this wavemeter are two vertically stacked, photosensitive layers, separated by a transparent, insulating layer. In order to achieve a spectral sensitivity, the top layer must consist of a material with a vertical absorption gradient. Here, we discuss the suitability of vertically graded $Zn_xMg_{1-x}O$ layers as top layer of such an ultra-compact wavemeter with wurtzite photosensitive ZnO layer as backside. The layers were deposited by pulsed laser deposition, using a vertical continuous composition spread (VCCS-PLD) technique. In doing so, we were able to achieve out-of-plane composition gradients from $x = 1.0$ up to $x \approx 0.5$. XRD $2\theta - \omega$-scans do not indicate a phase separation, and confirm the wurtzite phase. The Mg incorporation was also confirmed by photoluminescence spectroscopy. The suitability of the films as building blocks for the wavemeter was tested by photocurrent measurements. By radiation with monochromatic light of different wavelengths, a response similar to the theoretically calculated one [1] is obtained.

HL 7.32　Mon 13:00　P2/EG

Synthesis of bismuth ferrite hollow spheres and their application in the photocatalytic degradation of dyes — •Valeria Sanchez[1], Thomas Cadenbach[2], Alexis Debut[3], Karla Vizuete[3], and Maria J. Benitez[1] — [1]Departamento de Física, Facultad de Ciencias, Escuela Politécnica Nacional, Ladrón de Guevara E11-253, Quito, Ecuador — [2]Colegio de Ciencias e Ingenierías, Universidad San Francisco de Quito, Diego de Robles y Vía Intero-

ceánica, Quito, Ecuador — [3]Centro de Nanociencia y Nanotecnología, Universidad de las Fuerzas Armadas ESPE, Av. Gral. Rumiñahui s/n, Sangolquí, Ecuador

In this work, we show the synthesis and application of next generation semiconductor photocatalysts, i.e. GdxBi1-xFeO3 (x = 0, 0.05. 0.10, 0.15) hollow spheres which function as both, an advanced adsorption material and photocatalytic active semiconductor. The presented spheres were prepared by two distinct novel synthetic protocols, i.e. via a citric acid/urea/ethylene glycol assisted hydrothermal method and via an evaporation induced self-assembly strategy. In both cases, we study the mechanism of formation of phase pure GdxBi1-xFeO3 hollow spheres with a narrow size distribution by varying synthetic conditions such concentration, temperature and treatment time. The samples were characterized by X-ray powder diffraction, scanning electron microscopy and UV-vis diffuse reflectance spectroscopy. All synthesized materials were applied in the photocatalytic degradation of dyes under visible light irradiation. The photocatalysts show superior efficiencies which outperformed previously reported BiFeO3 materials.

HL 7.33　Mon 13:00　P2/EG

Monitoring Phase Transitions in (Hot-)Pressed $FAPbI_3$ Films by In-Situ Reflection Measurements — •Lorenz Kiel[1], Christina Witt[1], Konstantin Schötz[1], Nico Leupold[2], Ralf Moos[2], Anna Köhler[1], and Fabian Panzer[1] — [1]Soft Matter Optoelectronics, University of Bayreuth, Bayreuth 95440, Germany — [2]Department of Functional Materials, University of Bayreuth, Bayreuth 95440, Germany

In recent years, a remarkable increase in efficiencies of halide perovskite-based solar cells has been achieved. Record cells on laboratory scale, realized with the perovskite formamidinium lead iodide ($FAPbI_3$), are now competing with established silicon devices.[1] However, phase stability of $FAPbI_3$ is still challenging as the photoactive black α-phase is prone to degrade in the inactive yellow δ-phase or intermediate orange and red phases.[2, 3] To address this issue, we evaluate the temperature and pressure dependence of occurring phase transitions using in-situ reflection measurements during (hot-)pressing δ-$FAPbI_3$ powder, and analyze associated strain in the resulting thick films. We show that for our powder based thick films the phase transitions occur at significantly lower pressure and temperature compared to literature reports. The correlation of these parameters with resulting film properties like film morphology suggests strain to be decisive for the phase transition and phase stability.

Phase diagram of two-dimensional ferroelectric large polarons — •Florian Kluibenschedl, Georgios Koutentakis, and Mikhail Lemeshko — Institute of Science and Technology Austria (ISTA), Am Campus 1, 3400 Klosterneuburg, Austria

We present a minimal, coarse-grained, two-dimensional model of charge transport in lead halide perovskites, which provides an intuitive explanation for the recently proposed formation of ferroelectric large polarons [1]. The phase-diagram analysis reveals the presence of three phases characterized by the distinct order of the molecular dipole moments which is strongly dependent on the tunneling anisotropy of the carriers. The most striking outcome is the formation of ferroelectric domains that amplify the anisotropy in the carrier tunneling dynamics which has been argued to lead to improved optoelectronic properties. These results provide the groundwork for realizing a top-down approach for understanding the complex carrier dynamics in hybrid organic-inorganic perovskites.

Optical spectroscopy on hBN-encapsulated perovskites — •Lisa Böhme, Eugen Klein, Rico Schwartz, Christian Klinke, and Tobias Korn — University of Rostock, Institute of Physics, 18059 Rostock, Germany

Perovskites shows promising optoelectronic properties that can be used in a wide range of technologies. For example, they play a central role in the development of more efficient and low-cost solar cells and are also used in LED or low-threshold lasers. However, they pose experimental challenges that need to be solved: perovskites degrade in contact with air and lose their attractive properties. A possibility to avoid this is encapsulation in hexagonal Boron Nitride (hBN). We have examined how lead-halogen perovskites with organic ligands can be encapsulated and whether they retain their stability. We use the Scotch-Tape method to exfoliate hBN crystals and deposit perovskite crystals on top using drop casting. To check the successful encapsulation of the perovskites, photoluminescence measurements were taken over different time periods and at different temperatures. Our measurements showed that the fully encapsulated perovskites remained stable for more than ten days.

HL 7.36   Mon 13:00   P2/EG

Reflection Electron Energy Loss Spectroscopy of Organic and Perovskite Semiconductors — •Seren Dilara Öz and Selina Olthof — Department of Chemistry, University of Cologne, Greinstraße 4-6, 50939 Cologne, Germany

The analysis of fundamental semiconductor properties, such as energy level positions and bandgaps, are important to enhance our understanding of these materials and to further improve their performance in applications. In this context, many spectroscopic tools such as ultraviolet photoelectron spectroscopy or UV-vis measurements are exploited. In this project, we explore the use of reflection electron energy loss spectroscopy (REELS) which is a rarely used technique in order to investigate the surface density of states (DOS) and bandgap of organic and perovskite based semiconductor materials.

This measurement technique records the energy loss due to inelastic electron scattering processes which excites electronic transitions. It presents an intriguing technique to gain insights on the joint valence and conduction band density of states over a wide energy range. Due to the extreme surface sensitivity, the band gap of ultra-thin layers can be accessed.

In this work, we try to understand the observed energy loss spectra in order to establish guidelines to investigate surface properties of semiconductor materials. For that reason, information gathered using REELS are compared to UPS, IPES, and UV-vis measurements. Our results show that the REELS technique can be used as an effective tool to explore surface properties of perovskite and organic semiconductors.

HL 7.37   Mon 13:00   P2/EG

Combinatorial synthesis of BaZrS$_3$ thin films: Influence of off-stoichiometry on optoelectronic and electronic properties — •Adriana Röttger, Marin Rusu, Hannes Hempel, Daniel Abou-Ras, Orestis Karalis, Ibrahim Simsek, and Thomas Unold — Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Deutschland

The chalcogenide perovskite BaZrS$_3$ is composed of earth-abundant elements and has potential applications for photovoltaic energy conversion. In this work, compositionally graded BaZrS$_3$ thin films are synthesized from oxide precursors deposited by pulsed laser deposition. The compositional gradient in a range of $0.8 < [Ba]/[Zr] < 1.3$ enables a high throughput characterization approach of structural, optical and optoelectronic properties. Sulfurization was performed in a tube furnace using H$_2$S in Ar gas at 1000˚C. For all the examined compositions, BaZrS$_3$ forms as the main phase. Under Ba excess, Ruddlesden-Popper phases Ba$_3$Zr$_2$S$_7$ and Ba$_4$Zr$_3$S$_{10}$ emerge, while excess Zr forms ZrO$_2$ on the Zr-rich side. Optical absorption spectroscopy mapping shows that the band-gap energy exhibits a minimum at $1.0 < [Ba]/[Zr] < 1.1$ and ranges from 1.65 to 2.1 eV. Analysis of the optical constants n and k by ellipsometry mapping verified this trend. Low-temperature photoluminescence spectroscopy revealed deep defect states present for all compositions. Using time-resolved photoluminescence spectroscopy and optical -pump-terahertz probe spectroscopy, we found longer carrier lifetimes on the Ba-rich side, while the Zr-rich side features a higher mobility of charge carriers.

HL 7.38   Mon 13:00   P2/EG

Defect tolerance of halide perovskites solar absorbers via machine learning — •Anoop K. Chandran[1], Christoph Friedrich[1], Uwe Rau[2], Stefan Blügel[1], Thomas Kirchartz[2], and Irene Aguilera[3] — [1]Peter Grünberg Institute and Institute for Advanced Simulation, Forschungszentrum Jülich, Germany — [2]IEK5-Photovoltaik, Forschungszentrum Jülich, Germany — [3]Institute of Physics, University of Amsterdam, The Netherlands

The deformation potential measures the changes in the bandgap of materials upon compression of the bonds, which helps to identify the bonding or anti-bonding nature of the valence and conduction bands. Previous works indicate that the bonding or anti-bonding nature impacts a material's tendency to exhibit shallow or deep intrinsic defect levels. Our high-throughput search is based on all-electron density functional theory calculations. Among 1173 studied halide perovskites, only 18% present a favourable anti-bonding valence band. We also establish the calculation of the deformation potential as an effective way to determine the bonding or anti-bonding nature near the band edges. However, subsequent supercell calculations reveal no explicit connection between the nature of the band edges and the defect tolerance. Deep learning neural networks require large datasets. To overcome this limitation, we devised a novel approach for the one-shot binary classification of the deformation potentials. Instead of learning to classify a single material, the network learns the similarity or the difference between two materials.

HL 7.39   Mon 13:00   P2/EG

Dressed-state analysis of two-color excitation schemes — •Thomas Bracht[1,2], Tim Seidelmann[3], Yusuf Karli[4], Florian Kappe[4], Vikas Remesh[4], Gregor Weihs[4], Vollrath Martin Axt[3], and Doris E. Reiter[2] — [1]Institut für Festkörpertheorie, WWU Münster, DE — [2]Condensed Matter Theory, TU Dortmund, DE — [3]Theoretische Physik III, Universität Bayreuth, DE — [4]Institut für Experimentalphysik, Universität Innsbruck, AT

For coherent control of a few-level quantum emitter, typically pulses with an energy resonant to the transition energy are used, which requires sophisticated

filtering of the signal. However, two-color excitation protocols were recently employed to circumvent the necessity for filtering.

Here I present an analysis of two-color excitation schemes, using the laser dressed states of the system. It can be shown, that the two-color excitation approach can be understood as a driving of transitions between the dressed states. We investigate how these transitions depend on the pulse parameters and explain how the different combinations of laser energies can excite the system. In addition to the results for a simple two-level system (2LS), we consider a three-level exciton-biexciton system (3LS) that is typically found in semiconductor quantum dots and often used to generate entangled photon pairs. While in the 2LS, we can give clear conditions for the applicability, in the 3LS, due to strong state mixing, the conditions are less obvious. Nonetheless, we can find regimes of parameters to drive the system into either the exciton or the biexciton in the 3LS.

HL 7.40   Mon 13:00   P2/EG

Controlling the dimensions of top-down GaN nanowire ensembles via self-assembled metal islands — •Rose Mary Jose, Jingxuan Kang, Miriam Oliva, Thomas Auzelle, Abbes Tahraoui, Oliver Brandt, and Lutz Geelhaar — Paul-Drude-Institut für Festkörperelektronik, 10117 Berlin, Germany

The large surface-to-volume ratio of semiconductor nanowires and their potential for enhanced light absorption are attractive for photoelectrochemical applications. In this context, large-scale nanowire arrays are needed. For top-down fabrication, a scalable and rapid way to form a nano-island mask is the dewetting of a metal film.

In this work, we study how Pt films evolve upon thermal treatment into nanoislands which serve as a shadow mask for the top-down etching of GaN nanowire ensembles. To gain control over the nano-island ensembles' dimensions, we explore variations of the annealing conditions, Pt film thickness, and the surface energy by investigating Pt dewetting on GaN, SiNx, and SiOx surfaces. The islands' size and density are determined by the initial Pt film thickness. However, nano-island diameter and spacing are coupled by a fixed ratio. Therefore, individually controlling the spacing between nano-islands and their diameter is challenging in this approach.

Nanowire arrays are fabricated using Pt dewetting masks by plasma etching followed by KOH wet etching. The resulting nanowires' dimensions are consistent with those of the original nano-islands. In our experiments, diameters in the range 30 nm-200 nm and lengths of 500-1000 nm are demonstrated.

HL 7.41   Mon 13:00   P2/EG

Investigation of SiNWs [100] and [111] applying DFT with doping — •Nedhal Al-Nuaimi, Hilser Florian, and Gemming Sibylle — Chemnitz University of Technology, Chemnitz (Germany)

We present an ab initio study of Silicon nanowires (SiNW) with p-type impurities (doping) of Boron (B) and n-type impurities of Phosphorus (P) using Abinit and VESTA Software. We compare total energy and band dispersion in the [100] and [111] directions with that of pure bulk (semiconductor) silicon. The resulting band structure shows metallic behaviour due to additional states within the band gap. Furthermore dangling bonds lead to localized surface states without dispersion. Saturating these states can cause shifts in the electrostatic potential and may be used to tune the sensing properties of SiNWs.

HL 7.42   Mon 13:00   P2/EG

Growth and characterisation of local droplet etched InAs quantum dots in an InGaAs matrix — •Nikolai Spitzer, Hans-Georg Babin, Andreas Wieck, and Arne Ludwig — Ruhr-Universität Bochum, Lehrstuhl für Angewandte Festkörperphysik, Universitätsstraße 150, 44801 Bochum

We present a new local droplet etching (LDE) method for selforganized InGaAs quantum dots (QDs). We use gallium droplets to etch on an InGaAs matrix layer and fill the nanoholes with InAs. The impact of the indium concentration in the InGaAs-layer and of the deposited InAs amount after etching is investigated by atomic force microscopy and photoluminescence spectroscopy.

HL 7.43   Mon 13:00   P2/EG

Enhancement of Quantum Dot Emission in the Telecom C-Band via Photonic Micro Cavities — •Raphael Joos, Christian Rupp, Sascha Kolatschek, Stephanie Bauer, Cornelius Nawrath, Robert Sittig, Ponraj Vijayan, Michael Jetter, Simone Luca Portalupi, and Peter Michler — Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), Center for Integrated Quantum Science and Technology (IQST) and SCoPE, Universität Stuttgart, Allmandring 3, 70569 Stuttgart, Germany

Potential quantum technology applications such as quantum communication rely on the availability of carrier of quantum information. For that matter single-photons can be utilized as „flying-qubits" imprinting information in their polarization state. For these applications it is beneficial to operate at the telecom C-band which offers reduced dispersion and minimum loss in optical fibers. In the recent years InAs quantum dots (QDs) have shown to be capable of emission of single and entangled photons in the telecom C-band. However, as-grown QD structures have limited collection efficiency of the emitted light due to total internal reflection. To tackle this issue photonic cavity structures can be employed

which can enhance the photon extraction efficiency and decrease the decay time due the underlying Purcell effect. While there are different approaches to photonic structures ranging from planar cavities to Gaussian micro lenses, this work mainly deals with circular Bragg grating structures. These offer high collection efficiency in a broadband manner as well as a cavity spectrum which potentially allows simultaneous Purcell enhancement of exciton and biexciton.

HL 7.44   Mon 13:00   P2/EG

Voronoi-Cell Analysis of Density Modulated InAs Quantum Dots — •Peter Zajac[1], Nikolai Bart[1,2], Christian Dangel[2], Kai Müller[3], Andreas D. Wieck[1], Jonathan Finley[2], and Arne Ludwig[1] — [1]Ruhr-Universität Bochum, Universitätsstraße 150, 44801 Bochum, Germany — [2]Walter Schottky Institut and Physik Department, Technische Universität München, Am Coulombwall 4, 85748 Garching, Germany — [3]Walter Schottky Institut and Department of Electrical and Computer Engineering, Technische Universität München, Am Coulombwall 4, 85748 Garching, Germany

InAs quantum dots (QDs) grown by molecular beam epitaxy exhibit a density modulation upon growth on top of a GaAs gradient layer [1]. The local variation of the nucleation probability is ascribed to the roughness of the underlying GaAs layer. It is of interest to study the QD formation on such a surface under the scope of the capture-zone model [2]. Here, the results of AFM data analysis with focus on correlations between Voronoi cell areas and QD size parameters such as height and volume are presented.

HL 7.45   Mon 13:00   P2/EG

Enhancing the extraction efficiency of photons from low intensity decay processes with solid immersion lenses — •Patricia Kallert[1], Björn Jonas[2], Eva Schöll[1], Tim Langer[1], Dirk Reuter[1], Artur Zrenner[1], and Klaus D. Jöns[1] — [1]hqpd lab, PhoQS Institute and Department of Physics, Paderborn University, Germany — [2]Photonic Quantum Engineering Group, Walter Schottky Institute, and Department for Electrical and Computer Engineering, Technical University of Munich, Germany

Single photons are basic building blocks for photon-based quantum technologies, such as quantum computation and communication concepts. A promising source offering high single-photon purity and indistinguishability are semiconductor quantum dots in photodiodes. A major drawback of this platform is the low extraction efficiency. Due to the refractive index mismatch of the semiconductor and the surrounding environment, total internal reflection occurs already for very small angles of incidence on the interface. In this study, the enhancement capability and the practical limits of using solid immersion lenses of hemispherical and Weierstrass geometry are investigated and compared. The hemispherical lens is insusceptible to misalignment but offers a mediocre enhancement in collection efficiency. In contrast, the Weierstrass geometry is sensitive to nonperfect alignment but improves the extraction by a factor of up to 2.9. Avoiding the need of the fabrication of complex structures as micropillars and other cavities, consequently, we can triple the detection of photons from low-intensity decay processes.

Magnetic Field-Dependence of the Auger Recombination Rate in a Self-Assembled Quantum Dot — •Fabio Rimek[1], Hendrik Mannel[1], Marcel Zöllner[1], Arne Ludwig[2], Andreas D. Wieck[2], Axel Lorke[1], and Martin Geller[1] — [1]Faculty of Physics and CENIDE, University Duisburg-Essen, Germany — [2]Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

A quantum dot (QD) is an ideal system to study electron-electron interaction in a confined nanostructure [1]. The Auger recombination is a special case, where the recombination energy is transferred to a third charge carrier that leaves the dot [2] or is excited to a higher energy level. Therefore, the Auger effect destroys the radiative recombination of the charged exciton (trion) - an effect, which should be minimized for future applications that use spin states as stationary qubits, which can be transferred to photons via the QD trion transition. In this work, we investigate how the Auger rate is affected by an external magnetic field, applied perpendicular to the plane of the dots. In the magnetic field, the trion transition of a QD is no longer spin degenerate and splits up. We use two-color, time-resolved resonance fluorescence to investigate the quenching of the trion recombination due to the Auger effect. Two color excitation allows us to excite two quantum dot transitions (both trions or one trion and one exciton) and neglect spin relaxation as well as spin-flip Raman scattering. This ensures that we can directly measure the Auger and the tunneling rate of an electron into the dot.

Towards solid-state quantum emitters strongly coupled to crossed nanobeam cavities — •Jan-Gabriel Hartel, Oscar Camacho Ibarra, and Klaus D. Jöns — hqpd lab, PhoQS Institute and Department of Physics, Paderborn University, Germany

The strong coupling regime of quantum electrodynamics, theoretically described via the Jaynes-Cummings model, offers insight into purely quantum mechanical effects in the interaction of a two-level system and a single mode light field. An extension of this model to the interaction of a two-level system with two resonant modes yields the possibility of free exchange of the excitation between the light modes as well as subsequent applications in quantum gates. While the fundamental case has been experimentally studied, the realization of this extension has proven to be elusive due to the technological challenges of fabricating a stable coupled cavity system.

In this work, we seek to approach this realization by exploring nanofabrication of on-chip crossed nanobeam cavity systems, realized via Bragg mirrors. We numerically explore heuristic extensions of existing design recipes for 1D nanobeam cavities, based on the creation of a localized defect mode. We emphasize the challenges of conserving high Q-factors at the specified resonance frequency while minimizing coupling between the crossed cavities, developing novel design ideas.

HL 7.48   Mon 13:00   P2/EG

Towards frequency-converted polarization-entangled photon pairs from semiconductor quantum dots — •Tim Strobel[1], Andre Bisquerra[1], Tobias Bauer[2], Nand Lal Sharma[3], Marlon Schäfer[2], Stefan Kazmaier[1], Cornelius Nawrath[1], Lukas Wagner[1], Ankita Choudhary[3], Michael Jetter[1], Caspar Hopfmann[3], Christoph Becher[2], Simone L. Portalupi[1], and Peter Michler[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Science and Technology (IQST) and SCoPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart, Germany — [2]Fachrichtung Physik, Universität des Saarlandes, Campus E2.6, 66123 Saarbrücken, Germany — [3]Institute for Integrative Nanosciences, Leibniz IFW Dresden, Helmholtzstraße 20, 01069 Dresden, Germany

Fiber-based distribution of entangled, single photon pairs is a key requirement for future developments of terrestrial quantum networks. Quantum repeater schemes at telecom wavelengths can overcome the restriction set by fiber transmission losses over long distances. In this context semiconductor quantum dots (QDs) are promising candidates as deterministic sources of on-demand polarization-entangled photon pairs. Here, we investigate photons emitted via the biexciton-exciton cascade of GaAs QDs grown via Al droplet etching and integrated into a GaP solid immersion lens. To be compatible with existing fiber network infrastructures, quantum frequency conversion is employed to convert the QD emission from 780nm to telecom wavelengths.

HL 7.49   Mon 13:00   P2/EG

Strongly driven germanium qubit — •Bashab Dey and John Schliemann — Institute for Theoretical Physics, University of Regensburg, Regensburg, Germany

Hole qubits in germanium heterostructures are promising candidates for coherent control and manipulation of the spin degree of freedom by electric dipole spin resonance. The suppression of contact hyperfine interaction due to p-type character of the holes, possibility of nuclear-spin free isotopes and absence of valley degeneracies in germanium are favourable for sustaining longer spin coherence and relaxation times in these qubits. We study the time dynamics of a germanium qubit confined laterally by a parabolic potential and strongly driven by coherent circularly polarized radiation in presence of p-cubic Rashba spin-orbit coupling and perpendicular magnetic field. We calculate the transition rates between the lowest (Zeeman-split) levels of the qubit using Floquet theory. We observe peculiar beating patterns in the Rabi oscillations which depend on the strength of the driving field. When the driving frequency is resonant with Zeeman gap, the maxima of the oscillations is a decreasing function of driving amplitude which is in contrast to that of a harmonically driven two-level system. Furthermore, the time period of oscillations, time interval between the beating nodes and the number of oscillations between the nodes also decrease with the radiation amplitude.

HL 7.50   Mon 13:00   P2/EG

Swing-Up Dynamics in Quantum Dot Cavity Systems — •Nils Heinisch, Nikolas Köcher, David Bauch, and Stefan Schumacher — Physics Department and CeOPP, Paderborn University, Germany

In this work, we further investigate the recently proposed [1] and experimentally demonstrated [2] SUPER-scheme (Swing-UP of the quantum EmitteR population). In the SUPER-scheme optical excitation of a quantum emitter is achieved using two off-resonant red-detuned Gaussian pulses. Here, we expand the studies to quantum dot cavity systems and aim for high quality photons, generated during the decay process following the excitation. After successful proof-of-principle studies with a two-level system, we present the successful single-photon and photon-pair generation using the SUPER-scheme for excitation of diamond-

shaped exciton-biexciton quantum dot model systems. For a more realistic simulation we also take phonons into account. For all systems studied it can be concluded that a cavity neither hinders the swing-up process nor degrades the quality of the generated photons which is in contrast to excitation schemes using resonant Gaussian pulses. HL 7.51   Mon 13:00   P2/EG

Time-Resolved Wave-Function Mapping in Self-Assembled Quantum Qots — •Jens Kerski[1], Daniel Hecker[1], Nelson Creutzburg[1], Arne Ludwig[2], Andreas D. Wieck[2], Martin Geller[1], and Axel Lorke[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, Germany — [2]Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

The static and dynamic properties of self-assembled quantum dots (QDs) are often modeled using the QD's single particle wavefunctions. Although this approximation is very successful, the influence of the electron-electron interaction on the few-particle wave-functions and their nonequilibrium dynamics has not yet been studied in detail.

We investigate an ensemble of InAs/GaAs QDs, embedded in a high electron mobility transistor. The QDs are tunnel-coupled to a two-dimensional electron gas (2DEG). By applying a voltage pulse to the gate, we induce charge carriers from the 2DEG to tunnel into targeted quantum dot states. We monitor the temporal evolution of the conductivity σ_{2D} of the 2DEG, which is sensitive to the transfer of charge into the QDs. A rate-equation-based evaluation of σ_{2D} allows us to separate tunneling processes into different equilibrium or non-equilibrium QD states. We use an in-plane magnetic field perpendicular to the tunneling direction for wave-function mapping [1, 2] of the quantum dot states. This allows us to study the shape and dynamics of the (excited) electron states.

HL 7.52   Mon 13:00   P2/EG

Development and deterministic nanofabrication of quantum dot based single-photon sources with emission in the 780 nm-930 nm range — •Dinara Basharova[1], Stephan Reitzenstein[1], Sven Rodt[1], Caspar Hopfmann[2], Nand Lal Sharma[2], Normen Auler[3], and Dirk Reuter[3] — [1]Institute of Solid State Physics, Technische Universität Berlin, D-10623 Berlin, Germany — [2]Leibniz Institute for Solid State and Materials Research Dresden, 01069 Dresden, Germany — [3]Center of Optoelectronics and Photonics, Universität Paderborn, 33098 Paderborn, Germany

Important goals of quantum technology are to demonstrate the elementary building blocks of a quantum repeater and to integrate them into the infrastructure of a quantum network. A network of quantum repeaters allows the distribution of quantum entanglement, thereby enabling secure exchange of information between multiple parties. To implement such building blocks, we use semiconductor heterostructures (HS) with GaAs quantum dots (QDs) integrated into circular Bragg gratings (CBG). GaAs QDs are excellent single-photon emitters with almost negligible multi-photon emission probability and photon extraction efficiencies exceeding 60%. For this purpose, we deterministically integrate QDs on structures with back-side distributed Bragg reflector and in hybrid approach with backside Au mirror for comparison. In-situ electron beam lithography (iEBL) is an ideal technique for deterministic fabrication of such QD-based quantum light sources. The fabricated QDs are characterized by microphotoluminescence and quantum optical spectroscopy.

HL 7.53   Mon 13:00   P2/EG

Fabrication of electrically controllable quantum dots in PIN diodes integrated within circular Bragg gratings — •Setthanat Wijitpatima[1], Normen Auler[2], Sven Rodt[1], Dirk Reuter[2], and Stephan Reitzenstein[1] — [1]Institute of Solid-State Physics, Technische Universität Berlin, D-10623 Berlin, Germany — [2]Center of Optoelectronics and Photonics, Universität Paderborn, 33098 Paderborn, Germany

A quantum repeater is one emerging device of the decade that has been promised to play a crucial role in quantum communication. To produce an ideal quantum light source with high single-photon purity, nanophotonic structures must be fabricated on self-organized semiconductor quantum dots, which pose challenges due to their random occurrences and requirements of exact spatial and spectral integration. In addition to nanophotonic enhancement, such devices can be designed to allow an electrical manipulation of the excitonic state of quantum dots. Here, we propose a design that allows electrical controls via a PIN diode integrated within circular Bragg gratings (CBGs). Numerical simulations are done to optimize the design to yield the photon extraction efficiency (PEE) of 0.69 at N.A.=0.8. The deterministic fabrication is done with the use of cathodoluminescence (CL) scans and electron beam epitaxy (EBL), and the fabricated devices are characterized by electric-field dependent micro-photoluminescence (μPL) measurements.

HL 7.54   Mon 13:00   P2/EG

Patterned growth of vertical zinc oxide nanowires on sputtered zinc oxide thin films — •Jan Böhmer, Lukas Jäger, Alexander Koch, and Carsten Ronning — Institute of Soild State Physics, Friedrich Schiller University Jena, Max-Wien-Platz 1, 07743 Jena

Because of the wide band of zinc oxide, ZnO nanowires have promising applications in short wavelength optoelectronics, like building photodetectors or laser emitters using nanowire arrays. ZnO nanowires can be easily grown by vapor transport techniques in a high temperature furnace on silicon substrates utilizing the vapor-solid-liquid (VLS) mechanism. However, the nanowires produced in this way typically show random orientations and often overlap each other. A pre-deposited thin film of aluminum doped zinc oxide (Al:ZnO or AZO) by RF sputtering on the substrate creates a polycrystalline ZnO surface with a preferred orientation, on which the nanowires can grow epitaxially. The ZnO nanowires grown this way are almost all orientated perpendicular to the substrate surface resulting in vertical/upstanding nanowires. By now pattering the pre-deposited AZO thin films, selective area growth (SAG) of nanowires is possible. In this contribution, we will discuss our growth results and our goal to control the exact position of nanowire growth to create ordered nanowire arrays.

HL 7.55   Mon 13:00   P2/EG

Energy transfer between Si quantum dots and protoporphrin molecules as a function of distance, orientation and size — •Athanasios Koliogiorgos[1] and Tomas Polcar[2] — [1]Department of Condensed Matter Physics, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic — [2]Department of Control Engineering, Faculty of Electrical Engineering, Czech Technical University in Prague, Czech Republic

Organic molecules such as protoporphrin IX (PPIX) can be attached to bulk or nanostructured silicon to enhance its optical and electronic properties. In this study, the interaction between PPIX molecules (donor) and Si nanocrystals (acceptor) up to 2.5 nm for varying distances and orientations is studied by DFT, semi-empirical and TDDFT methods. Simulations show an effect on electronic structure, indicative of electron charge transfer in parallel orientation and very small distances and non-electron energy transfer for different orientations and larger distances. An absorption-emission spectral overlap is observed. We use the Transition Density Cube method to calculate the electronic couplings and energy transfer rates between donor and acceptor. The Si quantum dots with the smallest size yield larger couplings than the larger nanocrystals. The coupling is enhanced by adding a plasmon nanoparticle as a bridge between donor and acceptor. Results using Au nanoparticles show increased energy transfer rates up to four orders of magnitude and lower distance dependence.

HL 7.56   Mon 13:00   P2/EG

The internal photoeffect from a single solid-state quantum emitter: Excitation energy and band-structure dependence — •B. Maib[1], M. Zöllner[1], F. Rimek[1], P. Lochner[1], H. Mannel[1], A.D. Wieck[2], A. Ludwig[2], A. Lorke[1], and M. Geller[1] — [1]University of Duisburg-Essen and CENIDE, Germany — [2]Ruhr-University Bochum, Germany

The coherence time is one of the limiting factors for using single quantum emitters, like self-assembled quantum dots, in future applications of quantum information processing. Besides spin and charge noise [1] the physical limits are given by the Auger recombination [2] and an internal photoeffect [3] that is present even for resonant excitation.

We have studied in detail the photoeffect in a single self-assembled quantum dot for different energies of a non-resonant laser that excites a single electron from the bound quantum dot state into the continuum of the conduction band. These measurements are realized by time-resolved two-color resonance fluorescence (RF) excitation. The first resonant laser drives the exciton transition, while the second pulsed laser simultaneously excites the photoelectron to the final state in the conduction band, caused by the internal photoeffect.

The results can be used to reduce the internal photoeffect and therefore suppress the photoemission, which would increase the coherence time in such a single photon emitter even under resonant excitation.

Calibrating Photoluminescence Yield for Quantum emitters in Planar Photonic Heterostructures — •Timo Kruck, Hans-Georg Babin, Andreas D. Wieck, and Arne Ludwig — Ruhr-Universität-Bochum; Lehrstuhl für angewandte Festkörperphysik, Bochum, Deutschland

When performing photoluminescence (PL) measurements the spectral intensity of the emitted radiation strongly depends on the dielectric structure surrounding the quantum emitter. Here we show a method for calibrating PL measurements to obtain the unaltered spectrum of the optically active medium [1]. For this purpose, the spectral reflectivity and the wavelength dependent standing wave field are used. The reflectivity, which is determined by reflectometer measurements , and a simulation based on the transfer matrix method are used to compensate

for the true layer thickness. This is then used to calculate the standing wave field, the outcoupling efficiency and the quantum yield. To validate the method, the calibrated spectra are compared with cleaved-edge PL measurements where the QDs are excited from the side and the light is also collected from the side.

HL 7.58   Mon 13:00   P2/EG

Nanowire-based light absorber patterning for artificial photosynthesis — •Juliane Koch[1], Jiajia Qiu[2], Peter Kleinschmidt[1], Huaping Zhao[2], Yong Lei[2], and Thomas Hannappel[1] — [1]TU Ilmenau, Institute for Physics, Fundamentals of energy materials, Ilmenau, Germany — [2]TU Ilmenau, Institute for Physics, Applied nanophysics, Ilmenau, Germany

Due to the increased degrees of freedom in device structures and properties, III-V nanowires (NWs) have been predicted to outperform planar devices. In the context of energy conversion in solar cells and photoelectrochemical devices, the kinetics and transport behavior of different charge carriers in light absorbers are closely related to the selected materials and their shape. A key factor for commercially relevant development is the enhanced light absorption, in particular in an uniform NW array, combined with lower costs and material usage (e.g. of III-Vs) for nanowire-based light absorbers. This may ultimately require fabrication techniques with homogenous patterning over a large range. In this work we demonstrate the fabrication techniques for creation of a NW array and key requirements during MOVPE NW growth. By applying a surface patterning technique with anodic aluminum oxide (AAO) templates, arrays of gold droplets can be deposited on a surface, which acts as a catalyst for NW growth during metalorganic vapor phase epitaxy (MOVPE). Under defined process parameters vertical III-V semiconductor NW can be achieved via vapor-liquid-solid (VLS) growth in a horizontal MOVPE system.

HL 7.59   Mon 13:00   P2/EG

Enhancing spatial resolution for terahertz waveform near-field microscopy — •Fabian Brütting, Moritz Heindl, and Georg Herink — Experimental Physics VIII, University of Bayreuth, Germany

The quantum confined Stark-effect induces field-driven modulations in the optical transitions of quantum emitters. Harnessing this ultrafast interaction in colloidal quantum dots enables us to image THz near-field waveforms with fluorescence microscopy in the visible spectrum [1]. The spatial resolution of fluorescence microscopy is principally not diffraction-limited and can be extended to the few-nanometer scale using super-resolution techniques such as stimulated emission depletion (STED) microscopy. The efficient depletion of quantum dot emission presents a key requirement [2]. In this contribution, we present our investigations on the STED process in the quantum dots employed as field-probes in the luminescence-based Quantum-probe field microscopy (QFIM) scheme.

Investigation of the biexciton decay in semiconductor In(Ga)As/GaAs quantum dots — •Christopher Buchholz, Sebastian Krehs, and Artur Zrenner — Universität Paderborn, Paderborn, Deutschland

The biexciton-exciton cascade is a widely used promising emission mechanism in quantum dots for generating entangled photon pairs with high fidelity. An often overlooked critical parameter for the quality of the emitted photons is the different lifetimes of electron and hole. Since the lifetimes of excitonic states can be influenced via external electrical fields (quantum confined stark effect), we studied this parameter in Schottky-contacted GaAs heterostructures. We approached this challenge by placing the quantum dots at different distances to the n-contact, 40 nm and 80 nm, respectively. The quantum dots were first characterized by voltage-dependant photoluminescence (PLV) measurements under above-band excitation and further investigated by photocurrent spectroscopy (PC) under resonant excitation and PLV under two-photon excitation (TPE). From the resonances in the PC measurements, the electron lifetime was extracted, whereas the TPE measurements showed the occurrence of the biexciton and charged exciton states as a function of the voltage. The results suggest that an increased distance to the n-contact leads to a decreased tunneling rate of electrons into the quantum dot. At the same time, the tunneling from the quantum dot is not affected.

HL 7.61   Mon 13:00   P2/EG

Influence of the quantum dot geometry on higher excited states — •Jan Kaspari and Doris E. Reiter — Condensed Matter Theory, TU Dortmund, Otto-Hahn-Straße 4, 44227 Dortmund

The energetic structure and absorption spectra of semiconductor quantum dots are strongly dependent on the dot geometry. In particular the higher excited states, typically denoted as p- or d-shell, can become highly mixed and depend strongly on the specific dot. We derive a theoretical model to describe higher excited quantum dot states based on the envelope function approximation. The four-band Luttinger theory as well as the direct and short-range Coulomb in-

teractions are treated within a configuration interaction approach. The quantum dot confinement is approximated by an anisotropic harmonic potential. We show that a variation of the size of a cylindrical symmetric quantum leads to energetic shifts of higher excited quantum dot states. Breaking this cylindrical symmetry significantly alters the absorption spectrum as further energy splittings in the energetic structure appear and state mixtures change which results in differences of oscillator strenghts of some peaks. Our results give insight into the quantum dot energy structure especially for higher excited states, which become relevant in radiative Auger processes or for ultrafast quantum logic operations.

HL 7.62   Mon 13:00   P2/EG

Towards remote on-chip two-photon interference in gallium arsenide based-photonic integrated circuits — •Ulrich Pfister[1], Moritz Speidel[1], Florian Hornung[1], Stephanie Bauer[1], Robert Sittig[1], Eric Reutter[2], Michael Jetter[1], Simone L. Portalupi[1], Jürgen Weis[2], and Peter Michler[1] — [1]Institut für Halbleiter und Funktionelle Grenzflächen (IHFG), Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Allmandring 3, Germany — [2]Max-Planck-Institut für Festkörperforschung (MPI), University of Stuttgart, Heisenbergstraße 1, Germany

InGaAs quantum dots (QDs) are a promising source of single and indistinguishable photons for the on-chip realization of two-photon interference (TPI) with remote QDs. One of the challenges is the inhomogeneously distributed emission frequency of the QDs, which makes frequency tuning necessary. We show that strain-induced emission frequency tuning is applicable for ridge waveguides and it can be considered a promising step towards remote on-chip TPI [1]. Additionally, a successful TPI with one single QD and an on-chip multimode interference beamsplitter as a part of a Mach*Zehnder interferometer has been realized and the feasibility of remote on-chip TPI with MOVPE-grown InGaAs QDs is discussed.

HL 7.63   Mon 13:00   P2/EG

Quantum frequency conversion of entangled photon pair from GaAs Quantum dot to Sn-vacancy center in Diamond — •Ankita Choudhary, Tim Pokart, Nand lal Sharma, Moritz Langer, and Caspar Hopfmann — Institute for Integrative Nanosciences, Leibniz IFW Dresden, Helmholtzstraβe 20, 01069 Dresden, Germany

The distribution of entangled photons in future long-distance quantum networks requires both on-demand and high-fidelity entangled photon pair generation as well as their temporary storage in low dephasing quantum memory systems. While GaAs quantum dots have proven to be excellent entangled photon pair sources, this is system suffers from strong dephasing of its spin qubits. Diamond color centers on the other hand are excellent quantum memories, but not ideal entangled photon pair sources. In order to combine the complementary properties of both material system in a hybrid quantum network approach, the efficient conversion between the operating photon energies without the loss of quantum information using quantum frequency conversion is required. In this study we present quantum frequency conversion from of 780nm to 619nm, i.e. from GaAs quantum dot emission to the zero-phonon line of the diamond Sn vacancy center, using sum frequency generation in a periodically poled lithium niobate crystal and an infrared laser pump of about 3 *m wavelength. We find that a conversion efficiency of at least 25% can be achieved.

HL 7.64   Mon 13:00   P2/EG

Design of circular Bragg resonators in the telecom band for efficient emission of entangled and indistinguishable photons from semiconductor quantum dots — •Dustin Siebert, David Bauch, Klaus D. Jöns, Stefan Schumacher, and Jens Förstner — Electrical Engineering Department, Physics Department, CeOPP and PhoQS, Paderborn University, Germany

The generation of indistinguishable and entangled photons via the biexciton-exciton cascade in semiconductor quantum dots can be tailored by a photonic environment providing an increased emission rate through the Purcell effect and a cavity feedback [1,2].

Circular Bragg resonators exhibit exactly these properties and enable good collection efficiency over a large bandwidth. We developed an optimization strategy based on a two-step process. First, we use a batch of 2D electromagnetic simulations within Bayesian global optimization and finally polish the optimum through Nelder-Mead local optimization based on full 3D simulations.

The optical properties obtained are then used within a quantum mechanical simulation of the carrier dynamics in the semiconductor quantum dots including phonon interaction [3]. After optimization, we achieve a tremendous enhancement of the indistinguishability of the emitted photons even considering that real structures might suffer fabrication imperfections.

Origin of Antibunching in Resonance Fluorescence — •Lukas Hanschke[1], Eva Schöll[1], Eduardo Zubizarreta Casalengua[2,3], Melina Peter[4], Ailton Garcia Jr.[4], Saimon F. Covre da Silva[4], Santanu Manna[4], Armando Rastelli[4], Kai Müller[5], Fabrice P. Laussy[3], Elena del Valle[2], and Klaus D. Jöns[1] — [1]PhoQS, CeOPP, and Department of Physics, Paderborn University — [2]Departamento de Fisica Teorica de la Materia Condensada, Universidad Autonoma de Madrid — [3]Faculty of Science and Engineering, University of Wolverhampton — [4]Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz — [5]Walter Schottky Institute, Technical University of Munich

Resonance fluorescence, the coherent emission of a quantum two-level system under weak resonant driving, exhibits sub-natural linewidth and inherits the coherence properties of the excitation laser. While previous experiments suggest that this emission also maintains antibunched, our results prove recent theoretical insights into the origin of the antibunching and the underlying interplay between the coherent and incoherent emission of the quantum system. This allows us to specifically manipulate the composition of the resonance fluorescence by frequency filtering and interference with the excitation laser field to enable single photons with sub-natural linewidth [PRL 123, 170402 (2020)].

HL 7.66　Mon 13:00　P2/EG

Near Fourier-Transform Limited Blinking Free Quantum Dots — •Eva Schöll[1], Lukas Hanschke[1], Melina Peter[2], Ailton Garcia Jr.[2], Patricia Kallert[1], Francesco Salusti[1], Saimon Filipe Covre da Silva[2], Santanu Manna[2], Armando Rastelli[2], and Klaus D. Jöns[1] — [1]PhoQS, CeOPP, and Department of Physics, Paderborn University, Warburger Straße 100, 33098 Paderborn, Germany — [2]Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, 4040 Linz, Austria

Tailored quantum light sources are crucial building blocks for applications in quantum technologies. Al droplet etched GaAs Quantum Dots are promising candidates for such sources, as they show very good characteristics for example in terms of single-photon purity, indistinguishability on short time scales and entanglement fidelity. However, these QDs usually exhibit an unstable charge environment, which leads to reduced coherence on long time scales, broadened linewidths and blinking. Embedding the QDs into a p-i-n diode structure enables energy tuning via the Stark effect and stabilizes the charge environment. Here we demonstrate a solid-state single-photon source with no signs of blinking on up to ms time scales and near Fourier-transform limited linewidths. This opens up possibilities for experiments for a fundamentally deeper understanding of quantum level schemes and realization towards a quantum network, where quantum interference between separate sources is required.

Twist- and gate-tunable valley splitting in TMDC/CrI$_3$ heterostructures — •Klaus Zollner, Paulo E. Faria Junior, and Jaroslav Fabian — Institute of Theoretical Physics, University of Regensburg, 93053 Regensburg, Germany

Van der Waals heterostructures composed of twisted monolayers promise great tunability of electronic, optical, and magnetic properties. Twistronics has already demonstrated its potential in tuning proximity spin-orbit and exchange coupling in graphene-based heterostructures [1,2]. In this talk, we present the strong manipulation of the valley splitting upon twisting and gating in TMDC/CrI$_3$ heterostructures [3]. In particular, upon twisting from 0° to 30°, the proximity-induced TMDC valence band edge exchange splitting can be reversed (−2 to 2 meV), while the TMDC conduction band edge exchange splitting remains nearly constant (−3 meV). Further giant tunability (few meV) of the proximity exchange coupling is provided by a transverse electric field. Consequently, twisting and gating then allow to tailor the valley splitting of the first intralayer exciton peak in the range of 0 to 12 meV in WSe$_2$/CrI$_3$, which is equivalent to gigantic external magnetic fields of up to about 60 Tesla.

This work was supported by DFG SFB 1277, DFG SPP 2244, and the EU Horizon 2020 Research and Innovation Program (Graphene Flagship).

Giant Enhancement of Interlayer Exciton Luminescence in WSe$_2$/WSe$_2$/MoSe$_2$ in Heterotrilayers. — •Chirag Palekar, Ching-Wen Shih, Imad Limame, Bárbara Rosa, and Stephan Reitzenstein — Institute of Solid State Physics, Technische Universität Berlin, D-10623 Berlin, Germany

TMDC heterolayers have gained lot on interest as a promising platform to study intricate many-body physics phenomena. Here we observe giant enhancement of interlayer exciton PL in a WSe$_2$/WSe$_2$/MoSe$_2$ heterotrilayers (HTL) system prepared by employing exfoliation and dry transfer method. The IX exciton forming at the heterojuction in the HTL region exhibits 10-fold increase in PL yield when compared to HBL region on the same sample. Such an enhancement can be attributed to the close to 0^0 twist angle between stacked WSe$_2$ homobilayers providing smaller interlayer separation and hybridization in the WSe$_2$ band structure, which in turn results in an efficient charge transfer. Further, PLE and reflection contrast reveal the twist angle dependence of the enhancement factor in such type II HTL systems as the large twist angel between WSe$_2$ homobilayers (57^0) results in only up to 10% percent enhancement of IX PL in the HTL region when compared with the HBL. This fundamental study of excitons in the HTL system deepens the current understanding of physics of twisted TMDC heterostructures and paves the way for future experiments and theoretical work.

Photoluminescence tuning in hybrid devices of monolayer transition metal dichalcogenides and rylene dyes — •Theresa Kuechle[1], Gergely Knorr[2], Kalina Peneva[2], and Giancarlo Soavi[1] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany — [2]Institute of Organic Chemistry and Macromolecular Chemistry, Friedrich Schiller University Jena, Lessingstraße 8, 07743 Jena, Germany

Monolayer transition metal dichalcogenides (TMDs) are direct gap semiconductors that hold great promise for applications in nanoscale photonics and optoelectronic devices. A viable path for the development of devices with advanced functionalities and tunable properties is the integration with other nanoscale systems such as nanowires [1] and molecules [2]. Here, we realize hybrid devices based on TMDs and rylene dyes and study their optical properties via steady state photoluminescence. Preliminary results show that the PL emission in hybrid structures of WS$_2$/CN$_4$PMI can be quenched by a factor of 3, in the case of WSe$_2$/CN$_4$PMI by 300. We tentatively assign this variation to a different band alignment in the two heterostructures and to the interplay between charge transfer (in type II) and energy transfer (in type I). Future experiments including ultrafast pump-probe spectroscopy of pristine and hybrid systems as well as hybridization of different (tunable) molecules will further elucidate the role of band alignment in the ultrafast charge and energy transfer processes at the nanoscale.

Coherence of interlayer exciton ensembles in MoSe$_2$/WSe$_2$ heterobilayers — •Christos Paspalides[1], Mirco Troue[1], Johannes Figueiredo[1], Lukas Sigl[1], Manuel Katzer[2], Malte Selig[2], Andreas Knorr[2], Ursula Wurstbauer[3], and Alexander Holleitner[1] — [1]TU Munich — [2]Technische Universität Berlin — [3]University of Münster

Transition metal dichalcogenides exhibit strong light-matter interactions, which suggests them to be ideal candidates for novel 2D optoelectronic applications. Corresponding van der Waals heterostacks allow the excitation and formation of long-lived interlayer excitons [1]. We present coherence measurements of the ground state in such interlayer exciton ensembles by performing Michelson-Morley interferometry over a wide range of exciton density and temperature [2]. Moreover, we discuss the expansion dynamics of the interlayer excitons presumably driven by dipole-dipole interactions. The presented work paves the way towards a detailed understanding of excitonic many-body quantum phenomena in two-dimensional materials [3].

Theoretical description of interlayer excitons in TMD homobilayers — •Ruven Hübner[1], Alexander Steinhoff[1], and Matthias Florian[2] — [1]Institut für Theoretische Physik, Universität Bremen, Bremen, Germany — [2]University of Michigan, Dept. of Electrical Engineering and Computer Science, Ann Arbor, MI, USA

In recent years, interlayer excitons in bilayers of transition metal dichalcogenides (TMDs) have received a rapid increase in attention. On the one hand, they feature the main characteristics of conventional excitons in the corresponding monolayers, namely an absorption spectrum in the optical regime combined with a high binding energy. On the other hand, they differ to such intralayer

excitons by a massively increased life time, a non-zero dipole moment in the out-of-plane direction and a strong sensitivity to material combination as well as stacking arrangement of adjacent monolayers. In this talk we focus on special excitonic properties inside TMD homobilayers that are particularly demanding from a theoretical point of view. In this context we discuss moiré excitons in twisted bilayers as well as high-lying excitons and trions at around twice the band gap energy arising within a highly non-parabolic band dispersion.

HL 8.6   Mon 16:30   POT 81

Raman signature of interlayer coupling and lattice dynamics in 2D TMDCs — •YANG PAN[1,2] and DIETRICH R. T. ZAHN[1,2] — [1]Semiconductor Physics, Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany — [2]Center for Materials, Architectures, and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, Chemnitz, Germany

Vertical stacking of two-dimensional (2D) homo- and heterostructures are intriguing research objects, as they are essential for fundamental studies and a key towards 2D device applications. It is paramount to understand the interlayer coupling in 2D materials and to find a fast yet precise characteristic signature. In this work, we report on a Raman fingerprint of interlayer coupling in 2D transition metal dichalcogenides (TMDCs). We observed that the out-of-plane B_{2g} vibrational mode is absent when two monolayers form a vertical stack yet remain uncoupled but emerges after strong coupling. Using systematic Raman, photoluminescence (PL), and atomic force microscopy (AFM) studies of WSe_2/WSe_2 homo-bilayers and $MoSe_2/WSe_2$ hetero-bilayers, we conclude that the B_{2g} vibrational mode is a distinct Raman fingerprint of interlayer coupling in 2D TMDCs. Our further investigations confirmed its applicability on twisted 2D homo- and hetero-bilayers. Our results propose an easy, fast, precise, and reliable measure to evaluate the interlayer coupling and twisting angles in 2D TMDCs.

HL 8.7   Mon 16:45   POT 81

Correlated states of moiré interlayer excitons in twisted transition metal dichalcogenide heterostructures — •NILS-ERIK SCHÜTTE[1], NICLAS GÖTTING[1,2], FREDERIK LOHOF[1,2], and CHRISTOPHER GIES[1,2] — [1]Institute for Theoretical Physics, University of Bremen, Bremen — [2]Bremen Center for Computational Material Science, University of Bremen, Bremen

Stacking two transition metal dichalcogenide (TMD) monolayers on top of each other with a small relative twist yields a moiré pattern with a long lattice period. Quasiparticles perceive the resulting band-structure modulation as a potential landscape, making it possible to consider moiré heterostructures as a realization of a Bose-Hubbard model in a semiconductor material.

We address the question in how far correlated states of moiré excitons can emerge and study their phase transition behavior in relation to the twist angle between both monolayers. Expanding on previous results [1], we discuss the effect of nearest-neighbor interaction that gives rise to a variety of different phases, such as inhomogeneous insulating and supersolid phases. Special attention is paid to the possibility of local atomic reconstructions that are now known to occur at small twist angles.

Electronic structures of twisted bilayer graphene and tungsten diselenide investigated by transferable tight-binding-models — •XIAOYU LIU, STEFAN BLÜGEL, and HYUN-JUNG KIM — Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, D-52425 Jülich, Germany

Since the discovery of intrinsic unconventional superconductivity in the Moiré superlattice from bilayer graphene stacked with a small twist angle, a new venue so-called twistronics has opened. Beyond graphene, transition metal dichalcogenides as a class of two-dimensional (2D) materials have attracted much attention due to their interesting optical properties. With the growing interest in 2D layered materials, accurate models describing the band structure and electronic properties of twisted bilayer graphene and tungsten diselenide are highly desirable. Here, we provide sets of parameters for the transferable tight-binding (TB) model, based on the Slater-Koster (SK) scheme with the exponential scaling law for the interlayer and overlap integral parameters. The workflow, to obtain transferable TB model parameters, is automatized by introducing global optimization methods such as particle swarm optimization (PSO) and conformational space annealing (CSA) methods. The fitness of the parameter set is assessed not only by comparing with ab-initio band energies, but also with its orbital similarity. Accurately produced electronic structures of twisted bilayers graphene and tungsten diselenide provide a chance to research their unique electronic and optical attributes.

Time-resolved optical spectroscopy of 3R-stacked MoS_2 — •SWARUP DEB, MICHAEL KEMPF, RICO SCHWARTZ, and TOBIAS KORN — Institute of Physics, Rostock University

Manipulation of in-plane rotational and out-of-plane stacking symmetry in engineered two-dimensional (2D) crystals has provided means to realize a variety of exotic phases in extremely thin structures. The emergence of out-of-plane ferroelectricity in rhombohedrally-stacked 2D materials, such as boron nitride and transition metal dichalcogenides (TMDs), is a recent addition to this, but so far, most research on rhombohedrally stacked (3R) TMDs focussed on bilayer units.

Here, we present a systematic study of low-temperature absorption, differential reflectivity, and Kerr rotation in 3R-stacked MoS_2 as a function of thickness, aiming to probe the effects of ferroelectricity and interlayer charge transfer on ground-state exciton properties, valley and photocarrier dynamics. We observe clear signatures of an energetic splitting of the A exciton, as well as valley and energy relaxation dynamics on a few-ps timescale.

HL 8.10   Mon 18:00   POT 81

Constructing minimal tight-binding models for twisted TMDC bilayers — •MICHAEL WINTER, DOMINIK BENNER, and TIM WEHLING — I. Institute of Theoretical Physics, Universität Hamburg, Notkestraße 9-11, 22607 Hamburg, Germany

Transition metal dichalcogenides bilayers attract considerable attention within the last years due to the wide range of observable correlation effects, e.g. superconductivity, exciton condensation and there-like. One possible parameter to tune these phenomena is the twist angle between the two layers.

We study the electronic structure of twisted transition metal dichalcogenides from ab initio DFT calculations and subsequent Wannier construction on untwisted snapshots of commensurate structures. By choosing a subspace of only three Wannier orbitals per transition metal, we construct a minimal model for the description of twisted bilayers.

HL 9: Focus Session: Graphene quantum dots (joint session HL/TT)

Quantum dots have emerged as one of the contenders for a future quantum information processor. Bilayer graphene is now established as a material that allows high quality bi-polar Coulomb blockade measurement, time-dependent transport measurements and first relaxation time measurements. In contrast to the more conventional GaAs and Si-based systems, several exiting and unexpected observations in graphene have been explained by the peculiar graphene bandstructure, which is gate- tunable, the additional valley degree of freedom, and spin-valley coupling.

Spin and valley lifetime in graphene quantum dots — •GUIDO BURKARD — University of Konstanz, Germany

Graphene with its low nuclear spin density and weak spin-orbit coupling allows for long electron spin relaxation and coherence times. The spin and valley degrees of freedom of localized electrons can therefore be seen as potential embodiments of classical or quantum bits for computation. However, the formation of localized states in quantum dots requires some form of badgap engineering, and the mechanisms for spin and valley relaxation have not been completely un-

derstood so far. Bilayer graphene has an electrically controllable bandgap that allows for the formation of quantum dots. We present general theoretical considerations regarding the formation of quantum dots in graphene and report on recent progress in understanding the relevant physical mechanisms of spin and valley relaxation in electrostatically gated bilayer graphene quantum dots.

Invited Talk   HL 9.2   Mon 15:30   POT 361

Microscopic modelling of electrostatically induced bilayer graphene quantum dots — •ANGELIKA KNOTHE — Institut für Theoretische Physik, Universität Regensburg, D-93040 Regensburg, Germany

Quantum nanostructures, e.g., quantum wires and quantum dots, are needed for applications in quantum information processing devices, such as transistors or qubits. In gapped bilayer graphene, one can confine charge carriers purely electrostatically, inducing smooth confinement potentials and thereby limiting edge-induced perturbances while allowing gate-defined control of the confined structure. In this talk, I will give an overview of our recent contributions toward the theoretical modelling of gate-defined bilayer graphene quantum dots, taking into account microscopic details of the material properties and the confinement. As an outlook, I will point towards current and future challenges in describing coupled bilayer graphene nanostructures, e.g., setups with multiple bilayer graphene quantum dots.

Valley relaxation in a single-electron bilayer graphene quantum dot — •LIN WANG and GUIDO BURKARD — Department of Physics, University of Konstanz, D-78457, Germany

Bernal-stacked bilayer graphene (BLG) has a tunable gap controlled by an out-of-plane electric field. This makes BLG a possible candidate to form quantum dots (QDs) via quantum confinement. Spin-based qubits in BLG QDs have received great attention due to outstanding spin-coherence properties. Very recently, long spin relaxation times of a single-electron state in BLG QDs was reported [1,2]. In addition to spin, valley pseudospin is another degree of freedom in BLG. The two valleys experience opposite Berry curvatures and associated magnetic moments via an out-of-plane electric field. This provides a promising way to control valleys and further establish valley qubits. To assess the potential of valley qubits, the valley relaxation time is a crucial parameter since it directly limits the lifetime of encoded information. Here, we investigate the valley relaxation in a single-electron BLG QD due to intervalley coupling assisted by (i) 1/f charge noise and (ii) electron-phonon couplings arising from the deformation potential and bond-length change. Our calculation shows that valley relaxation time decreases with a power law dependence as a function of magnetic field, which is in a good agreement with very recent experiment.

Single-shot spin and valley Pauli blockade read-out in bilayer graphene quantum dots — •CHUYAO TONG[1], REBEKKA GARREIS[1], WISTER WEI HUANG[1], ANNIKA KURZMANN[1,2], JOCELYN TERLE[1], SAMUEL JELE[1], KENJI WATANABE[3], TAKASHI TANIGUCHI[3], THOMAS IHN[1], and KLAUS ENSSLIN[1] — [1]ETH Zurich,

CH-8093 Zurich, Switzerland — [2]RWTH Aachen University, Aachen, 52074, Germany — [3]National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan

In bilayer graphene quantum dots, apart from spins up and down, the additional valley degree of freedom K- and K+ gives rise to an unconventional single-dot two-carrier ground state: spin-triplet valley-singlet, altering the canonical even-odd double dot Pauli spin blockade picture. This ground state can be switched to a spin-singlet valley-triplet by a perpendicular magnetic field, allowing us to switch between valley-blockade at low, and spin-blockade at higher magnetic field for the two-carrier Pauli blockade (1,1) to (0,2). We employ charge sensing technology and perform single-shot Pauli blockade read-out at the two field regimes, probing characteristic relaxation times T1 between spin or valley -triplet and -singlet. The spin-T1 is measured to be up to 60ms, drastically decreasing with increasing inter-dot tunnel coupling and corroborating with recent experiments performed with single-dot Elzerman read-out. Moreover, we observe exceedingly long valley T1 longer than 500ms, robust with inter-dot tunnel coupling. These promisingly long spin- and valley T1 herald for long-living spin and valley bilayer graphene quantum dot qubits.

Particle-hole symmetry protects spin-valley blockade in graphene quantum dots — •CHRISTIAN VOLK[1,2], LUCA BANSZERUS[1,2], SAMUEL MÖLLER[1,2], KATRIN HECKER[1,2], EIKE ICKING[1,2], KENJI WATANABE[3], TAKASHI TANIGUCHI[4], FABIAN HASSLER[5], and CHRISTOPH STAMPFER[1,2] — [1]JARA-FIT and 2nd Institute of Physics, RWTH Aachen University — [2]Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich — [3]Research Center for Functional Materials, NIMS, Tsukuba, Japan — [4]International Center for Materials Nanoarchitectonics, NIMS, Tsukuba, Japan — [5]JARA-Institute for Quantum Information, RWTH Aachen University

Particle-hole symmetry plays an important role for the characterization of topological phases in solid-state systems. Graphene is a prime example of a gapless particle-hole symmetric system. The intrinsic Kane-Mele spin-orbit coupling in graphene leads to a lifting of the spin-valley degeneracy and renders graphene a topological insulator in a quantum spin-Hall phase while preserving particle-hole symmetry.

Here, we show that the Kane-Mele spin-orbit gap leads to a lifting of the spin-valley degeneracy in bilayer graphene quantum dots, resulting in Kramer's doublets with different ordering for electron and hole states preserving particle-hole symmetry. We observe the creation of single electron-hole pairs with opposite quantum numbers and use the electron-hole symmetry to achieve a protected spin-valley blockade in electron-hole double quantum dots. The latter will allow spin-to-charge and valley-to-charge conversion, which is essential for the operation of spin and valley qubits.

Surface Acoustic Wave Cavity Optomechanics with 2D Materials — •GALAN MOODY — University of California, Santa Barbara, CA, USA

Surface acoustic waves (SAWs) are a versatile tool for coherently interfacing with a variety of solid-state quantum systems spanning microwave to optical frequencies, including superconducting qubits, spins, and quantum emitters. In this presentation, I will discuss our progress on integrating 2D material quantum emitters with planar lithium niobate SAW resonators driven by superconducting electronics. Using steady-state photoluminescence spectroscopy and time-resolved single-photon counting, we map the temporal dynamics of modulated 2D emitters under coupling to different SAW cavity modes, showing energy-level splitting consistent with strong deformation potential coupling. We leverage the large anisotropic strain from the SAW to modulate the exciton and biexciton fine-structure splitting of 2D semiconductors, which may find applications for on-demand entangled photon-pair generation from 2D materials. I will conclude with a discussion on the prospects and outlook for SAW cavity optomechanics with 2D quantum emitters for high-speed single-photon modulators, efficient transducers, compact sensors, and exploring quantum electro-optomechanics with 2D materials.

Phononic Microresonators Coupled by Surface Acoustic Waves — •SARAH BENCHABANE, MACIEJ BARANSKI, FENG GAO, OLIVIER GAIFFE, VALÉRIE SOUMANN, ROLAND SALUT, and ABDELKRIM KHELIF — FEMTO-ST, CNRS, Université Bourgogne-Franche-Comté, Besancon, France.

The implementation of scalable phononic circuits has become an appealing prospect in view of increasing the versatility of electro-acoustic devices for radio-frequency signal processing. Recent demonstrations have made convincing steps

towards this objective by proposing phononic architectures inspired by photonic integrated circuits or combining the rich dynamics of micro- and nano-electromechanical (M/NEMS) resonators with propagating elastic waves. In this work, we propose to exploit the interaction between surface acoustic waves (SAW) and locally-resonant, micron-scale mechanical resonators in order to achieve coherent driving of the resonator motion with SAW and, reciprocally, to control the elastic energy distribution at a deep sub-wavelength scale. Optical measurements by laser scanning interferometry allows retrieving both the resonator frequency response and mode shape, hence enabling direct observation of the vectorial nature of the interaction. We investigate the proposed physical system both in the linear and non-linear regimes and reveal that the elastic field behavior can be further controlled through resonator-to-resonator coupling, leading to a variety of interaction schemes. The proposed devices illustrate the potential of SAW-based architectures for the implementation of high-frequency phononic-NEMS circuits.

Towards room temperature polaromechanics — •Ismael dP. Embid, Alexander S. Kuznetsov, Klaus Biermann, and Paulo V. Santos — Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany

Microcavity exciton-polaritons have emerged as a promising platform for novel solid-state devices ranging from low threshold lasers to quantum and classical simulators. The transition to a polariton condensate at high particle densities with long (ns) temporal coherence and enhanced sensitivity to vibrations has opened the way for polariton-based optomechanics in the GHz frequency domain [1]. Such highly coherent states have, however, so far been observed only at low temperatures (10K). Here, we show that long coherences can be maintained by confining the polariton condensates within μm-sized intracavity traps in (Al,Ga)As microcavities. In particular, we demonstrate temporal coherences in the GHz range up to temperatures exceeding 77K. Furthermore, we show that these condensates can be non-adiabatically modulated at these temperatures by electrically injected GHz phonons, leading to the formation of several phonon side bands. These results enable the generation of GHz optical frequency combs tunable by the electrical power, a relevant feature for the precise control of quantum states.

Readout of phonon statistics via resonance fluorescence of a single photon emitter — •Daniel Groll[1], Thilo Hahn[1], Ortwin Hess[2], Paweł Machnikowski[3], Tilmann Kuhn[1], and Daniel Wigger[2] — [1]Institute of Solid State Theory, University of Münster, Germany — [2]School of Physics, Trinity College Dublin, Ireland — [3]Department of Theoretical Physics, Wrocław University of Science and Technology, Poland

Single photon emitters in a solid state environment are inevitably coupled to phonon modes of the host material. On the one hand, decoherence induced by this coupling is often detrimental for harnessing the full potential of such emitters. On the other hand, this interaction in principle allows for control of the emitter not only optically, but also acoustically. Hybrid systems, comprised of optical, acoustic and excitonic components thus offer a high degree of flexibility by making use of all available interaction channels.

We consider here a single photon emitter located inside a phononic resonator and driven by an external laser. We derive analytical expressions for the resonance fluorescence (RF) spectrum, depending explicitly on the quantum statistics of the resonator mode. We show that, in principle, the statistics of the phonon mode can be determined from a given RF spectrum using our analytical model. We thus establish a simple and direct connection between the optical and acoustic components of such a hybrid system, paving the way for using single photon emitters as quantum transducers between the optical and acoustic domain.

Acousto-optoelectric spectroscopy on transition metal dichalcogenide monolayers with surface acoustic waves — Matthias Weiss[1,2], Benjamin Mayer[1], Tobias Petzak[2], Clemens Strobl[1], •Emeline Nysten[1,2], Ursula Wurstbauer[1], and Hubert Krenner[1,2] — [1]Physikalisches Institut, WWU Münster, Germany — [2]Lehrstuhl für Experimentalphysik 1, Universität Augsburg, Germany

Surface acoustic waves have proven to be a useful tool for the control of semiconductor nanostructures optical properties and the dynamical transport of charge carriers [1,2,3]. For instance, SAW spectroscopy was already used to probe the electrical transport inside CVD-grown MoS_2 on $LiNbO_3$ in a contact-free manner [1]. In this work, we integrated transition metal dichalcogenide monolayer flakes into $LiNbO_3$ surface acoustic wave devices through a classical exfoliation process. The impact of the SAW on the photoluminescence of the monolayer was systematically studied. The results show a clear increase in the photoluminescence intensity of the monolayer as well a SAW-periodic modulation which can be linked to the SAW-controlled diffusion of the excitons inside the monolayer.

Brillouin scattering selection rules in polarization-sensitive photonic resonators — Anne Rodriguez[1], Priya Priya[1], Edson Cardozo[1], Abdelmounaim Harouri[1], Isabelle Sagnes[1], Florian Pastier[2], Martina Morassi[1], Aristide Lemaître[1], Loic Lanco[1], •Martin Esmann[1,3], and Daniel Lanzillotti-Kimura[1] — [1]Université Paris-Saclay, CNRS, Centre de Nanosciences et de Nanotechnologies, Palaiseau, France — [2]Quandela SAS, Palaiseau, France — [3]Institut für Physik, Universität Oldenburg, Germany

Spontaneous Brillouin scattering in bulk crystalline solids is governed by intrinsic selection rules which lock the relative polarization of excitation laser and Brillouin signal. In this work, we independently manipulate the polarization states of the two, using polarization-sensitive optical resonances in elliptical micropillars [1,2].

The induced wavelength-dependent polarization rotation [3] enables a polarization-based filtering technique [4]. We employ it to experimentally detect acoustic phonon resonances with frequencies in the range of 20-100 GHz, difficult to access with both standard Brillouin and Raman spectroscopy techniques. The strong modification of selection rules extends to any optical system with polarization-sensitive modes: plasmonic resonators, photonic crystals, birefringent micro- and nanostructures. It is thus relevant for applications in optomechanical, optoelectronic, and quantum optics devices [1,2].

Local Chern patches and networks of chiral modes in quantum Hall phases with spatial magnetic field profiles. — •Suraj Hegde and Tobias Meng — Institute of Theoretical Physics and Wurzburg-Dresden Cluster of Excellence ct.qmat, Technische Universitat Dresden, 01069 Dresden, Germany.

Transport experiments on curved Hall bars show a variety of non-trivial transport signatures. Motivated by these experiments, we develop a model that accounts for various features in multi-terminal Hall bar measurements and perform numerical simulations using KWANT. We model the effect of curvature of the sample through spatial variation of the magnetic field profile and find that it results in patches of quantum Hall phases characterised by different local Chern markers. We find that most of the transverse and longitudinal transport can be understood in terms of local Chern patches and an intricate interplay of chiral modes at the interface of different patches. We also show that the spatial magnetic field textures could provide a novel platform to engineer lattices formed by networks of chiral modes.

HL 11.2   Mon 15:15   POT 251

Effect of the external fields in high Chern number quantum anomalous Hall insulators — •Yuriko Baba[1,2], Francisco Domínguez-Adame[1], and Rafael A. Molina-Ferández[2] — [1]GISC, Departamento de Física de Materiales, Universidad Complutense, E–28040 Madrid, Spain — [2]Instituto de Estructura de la Materia, IEM-CSIC, E–28006 Madrid, Spain

Multilayer structures consisting of alternating magnetic and undoped topological insulator layers have been proved so far to be a convenient platform for creating a quantum Anomalous Hall state with a high Chern number [1]. However, in previous proposals, the Chern number can only be tuned by varying the doping concentration or the width of the magnetic topological insulator TI layers. This restricts the applications of the dissipationless chiral edge currents in electronics, since the number of conducting channels remains fixed. In this work, we propose a way of varying the Chern number at will by means of an external electric field applied along the stacking direction. The electric field generates the hybridization of the inverted bands, generating new topological channels. In this way, the number of Chern states can be tuned externally in the sample, without the need of modifying the number and width of the layers or the doping level. We showed that this effect can be uncovered by the variation of the transverse conductance as a function of the electric field at constant injection energy at the Fermi level. [2]

Novel thermo-electric transport channel in the conformal limit of tilted Weyl semimetals — Thorvald Ballestad[1], Alberto Cortijo[2], Maria Vozmediano[3], and •Alireza Qaiumzadeh[1] — [1]Center for Quantum Spintronics, Norwegian University of Science and Technology, Trondheim, Norway — [2]Universidad Autonoma de Madrid, Madrid, Spain — [3]Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain

Recently, a new contribution to the Nernst current was proposed in 3D Dirac and Weyl semimetals, originated from quantum conformal anomaly [1,2]. In the present study, we analyze the effect of the tilt on the transverse thermo-electric coefficient of Weyl semimetals in the conformal limit, i.e., zero temperature and zero chemical potential. Using the Kubo formalism, we find a non-monotonic behavior of the thermoelectric conductivity as a function of the tilt perpendicular to the magnetic field, and a linear behavior when the tilt is aligned to the magnetic field. An "axial Nernst" current is generated in inversion symmetric materials when the tilt vector has a projection in the direction of the magnetic field. This analysis will help in the design and interpretation of thermo-electric transport experiments in recently discovered topological quantum materials [3].

HL 11.4   Mon 15:45   POT 251

Selective scattering between counter-propagating edge states in a topological insulator — •Meng Hao[1,2], Li-Xian Wang[1,2], Fabian Schmitt[1,2], Hartmut Buhmann[1,2], and Laurens W. Molenkamp[1,2] — [1]Institute for Topological Insulators, Würzburg, Germany — [2]Physikalisches Institut (EP III) Würzburg University, Würzburg, Germany

The quantum Hall state, known by its dissipationless nature, comprises chiral edge states in a two-dimensional electron gas (2DEG). In the ordinary quantum Hall effect, all edge states propagate in the same direction, populated equally. Thus, they are immune to inter-edge-state scattering. In contrast, counter-propagating edge states, populated unequally, are naturally sensitive to the scattering process. However, a realization of this scenario so far was only possible by stacked layers of high-mobility 2DEGs, e.g., quantum wells or graphene. Here we realize the counter-propagating edge states in a three-dimensional topological insulator controlled by top and bottom gates. Surprisingly, the counter-propagating edge states prove to scatter into each other selectively. Our first attempt shows that this inter-edge-state scattering occurs exclusively between Landau levels with the same Landau index. We further propose a cross bar equipped with split-gates to determine the selection rule of scattering and scattering parameters unambiguously. Following this proposal, we will show some preliminary results and report our experimental advances.

Edge modes, Hall conductivity and topological features of a dice lattice: Fate of flat bands under strain — •Sayan Mondal and Saurabh Basu — Indian Institute of Technology Guwahati

We study the topological properties of a dice lattice, which has three atoms per unit cell (A, B, and C). In addition, the bands are systematically deformed via the introduction of anisotropy among the nearest neighbour (NN) hoppings in two distinct ways. In the first case, we apply the uniaxial strain, which alters the NN hoppings (between the sublattices A-B and B-C) along the direction of applied strain. While in the second case, we selectively tune the NN hopping between A and B sublattices which may be achieved by a controlled chemical pressure. The first case yields the Chern insulating lobes in the phase diagram with $C = \pm 2$ till a certain critical anisotropy, where the spectral gap vanishes. The quantized plateau in the anomalous Hall conductivity and the pair of chiral edge modes at each edge of a ribbon support the obtained values of the Chern numbers. Whereas, the second case (selective strain) shows distorted flat band in the dispersion spectrum, which alters the gap-closing condition as compared to the case of uniaxial strain. Also, the Chern insulating lobes in the phase diagram and the Hall conductivity have distinct features compared to the case above. However, in both cases, topological phase transitions take place which is demonstrated via the Chern number changing discontinuously from ± 2 to zero across the gap-closing transitions.

HL 11.6   Mon 16:45   POT 251

Structure-imposed electronic topology in graphene nanoribbons — •Florian Arnold[1], Tsai-Jung Liu[1], Agnieszka Kuc[2], and Thomas Heine[1,2,3] — [1]Technische Universität Dresden, Dresden, Germany — [2]HZDR, Leipzig, Germany — [3]Yonsei University, Seoul, Republic of Korea

Zigzag graphene nanoribbons (ZGNR) can be transformed into new structure types by removing terminal carbon atoms in a regular pattern. When a single atom is removed on each zigzag edge so-called cove-edged ZGNR (ZGNR-C) are created, while removing multiple atoms results in gulf-edged ZGNR (ZGNR-G). In our seminal work, we demonstrated the direct structure-electronic structure relation based on the structural parameters that unambiguously characterize ZGNR-C. This allowed to create a scheme that classifies their electronic state, i.e., if they are metallic, topological insulators or trivial semiconductors, and to find an empirical formula for the band gap of the semiconducting ribbons. Since then, we were able to expand this description to ZGNR-G systems where the chemical space of possible structures increases further due to the variable size of the gulf edges. With this, we give guidance to realize new graphene nanoribbon heterojunctions hosting topological states and investigate the transport properties of exemplary systems.

HL 11.7　Mon 17:00　POT 251

Massive and topological surface states in strained HgTe and evidence for parity anomaly — •Wouter Beugeling[1,2], Lixian Wang[1,2], David M. Mahler[1,2], Valentin L. Müller[1,2], Ewelina M. Hankiewicz[3], Hartmut Buhmann[1,2], and Laurens W. Molenkamp[1,2] — [1]Institute for Topological Insulators, Würzburg, Germany — [2]Physikalisches Institut (EP III), Würzburg University, Würzburg, Germany — [3]Institute for Theoretical Physics and Astrophysics (TP IV), Würzburg University, Würzburg, Germany

The idea that band inversion in a narrow-gap material can lead to Dirac-type surface states was noted by Volkov and Pankratov in the 1980's. Only about two decades later, it was realized that the surface states of topological insulators are

the gapless Dirac states predicted by them. The massive Volkov-Pankratov states received much less attention. They are pulled from the bulk in a sufficiently large electric field and are topologically trivial. Until recently, direct evidence in the form of transport measurements was elusive.

From our magneto-transport experiments on a three-dimensional topological insulator heterostructure (strained HgTe), we demonstrate the coexistence of massless and massive Volkov-Pankratov states. The well-developed Hall quantization in the n- and the p-type regime is due to the topological surface state and the massive Volkov-Pankratov states, respectively, as confirmed by k·p theory. In a second series of experiments, we find a remarkable re-entrant quantum Hall effect in the p-type regime, which we can trace to spectral asymmetry, a salient manifestation of parity anomaly in a solid-state system.

HL 12: Semiconductor lasers I

HL 12.1　Mon 15:00　POT 112

Adjustment of the active region on an InGaAsP VECSEL around 760nm for red pumping — •Rebecca Rühle, Marius Grossmann, Michael Jetter, and Peter Michler — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, Universität Stuttgart, Allmandring3, 70569 Stuttgart, Germany

The quantum defect between the emission and the pump wavelength of vertical external-cavity surface-emitting lasers (VECSEL) has a huge impact on the performance of the structure. Especially to improve the thermal behavior, a longer wavelength pump laser is favorable. For the InGaAsP quantum well (QW) VECSEL with an emission wavelength at around 760nm, a pump laser at 675nm is preferable to one at 532nm. But the QWs are embedded in GaInP-barriers, thus are transparent for the pump light and the pump efficiency is rather small. To overcome this the composition of the GaInP can be changed so that the barrier again can absorb the pump light. The effects of adjusting the barrier in the active region and the performance of the VECSELs have now been investigated in detail. Photoluminescence and laser output power measurements were performed to compare the behavior of the different structures. A further study was carried out to evaluate the effect of the different gallium to indium ratio in the crystal structure on the surface roughness of the device.

HL 12.2　Mon 15:15　POT 112

Cavity effects in hybrid resonators embedding InGaAs quantum dots — •Kartik Gaur, Sarthak Tripathi, Imad Limame, Ching-Wen Shih, Chirag Palekar, Sven Rodt, and Stephan Reitzenstein — Institut für Festkörperphysik, Technische Universität Berlin, Germany

InGaAs quantum dots (QDs) embedded in microcavities based on highly reflective distributed Bragg reflectors (DBRs) allow for the development of high Q-factor, low mode volume micropillar cavities which feature high light-matter interaction. This makes them almost ideal candidates for quantum light sources and high-β microlasers. However, epitaxially grown GaAs/AlAs DBRs suffer from relatively low refractive index contrast, and often high absorption of the optical pumping laser. Here, we propose replacing the upper III-V DBR with dielectric DBR based on $\lambda/4$-thick layers of SiO_2 and Si_3N_4 deposited using plasma-enhanced chemical vapor deposition. Numerical simulations are carried out to optimize the fabrication parameters and subsequently validate the optical properties. The MOCVD-grown InGaAs QD active region is integrated in the central one-λ GaAs cavity on top of the bottom DBR with 33 $Al_{0.2}Ga_{0.8}As/Al_{0.9}Ga_{0.1}As$ mirror pairs, followed by electron beam lithography processing step to define photonic defects for lateral mode confinement. Such defects in the form of microlenses are created using a SiO_2 hard mask and wet chemical etching. We then deposit dielectric top DBR consisting of 15 $\lambda/4$-thick SiO_2 and Si_3N_4 mirror pairs. The final structure is investigated via low-temperature micro-photoluminescence.

HL 12.3　Mon 15:30　POT 112

Latest developments on membrane external-cavity surface-emitting lasers (MECSELs) — •Hermann Kahle[1,2], Patrik Rajala[2], Philipp Tatar-Mathes[2], and Mircea Guina[2] — [1]Institute for Photonic Quantum Systems (PhoQS), Department of Physics, Paderborn University, Warburger Straße 100, 33098 Paderborn, Germany — [2]Optoelectronics Research Centre (ORC), Physics Unit / Photonics, Tampere University, Korkeakoulunkatu 3, 33720 Tampere, Finland

MECSELs have experienced a rapid progress in recent years. Based on the membrane geometry of MECSELs, an intrinsically excellent beam quality is one important benefit of this new vertically emitting kind of lasers. The most important recent progress, like continuous wave broadband tuning ($\Delta\lambda_{FWHM} \approx 70$ nm around $\lambda_0 = 985$ nm) and anti-resonant gain membrane design will be discussed.

HL 12.4　Mon 15:45　POT 112

Membrane saturable absorber mirror (MESAM) in a red-emitting VECSEL for the generation of stable ultrashort pulses — •Ana Ćutuk, Marius Grossmann, Michael Jetter, and Peter Michler — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, Universität Stuttgart, Allmandring 3, 70569 Stuttgart

Optically-pumped semiconductor disk lasers, also known as vertical external-cavity surface-emitting lasers (VECSELs), provide several advantageous properties like near-diffraction-limited beam profile and the flexibility to add optical components inside the laser cavity and thereby modify the laser characteristics. One example is the semiconductor saturable absorber mirror (SESAM), a monolithic semiconductor structure consisting of a saturable absorber region on top of a distributed Bragg reflector (DBR). However, the epitaxial growth of SESAMs can be limited by the DBR design, making it difficult to fabricate pulsed lasers with wavelengths within spectral gaps. We demonstrate a membrane saturable absorber mirror (MESAM) which overcomes the growth restrictions of the DBR. A membrane containing the active region only is combined with a dielectric mirror and thus simulates a SESAM with an increased flexibility in design. We compare the dynamic properties of a SESAM- and MESAM-mode-locked VECSEL. With both devices we obtain fundamental mode locking with pulse durations in the ps-range.

HL 12.5　Mon 16:30　POT 112

AlGaInP-based VECSELs with grating waveguide structures — •Peter Gierss[1], Ana Ćutuk[1], Maxim Leyzner[2], Uwe Brauch[2], Marwan Abdou Ahmed[2], Michael Jetter[1], Thomas Graf[2], and Peter Michler[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, Universität Stuttgart, Allmandring 3, 70569 Stuttgart — [2]Institut für Strahlwerkzeuge, Universität Stuttgart, Pfaffenwaldring 43, 70569 Stuttgart

Vertical external-cavity surface-emitting lasers (VECSELs) provide several superior properties like a near-diffraction beam profile and the flexibility to add optical components inside the cavity for further tailoring of the laser parameters. However, the heat generated by the pump laser within the active region proves to be a limiting factor for achieving higher output powers. This is mainly due to the poor thermal conductivity of the thick distributed Bragg reflector (DBR), which could be overcome by placing a heatspreader right next to the active region.

In this contribution, we present our recent progress in the development of an AlGaInP-VECSEL based on a grating waveguide structure (GWS). Excluding the DBR and adding a heatspreader instead improves the heat removal from the gain region while the guided-mode resonances from the GWS should provide good coupling of the pump and laser field and a high reflectivity to replace the function of the DBR. Our current research focuses on the fabrication and characterization of the high-contrast grating on top of a gain membrane.

HL 12.6　Mon 16:45　POT 112

Manipulating the emission characteristics of VCSEL in the red spectral range with polymer microlenses and etched surface reliefs — Farnaz Khamseh, •Lena Engel, Michael Zimmer, Sergej Vollmer, Michael Jetter, and Peter Michler — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, Universität Stuttgart, Allmandring 3, 70569 Stuttgart

Vertical-cavity surface-emitting lasers (VCSELs) are promising candidates for various applications like sensing, printing and data transfer due to their low power consumption and the possibility of arranging them in arrays. Especially in the red spectral range around 660nm VCSEL are interesting for example in

biomedical applications. However, their implementation is often hampered as light is emitted under an angle of divergence of 10° for single mode operation and higher order transverse modes are emitted especially for higher output power operation, further increasing the divergence and limiting the fiber coupling efficiency. Thus, the aim of this work is to improve the emission characteristics of red emitting VCSELs. Therefore, polymer microlenses for beam collimation are integrated directly on the VCSEL surface. Their ideal geometry and the tolerances for the alignment relative to the oxide aperture are thoroughly investigated utilizing ray-optics simulations. Additionally, etched surface reliefs are used to suppress the emission of higher order modes via a spatial modulation of the top mirror loss.

HL 12.7   Mon 17:00   POT 112

Multifold lasing threshold reduction of optically pumped micropillar lasers with low-absorbing $Al_{0.2}Ga_{0.8}As/Al_{0.9}Ga_{0.1}As$ distributed Bragg reflectors — •Ching-Wen Shih[1], Imad Limame[1], Chirag Palekar[1], Sebastian Krüger[1], Aris Koulas-Simos[1], Daniel Brunner[2], and Stephan Reitzenstein[1] —

[1]Institut für Festkörperphysik, Technische Universität Berlin, Berlin, Germany — [2]Département d'Optique P. M. Duffieux, Institut FEMTO-ST, Université Bourgogne-Franche-Comté CNRS UMR 6174, Besançon, France

Micropillar photonic devices, where the active layers are in an optical cavity sandwiched between epitaxially grown dielectric Bragg mirrors (DBRs), are one of the fundamental elements to study cavity quantum electrodynamics and to enable devices for quantum technology applications. Here, we report on the experimental realization of multifold lasing threshold reduction of optically pumped micropillar lasers by simply replacing the commonly used $GaAs/Al_{0.9}Ga_{0.1}As$ DBRs with low-absorbing $Al_{0.2}Ga_{0.8}As/Al_{0.9}Ga_{0.1}As$ DBRs, which minimizes the DBRs absorption of the optical pump power. In pump-wavelength-dependent I/O measurements, we demonstrate that the incorporation of 20% Al content in the DBRs opens an optical pumping window from the absorption edge of $Al_{0.2}Ga_{0.8}As$ at 700 nm to the one of GaAs at 820 nm, where the excitation laser light can effectively reach the GaAs cavity above its bandgap while remaining transparent to the DBRs, resulting in high power conversion efficiency, low lasing threshold, and high thermal stability.

HL 13: Focus Session: Frontiers of Electronic-Structure Theory II (joint session O/HL)

Time: Monday 15:00–17:15   Location: TRE Ma

Topical Talk   HL 13.1   Mon 15:00   TRE Ma
Coupled-cluster theory for complex solids made ready — •Andreas Grüneis — TU Wien, Institute for Theoretical Physics, Wiedner Hauptstraße 8-10/136, 1040 Vienna, Austria
This talk will review recent progress in applying periodic coupled-cluster theory, which has the potential to achieve a systematically improvable level of accuracy, to solids and surfaces. We will discuss novel techniques that reduce the computational cost by accelerating the convergence of calculated properties towards the complete basis set as well as the thermodynamic limit. The newly developed techniques have been implemented in the free and open source simulation software Cc4s that is interfaced to a growing number of widely-used electronic structure theory codes. These developments have enabled an increasing number of ab initio studies and allowed for assessing the level of accuracy of coupled-cluster theory by comparing to experimental findings as well as quantum Monte Carlo results. The presented applications will cover a wide range of materials science problems including the study of phase diagrams, molecule-surface interactions and properties of defects.

HL 13.2   Mon 15:30   TRE Ma
Speedup of structural optimisations using hybrid functionals: Case studies for energy materials — •Daniel Fritsch — Weierstrass Institute for Applied Analysis and Stochastics, Mohrenstr. 39, 10117 Berlin, Germany — Helmholtz-Zentrum Berlin für Materialien und Energie, Hahn-Meitner-Platz 1, Berlin, 14109, Germany
First-principles calculations based on density functional theory have been established as de facto standard for computational materials investigations. Depending on the size of the unit cell, for every material of interest a suitable choice for the unknown exchange and correlation functional has to be made; taking not only into account the desired accuracy, but also the available computational resources.

In recent years, a promising combination of two approaches emerged, starting from a structural relaxation based on a simpler (semi)local functional, supplemented by a single shot hybrid functional calculation. Here, we propose a new method for combining different levels of exchange and correlation functional for structural relaxations.

In a first benchmarking step, this new method will be applied to various sets of promising energy materials, where full hybrid functional calculations are available, with a main focus on the performance of this new approach on the structural properties and the required computational resources. In a second step, this new approach will be applied to materials, which up-to-now have not been accessible to hybrid functional calculations due to the required computational resources. All the presented results on the structural, electronic, and optical properties will be critically discussed alongside experimental findings.

HL 13.3   Mon 15:45   TRE Ma
All-Electron Large-Scale Hybrid Density Functional Simulations — Florian Merz[1], Andreas Marek[2], •Sebastian Kokott[3], Christian Carbogno[3], Yi Yao[3], Mariana Rossi[4], Markus Rampp[2], Matthias Scheffler[3], and Volker Blum[5] — [1]Lenovo HPC Innovation Center, Stuttgart — [2]Max Planck Computing and Data Facility, Garching — [3]The NOMAD Laboratory at the FHI-MPG and IRIS-Adlershof HU, Berlin — [4]MPI for the Structure and Dynamics of Matter, Hamburg — [5]Duke University, North Carolina, USA
The localized resolution-of-identity approach [1] enables $O(N)$ hybrid density functional simulations and, thus, the computation of accurate electronic prop-

erties of large scale atomistic models in the range of ten thousands of atoms in *FHI-aims* [2]. In this range, parallelization and memory requirements of the exact exchange part, and the evaluation of the Hartree potential remain challenging. The solution of the generalized eigenvalue problem with direct eigensolvers like ELPA [3] naturally becomes a bottleneck due to $O(N^3)$ scaling. In this work, we present recent algorithmic advances for the exact exchange part and the evaluation of the Hartree potential, as well as optimizations of the ELPA library. We systematically perform benchmark tests on CPU and GPU-accelerated architectures covering inorganic solids, large molecules, and organic crystals with up to 50,000 atoms.

A Koopman's compliant exchange correlation potential for semiconductors — •Michael Lorke[1], Peter Deak[2], and Thomas Frauenheim[2] — [1]Institute for Theoretical Physics, University of Bremen, Otto-Hahn-Allee 1, Bremen, 28359, Germany — [2]BCCMS, University of Bremen, Germany
Density functional theory is the workhorse of theoretical materials investigations. Due to the shortcoming of (semi-)local exchange correlation potentials, hybrid functionals have been established for practical calculations to describe surfaces, molecular adsorption, and defects. These functionals operate by mixing between semi-local and Hartree-Fock exchange semi-emprically. However, their parameters have to be optimized for every material separately. To treat materials with a more physics driven approach and without the need of parameter optimization is possible with many-body approaches like GW, but at an immense increase in computational costs and without the access to total energies and hence geometry optimization. We propose a novel exchange correlation potential[1] for semiconductor materials, that is based on physical properties of the underlying microscopic screening. We demonstrate that it reproduces the low temperature band gap of several materials. Moreover it respects the required linearity condition of the total energy with the fractional occupation number, as expressed by the generalized Koopman*s theorem. We also show that this novel functional can be used as a kernel in linear response TDDFT to reproduce excitonic effects in optical spectra [1] Physical Review B 102 (23), 235168 (2020)

HL 13.5   Mon 16:30   TRE Ma
Accurate and efficient treatment of spin-orbit coupling via second variation employing local orbital basis functions — •Hannah Kleine[1], Andris Gulans[2], Sven Lubeck[1], Cecilia Vona[1], and Claudia Draxl[1] — [1]Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin — [2]Department of Physics, University of Latvia
Spin-orbit-coupling (SOC) effects can significantly change the properties of materials containing heavy elements, mostly by introducing shifts and splittings in the band structure. Including SOC effects in density-functional-theory (DFT) calculations can be challenging. In the linearized augmented planewaves plus local orbitals (LAPW+LO) method, SOC is treated as a perturbation and solved by a second variational (SV) scheme where eigenvectors of the scalar-relativistic Kohn-Sham Hamiltonian are used as basis functions for the SO-coupled problem. For certain materials, especially those with strong SOC effects, many SV basis functions are required which leads to high computational costs. By adding

LOs to the SV basis, we are able to drastically reduce the basis-set size and thus the computational cost. We implement this approach in the all-electron full-potential computer package exciting [1] and combine it with the use of relativistic LOs to achieve high accuracy results for a variety of different materials.

HL 13.6 Mon 16:45 TRE Ma
Exact sum-rule approach to polarizability and asymptotic van der Waals functionals – derivation of exact benchmarks — •ALBERTO AMBROSETTI[1], JOHN DOBSON[2], MATTEO RICCI[1], and PIER LUIGI SILVESTRELLI[1] — [1]Dipartimento di Fisica e Astronomia, Università degli Studi di Padova, via Marzolo 8, 35131, Padova, Italy — [2]Nanoscale Science and Technology Centre, Griffith University, Nathan, Queensland 4111, Australia

Using a sum-rule approach we develop an exact theoretical framework for polarizability and asymptotic van der Waals correlation energy functionals of isolated objects[1]. The functionals require only monomer groundstate properties as input. Functional evaluation proceeds via solution of a single position-space differential equation, without the usual summations over excited states or frequency integrations. Explicit functional forms are reported for reference physical systems, including atomic hydrogen and single electrons subject to harmonic confinement, and immersed in a spherical-well potential. Direct comparison with the popular Vydrov-van Voorhis density functional shows that this performs best when density decay occurs at atomic scales. The adopted sum-rule approach implies general validity of our theory, enabling exact benchmarking of van der Waals density functionals, and direct inspection of the subtle long-range correlation effects that constitute a major challenge for approximate (semi-)local density functionals.

Interacting electrons and bosons in the doubly screened $G\widetilde{W}$ approximation — •YAROSLAV PAVLYUKH — Department of Theoretical Physics, Wroclaw University of Science and Technology

In Ref. [1] we built on the Generalized Kadanoff-Baym Ansatz for electrons and bosons to map a broad class of nonequilibrium Green's function theories onto a coupled system of ordinary differential equations with linear time-scaling. Available methods to treat e-e correlations include GW [2], T-matrix and Faddeev, while e-b correlations are described by Ehrenfest and second-order diagrams in the e-b coupling [3].

In this work we present a substantial advance in the treatment of correlations, requiring no extra computational cost and preserving all conserving properties. Specifically, we include the effects of dynamical screening due to *both e-e* and *e-b* interactions ($G\widetilde{W}$ approximation). The $G\widetilde{W}$ extension opens the door to a wealth of phenomena ranging from carrier relaxation and exciton recombination to molecular charge migration and transfer in optical or plasmonic cavities.

HL 14: 2D Materials III (joint session HL/CPP)

Time: Tuesday 9:30–12:15

Location: POT 81

HL 14.1 Tue 9:30 POT 81
Sub-THz detection in two dimensional systems and CVD graphene heterostructures — FRANZISKA LINSS[1], VINCENT STRENZKE[1], PAI ZHAO[1], CHITHRA S. SHARMA[1], LARS TIEMANN[1], •QIN HUA[2], and ROBERT H. BLICK[1] — [1]Center for Hybrid Nanostructures, Universität Hamburg, Luruper Chaussee 149, 22761 Hamburg, Germany — [2]Suzhou Institute of Nanotech and Nanobionics (SINANO) of the Chinese Academy of Sciences (CAS), China

Electromagnetic radiation in the THz range can induce surface plasmons, i.e., a collective motion of electrons, in graphene-based devices. We fabricated a field-effect-transistor with asymmetric dual-grating gates (ADGG) to detect sub-THz radiation using large-scale graphene that was synthesized by chemical vapor deposition (CVD). The CVD graphene sheet is encapsulated between two flakes of hBN and placed on a highly doped Si wafer that acts as a back gate. The ADGG was structured on the top hBN flake. The control of the carrier concentration via electrostatic gates is crucial to match the resonance condition of the plasmons. The sample was characterized by sweeping the top gate voltage from -1 V to 2 V and the charge neutrality point was reached at a top gate voltage of 0.87 V at 4.2 Kelvin. Furthermore, we used a high electron mobility transistor (HEMT) to detect THz radiation, where the detection mechanism is based on a mixing with a reference radiation in a nonlinear medium. In this device, we can demonstrate sub-THz radiation at room temperature.

HL 14.2 Tue 9:45 POT 81
Theory of non-local Andreev reflection through Andreev molecular states in graphene Josephson junctions — •ANDOR KORMÁNYOS[1], EDUÁRD ZSURKA[1], NOEL PLASZKÓ[1], and PÉTER RAKYTA[1,2] — [1]Department of Physics of Complex Systems, Eotvos Lorand University, Budapest, Hungary — [2]Wigner Research Center for Physics, 29-33 Konkoly-Thege Miklos Str., H-1121 Budapest, Hungary

We propose that a device composed of two vertically stacked monolayer graphene Josephson junctions can be used for Cooper pair splitting. The hybridization of the Andreev bound states of the two Josephson junction can facilitate non-local transport in this normal-superconductor hybrid structure, which we study by calculating the non-local differential conductance. Assuming that one of the graphene layers is electron and the other is hole doped, we find that the non-local Andreev reflection can dominate the differential conductance of the system. Our setup does not require the precise control of junction length, doping, or superconducting phase difference, which could be an important advantage for experimental realization.

HL 14.3 Tue 10:00 POT 81
Quantum Hall measurements near electric field controlled Lifshitz transitions in trigonally warped bilayer graphene — •MARTIN STATZ, ANNA SEILER, JONAS PÖHLS, MORITZ KNAAK, FRANCESCA FARLORSI, and THOMAS WEITZ — 1st Physical Institute, Faculty of Physics, University of Göttingen, Friedrich-Hund-Platz 1, Göttingen 37077, Germany

Various spontaneous symmetry broken phases such as Stoner ferromagnetism, spin-polarized superconductivity, a quantum anomalous Hall octet and a topologically non-trivial Wigner-Hall crystal phase have recently been reported in bilayer graphene (BLG) [1]. Since these interaction-driven phenomena are dictated by the ratio of the Coulomb and kinetic energy of carriers, they can be promoted by the formation of flat bands and a divergent density of states (DoS) near Lifshitz transitions (LT). Trigonally warped BLG at low vertical displacement fields (D-field) and carrier densities ($\sim 10^{11}$ cm^{-2}) displays one centre and three off-centre Dirac cones in each valley, and therefore offers a rich playground for correlated phases (CP) and changes in the Fermi surface topology by inducing charge density and D-field driven LT. Here, we report on quantum Hall measurements near charge density and D-field driven LT in trigonally warped BLG encapsulated in hexagonal boron-nitride in a dual-gated architecture with graphite contacts and graphite gates at 10 mK. We further outline our status on the temperature dependence of several CP in the aforementioned regimes.

HL 14.4 Tue 10:15 POT 81
Tuning electronic properties of graphene with a transferred ultrathin Ga_2O_3 encapsulation — MATTHEW GEBERT[1], •SEMONTI BHATTACHARYYA[2], CHRISTOPHER BOUNDS[1], NITU SYED[3,4], TORBEN DAENEKE[4], and MICHAEL S. FUHRER[1] — [1]School of Physics and Astronomy, Monash University, Melbourne — [2]Leiden Institute of Physics, Leiden University, Leiden — [3]School of Physics, The University of Melbourne, Parkville, Melbourne — [4]School of Engineering, RMIT University, Melbourne

Although graphene holds immense potential for future electronics and spintronics, it is tricky to find a suitable large-area encapsulation layer for graphene that enhances its properties. In this talk, I will demonstrate a large-area passivation layer for graphene by mechanical transfer of ultrathin Ga_2O_3 synthesized on the surface of liquid Ga metal.[1]

Electrical measurements of millimetre-scale passivated and bare CVD graphene on SiO_2 substrate indicate that the passivated graphene maintains its high field effect mobility, desirable for applications. Surprisingly, the temperature-dependent resistivity is reduced in our passivated graphene over a range of temperatures below 230 K, due to the interplay of screening of the remote optical phonon modes of the SiO_2 by the high dielectric constant of Ga_2O_3, and the relatively high characteristic phonon frequencies of Ga_2O_3. Raman spectroscopy and electrical measurements indicate that Ga_2O_3 passivation also protects graphene from further processing such as plasma-enhanced atomic layer deposition of Al_2O_3.

HL 14.5   Tue 10:30   POT 81

Hopping transport in ultraclean dual graphite gated bilayer graphene — •David Alexander Darek Emmerich[1], Eike Thomas Icking[1,2], Philipp Schmidt[1,2], Frank Volmer[1,3], Kenji Watanabe[4], Takashi Taniguchi[5], Bernd Beschoten[1], and Christoph Stampfer[1,2] — [1]RWTH Aachen University, Germany — [2]Forschungszentrum Jülich, Germany — [3]AMO GmbH, Advanced Microelectronic Center Aachen (AMICA), Germany — [4]Research Center for Functional Material, Japan — [5]International Center for Materials Nanoarchitectonics, Japan

Bernal-stacked bilayer graphene (BLG) is a material that has a unique property: BLG is intrinsically a semimetal, but becomes a semiconductor under the applicaton of an out-of-plane displacement field. This controlled opening of a gate-tunable band gap makes it a promising material for realizing highly-tunable transistors and photodetectors. The limiting factor of BLG-based devices is disorder. Only by using graphitic bottom gates a true band insulating state was achieved in BLG, which exhibits a clean gap opening with faint signs of residual disorder. Using finite bias spectroscopy, we show that BLG devices with graphitic top and bottom gate electrodes exhibit extremely low disorder. We perform transport measurements down to the sub-Kelvin regime and analyse the temperature-dependent transport behaviour. For small displacement fields, where gap and disorder are expected to be of the same order of magnitude, the low-temperature hopping transport data are investigated concerning the dominant hopping mechanism.

HL 14.6   Tue 11:00   POT 81

high responsivity monolayer MoS_2 photodetectors on cyclic olefin copolymer-passivated SiO_2 gate dielectric — •Emad Najafidehaghani[1], Sirri Batuhan Kalkan[2], Ziyang Gan[1], Jan Drewniok[2], Michael F Lichtenegger[2], Uwe Hübner[3], Alexander S Urban[2], Antony George[1], Bert Nickel[2], and Andrey Turchanin[1] — [1]Friedrich Schiller University Jena, Institute of Physical Chemistry, Jena — [2]Ludwig Maximilian University of Munich, Faculty of Physics, Munich — [3]Leibniz Institute of Photonic Technology (IPHT), Jena

2D material-based photodetectors attracted significant research interest due to their high responsivity, flexibility and transparency. However, the trap states present at the surface of SiO_2 gate dielectrics diminishes the performance of 2D material-based photodetectors. To reduce the detrimental effect of SiO_2 surface traps, an ultrathin film (5 nm) of cyclic olefin copolymer (COC) layer is employed as a surface passivator. Due to the reduction of the interface trap density, the photoresponsivity of the MoS_2 devices on passivated SiO_2 is enhanced by four orders of magnitude compared to non-passivated MoS_2 devices. Under optimized conditions a record photoresponsivity of 3×10^7 A/W in combination with a short response time is observed. Our findings show that the ultrathin COC passivation of the gate dielectric enables to probe exciting properties of the atomically thin 2D semiconductors.

HL 14.7   Tue 11:15   POT 81

Atomic layer deposition of horizontal and vertical MoS_2/WS_2 heterostructures — •Christian Tessarek, Tim Grieb, Andreas Rosenauer, and Martin Eickhoff — Institut für Festkörperphysik, Universität Bremen

Beyond the properties of single two-dimensional (2D) layers, heterostructures made of 2D transition metal dichalcogenides promise new properties based on moiré physics and interlayer excitons.

Vertical and horizontal MoS_2 and WS_2 heterostructures were grown by atomic layer deposition (ALD) and analyzed by Raman and photoluminescence spectroscopy. The influence of the the ALD growth sequence, i.e. MoS_2/WS_2 vs. WS_2/MoS_2, was investigated. Elemental distribution of Mo and W in a horizontal heterostructure was studied by high resolution transmission electron microscopy and energy-dispersive X-ray spectroscopy. Additional high temperature annealing was performed to improve the structural and optical properties of the layers.

HL 14.8   Tue 11:30   POT 81

Fully automated platform for 2D material flake detection using real-time machine learning techniques — •Jan-Lucas Uslu, Taoufiq Ouaj, Bernd Beschoten, Lutz Waldecker, and Christoph Stampfer — JARA-FIT and 2nd Institute of Physics A, RWTH Aachen University, Aachen, Germany

As of today, most of fundamental experimental 2D material research is based on mechanically exfoliated flakes, finding suitable flakes for the fabrication of van der Waal heterostructures is time-consuming and time-critical part requiring expert knowledge and manpower.

In order to mitigate this problem, we demonstrate a simple and robust real time-capable algorithm based on Gaussian mixture models, a machine learning technique, to allow for a fast automated search of exfoliated flakes of different 2D materials in a single run with an automated microscope setup to analyze batches of exfoliated material.

The algorithm solves the task of automatically detecting various flakes on Si++/SiO2 wafer dices, allows to index the location and segmentation of each flake and provides metrices such as size, thickness and shape.

The algorithm is evaluated on more than 500.000 images of different 2D materials including graphene and multilayer graphene, hexagonal boron nitride, transition metal dichalcogenides and 2D magnets.

HL 14.9   Tue 11:45   POT 81

CVD Growth of Hexagonal Boron Nitride on CMOS-compatible Substrates — •Max Franck[1], Jarek Dabrowski[1], Markus Andreas Schubert[1], Walter Batista Pessoa[2], Dominique Vignaud[2], Luc Henrard[3], Christian Wenger[1,4], and Mindaugas Lukosius[1] — [1]IHP - Leibniz-Institut für innovative Mikroelektronik, Im Technologiepark 25, 15236 Frankfurt (Oder), Germany — [2]University Lille, CNRS, Centrale Lille, JUNIA ISEN, University Polytechnique Hauts de France, UMR 8520-IEMN F-59000 Lille, France — [3]Department of Physics, Namur Institute of Structured Materials, University of Namur, Rue de Bruxelles 61, 5000 Namur, Belgium — [4]Semiconductor Materials, BTU Cottbus-Senftenberg, Platz der Deutschen Einheit 1, 03046 Cottbus, Germany

Hexagonal boron nitride (hBN) is a two-dimensional insulator with a range of promising applications, including DUV optoelectronics and protection layers for high-mobility graphene. Most commonly, high-quality hBN is grown via CVD on catalytic transition metal substrates. However, the hBN films require transfer to CMOS-compatible substrates, which leaves residual metal contaminations at concentrations unacceptable for Si technology integration.[1] Therefore, growth of hBN thin films directly on CMOS-compatible substrates, such as Si, Ge or dielectrics, is desirable. We present recent results regarding CVD synthesis of well-oriented, few-layer hBN films on such substrates using borazine as a single-source precursor. Morphology and crystallline quality were characterized using XPS, AFM, Raman spectroscopy and TEM. [1] G. Lupina, J. Kitzmann, et al. ACS Nano 2015, 9, 4776-4785.

HL 14.10   Tue 12:00   POT 81

Microwave plasma driven 2H-1T phase modulation of WSe2 for improving NO2 gas sensing performance — •Yu Duan[1,2], Sam Zhang[2], Huaping Zhao[1], and Yong Lei[1] — [1]Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — [2]Center for Advanced Thin Films and Devices, School of Materials and Energy, Southwest University, Chongqing, 400715, China

Transition metal dichalcogenides (TMDs) have been widely used in recent years for gas sensors. Herein, we constructed a simple microwave plasma device by modifying a home microwave oven for surface treatment of WSe2. A 1T/2H hybrid phase structure was constructed by phase modulation and Se vacancies were introduced to effectively enhance its gas sensing performance. The sample after 60 s of treatment exhibited high response (52.24%), fast response rate (49.8 s), short recovery time (14.9 mins), and outstanding stability and selectivity for 1 ppm NO2 at room temperature. In addition, molecular model of the microwave plasma-treated sample is proposed, leading to the intrinsic mechanism of its performance enhancement. It is demonstrated that microwave plasma treatment is a promising method to enhance the gas sensing performance of TMDs.

HL 15: Spin phenomena in semiconductors

Time: Tuesday 9:30–10:30   Location: POT 361

HL 15.1   Tue 9:30   POT 361

Photoexcited charge carrier and spin dynamics in methylammonium lead bromide doped by magnetic transition metals. — •Stanislav Bodnar, Jonathan Zerhoch, Shangpu Liu, Andrii Shcherbakov, and Felix Deschler — PCI, Universität Heidelberg, Im Neuenheimer Feld 253, 69120 Heidelberg

One of the most challenging tasks for LED applications is emitting 100% polarized light from the device. Typically, this is achieved by introducing an additional layer of polarization filter which leads to losing half of the light intensity. To overcome this issue, one has to find a system with a high degree of photoluminescence (PL) polarization. A promising approach here is using magnetic metal doping in combination with a highly efficient semiconductor. We have chosen to use transient absorption (TA) spectroscopy at cryogenic temperatures to investigate changes in the optical properties induced by magnetic metal doping in CH3NH3PbBr3 since it gives spectral information about the energies of electronic states and dynamic properties of the photoexcited carriers. We find a change in the main ground state bleach (GSB) peak position in

doped CH3NH3PbBr3, which depends on the transition metal used. The main GSB peak of pure CH3NH3PbBr3 at 4 K is at 2.32 eV. Doping CH3NH3PbBr3 with Mn leads to a shift of the main peak to lower energies by 0.04 eV. The modifications of the TA spectra are associated with changes in the bandgap energy, which is the result of doping-induced lattice expansion. Additionally, we observed changes in the spin lifetime by an order of magnitude which could be associated with modification of the Rashba field.

HL 15.2　Tue 9:45　POT 361

Mode locking of hole spin coherences in CsPb(Cl,Br)$_3$ perovskite nanocrystals — •Erik Kirstein[1], Nataliia E. Kopteva[1], Dmitri R. Yakovlev[1,2,3], Evgeny A. Zhukov[1,2], Elena V. Kolobkova[4,5], Maria S. Kuznetsova[6], Vasily V. Belykh[3], Irina A. Yugova[6], Mikhail M. Glazov[2], Manfred Bayer[1], and Alex Greilich[1] — [1]Experimental Physics 2, Department of Physics, TU Dortmund, 44227 Dortmund, Germany — [2]St. Petersburg, Russia — [3]Moscow, Russia — [4]St. Petersburg, Russia — [5]St. Petersburg, Russia — [6]St. Petersburg, Russia

The spin physics of perovskite nanocrystals is attracting increasing attention, both for fundamental studies and spintronic applications. Here, stable CsPb(Cl$_{0.5}$Br$_{0.5}$)$_3$ lead halide perovskite nanocrystals embedded in a fluorophosphate glass matrix are studied by time-resolved optical spectroscopy to unravel the coherent spin dynamics of holes and their interaction with nuclear spins of the ^{207}Pb isotope. We demonstrate the spin mode locking effect and nuclear induced frequency focussing leading to the synchronization of the hole spin Larmor precession frequencies of the nanocrystal ensemble.

HL 15.3　Tue 10:00　POT 361

Spin-flip Raman scattering on resident electrons and holes in two-dimensional (PEA)2PbI4 perovskites — •Carolin Harkort[1], Dennis Kudlacik[1], Natalia E. Kopteva[1], Dmitri R. Yakovlev[1], Marek Karzel[1], Erik Kirstein[1], Oleh Hordiichuk[2,3], Maksym V. Kovalenko[2,3], and Manfred Bayer[1] — [1]Experimentelle Physik 2, Technische Universität Dortmund, 44221 Dortmund — [2]Laboratory of Inorganic Chemistry, Department of Chemistry and Applied Biosciences, ETH Zürich, CH-8093 Zürich, Switzerland —

[3]Laboratory for Thin Films and Photovoltaics, Empa-Swiss Federal Laboratories for Materials Science and Technology, CH-8600 Dübendorf, Switzerland

Two-dimensional lead halide perovskites are promising material systems for photovoltaic and optoelectronic applications. They are attractive for optical control of carrier spins due to an increased chemical stability compared to bulk lead halide perovskites. With the technique of Spin-flip Raman scattering we investigated in 2D Ruddlesden-Popper type (PEA)$_2$PbI$_4$ perovskites the Zeeman splitting of carrier spins, resident electrons and holes, that can be detected through the exciton emission. The Landé-factors of these electrons and holes and their anisotropy are measured at a low temperature of 2 K. We show that the hole Zeeman splitting is affected by the Overhauser field resulting from the dynamic nuclear polarization which allows us to define the sign of the hole Landé-factor. In this structure the Overhauser field has a maximum value of 600 mT.

HL 15.4　Tue 10:15　POT 361

Microscopic origin of the effective spin-spin interaction in a semiconductor quantum dot ensemble — Fredrik Vonhoff[1,2], Andreas Fischer[1], •Kira Deltenre[1], and Frithjof B. Anders[1] — [1]Department of Physics, TU Dortmund University, D-44227 Dortmund — [2]Department of Physics, Technical University of Munich, D-85748 Garching

We present a microscopic model for a singly charged quantum dot (QD) ensemble to reveal the origin of the long-range effective interaction between the electron spins in the QDs. Wilson's numerical renormalization group (NRG) is used to calculate the magnitude and the spatial dependency of the RKKY interaction mediated by the growth-induced wetting layer.

Using the NRG results obtained from realistic parameters as input for a semiclassical simulation for a large QD ensemble, we demonstrate that the experimentally reported phase shifts in the coherent spin dynamics between single and two-color laser pumping can be reproduced by our model [1], solving a longstanding open problem of the microscopic origin of the inter-QD electron spin-spin interaction.

HL 16: Quantum dots: Transport (joint session HL/TT)

Time: Tuesday 9:30–12:15　　　　　　　　　　　　　　　　　　　　　　　Location: POT 151

HL 16.1　Tue 9:30　POT 151

Contact formation analysis of nickel to SiGeOI to form Nickel-Germano-silicide using Flash lamp annealing — •Muhammad Moazzam Khan[1], Slawomir Prucnal[1], and Yordan M. Georgiev[1,2] — [1]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, D-01328 Dresden, Germany — [2]Institute of Electronics at the Bulgarian Academy of Sciences, 72, Tzarigradsko chaussee blvd, 1784-Sofia, Bulgaria

In CMOS technology, parasitic source/drain (S/D) resistance becomes more crucial in determining the overall device performance as the device dimensions get smaller. The contact resistance dominates this parasitic S/D resistance to a great extent, which limits the drive current. In order to have minimal impact on electrical performance, the contact should have linear Current-Voltage characteristics and negligible resistance in comparison to the device resistance. When replacing silicon with silicon-germanium as a channel material in future devices, it is necessary to investigate the contact formation mechanism in order to develop suitable contacts for energy-efficient devices. In this work, we are investigating metal semiconductor contact formation on SiGeOI using flash lamp annealing and studying their properties using structural and electrical characterization.

HL 16.2　Tue 9:45　POT 151

Predicting charge density maps in 2D nanostructures with machine learning techniques — •Amanda Teodora Preda[1,2,3], Calin Andrei Pantis-Simut[1,2,3], Nicolae Filipoiu[2,3], Lucian Ion[2], Andrei Manolescu[4], and George Alexandru Nemnes[1,2,3] — [1]Research Institute of the University of Bucharest (ICUB), Sos. Panduri 90, Bucharest, Romania — [2]University of Bucharest, Faculty of Physics, 077125 Magurele-Ilfov, Romania — [3]Horia Hulubei National Institute for Physics and Nuclear Engineering, 077126 Magurele-Ilfov, Romania — [4]Department of Engineering, Reykjavik University, Menntavegur 1, IS-102 Reykjavik, Iceland

Machine learning (ML) models have the potential to significantly improve and assist the design process of nanodevices that require precise control of the quantum states.

For 2D nanoelectronic structures, charge and spin densities are relevant observables and are also suited for ML techniques which employ image processing. The model systems that we considered are two dimensional quantum dots with multiple electrons and random confinement potentials. With convolutional neural networks, we built a ML model to predict whether a configuration displays

singlet-triplet transitions in the ground state. For image translation problems, we used models based on conditional generative adversarial networks in order to predict the charge density distribution for arbitrary interacting systems taking as input either the non-interacting cases or just the shape of the confining potential.

HL 16.3　Tue 10:00　POT 151

Mesoscopic transport properties of individually prepared GaN-nanowire field-effect transistors — •Hannes Hergert[1,2], Matthias T. Elm[1,2,3], and Peter J. Klar[1] — [1]Institute of Experimental Physics I, Giessen, Germany — [2]Center for Materials Research, Giessen, Germany — [3]Institute of Physical Chemistry, Giessen, Germany

In order to keep the optimization of transistors within Moore's law new material systems as well as new transistor concepts such as GaN-nanowire field effect transistors (NW-FET) are needed. In this work we characterize the electrical transport properties of single NW-FET. Furthermore, we are able to obtain a deeper understanding of the mesoscopic transport processes. Unintentionally doped GaN-nanowires were fabricated using molecular-beam-epitaxy and device fabrication was performed by a combination of different lithographic methods and atomic layer deposition. After an annealing process the nanowire's resistance shows an ohmic behaviour. Electrical transport measurements were performed between 2 and 280 K. The investigated NW-FET exhibits a transfer characteristic identical to those of classical field-effect transistors. We show that the electrical transport is dominated by two transport processes: a transport within a metal-like impurity band at low temperatures and a hopping process at higher temperatures. Furthermore we were able to identify universal conductance fluctuations at temperatures below 140 K, which arise from the shift of the Fermi level when applying a topgate voltage.

HL 16.4　Tue 10:15　POT 151

Multi-Channel Kondo Effect in Few-Electron Quantum Dots — •Olfa Dani[1], Johannes C. Bayer[1], Timo Wagner[1], Gertrud Zwicknagl[2], and Rolf J. Haug[1] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, Germany — [2]Institut für Mathematische Physik, Technische Universität Braunschweig, Germany

The Kondo effect is a many particle entangled system, that involves the interaction between a localized spin in the quantum dot and free electrons in the electron reservoirs. This entanglement can be calculated using simplifying assumptions concerning the electronic structure of the quantum dot.

In this work we investigate a quantum dot device formed electrostatically in a two-dimensional electron gas using top-gates. A quantum point contact is used as a sensitive charge detector to detect single-electrons tunneling through the system. This enables us to know the exact number of electrons in the quantum dot (N_e). By changing the applied gate voltage, we are able to control N_e.

A Zero-bias anomaly is observed for a strong coupling to the leads and possible symmetrical tunnel barriers. This Kondo resonance appears for successive N_e showing a deviation from the conjectured odd-even behavior. The Kondo resonance is strongest for $N_e=9$ and displays a particle-hole symmetry for $N_e=7,..,11$. It is absent for $N_e=6$ and $N_e=12$. These observations indicate the influence of the shell structure [1] of the electronic states in the quantum dot where orbital degeneracy is present.

HL 16.5 Tue 10:30 POT 151

Highly Conductive Silicon Nanowires by Modulation-Doping via Aluminum-Induced Acceptor States in an SiO2-shell — •Daniel Hiller[1], Ingmar Ratschinski[1], Soundarya Nagarajan[2], Jens Trommer[2], Thomas Mikolajick[2,3], and Dirk König[4] — [1]Institute of Applied Physics, TU Bergakademie Freiberg, Germany — [2]Nanoelectronic Materials Laboratory gGmbH, Dresden, Germany — [3]Institute of Semiconductors and Microsystems, TU Dresden, Germany — [4]Integrated Materials Design Lab, ANU, Canberra, Australia

Silicon nanowires (Si NWs) enable maximum gate control over the source-drain current when configured in a gate-all-around FET-architecture. However, Si NWs with few nm in diameter suffer from severe difficulties with efficient impurity doping due to a multitude of physical and technological problems (diffusion, dielectric and quantum confinement, statistics of small numbers, etc.). Here, we present a novel doping concept for Si NWs comparable to the modulation doping approach of III-V semiconductors. Based on results from density functional theory (DFT) calculations, we use Al-doped SiO2 shells around the Si NWs, which contain unoccupied Al-induced acceptor states that are energetically located below the Si valence band edge. These states can capture electrons from the Si, creating free holes as majority charge carriers [1-5]. In this presentation, recent results from the experimental realization of this concept on Si NWs are shown. We demonstrate that modulation doping using SiO2:Al-shells allows for several orders of magnitude lower resistances when compared to undoped SiO2-shells.

30 min. break

HL 16.6 Tue 11:15 POT 151

Carrier dynamics in quantum-dot tunnel- injection structures: microscopic theory and experiment — •Michael Lorke[1], Igor Khanonkin[2], Stephan Michael[1], Johann Peter Reithmaier[3], Gadi Eisenstein[2], and Frank Jahnke[1] — [1]Institute for Theoretical Physics, University of Bremen, Otto-Hahn-Allee 1, Bremen, 28359, Germany — [2]Electrical Engineering Department and Rus- sel Berrie Nanotechnology Institute, Technion, Haifa, 32000, Israel — [3]Technische Physik, Institute of Nanostructure Technologies and Ana- lytics, Center of Interdisciplinary Nanostructure Science and Technol- ogy (CINSaT), University of Kassel, Kassel, 34132, Germany

Among the challenges for the next generation of semiconductor lasers is the enhancement of their modulation speed to satisfy the need for higher data transfer rates. For this purpose, tunnel injection lasers are an appealing concept, as they promise improved modulation rates and better temperature stability. Moreover, they eliminate a major detri- mental effect of quantum dot lasers, which is the gain nonlinearity caused by hot carriers. It is shown in this work how the aforemen- tioned improvements depend on the design of tunnel-injection devices. We perform a theory-experiment comparison on scattering times in tunnel injection devices to highlight the importance of alignment be- tween the injector well and the quantum dot ensemble. It is shown how differences in the coupling to the injector quantum well caused by the alignment lead to scattering times into the quantum dot ensemble that vary by an order of magnitude.

HL 16.7 Tue 11:30 POT 151

Electron transport through a quantum dot in controlled heat bath environment — •Hatef Ghannadi maragheh, Johannes C. Bayer, and Rolf J. Haug — Institute for Solid State Physics, Leibniz Universität Hannover, Appelstraße 2, 30167 Hannover, Germany

For optimizing any device, amongst them semiconductor-based qubit, one has to understand the effects of the environment on them. In this sort of devices, not just quantum states of the channel but also the state of the particles is affected [1-3]. The device consists of split-gate quantum dot in a GaAs/AlGaAs heterostructure. The temperature of the measurement ranged from 49.9 mK to 800 mK.

There have been several works on explaining how electron transport through the quantum dot system would behave for different temperatures [4-5]. As the temperature changes, the Fermi distribution of the lead*s changes. This influenced the conductivity of the dot since in the presence of the bias voltage the transport window gets altered. Besides, depending on the presence of energy levels in the transfer window, the conductivity is manipulated by changing the temperature. For low temperatures, due to the local density of states and coupling of the barrier gates to the leads, fluctuations start to emerge.

HL 16.8 Tue 11:45 POT 151

Manipulation of temporal correlations in single-electron tunneling — •Johannes C. Bayer, Adrian Schmidt, Timo Wagner, and Rolf J. Haug — Institut für Festkörperphysik, Leibniz Universität Hannover

Precisely timed single-particle operations are of critical importance for quantum technologies operating at fixed clock cycles. A detailed understanding of the interplay between an external drive and the response of the single-particle source is essential for achieving and improving the accuracy in the time domain. We here demonstrate a high level of control over the time domain of a driven single electron transistor (SET). Using a gate defined quantum dot connected to a highly sensitive charge detector [1] allows detecting electrons tunneling into and out of the SET in real-time [2, 3]. The tunneling rates of such devices are controllable by gate voltages. We drive the SET by modulating gate voltages periodically in time and use time-dependent tunneling rates [2] and waiting time distributions [4] to analyze the impact of the driving parameters on temporal correlations in the tunneling times.

Scalable integrated readout electronics for semiconductor quantum dots — •Jonas Bühler[1], Arun Ashok[1], Lammert Duipmans[1], Patrick Vliex[1], Christian Grewing[1], André Zambanini[1], and Stefan Van Waasen[1,2] — [1]Central Institute of Engineering, Electronics and Analytics, Electronics Systems (ZEA-2) Forschungszentrum Jülich GmbH, 52428 Jülich, Germany — [2]Faculty of Engineering, Communication Systems, University Duisburg-Essen, 47057 Duisburg, Germany

Quantum computing is one of the promising candidates to overcome the limitations of *classical* computing, e.g. von Neumann architecture. Nowadays much progress has been made on the implementation of scalable qubits. This work focuses on semiconductor qubits, which need operating temperatures near 0 K. Room temperature electronics for control and readout, which are limiting the bandwidth and the scalability due to parasitic elements and heat conduction, are still widely used. Some progress has been made to integrate the qubit control and readout in the direct vicinity of the qubit at cryogenic temperatures. Especially readout electronics still have a limited scalability because of circuit size and power consumption. This work tries to overcome those limitations by comparing different readout architectures and implement a multiplexed and integrated readout circuit with lower area and power consumption. This integrated circuit in a 22nm FD-SOI technology will be placed on top of scalable quantum computing architectures and therefore might be a crucial step on the way to a multi-million qubit quantum computer.

HL 17: THz and MIR physics in semiconductors

Terahertz-induced anomalous currents after optical excitation of excitons in quantum wells — •Cong Ngo[1], Shekhar Priyadarshi[2], Huynh Thanh Duc[3], Mark Bieler[2], and Torsten Meier[1] — [1]Department of Physics, Paderborn University, Warburger Strasse 100, D-33098 Paderborn, Germany — [2]Physikalisch-Technische Bundesanstalt, 38116 Braunschweig, Germany — [3]Institute of Applied Mechanics and Informatics, VAST, 1 Mac Dinh Chi, District 1, Ho Chi Minh City, Vietnam

We study transient anomalous currents in GaAs quantum wells by solving the multi-band semiconductor Bloch equations in the length gauge, including excitonic effects and carrier longitudinal-optical and acoustic phonons scattering process. The band structure is obtained by diagonalizing a 14-band $\mathbf{k} \cdot \mathbf{p}$ model within the envelope function approximation. To solve the random phase problem originating from the numerical diagonalization of the band structure model, we apply a smoothing gauge transformation [1]. Our numerical results show quite strong anomalous currents appear for optical excitation near the excitonic resonances and simultaneous Terahertz excitation. The current transients oscillate with a frequency corresponding to the inverse of the energy difference between the 1s and 2s exciton states. The numerical results including excitons are in good agreement with experiments [2].

Generation of THz vortex beams and interferometric determination of their topological charge — •Samuel W. Pinnock, Seulki Roh, Tobias Biesner, Artem V. Pronin, and Martin Dressel — 1. Physikalisches Institut, Universität Stuttgart, 70569 Stuttgart, Germany

We developed and demonstrated the efficacy of 3D printed spiral phase plates for the generation of vortex THz beams with orbital angular momenta $\ell = \pm 1$ and $\ell = \pm 2$. The vortex beam generation was confirmed by means of frequency-domain transmission spectroscopy. The topological charge of the vortex beams was determined via phase-sensitive Mach-Zehnder interferometry, which enabled the superposition of a vortex beam with ℓ and its conjugate beam with $-\ell$. The resulting interference patterns were found to be consistent with the expected intensity distributions for a given ℓ, which provides strong confirmation of the spatial phase structure of the generated vortex beams in the THz regime. Such THz vortex beams could be used in spectroscopic studies of optical transitions with $\Delta \ell \neq 0$ in different condensed-matter systems, including semiconductors and topological materials.

HL 17.3   Tue 10:00   POT 251

Ultrafast Terahertz-Wave Emission from Photoconductive Antenna Arrays and Spin Emitters — •Osama Hatem[1], Thales V. A. G. de Oliveira[2], Susanne C. Kehr[1], and Lukas M. Eng[1,3] — [1]Institute of Applied Physics, Technische Universität Dresden, 01062 Dresden, Germany — [2]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — [3]ct.qmat: Würzburg-Dresden Cluster of Excellence - EXC 2147, Technische Universität Dresden, Dresden, Germany

For long time, terahertz (THz) radiation (0.1 THz to 10 THz) was little used in science and technology owing to the lack of efficient terahertz sources and detectors. However, recent advances in laser technology and semiconductors industry sparked the interest in exploring this spectral range further. Recently, THz radiation has shown great importance in a wide range of potential applications including THz time-domain spectroscopy and imaging [1-2].

In this work, we report the emission of THz waves from GaAs photoconductive antenna arrays and Fe/Pt spin emitters upon excitation with femtosecond laser pulses at 800 nm. THz waves with bandwidth of 0.1- 5 THz and SNR > 500 below 1 THz were measured. Moreover, detection of THz waves by electro-optic sampling was investigated using ZnTe, GaP, and GaSe crystals of varying thickness. The results are of great significance for THz nanoscopy and imaging applications.

Characterization of semiconductors and their properties using terahertz TDS and the Drude-Lorentz model — •Joshua Hennig[1,2], Jens Klier[1], Stefan Duran[1], Kuei-Shen Hsu[3], Antje Hirsch[3], Christian Röder[3], Jan Beyer[3], Franziska Beyer[4], Georg von Freymann[1,2], and Daniel Molter[1] — [1]Center for Materials Characterization and Testing, Fraunhofer ITWM, Kaiserslautern — [2]Department of Physics and Research Center Optimas, Technische Universität Kaiserslautern (TUK), Kaiserslautern — [3]Institut für Angewandte Physik, TU Bergakademie Freiberg, Freiberg — [4]Department of Crystal Growth, Fraunhofer IISB, Freiberg

Semiconductors play an important role in our modern world enabling many of the technological advancements. Therefore, it is of vital interest for an ever-growing industry as well as scientifically to find techniques to characterize optical and electrical properties such as the refractive index as well as the resistivity of these materials. Here, first steps in such characterizations using terahertz time-domain spectroscopy, a nondestructive technology proven to be capable of these challenging tasks, are shown. First, measurements performed on silicon, one of the most commonly used semiconductors, are evaluated to show the measurement principle and confirm the Drude-Lorentz model to be suitable to describe the charge carrier behavior. Next, samples of silicon carbide, an important semiconductor material with applications e.g. in power electronics are examined. The knowledge of these important semiconductor properties can be helpful in quality checks in the production process and any future work with those materials.

HL 17.5   Tue 10:30   POT 251

Interband cascade infrared photodetectors based on Ga-free InAs/InAsSb superlattice absorbers — •Andreas Bader[1], Florian Rothmayr[2], Nabeel Khan[2], Fauzia Jabeen[1], Johannes Koeth[2], Sven Höfling[1], and Fabian Hartmann[1] — [1]Technische Physik, Physikalisches Institut and Würzburg-Dresden Cluster of Excellence ct.qmat, Am Hubland, D-97074 Würzburg, Germany — [2]nanoplus Nanosystems and Technologies GmbH, Oberer Kirschberg 4, D-97218 Gerbrunn, Germany

We present results on interband cascade infrared photodetectors (ICIP) based on Ga-free InAs/InAsSb superlattice (SL) absorbers. An alternative extraction path of photogenerated carriers is required when substituting the more standard InAs/Ga(In)Sb SL absorbers for Ga-free SLs. The device operates in the photovoltaic mode in the mid infrared spectral range with cut-off wavelengths between around 6.5 um at 100 K and 9 um at RT. At elevated temperatures, features of negative-differential-conductance (NDC) emerge. Under illumination, these NDC features can supply gain in the device leading to a peak responsivity of 0.45 A/W at room temperature. At 300 K the zero-bias detectivity D* of the presented device is around 1*10^8 Jones which compares well to similar ICIPs based on InAs/GaSb SL absorbers.

HL 17.6   Tue 10:45   POT 251

Assessment of epitaxially grown p-doped InAs on undoped GaSb exhibiting terahertz emission — •Cyril Salang[1], Dean Von Johari Narag[1], Rommel Jagus[1], Gerald Angelo Catindig[2], Mae Agatha Tumanguil[1], Alexander De Los Reyes[2], Ivan Cedrick Verona[2], Hannah Bardolaza[2], Armando Somintac[2], Elmer Estacio[2], and Arnel Salvador[2] — [1]Materials Science and Engineering Program, University of the Philippines Diliman, Philippines — [2]National Institute of Physics, University of the Philippines Diliman, Philippines

A p-InAs/undoped-GaSb thin film was grown via molecular beam epitaxy. The 260 Å p-InAs was grown on 260 nm undoped InAs over 10 periods of InGaAs(3 nm)/GaAs(3 nm) superlattice to minimize the surface roughness prior to the p-InAs growth. Three periods of 20-nm undoped GaAs/260-nm undoped InAs served as a buffer with growth interruption applied on the first 2 mins of deposition of each GaAs and InAs layer. X-ray diffraction shows a peak at $2\theta \sim 61^o$ corresponding to InAs. The sample's resistance was measured to be 43 Ω. The terahertz (THz) emission was evaluated using 1.55 μm femtosecond laser excitation in reflection geometry. The current sample emits at ~20 times lower THz intensity compared to that of a previously investigated 1±0.4 μm p-InAs/n-GaSb sample possibly due to the lesser thickness leading to a lower photo-Dember response, and differing crystal qualities from the different growth processes. Nonetheless, exploring growth techniques for producing thin InAs films is desired to realize photoconductive antennas for transmission geometry.

HL 17.7   Tue 11:30   POT 251

Coherent State Steering in Condensed Matter Systems with Strong Light-Matter Engineering — •Michael Spencer, Joanna Urban, Maxamillian Frenzel, and Sebastian Maehrlein — Department of Physical Chemistry, Fritz Haber Institute of the Max Planck Society, Faradayweg 4-6, 14195 Berlin, Germany

Physical properties of materials are derived largely from their chemical constituents, structural arrangement, and local properties such as temperature and dielectric environment. Next-generation materials science is increasingly focused on manipulation of structural properties in order to access material properties on-demand, in search of emergent, enhanced, or even hidden states of matter. One such method to transiently modify crystalline materials is the application of intense terahertz (THz) laser pulses. These pulses allow for resonant

and selective excitation of infrared-active vibrational modes (phonons) of a crystal, allowing for coherent and ultrafast modulation of condensed-matter system properties. With the introduction of an electromagnetic cavity, the subsequent enhancement of this light-matter interaction between the intense THz radiation and the phonons will provide expanded control over excited-state steering, allowing access to exotic, transient states of matter. I will present our steps towards first realizations of such strongly-coupled light-matter interactions of phonons in crystalline materials within the THz frequency range. In addition, I will discuss our novel measurement techniques for the detection of strong light-matter interactions, where we utilize the unique technical capabilities of terahertz time-domain spectroscopy.

HL 17.8   Tue 11:45   POT 251
Terahertz cyclotron emission from HgTe QWs — •S. Gebert[1,2], C. Consejo[1], S. Ruffenach[1], J. Torres[2], B. Jouault[1], and F. Teppe[1] — [1]Laboratoire Charles Coulomb (L2C), UMR 5221 CNRS, Université de Montpellier, F-34095 Montpellier, France — [2]Institut d'Electronique et des Systèmes (IES), UMR 5214 CNRS, Université de Montpellier, F-34095 Montpellier, France

Motivated by the emergence of graphene, several concepts for Landau-level (LL) lasers, tunable by a magnetic field over the whole terahertz (THz) frequency range, have been proposed. One hoped in particular was, that the non-equidistance of the LLs from Dirac fermions could efficiently suppress the non-radiative Auger recombination, which typically prevails over the radiative recombination. However, despite this non-equidistance an unfavorable non-radiative process still persists in Landau-quantized graphene, and no cyclotron emission from Dirac fermions has yet been reported. To eliminate this last non-radiative process, it is sufficient to slightly modify the dispersion of the Landau levels, e.g. by opening a small gap in the linear band structure. A proven example of such gapped graphene-like materials are HgTe quantum wells (QWs) close to the topological phase transition. We here experimentally demonstrate spontaneous Landau emission from Dirac fermions in such HgTe QWs, where the emission is tunable between 0.5 THz and 3 THz by both the magnetic field and the carrier concentration [1].

Coherent phonon dynamics in quasi-2D perovskites probed by THz-induced Kerr effect — •Joanna M. Urban[1], Marie Cherasse[1,2], Maximilian Frenzel[1], Michael Spencer[1], Gaelle Trippe-Allard[3], Emmanuelle Deleporte[3], Luca Perfetti[2], Martin Wolf[1], and Sebastian F. Maehrlein[1] — [1]FHI of the Max Planck Society, Faradayweg 4-6, 14195 Berlin, Germany — [2]LSI, Palaiseau, France — [3]Université Paris-Saclay, LuMIn, Gif-sur-Yvette, France

2D hybrid organic-inorganic perovskites (HOIP) are self-assembled multiple quantum well structures, formed by metal halide octahedral layers alternating with large organic spacer cations. They combine the intriguing properties of the 3D HOIP polar, anharmonic lattice with optoelectronic properties arising due to low dimensionality. We study a family of 2D HOIPs in the Ruddlesden-Popper phase $(PEA)_2(MA)_{n-1}Pb_nI_{3n+1}$ (n=1,2,3). Using intense, close to single-cycle THz fields we excite coherent optical phonons and probe the lattice dynamics via THz-induced Kerr effect (TKE). Strikingly, we observe long-lived coherent

phonon oscillations at room temperature. Comparison with static Raman spectroscopy results as well as the measured fluence and temperature dependence confirm that the observed features in the 0.5-3 THz range correspond to Raman-active modes of the inorganic sublattice, excited via a nonlinear driving process. The nontrivial azimuthal angle dependence of the TKE signal can be explained considering the crystal structure and the symmetry of the Raman modes using the $\chi^{(3)}$ nonlinear susceptibility tensor formalism.

Optically excited charge-carrier dynamics in the antiferromagnetic semiconductor MnTe — •Changqing Zhu[1], Patrick Pilch[1], Anneke Reinold[1], Gunther Springholz[2], Mirko Cinchetti[1], and Zhe Wang[1] — [1]TU Dortmund University, Germany — [2]Johannes Kepler University of Linz, Austria

Room-temperature antiferromagnetic semiconductors are very interesting for possible spintronic applications. With a long-range antiferromagnetic order (T_N = 307 K) at room temperature, the hexagonal α-MnTe is a relevant candidate for those applications. Here we report on time-resolved measurements of ultrafast dynamics of optically excited charge carriers in α-MnTe thin film, by optical pump - optical probe and optical pump - THz probe spectroscopic techniques at room temperature. In contrast to a phononic oscillation mode at 5.3 THz as observed by 2.4 eV pump [1], our studies with an 1.5 eV pump pulse cannot reveal the optical phonon mode but rather low-energy acoustic phonon-like behavior at high pump fluence. Moreover, nonlinear dependence on pump fluence is observed both in our optical and terahertz probes, for a pump fluence above ~ 2.0 mJ/cm^2. This indicates a different physical mechanism than in the previous studies. The observed relaxation processes can be associated to electron-hole recombination and electron-phonon scattering.

HL 17.11   Tue 12:30   POT 251
Time-resolved nanospectroscopy on Si-doped GaAs-InGaAs core-shell nanowires — •Andrei Luferau[1,2], Maximilian Obst[2], Susanne Kehr[2], Lukas Eng[2], Stephan Winnerl[1], Alexej Pashkin[1], Emmanouil Dimakis[1], and Manfred Helm[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Institute of Applied Physics, Technische Universität Dresden, Dresden, Germany

High-quality epitaxial nanowires (NWs) based on III-V semiconductors offer the possibility to fabricate ultrafast optical devices due to their direct bandgap and the high electron mobility. Contactless investigation of photoexcited carriers within single NWs is enabled by optical-pump THz-probe scanning near-filed optical microscopy (SNOM) experiment. Here we report on first THz-pump MIR-probe SNOM studies on Si-doped GaAs-InGaAs core-shell NWs utilizing THz radiation from the free-electron laser FELBE. The experiment was carried out with SNOM setup from Neaspec equipped with nanoFTIR module, where a broadband MIR source (5-15μm) serves as a probe. Upon intraband THz-pump (25μm) we observed a red shift of amplitude and phase of the NW plasma resonance, while control interband optical pumping (780nm) induced a blue shift of the resonance, and in both cases an exponential decay with a time constant of 4-5ps is seen. We attribute the blue shift to the contribution of photogenerated carriers. The red shift is assigned to the heating of the electrons in the conduction band and the subsequent increase of the effective mass in the nonparabolic Γ-valley due to high peak electric fields of THz pulses.

HL 18: Optical Properties (joint session HL/CPP)

Time: Tuesday 9:30–13:00   Location: POT 112

HL 18.1   Tue 9:30   POT 112
Can Ge and Si be optoelectronic materials: Hexagonal polytypes — •Martin Keller[1], Abderrezak Belabbes[1,2], Jürgen Furthmüller[1], Friedhelm Bechstedt[1], and Silvana Botti[1] — [1]Friedrich-Schiller-Universität Jena, Institut für Festkörpertheorie und -optik, Max-Wien-Platz 1, 07743 Jena, Germany — [2]Department of Physics, Sultan Qaboos University, P.O. Box 36, PC 123, Muscat, Oman

The group IV elements silicon and germanium crystallize in cubic diamond structure under ambient conditions and feature indirect bandgaps. Therefore they cannot emit light efficiently and are not applicable in active optoelectronic devices. Under high pressure, however, as well as using different growth techniques, several Si and Ge polymorphs, including hexagonal polytypes, have been observed. Lonsdaleite Ge as well as Ge-rich hexagonal alloys have even been found to have a direct bandgap and strongly emit light with varying frequency. Thus hexagonal systems have become of great interest for potential optical emitters that may be integratable with CMOS technology. We have performed extensive ab initio studies of the energetic, structural, elastic and electronic properties as well as the strengths of some dipole transitions of the hexagonal Si and Ge polytypes 2H, 4H and 6H using Density Functional Theory and approximate quasiparticle treatments, and trends between the different geometries are anal-

ysed. The results for cubic and hexagonal Si and Ge agree excellently with existing experimental findings. The electronic structures point to promising optical properties.

HL 18.2   Tue 9:45   POT 112
Many-body effects in the mid-infrared dielectric function of InSb from 80 to 800 K — Melissa Rivero Arias, Cesy Zamarripa, Jaden Love, Carlos Armenta, Carola Emminger, Sonam Yadav, and •Stefan Zollner — New Mexico State University, Las Cruces, NM, USA

We describe measurements of the mid-infrared dielectric function of bulk InSb near the direct band gap using Fourier-transform infrared spectroscopic ellipsometry from 80 to 800 K in an ultra-high vacuum cryostat. Indium antimonide is the zinc blende compound semiconductor with the smallest direct band gap (E_0=0.18 eV at 300 K) due to its heavy elements and the large resulting spin-orbit splitting and Darwin shifts. The band gap is extracted from the dielectric function by fitting with a parametric oscillator model. It decreases from 80 to 450 K following a Bose-Einstein model, then remains constant up to 550 K, and increases again at the highest temperatures. This is explained with a thermal Burstein-Moss shift: The onset of optical absorption increases as electron-hole pairs are thermally excited at the highest temperatures. The intrinsic car-

rier concentration determined from the Drude tail in the ellipsometry spectra agrees qualitatively with temperature-dependent Hall experiments and calculations based on degenerate Fermi-Dirac statistics.

HL 18.3   Tue 10:00   POT 112

Polarized Raman scattering study of epitaxially grown GeSn layers with various Sn content — •Agnieszka Anna Corley-Wiciak[1], Omar Concepción[2], Marvin Hartwig Zoellner[1], Detlev Grützmacher[2], Dan Buca[2], Giovanni Capellini[1,3], and Davide Spirito[1] — [1]IHP Leibniz-Institut für innovative Mikroelektronik, Im Technologiepark 25, 15236 Frankfurt (Oder), Germany — [2]Peter Grünberg Institute 9 (PGI-9) and JARA-Fundamentals of Future Information Technologies — [3]Dipartimento di Scienze, Università Roma Tre, V.le G. Marconi 446, 00146 Roma, Italy

$Ge_{1-x}Sn_x$ alloys are an excellent candidate for developing mid-infrared light sources integrated with CMOS technology. The challenges in the controlled growth with high crystal quality have highlighted the peculiarity of these alloys, which can be monitored by their vibrational properties. To this purpose, Raman spectroscopy is an effective experimental method to determine these properties, as this technique is non-destructive, contactless, fast, and locally resolved. We use Raman scattering with different polarization configurations to investigate $Ge_{1-x}Sn_x$ ($0.05 \leq x \leq 0.14$) alloys grown by Chemical Vapour Deposition on Ge/Si virtual substrates. Measurements were performed in backscattering geometry with parallel and cross polarizations. In this way, we identify multiple components in the vibrational modes and how they deviate from simplified models. Our results will help to understand the fundamental properties of $Ge_{1-x}Sn_x$ alloys to enable fast assessment for their applications in optoelectronic and thermoelectric.

HL 18.4   Tue 10:15   POT 112

Eigenmodes and Polarization Structure of Coupled Elliptical Microcavities — •Johannes Düreth[1], Simon Betzold[1], Monika Emmerling[1], Antonina Bieganowska[2], Jürgen Ohmer[3], Utz Fischer[3], Sven Höfling[1], and Sebastian Klembt[1] — [1]Technische Physik, RCCM and Würzburg-Dresden Cluster of Excellence ct.qmat, University of Würzburg, Germany — [2]Faculty of Problems of Fundamental Technology, Department of Experimental Physics, Laboratory for Optical Spectroscopy of Nanostructures, Wroclaw, Poland — [3]Department of Biochemistry, University of Würzburg, Germany

Elliptical potentials give rise to a set of eigenmodes called Ince-Gaussian modes. Contrary to hemispherical potentials, the geometric shape leads to a mode splitting of the otherwise degenerate fundamental mode. Theoretically, this behaviour can be exploited to realize interesting topological phenomena like non-reciprocal transport, the non-hermitian skin-effect or engineer artificial gauge fields. On the way to an experimental implementation of such systems, the singular building blocks of these photonic potentials - single and coupled elliptical potentials - have to be experimentally studied.

Here we present an investigation of the mode splitting and polarisation in single elliptical microcavities, as well as an examination of the coupling between differently angled ellipses.

HL 18.5   Tue 10:45   POT 112

Optical properties of $Ag_xCu_{1-x}I$ alloy thin films — •E. Krüger[1], M. Seifert[2], V. Gottschalch[3], H. Krautscheid[3], C.S. Schnohr[1], S. Botti[2], M. Grundmann[1], and C. Sturm[1] — [1]Universität Leipzig, Felix-Bloch-Institut für Festkörperphysik, Germany — [2]Friedrich-Schiller-Universität Jena, Institut für Festkörpertheorie und Optik , Germany — [3]Universität Leipzig, Institut für Anorganische Chemie, Germany

Copper iodide (CuI) is a promising wide bandgap semiconductor for applications in transparent optoelectronic devices. In this context, the specific tuning of electrical and optical properties, which can potentially be achieved with ternary alloys such as $CuBr_xI_{1-x}$ [1] and $Ag_xCu_{1-x}I$ [2], is crucial for the development of novel CuI-based devices. In particular, $Ag_xCu_{1-x}I$ is of great interest because the intrinsic conductivity changes from p-type to n-type with increasing Ag content.

Here we present the bandgap energy and spin-orbit splitting in $Ag_xCu_{1-x}I$ alloys as a function of alloy composition and temperature, studied by a combination of experimental and computational methods. The non-linear bandgap dependence on Ag content can be described by a quadratic bowing parameter of 0.54 eV and is dominated by charge carrier redistribution effects in the presence of unequal element-specific bond lengths. The slight increase of the spin-orbit splitting from 640 meV for CuI to about 790 meV for AgI is discussed in terms of decreasing p-d hybridization of the valence bands at the Γ-point.

Multipole theory of optical spatial dispersion in crystals — •Óscar Pozo — Centro de Física de Materiales, Universidad del País Vasco, 20018 San Sebastián, Spain

Natural optical activity is the paradigmatic example of an effect originating in the weak spatial inhomogeneity of the electromagnetic field on the atomic scale. In molecules, such effects are well described by the multipole theory of electromagnetism, where the coupling to light is treated semiclassically beyond the electric-dipole approximation. That theory has two shortcomings: it is limited to bounded systems, and its building blocks - the multipole transition moments - are origin dependent. In this work, we recast the multipole theory in a translationally-invariant form that remains valid for periodic crystals. Working in the independent-particle approximation, we introduce 'intrinsic' multipole transition moments that are origin independent and transform covariantly under gauge transformations of the Bloch eigenstates. Electric-dipole transitions are given by the interbank Berry connection, while magnetic-dipole and electric-quadrupole transitions are described by matrix generalizations of the intrinsic magnetic moment and quantum metric. In addition to multipole-like terms, the response of crystals at first order in the wave vector of light contains band-dispersion terms that have no counterpart in molecular theories. The rotatory-strength sum rule for crystals is found to be equivalent to the topological constraint for a vanishing chiral magnetic effect in equilibrium, and the formalism is validated by numerical tight-binding calculations.

HL 18.7   Tue 11:15   POT 112

Predicting bandgap in strain-engineered multinary III-V semiconductors — •Badal Mondal and Ralf Tonner-Zech — Wilhelm-Ostwald-Institut für Physikalische und Theoretische Chemie, Universität Leipzig, 04103 Leipzig, Germany

The tuning of the type and size of bandgaps of III-V semiconductors is a major goal for optoelectronic applications. Varying the relative composition of several III- or V-components in compound semiconductors is one of the major approaches here. Alternatively, straining the system can be used to modify the bandgaps. By combining these two approaches, bandgaps can be tuned over a wide range of values, and direct or indirect semiconductors can be designed. However, an optimal choice of composition and strain to a target bandgap requires complete material-specific composition, strain, and bandgap knowledge. Exploring the vast chemical space of all possible combinations of III- and V-elements with variation in composition and strain is experimentally not feasible. We thus developed a density-functional-theory-based predictive computational approach for such an exhaustive exploration. This enabled us to construct the 'bandgap phase diagram' [1] by mapping the bandgap in terms of its magnitude and nature over the whole composition-strain space. Further, we have developed efficient machine-learning models to accelerate such mapping. We will show the application to binary [2], ternary and quaternary material combinations and the possible impact on device design.

GeSn vertical p/n photodetectors formed by 2-step ion implantation — •Shuyu Wen[1,2], Saif Shaikh[1], Oliver Steuer[1], Yonder Berencen[1], Slawomir Prucnal[1], and Shengqiang Zhou[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, Dresden, Germany — [2]Institute of Semiconductors, Chinese Academy of Sciences, Bejing, China

Germanium (Ge) is a promising material in integrated circuit (IC) due to the high mobility of hole carrier and highly compatibility in the Si-base IC technology. However, the indirect band structure of Ge leads to the low radiative recombination efficiency, limiting the application in opto-electronics. Alloying Ge with Tin (Sn) is a promising method to obtain energy band modification even to a direct band. Here, high quality Ge0.97Sn0.03 and Ge0.955Sn0.045 alloy is obtained by CMOS-compatible ion implantation method. Tensile strain leads by Sn alloying and damage recovery after Flash annealing (FLA) are characterized by Raman and XRD measurements. A subsequently phosphors implantation is applied to obtain vertical pn photodetectors (PD). The device shows an extended spectral response comparing with commercial Ge PD. This work provides a new CMOS-compatible method to fabricate photodetectors in short-wave infrared.

Interplay between strain, Sn content and temperature in GeSn-based optoelectronic devices — •Ignatii Zaitsev[1], Agnieszka A. Corley-Wiciak[1], Dan Buca[2], Omar Concepción[2], Michele Virgilio[3], Giovanni Capellini[1,4], Costanza L. Manganelli[1], and Davide Spirito[1] — [1]IHP - Leibniz-Institut für innovative Mikroelektronik, Frankfurt (Oder), Germany — [2]PGI 9, Jülich, Germany — [3]Università di Pisa, Pisa, Italy — [4]Università Roma Tre, Roma, Italy

Several works have shown the subtle interplay between thermomechanical strain, Sn content and band occupation in optoelectronic devices based on CMOS-integratable group-IV materials (Ge, SiGe, SiGeSn). This is especially the case when temperature plays a key role, e.g. devices operating at cryo-

genic temperature or in presence of high power. Here we provide a theoretical-experimental approach combining 3D FEM calculations, Raman and photoluminescence spectroscopy to fully capture the influence of mechanical and thermo-mechanical features on the optical properties. We apply this method to strained GeSn microdisks, a device geometry aimed at laser in the MIR range. With the presented methods, we can develop a thorough guidelines for the assessment and design of integrated light emitters.

HL 18.10   Tue 12:15   POT 112

Excitons in MoS$_2$ bilayers under pressure — •Jan-Hauke Graalmann[1], Paul Steeger[2], Robert Schmidt[2], Steffen Michaelis de Vasconcellos[2], Rudolf Bratschitsch[2], and Michael Rohlfing[1] — [1]Institute of Solid State Theory, University of Münster, 48149 Münster, Germany — [2]Institute of Physics, University of Münster, 48149 Münster, Germany

Theoretical and experimental studies have shown that the optical spectrum of the MoS$_2$ bilayer changes under pressure.

Our theoretical investigations are based on DFT, *GdW* and the Bethe-Salpeter equation. For the specific stress conditions of the experiment, our calculations show an effective shift of the excitation energies of the A exciton towards higher energies with increasing pressure. This behaviour can be explained with an approximately constant direct band gap at the K point while the binding energy decreases. Due to a growing valence band splitting for increasing pressures, the interlayer exciton shows a smaller shift. These results are substantiated by measurements using a piston type diamond anvil cell (DAC) to create pressures in the GPa range.

The reason for only small changes of the fundamental band gap is a significant influence of interlayer interaction. The effect of a decreasing gap by biaxial lateral shrinking of each single layer under an external pressure gets counterbalanced by the reduction of the interlayer distance. Furthermore, the real space distribution shows an increased interlayer character for the A and interlayer exciton under pressure.

HL 18.11   Tue 12:30   POT 112

Optical properties of a vacancy-related complex in 4H-SiC — •Maximilian Schober[1], Nicolas Jungwirth[1], Takuma Kobayashi[2], Johannes A. F. Lehmeyer[2], Michael Krieger[2], Heiko B. Weber[2], and Michel Bockstedte[1] — [1]Institute for Theoretical Physics, Johannes Kepler University Linz, Austria — [2]Lst. f. Angewandte Physik, Friedrich-Alexander-University Erlangen-Nürnberg, Germany

SiC is host to multiple color centers, such as the silicon vacancy, the divacancy, and the carbon antisite-vacancy complex, with relevant applications as qubits, single photon sources and in quantum metrology. Recently, the carbon di-vacancy-antisite complex was identified as an annealing product of vacancy related defects [1], and is expected to feature favorable properties for quantum technology. The presence of strongly localized silicon and carbon dangling bonds points to rich photo- and spin physics that has so far not been explored in detail. In this work we probe the basal and axial configurations of $V_C C_{Si} V_C$ for their electronic-, optical- and radiative properties using a theoretical framework of hybrid density functional and many body approaches. We obtain the principal transitions, as well as the associated static- and transition dipole moments of the relevant charge states. Our results suggest a tentative identification of the carbon di-vacancy-antisite with the temperature-stable (TS) center [2].

Defects or Dots – what semiconductor physics can bring into optical super-resolution imaging — •Philipp Kellner[1], Jana Sütterlin[1], Paul Konrad[2], Andreas Sperlich[2], and Christian Eggeling[1,3] — [1]Institut für angewandte Optik und Biophysik, FSU Jena, Philosophenweg 7, 07743 Jena — [2]Physikalisches Institut, Julius-Maximilians Universität Würzburg, Am Hubland, 97074 Würzburg — [3]Institut für physikalische Hochtechnologie, Albert-Einstein-Straße 9, 07745 Jena

Super-resolved optical microscopy is a widely used tool throughout the medicine and biology community. Mostly and routinely done with organic dyes super-resolution imaging has led to various insights into cell structures and diffusional dynamics. The fundamental problem occuring with organic dyes is their rather dim brightness and their lack of photostability paired with photo-toxicity. This presentation will shed light on novel semi-conductor-based chromophores, like NV-centers in diamond, defects in hBN and CdTe quantum dots, and their use in optical nanoscale sensing schemes like StED-imaging or fluorescence correlation microscopy.

Two-component GW implementation for molecular valence excitations — •Qinglong Liu, Ramón L. Panadés-Barrueta, and Dorothea Golze — Chair of Theoretical Chemistry, Technische Universit at Dresden, 01062 Dresden, Germany

We present an all-electron *GW* implementation for the computation of charged molecular excitations, that includes scalar relativistic effects and spin-orbit coupling (SOC). Our method is based on a two-component (2c) approach, which can process 2c spinors and their corresponding eigenvalues from different levels of theory. The relativistic input for our 2c *GW* calculation is obtained in two ways: One approach is a non-self-consistent second variation SOC scheme, i.e. a scalar relativistic (SR) calculation is performed followed by an expansion of the spinors on top of the SR eigenvectors [1]. Another approach is the spinors and their eigenvalues are obtained by running a self-consistent relativistic DFT calculation with the X2C method [2]. Our algorithm has been implemented in the FHI-aims program package, which is based on numeric atom-centered orbitals (NAOs). In our 2c *GW* algorithm we combine the all-electron NAO scheme with the resolution of the identity technique based on the Coulomb metric (RI-V) and use the analytical continuation to evaluate the $G_0 W_0$ self energy. We present results for the numerical validation of our implementation and for the influence of the relativistic input (second variation SOC vs X2C) on the valence excitations of small heavy molecules.

Screened potential in two-dimensional GW calculations within the LAPW framework — •Ben Alex, Sven Lubeck, and Claudia Draxl — Physics Department and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany

To calculate two-dimensional (2D) materials in a three-dimensional periodic code, one has to consider periodically repeated layers. The calculation of quasiparticle energies for 2D materials within the *GW* approximation requires the introduction of a 2D cutoff for the Coulomb potential as the layers would otherwise interact with each other. This cutoff leads to a stronger q dependence of the dielectric function around $q = 0$ which requires much denser sampling of the first Brillouin zone. In order to address this issue, an analytic expression for the dielectric function was previously derived for a plane-wave basis [1]. This expression is then integrated numerically in a small region around $q = 0$. The goal of this work is to adapt this technique to the linearized augmented planewave + local-orbital (LAPW+lo) basis as implemented in the full-potential all-electron code `exciting`. We show that also in our case, we obtain a significant computational speedup. Furthermore, this approach is compared with an approach where the dielectric function is interpolated to a denser q-grid.

GW multipole approach for the frequency description of the dielectric screening — •Claudia Cardoso[1], Dario A. Leon[2], Andrea Ferretti[1], Daniele Varsano[1], and Elisa Molinari[1] — [1]S3 Centre, Istituto Nanoscienze, CNR, 41125, Modena (Italy) — [2]Department of Mechanical Engineering and Technology Management, Norwegian University of Life Sciences, 1430, Ås (Norway)

In the present work, we discuss a numerical approach for GW calculations that takes into account the frequency dependence of the screening via a multi-pole approximation (MPA), an accurate and efficient alternative to current full-frequency methods, that overcomes several limitations of the plasmon pole approximation (PPA).

MPA was recently developed and validated for semiconductors[1]. We now extend the use of MPA to metallic systems by optimizing the frequency sampling for these class of materials and propose a simple method to include the zero q limit of the intra-band contributions. The good agreement between MPA and full frequency results for the calculations of quasi-particle energies, polarizability, self-energy and spectral functions in different metallic systems confirms the accuracy and computational efficiency of the method. Finally, we discuss the physical interpretation of the MPA poles through a comparison with experimental electron energy loss spectra for Cu.

Topical Talk   HL 20.4   Tue 11:15   TRE Ma
Towards low-scaling GW calculations for 2D materials — •Jan Wilhelm — Institute of Theoretical Physics, University of Regensburg
Semiconducting two-dimensional materials are an ideal platform to study excitons thanks to the strong exciton binding energy and good experimental accessibility of the excitons. The GW+Bethe-Salpeter approach (GW+BSE) has been successful in analyzing excitons in single-layer 2D materials [1], but the application of GW+BSE is challenging for 2D double layers and moiré structures [2]. This is because the large unit cells in these structures contain hundreds to thousands of atoms, resulting in a high computational cost for GW+BSE calculations. In this talk, I will present a low-scaling GW algorithm for 2D materials that potentially allows for the inclusion of more than a thousand atoms in the simulation [3]. This algorithm is based on localized basis functions and can handle periodic boundary conditions and the divergence of Coulomb interactions in the Brillouin zone. I will present first benchmark calculations.

Accelerating core-level GW calculations by combining the contour deformation with the analytic continuation of W — •Ramón L. Panadés Barrueta and Dorothea Golze — Theoretische Chemie, Technische Universität Dresden, Bergstr. 66c, 01062 Dresden, Deutschland
Many-body methods, like the GW approximation, have recently proven to be a highly effective tool for computing core-level excitations [1]. In particular, the contour deformation (CD) is an efficient, scalable and numerically stable approach that has enabled core-level calculations on systems up to 100 atoms [2]. In this work, we reduce the scaling of CD applied to core-levels from $O(N^5)$ to $O(N^4)$, using an analytic continuation of the screened Coulomb interaction W [3]. The new method (CD-WAC) has been implemented in FHI-aims. CD-WAC has been extensively tested on well established benchmark sets like the GW100 and the CORE65, reporting MAEs of less than 5 meV with respect to

CD. The theoretical scaling has been confirmed by performing scaling experiments on large acene chains and amorphous carbon. Speedups of 5 times have been attained with CD-WAC for the largest systems.

Many-Body Effects of Metals Investigated by Means of the GW Method — •Zimo Zhou, Nakib Protik, and Claudia Draxl — Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany
Even if semilocal exchange-correlation functionals of density-functional theory (DFT) can capture the overall band structure of many metals well, they fail to obtain the correct position of the d-bands. This leads, for instance, to the underestimation of the interband absorption onset in the corresponding optical spectra as shown for a set of elemental metals [1]. In this work, we provide a systematic investigation of the quasi-particle band structure and the optical properties of this set of materials. To this extent, the self-energy corrections to the DFT results are computed by the GW approach of many-body perturbation theory as implemented in the full-potential all-electron code exciting [2,3]. We show that the optical absorption spectra based on these quasi-particle bands remedy the shortcomings of semi-local DFT, accurately reproducing the experimental counterparts.

Separable Resolution-of-Identity in an all-electron numeric atom-centered basis set framework — •Francisco Delesma[1], Dorothea Golze[2], and Patrick Rinke[1] — [1]Department of Applied Physics, Aalto University, Espoo, Finland — [2]Faculty of Chemistry and Food Chemistry, Technische Universität Dresden, Dresden, Germany
The resolution-of-identity (RI) is a common way in quantum chemistry and computational materials science to reduce the computational cost of two-electron Coulomb integrals, another central entity in computational quantum mechanics. In 2019, Duchemin and Blase proposed the separable-RI approach [1], which preserves the accuracy of the standard, global RI method with the Coulomb metric (RI-V) and permits the formulation of cubic-scaling random-phase approximation (RPA) and Green's function based GW approaches.

In this work, we present the first implementation of the separable-RI in an all-electron numeric atom-centered orbital framework. Separable-RI is implemented in the FHI-aims code [2] and optimized for massively parallel execution. We extend the separable-RI framework beyond the original Hartree-Fock (HF) and GW implementations of Duchemin and Blase to MP2 and RPA, SO-SEX and CCSD. Our separable-RI total energies and GW quasiparticle energies for the Thiel test set of small organic molecules reproduce the exact two-electron Coulomb integral calculations within 1 meV or better.

HL 21: Thermal properties

Time: Tuesday 11:00–11:45   Location: POT 361

HL 21.1   Tue 11:00   POT 361
Wigner thermal transport in rare-earth zirconates and their solid solutions — •Anees Pazhedath[1], Lorenzo Bastonero[1], Nicola Marzari[1,2], and Michele Simoncelli[3] — [1]U Bremen Excellence Chair, Bremen Center for Computational Materials Science, and MAPEX Center for Materials and Processes, University of Bremen, D-28359 Bremen, Germany — [2]Theory and Simulation of Materials (THEOS), and National Centre for Computational Design and Discovery of Novel Materials (MARVEL), École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland — [3]Cavendish Laboratory, Theory of Condensed Matter Group, University of Cambridge, England
Anharmonicity and disorder are both limiting factors for heat transport, and understanding how their interplay determines thermal conductivity is crucial to devise design strategies for thermal barrier coatings (TBC). Rare-earth (RE) zirconates are prospective TBC materials, owing to their strong anharmonicity and disorder tunable through alloying. Here, we use the Wigner transport equation in conjunction with state-of-the-art first-principles simulations to elucidate the microscopic physics underlying thermal transport in solid solutions of RE-zirconates, analyzing solutions of $La_2Zr_2O_7$ and $Yb_2Zr_2O_7$ as a paradigmatic

test case. This work deepens our understanding on how the interplay between disorder and anharmonicity affects thermal transport in complex crystals with glass-like conductivity, also extending the reach of first-principles simulations to the description of thermal transport in RE-zirconate solid solutions

HL 21.2   Tue 11:15   POT 361
The Influence of Anharmonicity on Negative Thermal Expansion of α-Sn — •Reinhard K. Kremer[1], Paweel T. Jochym[2], Jan Lazewski[2], Andrzej Ptok[2], Przemyslaw Piekarz[2], Andrzej M. Olés[3], and Eva Brücher[1] — [1]MPI for Solid State Research, Stuttgart, Germany — [2]Institute of Nuclear Physics, Polish Academy of Sciences, Krakow, Poland — [3]Institute of Theoretical Physics, Jagiellonian University, Krakow, Poland
The lattice vibrational properties of α-Sn (gray tin) were investigated experimentally by temperature dependent x-ray diffraction and theoretically by density functional theory calculations. Similar to the other elements of group IV, α-Sn exhibits a lattice anomaly at low temperatures and negative thermal expansion, with a minimum at ~ 27 K and a magnitude three times larger than in Si. Influence of anharmonic effects up to 4th order potential terms on the phonon dispersion relations, the lattice parameters, and the thermal expansion coefficient

have been tested. The performed analysis gives an excellent agreement with experiment when quartic potential terms are included in the theory. We point out that negative thermal expansion in α-Sn is not driven by anharmonicity of interatomic potential. This resolves the long-standing puzzle in the thermal behavior of α-Sn.

HL 21.3   Tue 11:30   POT 361

Origin of thermal anisotropy in monoclinic $\beta - Ga_2O_3$ — •Markus R. Wagner[1,2], Benjamin M. Janzen[2], Zbigniew Galazka[3], Bartlomiej Graczykowski[4], Kai Xu[5], Ricardo Rurali[5], and Juan Sebastian Reparaz[5] — [1]Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany — [2]Technische Universität Berlin, Germany — [3]Leibniz-Institut für Kristallzüchtung, Berlin, Germany — [4]Faculty of Physics, Adam Mickiewicz University, Poland — [5]Institut de Ciència de Materials de Barcelona, ICMAB-CSIC, Spain

We present a comprehensive all-optical contact-free investigation of the anisotropy of GHz and THz phonon-mediated material properties in $\beta - Ga_2O_3$. The full thermal conductivity tensor is determined by a newly developed all-optical experimental technique that enables sub-degree angular resolution in the measurement of the in-plane anisotropy of the thermal conductivity based on anisotropic frequency-domain thermoreflectance. Using this novel approach we determine the in-plane anisotropy of the thermal conductivity and its anisotropy ratio with high precision. The anisotropy of the sound velocity, elasticity, and Young modulus is measured by polarized, angular-resolved Brillouin light scattering of GHz acoustic phonons. Based on the experimental anisotropy maps of acoustic phonon velocities and thermal conductivity in combination with calculations of the phonon density of states and phonon lifetimes, we discuss the individual contributions of phonon velocities and phonon lifetimes to the anisotropy of the thermal conductivity.

HL 22: 2D Materials IV (joint session HL/CPP)

Nonlinear optical characterization of atomically thin layers of the transition metal dichalcogenides WSe$_2$ and MoS$_2$ — •Henry Volker Hübschmann[1], Gerhard Berth[1], Ioannis Caltzidis[1], Katharina Burgholzer[2], Alberta Bonanni[2], and Klaus D. Jöns[1] — [1]Department of Physics, Paderborn University, 33098 Paderborn, Germany — [2]Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, 4040 Linz, Austria

In the field of quantum technologies functional 2D-structures based on transition metal dichalcogenides like WSe$_2$ and MoS$_2$ represent a novel material platform due to their specific optical and electronic properties. In contrast to semimetallic graphene they feature an electronic band gap and a strong spinorbit coupling. Applications of such layered 2D-materials in functional structures are to be found within photonics, spinorbitronics or nanoelectronics. In this work we present our fundamental nonlinear study on mechanically exfoliated atomically thin layers of the semiconductors WSe$_2$ and MoS$_2$. In this context, the second harmonic generation was determined for both van der Waals layered material systems as a function of the layer number. The respective nonlinear behavior was proven by a power-dependent characterization and supplemented by polarimetric analysis. Nonlinear imaging of the flakes was successfully performed by confocal SH-microscopy. In a further step the oxidation of MoS$_2$ layered systems was analyzed, here it was shown that for an even number of layers the oxidation leads to a break of their centrosymmetric structure, which is manifested in the clear presence of a relatively strong second harmonic signal.

HL 22.2   Wed 9:45   POT 81

Single Photon Emitters in hBN via ultra-low energy helium ion implantation — •Prokhor Tkhor[1,2], Minh Bui[1,2], Renu Rani[1], Thorsten Brazda[1], and Beata E. Kardynał[1,2] — [1]Peter Grünberg Institut-9, Forschungszentrum Jülich, Jülich — [2]Department of Physics, RWTH Aachen, Aachen

Properties of heterostructures of transition metal dichalcogenides depend strongly on the moire lattice configuration and on the strength of coupling between the constituent monolayers. The first one can be controlled by the lattice constant of the constituent monolayers and their relative orientation, while the latter can be tuned by changing the spacing between them. In this contribution, we study a heterostructure of monolayers of WSe2/ hBN/ WSe2 with a moire potential periodicity of around 5 nm. The insertion of a monolayer of hBN between the two WSe2 monolayers results in a weak coupling between them. We discuss the results of the measurements of the dependence of the photoluminescence on the doping and electric field in this system. In this system the lowest intralayer excitonic states are optically spin-forbidden and at low electron concentration the effect of the moire potential on scattering of electrons and excitons dominates the optical signal masking the effect of correlations. Further, we discuss the observed non-monotonic charge shifts between the monolayers as a function of applied electric field.

HL 22.3   Wed 10:00   POT 81

Thin hexagonal boron nitride in the deep-UV: The pursuit of single photon emitters and their properties — •Nils Bernhardt[1], Luka Choi[1], Felix Nippert[1], Angus Gentle[2], Milos Toth[2], and Markus R. Wagner[1,3] — [1]Technische Universität Berlin, Berlin, Germany — [2]University of Technology Sydney, Sydney, Australia — [3]Paul-Drude-Institut, Berlin, Germany

Interest in hexagonal boron nitride (hBN) continues to grow in optoelectronics with the discovery of an increasing number of quantum emitters in all spectral ranges. The wide band gap and chemical stability inherent to this material encourage hBN as a semiconductor substrate, while the possibility of reliably fabricating thin films entails unusual and unique properties. Consequently, room-temperature defect quantum emitters with reproducible emission prop-

erties from the UV to the near-IR can be engineered for applications such as quantum communication.

In this work, we investigate the recently observed luminescence of hBN at 4.1eV with a pulsed, frequency-tripled titanium-sapphire laser at 240nm. Experimental methods such as photoluminescence spectroscopy and time-resolved fluorescence spectroscopy are utilized alongside a Hanbury Brown and Twiss interferometer for correlation measurements in the deep UV as a means to identify single-photon emitters. Through this approach, we are able to establish a scientific basis for further investigation into the UV emission of hBN.

HL 22.4   Wed 10:15   POT 81

Electrical control of excitonic complexes in MoSe$_2$ homobilayers — •Bárbara Rosa[1], Chirag Palekar[1], Alisson Cadore[2], Yuhui Yang[1], Aris Koula-Simos[1], Sefaattin Tongay[3], and Stephan Reitzenstein[1] — [1]Institut für Festkörperphysik, Technische Universität Berlin, Berlin, Germany — [2]Brazilian Nanotechnology National Laboratory, Campinas, Brazil — [3]School for Engineering of Matter, Transport and Energy, Arizona State University, Tempe, USA

Effects of periodic Moiré potential in transition metal dichalcogenides (TMDs) bilayers are directly controlled by the twist angle between the monolayers. Novel features arising from intra- and interlayer excitons, such as their ultrafast formation and charger transfer, long population recombination lifetimes, and binding energy of dozens of meVs, turn TMD heterostructures into an attractive device for the study and manipulation of optical and transport properties via electrical fields. Moreover, such effects may appear even more pronounced at twisted homobilayers, since the absence of lattice mismatch promotes the appearance of larger Moiré superlattices. In this work, we explore the ability to control excitonic complexes in MoSe$_2$/MoSe$_2$ twisted bilayers (t-BLs) by performing gate-dependent microphotoluminescence (μPL) spectroscopy at room temperature. We observe the energy tunability of several meVs occurring at the emission of excitonic complexes derived from the t-BL region. In addition, other effects, such as the emergence of new excitonic features, are observed through μPL spectroscopy at cryogenic temperatures.

HL 22.5   Wed 10:45   POT 81

Tailoring Coulomb interactions in WS$_2$-graphene heterostructures — •David Tebbe[1], Marc Schütte[1], Kenji Watanabe[2], Takashi Taniguchi[3], Christoph Stampfer[1], Bernd Beschoten[1], and Lutz Waldecker[1] — [1]2nd Institute of Physics A, RWTH Aachen University — [2]Research Center for Functional Materials, Japan — [3]International Center for Materials Nanoarchitectonics, Japan

The exciton binding energy and the quasiparticle bandgap in two dimensional semiconductors depend on their dielectric environment.

We investigate the screening of Coulomb interactions in heterostructures of WS$_2$ and graphene, separated through thin spacer layers of hexagonal boron nitride (hBN). By using hBN spacers from one to 16 atomic layers, we experimentally determine the tuning of the exciton binding energy and the quasiparticle bandgap as a function of the WS$_2$-to-graphene interlayer spacing.

This change in both energies is well described by a one over distance dependence, which is consistent with a screening arising from an image charge induced by the graphene layer.

Additionally, by doping the graphene with a graphitic back gate, we show that the ability of the graphene to screen Coulomb interactions in neighbouring layers is strongly modified. We determine the change in screening strength to be approximately 20% at room temperature, demonstrating that Coulomb-interactions in WS$_2$ can be modified in-situ without changing the doping level of the material itself.

HL 22.6 Wed 11:00 POT 81

Evidence for equilibrium exciton condensation in monolayer WTe2 — •MASSIMO RONTANI — CNR-NANO, Modena, Italy

We present evidence [1] that the two-dimensional bulk of monolayer WTe2 contains electrons and holes bound by Coulomb attraction, excitons, that spontaneously form in thermal equilibrium. On cooling from room temperature to 100 K, the conductivity develops a V-shaped dependence on electrostatic doping, while the chemical potential develops a step at the neutral point. These features are much sharper than is possible in an independent-electron picture, but they can be accounted for if electrons and holes interact strongly and are paired in equilibrium. Our calculations from first principles show that the exciton binding energy is larger than 100 meV and the radius as small as 4 nm, explaining their formation at high temperature and doping levels. Below 100 K, more strongly insulating behaviour is seen, suggesting that a charge-ordered state forms. The observed absence of charge density waves in this state is surprising within an excitonic insulator picture, but we show that it can be explained by the symmetries of the exciton wavefunction. Therefore, in addition to being a topological insulator, monolayer WTe2 exhibits strong correlations over a wide temperature range.

This work is done in collaboration with Elisa Molinari, Daniele Varsano, Samaneh Ataei, Maurizia Palummo, Bosong Sun, David Cobden. It is partially funded by MUR PRIN2017 No. 2017BZPKSZ EXC-INS and MaX EU Center of Excellence.

HL 22.7 Wed 11:15 POT 81

Charge and exciton quenching at defect states in TMDC-graphene heterostructures — •DANIEL HERNANGÓMEZ-PÉREZ[1], AMIR KLEINER[1], ANDREA DONARINI[2], and SIVAN REFAELY-ABRAMSON[1] — [1]Department of Molecular Chemistry and Materials Science, Weizmann Institute of Science, 7610001 Rehovot, Israel — [2]Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany

In recent years, studies of charge transfer and excitonic properties of van der Waals heterostructures have revealed a fertile research arena, spanning Coulomb blockade physics [1], ultrafast interlayer charge separation [2] or graphene-quenched photoluminescence [3]. We theoretically study charge transfer and excitonic properties in XS_2-graphene (X = W, Mo) heterobilayers with monoatomic chalcogen vacancies [4-5]. We discuss the impact of the subgap defect-based features in the microscopic dynamics, as well as the interplay between spatial symmetries and the spin degree of freedom through the spin-orbit interaction. Finally, we report the electronic and optical properties computed by many-body perturbation theory and show how defects and graphene alter the absorption properties of the TMDC due to a combination of folding, commensuration and impact of defect in-gap energy bands.

The influence of anisotropy on excitons in magnetic semiconductors — •MARIE-CHRISTIN HEISSENBÜTTEL, THORSTEN DEILMANN, and MICHAEL ROHLFING — Institute of Solid State Theory, University of Münster, Germany

Understanding the peculiar interrelation between crystal structure, magnetic properties and light-matter interaction in semiconducting two-dimensional-like magnets is of fundamental interest. From our ab-initio GW/Bethe-Salpeter equation calculations, we are able to examine electronic and excitonic properties on the same footing.

Because of its large crystal anisotropy combined with in-plane ferromagnetism, the van-der-Waals stacked CrSBr has recently come to the fore e.g. to study correlated phenomena. Due to the unique interplay of anisotropy, two-dimensional magnetism and optoelectronic properties resulting in a quantum confinement, we observe very flat dispersions, different effective masses and a quasi-1D behaviour of excitons within a monolayer of CrSBr [1]. Moreover, we find that the Rydberg series of two excitonic states is intricately modified by the different extension of the wavefunctions within momentum space.

HL 22.9 Wed 12:00 POT 81

From MoSe$_2$ to MoS$_2$ and everything in-between — •JENNIFER SCHMEINK, VLADISLAV MUSYTSCHUK, NICOLAS HILLE, ERIK POLLMANN, PETER KRATZER, and MARIKA SCHLEBERGER — Universität Duisburg-Essen, Fakultät für Physik, Germany

Asymmetrical, or Janus transition metal dichalcogenide (TMDC) monolayers such as MoSSe are a current hot topic in the field of two-dimensional (2D) materials due to their unique properties. The most common approach of fabrication is to start off from one of the two base TMDCs' monolayer and selectively substitute the top-most layer of chalcogen atoms with another kind. However, if the substitution is partial, the resulting material resembles more an alloy than a Janus-type structure. These in-between materials show their own interesting features, as they allow for example a fluid optical bad-gap tuning from that of MoSe$_2$ at 1.54 eV over 1.70 eV for MoSSe up to 1.84 eV of MoS$_2$. In my talk I want to show off the varying optical and electronic properties of these $MoS_{2(1-x)}Se_{2x}$ ($0 \leq x \leq 1$) structures with a special focus on the Janus-type MoSSe monolayer. This talk will explore the fascinating question of what lies in between.

HL 22.10 Wed 12:15 POT 81

Optimized Irradiation Protocol for Quantum Sensors in Hexagonal Boron Nitride — •PAUL KONRAD[1], ANDREAS GOTTSCHOLL[1], ANDREAS SPERLICH[1], IGOR AHARONOVICH[2], and VLADIMIR DYAKONOV[1] — [1]Experimental Physics 6, Julius-Maximilians-University of Würzburg, 97074 Würzburg — [2]School of Mathematics and Physical Sciences, University of Technology Sydney, Ultimo, NSW 2007, Australia

Colour centres in solid-state materials show great potential in quantum information technology and sensing applications. The lately discovered negatively charged boron vacancy (V_B^-) in hexagonal boron nitride (hBN)[1] has shown that the defect exhibits a spin-triplet ground state with spin-dependent photoluminescence. The system can be exploited in terms of its application as temperature, magnetic field, and pressure sensor [2,3] which extends the already known applications of e.g. NV-centers in diamond not only due to its 2D character but also by highly improved temperature sensing especially at low temperatures.

Here we present an irradiation protocol for creation of V_B^- by nitrogen ions, leading to optimized spin relaxation parameters and therefore improving quantum metrology limits. We also present tremendous improvement of ODMR contrast showing hyperfine interaction on flakes of down to 80nm thickness.

HL 23: Focus Session: Breakthroughs in wide-bandgap semiconductor laser diodes I

Recently, a number of significant breakthroughs have taken place in the area of wide-bandgap semiconductor laser diodes. The exploration of the limits of III-nitride materials, the improved understanding of the optical and electronic properties allowed to push the lasing wavelength towards the UV-B and UV-C spectral range with AlGaN-based laser diodes emitting at record short wavelength near 270 nm and 300 nm. In addition, advanced designs and fabrication technologies have led to the realization of novel devices in the blue-violet and even UV spectral range such as low-threshold VCSELs, narrow-linewidth GaN-based DFB laser diodes and photonic crystal lasers. In this focus session we will review these recent developments and discuss the future challenges and application for these devices.

Organized by Tim Wernicke, Ulrich Schwarz, and Michael Kneissl

Time: Wednesday 9:30–12:15

Location: POT 361

Invited Talk   HL 23.1   Wed 9:30   POT 361
Vertical-cavity surface-emitting lasers – this is the way — •Å. Haglund[1], G. Cardinali[2], L. Persson[1], F. Hjort[1], J. Enslin[2], E. Torres[1], C. Kuhn[2], S. Graupeter[2], M. Grigoletto[2], M. A. Bergmann[1], N. Prokop[2], M. Guttmann[2], L. Sulmoni[2], N. Lobo Ploch[3], M. Cobet[2], T. Kolbe[3], J. Gustavsson[1], F. Nippert[2], I. Häusler[2], M. R. Wagner[2], J. Ciers[1], T. Wernicke[2], and M. Kneisl[2,3] — [1]Chalmers University of Technology, Göteborg, Sweden — [2]Technische Universität Berlin, Berlin — [3]FBH, Berlin

In recent years, there has been tremendous improvement in the performance of blue-emitting vertical-cavity surface-emitting lasers (VCSELs). Ultraviolet (UV)B (280-320 nm) and UVC (<280 nm) VCSELs have also been demonstrated, but so far only under optical pumping. All VCSELs require high reflectivity mirrors with an accurate cavity length control, but there is today no consensus on which is the best approach to realize this. We will summarize state of the art and then go into depth on our concept which is based upon using all-dielectric distributed Bragg reflectors where substrate removal is achieved by selective electrochemical etching. This approach has enabled the world's first UVB VCSEL at 310 nm. It also gives access to both sides of the cavity which allows for detuning postgrowth with drastically reduced lasing thresholds as well as an athermalized lasing wavelength. Thus, we believe that - this is the way - for nitride VCSELs. As a first step towards electrically injected UV VCSELs, we will demonstrate resonant cavity light emitting diodes with tunnel junctions.

Invited Talk   HL 23.2   Wed 10:00   POT 361
Towards GaN-based diode lasers with narrow linewidth and high reliability — •Sven Einfeldt[1], Erik Freier[1], Ji-Hye Kang[1], Hans Wenzel[1], Anna Mogilatenko[1], Johannes Glaab[1], Asmaa Abou-Shewarib[1], Veit Hoffmann[1], Johannes Enslin[1], Martin Guttmann[1], Saad Makhladi[1], Jörg Fricke[1], Olaf Brox[1], Mathias Matalla[1], Maria Norman-Reiner[1], Christoph Stölmacker[1], Markus Weyers[1], Luca Sulmoni[2], Michael Kneissl[2], Lukas Uhlig[3], and Ulrich T. Schwarz[3] — [1]Ferdinand-Braun-Institut (FBH), Berlin, Germany — [2]Technische Universität Berlin, Institut für Festkörperphysik, Berlin, Germany — [3]Technische Universität Chemnitz, Institut für Physik, Chemnitz, Germany

Various applications require GaN-based diode lasers that not only operate in single-mode at well-defined wavelengths, but also exhibit a small linewidth and high reliability. Single-mode operation can be achieved via the distributed feedback (DFB) or distributed Bragg reflector (DBR) laser design, i.e. monolithic integration of gratings in the chip. We present here the current state of the art in fabrication technology and properties of DFB and DBR diode lasers with high-order laterally coupled surface gratings. These include continuous wave single-mode operation at room temperature with an optical power of up to 20 mW (DBR) and 70 mW (DFB), respectively, and spectral half widths of about 20 pm. We also show results of selected studies on the reliability of GaN-based lasers, in particular on the stability of the operating voltage, the evolution of spatial inhomogeneities in the current distribution in the chip, and the stability of the facets.

Invited Talk   HL 23.3   Wed 10:30   POT 361
Use of wafer patterning for new functionalities of InGaN light emitters — •Anna Kafar[1,2], Ryota Ishii[3], Atsushi Sakaki[4], Kiran Saba[1], Conny Becht[5], Szymon Grzanka[1,2], Ulrich Schwarz[5], Mitsuru Funato[3], Yoichi Kawakami[3], and Piotr Perlin[1,2] — [1]Institute of High Pressure Physics PAS, Warsaw, Poland — [2]TopGaN Ltd., Warsaw, Poland — [3]Kyoto University, Kyoto, Japan — [4]Nichia Corporation, Tokushima, Japan — [5]Chemnitz University of Technology, Chemnitz, Germany

In this work we present the use of patterning of bulk GaN substrates to control the growth of InGaN layers by metalorganic vapour-phase epitaxy. We demonstrate that using local change of substrate miscut, it is possible to obtain a spatial shift of emission energy of above 25 nm. Synchrotron radiation microbeam X-ray diffraction reveals that a significant change of In content in the QWs is possible between 9% and 18%. This approach can be used for example in fabri-

cation of micro-arrays of laser diodes with different lasing wavelength. Another application is the fabrication of superluminescent diodes with broadened emission spectra by utilizing a profile of indium content along the device waveguide. Furthermore, we use the same concept to demonstrate monolithic light-guides integrated with laser diodes on the same wafer and fabricated based on the same epitaxy. We also study the possibility to use substrate patterning in a form of micro strips and discs regions of improved quality InGaN which can be used for fabrication of the active regions of the micro LEDs and laser diodes.

HL 23.4   Wed 11:30   POT 361
Time-dependent intensity and wavelength dynamics of blue laser diodes with wide quantum wells — •Jannina Tepass[1], Lukas Uhlig[1], Mateusz Hajdel[2], Grzegorz Muziol[2], and Ulrich Theodor Schwarz[1] — [1]Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany — [2]Institute of High Pressure Physics, Polish Academy of Sciences, Poland

In this study, thick quantum wells with two different thicknesses of 10.4 nm and 25 nm are analyzed. The very low overlap of the electron and hole wavefunction in such QWs due to the quantum confined Stark effect would indicate inefficient devices. However, it has been shown that thick QWs can be more effective and achieve high optical gain. This can be explained by the electric field screening that leads to a high overlap of the excited electron and hole states, which enable lasing. In this work, a pulsed electrical excitation scheme is used in which carrier injection at forward voltage is largely separated from carrier recombination at zero or reverse voltage. Due to this effect, the interplay between the piezoelectric field and the built-in potential on the charge carrier recombination in dependence on an external bias voltage can be observed. In particular, a sharp increase in the radiative recombination rate after the trailing edge of the driving pulse is observed, as well as a wavelength shift.

HL 23.5   Wed 11:45   POT 361
Single-mode lasing in optically pumped UVB VCSELs with circular relief structures — •Giulia Cardinali[1], Filip Hjort[2], Johannes Enslin[1], Munise Cobet[1], Michael A. Bergmann[2], Johan Gustavsson[2], Joachim Ciers[2], Tim Kolbe[3], Felix Nippert[1], Markus R. Wagner[1], Tim Wernicke[1], Åsa Haglund[2], and Michael Kneissl[1,3] — [1]Institute of Solid State Physics, Technische Universität Berlin, Berlin, Germany — [2]Department of Microtechnology and Nanoscience, Chalmers University of Technology, Gothenburg, Sweden — [3]Ferdinand-Braun-Institut (FBH), Berlin, Germany

Extending the emission wavelength of vertical-cavity surface-emitting lasers (VCSELs) in the ultraviolet (UV) range would allow advances in many applications, e.g. in medical diagnostics, material curing, and sterilization. UV VCSELs have been demonstrated only under optical pumping and they suffer from strong filamentation (i.e. spatially inhomogeneous emission), resulting in multimode lasing. In this work, we study the emission characteristic of optically pumped UVB VCSELs with circular reliefs dry-etched on the bottom cavity. Single-mode lasing near 312 nm was achieved for VCSELs with 25 nm-deep reliefs with diameters smaller than 5 μm, when pumped up to 80 MW/cm^2. Here, the lateral size of the cavity was reduced below the dimension of one filament. VCSELs with 5 nm-deep reliefs did not show single mode lasing. 50 nm-deep structures did not lase for diameters below 6 μm. The higher thresholds in this sample are due to defect generation in the quantum-well by the dry etching, which was confirmed by time-resolved photoluminescence measurements of the carrier lifetimes.

HL 23.6   Wed 12:00   POT 361

HL 24.1   Wed 9:30   POT 151

Raman spectroscopic structure analysis of colloidal semiconductor core-shell quantum dots for the achievement of near-unity quantum efficiency
— •Sandra Zech[1,2], Sonja Krohn[2], Hannes Van Avermaet[3], Zeger Hens[3], Jan Steffen Niehaus[4], Janina Maultzsch[1], and Holger Lange[2] — [1]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [2]Institute of Physical Chemistry, University of Hamburg, Hamburg, Germany — [3]Physics and Chemistry of Nanostructures, Ghent University, Ghent, Belgium — [4]Fraunhofer IPA Center for Applied Nano-Technology CAN, Hamburg, Germany
State of the art applications of quantum dots (QDs) require near-unity photoluminescence quantum yield (PLQY). This demand is rarely achieved and therefore the synthesis process is under constant optimization and nanocrystals consisting of a core with one or more shells of different materials are paving the way to achieve high PLQY. As those components have diverse lattice parameters, the induction of strain within the QDs is inevitable. Recently, we applied Raman spectroscopy for in depth structure characterization and a strain minimization approach to optimize the synthesis of InP/ZnSe/ZnS QDs towards near-unity PLQY. A similar effect plays a role in CdSe/CdS QDs when aiming for high PLQY. In these QDs, the formation of an alloyed interface between the CdSe core and CdS shell is assumed. By Raman spectroscopy, we are able to monitor the formation of these alloyed domains for different QD parameters and correlate it with the PLQY.

HL 24.2   Wed 9:45   POT 151

Collective Excitation of Spatio-Spectrally Distinct Quantum Dots Enabled by Chirped Pulses
— •Florian Kappe[1], Yusuf Karli[1], Thomas Bracht[2], Saimon Covre da Silva[3], Tim Seidelmann[4], Vollrath Martin Axt[4], Armando Rastelli[3], Gregor Weihs[1], Doris Reiter[2,5], and Vikas Remesh[1] — [1]Institute für Experimentalphysik, Universität Innsbruck, Innsbruck, Austria — [2]Institut für Festkörpertheorie, WWU Münster, Münster, Germany — [3]Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, Linz, Austria — [4]Theoretische Physik III, Universität Bayreuth, Bayreuth, Germany — [5]Condensed Matter Theory, TU Dortmund, Dortmund, Germany
To boost the communication rate in quantum communication devices, it is desirable to have an ensemble of single photon sources that can be collectively excited, despite their spectral variability. Rabi rotation, the most popular method for resonant excitation of the quantum dot, cannot assure a highly efficient state preparation, due to its sensitivity to the excitation parameters. Here, we demonstrate the robustness of Adiabatic Rapid Passage, using chirped laser pulses and collectively excite biexciton states [1] in energetically and spatially distinct quantum dots. We also demonstrate a regime of phonon contribution that widens the detuning range. Being able to generate high-purity photons from spatially multiplexed quantum dot sources with high efficiency is a big step towards the implementation of high photon rate quantum key distribution protocols. [1] Kappe et al, https://arxiv.org/abs/2209.08972 (in peer review)

HL 24.3   Wed 10:00   POT 151

Prospects of atomic vapor-based storage of single photons emitted by a deterministically fabricated quantum dot device
— •Avijit Barua[1], Benjamin Maass[2], Norman Vincenz Ewald[2], Suk-in Park[3], Sung-yul Park[3], Jin-Dong Song[3], Janik Wolters[2], and Stephan Reitzenstein[1] — [1]Technische Universität Berlin, Berlin, Germany — [2]German Aerospace Center (DLR), Berlin, Germany — [3]Korea Institute of Science and Technology, Seoul, Republic of Korea
Semiconductor quantum dots (QDs) are extensively investigated as single-photon sources for applications in photonic quantum technology. Here, we develop bright and strain-tunable QD single-photon sources at the Cs D1 transition wavelength and explore the storage ability of semiconductor QD in atomic quantum memories. The devices are designed and numerically optimized to maximize extraction efficiency using the finite element method. By considering circular Bragg resonators with integrated QDs and Au-backside mirror, we numerically demonstrate a photon extraction efficiency of 65% and a Purcell factor of 0.72. In the experimental development, we implement in-situ electron-beam lithography to precisely integrate selected single QDs at 894 nm in such structures to create bright single-photon sources. The emission from the developed quantum devices is studied by means of photon autocorrelation measurements. Furthermore, we explore the prospects of interfacing the QD single photons with a vapor-based quantum memory by employing a ladder-type EIT configuration that allows for low-noise storage and retrieval at high repetition rates.

HL 24.4   Wed 10:15   POT 151

Double pulse excitation schemes for enhanced multiphoton interference
— •Yusuf Karli[1], Florian Kappe[1], Julian Munzberg[1], Thomas Bracht[2], Saimon Covre da Silva[3], Armando Rastelli[3], Doris Reiter[2,4], Robert Keil[1], Vikas Remesh[1], and Gregor Weihs[1] — [1]Institute für Experimentalphysik, Universität Innsbruck, Innsbruck, Austria — [2]Institut für Festkörpertheorie, WWU Münster, Münster, Germany — [3]Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, Linz, Austria — [4]Condensed Matter Theory, TU Dortmund, Dortmund, Germany
High-efficiency generation multiphoton states is an important prerequisite for linear quantum computing applications. Semiconductor quantum dots are high-brightness sources of highly indistinguishable single photons, which can then be used to generate multiphoton states via active temporal-to-spatial demultiplexing. Resonant s-shell excitation is the most popular method to generate high-indistinguishability single photons from a quantum dot [1], however, at the cost of brightness from cross-polarization filtering. Here, we advocate the versatility of novel double-pulse excitation schemes by demonstrating an 8-fold enhancement in four-photon coincidence rates.

HL 24.5   Wed 10:30   POT 151

Towards deterministic generation of time-bin entangled photons from GaAs quantum dots
— •Florian Kappe[1], Yusuf Karli[1], Thomas Bracht[2], Saimon Covre da Silva[3], Armando Rastelli[3], Vikas Remesh[1], Doris Reiter[2,4], and Florian Kappe[1] — [1]Institut für Experimentalphysik, Universität Innsbruck, Innsbruck, Austria — [2]Institut für Festkörpertheorie, WWU Münster, Münster, Germany — [3]Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, Linz, Austria — [4]Condensed Matter Theory, TU Dortmund, Dortmund, Germany
Semiconductor quantum dots are bright, on-demand single photon sources suitable for realising quantum communication devices. Here, we present our first results towards the deterministic generation of time-bin entangled photon states via dark exciton states from GaAs/AlGaAs quantum dots. Our schemes employ chirped laser pulses and an external magnetic field that enables the coupling of bright and dark exciton states in the quantum dot [1,2]. Based on numerical methods we analyze the quantum dot dynamics and state preparation fidelity and identify that the preparation schemes are quite robust against the phonon influence.

Generation of indistinguishable and entangled photons at telecom frequencies using tailored cavity designs
— •David Bauch, Dustin Siebert, Jens Förstner, Klaus D. Jöns, and Stefan Schumacher — Department of Physics, Electrical Engineering and CeOPP, Paderborn University, Germany
The commonly utilized biexciton-exciton cascade yields photons with intrinsically limited indistinguishability [1]. By tuning the biexciton-exciton lifetime ratio, large increases in single photon indistinguishability can be achieved [1,2]. Using the cavity-induced Purcell enhancement is a simple method for radiative lifetime tuning. Employing a circular Bragg reflector at telecom wavelengths for suitable quantum dots allows for a Purcell enhanced biexciton-exciton transition, while still maintaining high extraction efficiency for the exciton-ground state transition. The decreased lifetime of the biexciton results in a faster emission of then indistinguishable single photons. Here, we demonstrate this effect numerically and determine the theoretically required parameters for the biexciton-exciton transition to yield highly indistinguishable single photons, which are also entangled with their exciton-ground state emission counterpart. We guide our calculations using Maxwell simulations for the cavity design, allowing for

close-to real-life system predictions. Our simulation demonstrates the robust increase of the indistinguishability of the emitted photons even when accounting for electron-phonon coupling at low temperatures.

Exciton diffusion in a quantum dot ensemble — •Karol Kawa and Paweł Machnikowski — Wrocław University of Science and Technology, 50-370 Wrocław, Poland

We study theoretically Förster transfer [1] of an exciton in an ensemble of quantum dots (QDs) randomly distributed on a circular mesa. In such a system energy transfer was observed experimentally within a spatially resolved photoluminescene sprectroscopy [2]. The analytical form of Förster coupling in the general ensemble of quantum dipole emitters is known [3–5]. It is a sum of three power-law terms diminishing with distance, each multiplied by an oscillating factor. The fundamental transition energy in each QD is randomized. We solve the equation of motion for the density matrix using the stochastic simulation method with a given exciton decay rate. Then, we present the evolution of the exciton mean square displacement (MSD) from the initially excited QD. It runs in three time stages. First, a ballistic motion, followed by a standard diffusion, which ends at saturation. Using an approximate analytical approach [6], we provide formulas that qualitatively reproduce all stages of the MSD.

Preparation of spin qubits in droplet-etched GaAs quantum dots using quasi-resonant excitation — •Caspar Hopfmann[1], Nand Lal Sharma[1], Weijie Nie[1], Robert Keil[1], Fei Ding[2], and Oliver G. Schmidt[1,3,4] — [1]Institute for Integrative Nanosciences, IFW Dresden, Helmholtzstr. 20, 01069 Dresden — [2]Institut für Festkörperphysik, Leibniz Universität Hannover, Appelstr. 2, 30167 Hannover — [3]Material Systems for Nanoelectronics, Technische Universität Chemnitz, 09107 Chemnitz — [4]Nanophysics, Faculty of Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, 01062 Dresden

Optically accessible quantum memories are fundamental for implementations of quantum networks as they facilitate the synchronization required for schemes of long-distance quantum information exchange. In order to use GaAs quantum dots, which so far has proven to be bright on-demand sources of entangled photon pairs, deterministic preparation of specific spin states is necessary. We present a comprehensive study on heralded spin preparation employing excited state resonances of droplet etched GaAs quantum dots. By observation of excitation spectra for a range of fundamental excitonic transitions the properties of different quantum dot energy levels, i.e. shells, are revealed. The innovative use of polarization-resolved excitation and detection in the context of quasi-resonant excitation spectroscopy of quantum dots greatly simplifies the determination of the spin preparation fidelities. By employing this method, spin preparation fidelities of quantum dot ground states of up to 85 % are found.

HL 24.9　Wed 12:00　POT 151

Effect of tunnel barrier thickness on optical properties of GaAs quantum dots embedded in Schottky diode structures — •Nand Lal Sharma[1], Moritz Langer[1], Ankita Choudhary[1], Oliver G. Schmidt[2], and Caspar Hopfmann[1] — [1]Institute for Integrative Nanosciences, IFW Dresden, Helmholtzstrasse 20, 01069 Dresden, Germany — [2]Material Systems for Nanoelectronics, Technical University Chemnitz, 09107 Chemnitz, Germany

GaAs quantum dots (QDs) are promising candidates for on demand generation of single and entangled photon pair sources for quantum communication applications. In these QDs, the charge stability and optical linewidth depend on the solid-state environment, which can be controlled by embedding them in a diode structure [1]. In this work we investigate the effect of tunnel barrier thickness on the optical properties of droplet etched GaAs/AlGaAs QDs [2], embedded in Schottky diode structures. The QD photoluminescence from different charge states is controlled by application of an external bias. The effects of quantum dot charging, quantum confined Stark effect and photon coherence are investigated as a function of tunnel barrier thickness.

HL 24.10　Wed 12:15　POT 151

Size-dependence of the Auger process in self-assembled quantum dots — •Hendrik Mannel[1], Marcel Zöllner[1], Fabio Rimek[1], Arne Ludwig[2], Andreas Wieck[2], Martin Geller[1], and Axel Lorke[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, Duisburg, Germany — [2]Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

Auger recombination is a non-radiative process, where the recombination energy of an electron-hole pair is transferred to a third charge carrier. In nanostructured materials, it is a common effect especially in colloidal quantum dots (QD), where short Auger recombination times $\tau_{Au} < 1\ ns$ quench the radiative recombination. In self-assembled QDs, an Auger recombination rate of $\tau_{Au} \approx 1\ ms$ has been observed [1].

We use resonance fluorescence to measure the Auger rate of differently sized self-assembled QDs having exciton recombination energies in the range of 920 to 980 nm [2]. The dots are charged with one electron before driving the trion transition to observe the quenching of this transition time-resolved on the investigated sample structure without a wetting layer.

Independently we can change the charge carrier occupation of the dot by gate voltage-dependent electron tunneling from the reservoir. This is a step to further understand the Auger effect and hopefully supress this unwanted effect in future application of quantum information processing.

HL 24.11　Wed 12:30　POT 151

Single Mode Coupled Emission of Resonant Excited GaAs Quantum Dots — •Martin Kernbach[1,2], Julian Siller[1], Sophia Fuchs[1], and Andreas W. Schell[1,2] — [1]Leibniz Universität Hannover, Deutschland — [2]Physikalisch-Technische Bundesanstalt, Braunschweig, Deutschland

Quantum technologies like computing, QKD, or sensing demand for deterministic bright sources of single indistinguishable photons. In order to provide quantum light of isolated systems properly usable for quantum information science, an efficient excitation and extensive collection in a single mode is required. Single molecules and cavity confined quantum dots are convenient sources. The coupling to the excited state is maximized on resonance, but challenges the usability of the emitter due to the costs for the separation of the optical excitation mode from the mode of emission. A temporal, spacial, spectral, or combined method for separation is typically used. Here we present a realization of a single emitter under resonant excitation in a con- focal setup coupled into a single mode fiber with the emission mode filtered by polarization. So far, a free beam is directed on the objective mounted with the scanning stages on a 1 m long stick in a liquid helium reservoir. For resonant cw excitation of GaAs semiconductor quantum dots a SNR of polarization suppression up to 100 and count rates of 280 kcps are archived by using a collecting lens with NA 0.68 only. Under this scheme further investigations regarding the blinking behavior are possible as well as probing alternative emitters like single molecules.

HL 24.12　Wed 12:45　POT 151

The role of charge transfer for light emission from excitonic complexes in a single quantum emitter — •Marcel Zöllner[1], Fabio Rimek[1], Hendrik Mannel[1], Andreas D. Wieck[2], Arne Ludwig[2], Martin Geller[1], and Axel Lorke[1] — [1]University of Duisburg-Essen, Germany — [2]Ruhr-University Bochum, Germany

Due to the non-radiative Auger recombination in self-assembled quantum dots [1], the light emission of the trion X^- is reduced. However, for devices and statistical analyses, such as random telegraph signals, the amount of quantum dot photons is of great importance.

With time-resolved resonance fluorescence (RF) measurements, we investigate a comparatively small quantum dot, where we can tune the rate of the electron tunneling from the back contact into the quantum dot by increasing the gate voltage. This results in an up to two orders of magnitude higher trion intensity. Due to the large gate voltages (i.e. energetically strongly tilted conduction band) the electrons can easily overcome the tunnel barrier. Thus, the electron tunneling becomes the dominant effect and charges the quantum dot significantly faster than the Auger effect can discharge it.

Our results indicate that thin tunneling barriers, which can quickly equilibrate states in a quantum dot, make its radiative recombination more resilient against spurious charge transfer (Auger, electron capture, internal photoemission). However, this improvement goes along with a short coherence time.

Single photon source in a topological cavity — Jonathan Jurkat[1], Sebastian Klembt[1], Marco De Gregorio[1], •Moritz Meinecke[1], Quirin Buchinger[1], Tristan Hader[1], Johannes Beierlein[1], Oleg Egorov[3], Monika Emmerling[1], Constantin Krause[1], Christian Schneider[2], Tobias Huber-Loyola[1], and Sven Höfling[1] — [1]Technische Physik, Physikalisches Institut and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany — [2]Lehrstuhl für Physik, Universität Oldenburg, 26129 Oldenburg, Germany — [3]Lehrstuhl für Kondensierte Materietheorie und Optik, Friedrich-Schiller-Universität Jena, 07743 Jena, Germany

The introduction of topological physics into the field of photonics has led to the development of photonic devices endowed with robustness against structural and photonic disorder. While a range of platforms have been successfully implemented demonstrating topological protection of light in the classical do-

main, the implementation of quantum light sources in photonic devices harnessing topologically non-trivial resonances is largely unexplored. Here, we demonstrate a single photon source based on a single semiconductor quantum dot coupled to a topologically non-trivial Su-Schrieffer-Heeger (SSH) cavity mode. We provide an in-depth study of Purcell enhancement for this topological quantum light source and demonstrate its emission of non-classical light on demand. Our approach is a promising step towards the application of topological cavities in quantum photonics.

HL 25: Perovskite and photovoltaics II (joint session HL/CPP)

Interfaces in perovskite optoelectronics: role of energy level alignment and interface chemistry — •SELINA OLTHOF — Universität zu Köln, Institut für Physikalische Chemie

Optoelectronic devices, such as perovskite solar cells, are typically multi-layer stacks in which the absorber layer is sandwiched between metal oxide and/or organic transport layers in order to facilitate charge extraction or ensure charge selectivity. As the perovskite absorber layer has been extensively optimized in the past years, the awareness is rising that device efficiency and stability is limited by the interfaces present in the device. However, in perovskite-based devices, the role of this energy level alignment remains to be elusive and rather inconclusive studies can be found in literature, which I will briefly outline. More important for the device seems to be the perovskite composition at the interface which can be significantly influenced by chemical reactions taking place, in particular next to metal oxides. I will summarize our work on a variety of metal oxides in which we use photoelectron spectroscopy to analyze which components are responsible for the strong interface chemistry. We show that the reactivity strongly depends on the choice of perovskite and that different metal oxides show fundamentally different reaction/degradation pathways. Intriguingly, we are able to introduce surface treatments which change the surface defect density and thereby affect the degree of perovskite degradation significantly.

HL 25.2   Wed 10:00   POT 251
Silver-nanoclusters and -vacancies influence the optical properties of Cs2AgBiCl6 nanocrystals — •FEI HE[1], YIOU WANG[1], QUINTEN A. AKKERMAN[1], MARKUS DÖBLINGER[2], AMRITA DEY[1], and JOCHEN FELDMANN[1] — [1]Chair for Photonics and Optoelectronics, Nano-Institute Munich and Department of Physics, Ludwig-Maximilians-Universität, Königinstraße 10, 80539 Munich, Germany — [2]Department of Chemistry, Ludwig-Maximilians-Universität München, Butenandtstrasse 5-13 (E), 81377 München, Germany

Though being indirect semiconductors Cesium-Silver-Bismuth-Halides (so-called double perovskites) have attracted much attention as a non-toxic alternative to Lead Halide Perovskites. Novel applications for solar cells and X-ray detectors have already been developed.

Here, we report on the successful synthesis of spherical Cs2AgBiCl6 nanocrystals showing good stability and characteristic photoluminescent spectra. In transmission electron microscopy (TEM) images we observe Ag-clusters on the surface of the nanocrystals. It is known that silver ions are easily reduced into metallic Ag leading to silver vacancies in the double perovskite material and probably to Ag-clusters on the surface. We discuss how silver-nanoclusters and -vacancies influence the luminescent behavior of the double perovskite nanocrystals and explain possible microscopic origins.

Accelerating research on solar cell materials with NOMAD — •JOSE MARQUEZ[1], LAURI HIMANEN[1], MARKUS SCHEIDGEN[1], CLAUDIA DRAXL[1], JENS HAUCH[2], CHRISTOPH BRABEC[2], and THOMAS UNOLD[3] — [1]Humboldt Universität zu Berlin — [2]Helmholtz Institute Erlangen-Nürnberg for Renewable Energy — [3]Helmholtz-Zentrum Berlin

New solar cell technologies need decades to overcome the 20% power conversion efficiency threshold needed to make them commercially viable. With thousands of possible chemical compositions for new absorber layer materials and an unlimited number of possible device architectures, it becomes impossible to navigate this material space without the help of data science. To radically accelerate and democratize this development process, FAIR data management activities involving experimental solar cell data are needed. The NOMAD Laboratory (https://nomad-lab.eu) is a platform and open-source software driven by the NFDI consortium FAIRmat (https://fairmat-nfdi.eu) for making materials-science data FAIR. We show how the NOMAD infrastructure is evolving to support this task in the context of solar cells, demonstrated by an app for visualizing and searching rich and AI-ready experimental big solar cell data. NOMAD also provides an electronic lab notebook (ELN) which can be customized by research labs for AI-ready data/metadata entry, transfer, and processing in a FAIR-database context.

HL 25.4   Wed 10:30   POT 251
Interdiffusion of Cu(In,Ga)Se2 and Ag(In,Ga)Se2 investigated by In-Situ X-Ray Diffraction — •JULIA HORSTMANN[1], ROLAND MAINZ[2], KARSTEN ALBE[3], HEIKO KEMPA[1], TORSTEN HÖLSCHER[1], and ROLAND SCHEER[1] — [1]Martin-Luther-Universität Halle-Wittenberg, Germany — [2]Helmholtz-Zentrum Berlin, Germany — [3]Technische Universität Darmstadt, Germany

The partial substitution of Ag with Cu in the chalcopyrite-based absorber of thin film solar cells is a promising approach towards higher power conversion efficiencies. The resulting (Ag,Cu)(In,Ga)Se2 (ACIGSe) alloy achieves a bandgap widening up to 0.2 eV, increased grain growth and a lower melting temperature. The latter might reduce structural defects and therefore recombination losses in the absorber. This is favorable especially for wide-bandgap solar cells, used as top subcells in tandem devices, whose device performance is mainly limited by deep defects. To gain a better understanding of the diffusion on the (I) sublattice, we experimentally explored the interdiffusion of Cu(In,Ga)Se2 and Ag(In,Ga)Se2 layers by in-situ X-ray diffraction (IS-XRD) and glow discharge optical emission spectroscopy. Besides the positive aspects of Ag-alloying, thermodynamic simulations have shown a miscibility gap for temperatures between 100°C and 400°C. It is theoretically proposed, that ACIGSe with a high Ga content and with a [Ag]/([Ag]+[Cu]) ratio between 0.25 and 0.75 decomposes into Ag-rich and Ag-poor phases. We have studied the phase stability of Ga-free and Ga-rich samples using IS-XRD during post-annealing processes.

HL 25.5   Wed 10:45   POT 251
NiO in perovskite solar cells: a peculiar interplay of degradation, passivation and device performance — •JOHN MOHANRAJ[1], BIPASA SAMANTA[2], MAYTAL CASPARY TOROKAR[2], and SELINA OLTHOF[1] — [1]University of Cologne, 50939 Cologne, Germany — [2]Technion - IIT, Haifa, 3200003 Israel

The degradative interactions at the NiO/perovskite interface are notorious in the perovskite community as they lead to significant Voc and stability losses in p-i-n type perovskite solar cells (PSCs). So far, various Lewis bases have been introduced at this interface to passivate the metal oxide surface defects. Despite this process being successful in minimizing Voc and stability losses in PSCs, in-depth understanding of surface passivation and consequent suppression of the chemical processes at the NiO/perovskite interface are still elusive. This calls for a comprehensive surface investigation. To address these issues, we investigated solution processed NiO surfaces, their treatment with a series of passivating compounds, and the interface towards MAPbI3 in order to systematically probe the interface stability. Our methods include X-ray and UV photoelectron spectroscopy (XPS/UPS), XRD, SEM and UV-Vis absorption techniques. In parallel, first principle DFT calculations on differently treated NiO/MAPbI3 interfaces were carried out. These complementary investigations reveal changes in surface composition of the treated NiO and help us to suggest possible mechanisms for the degradative interactions. Finally, PSCs were fabricated using the stabilized NiO interfaces, and the impact on photovoltaic characteristics and device stability have been investigated.

Resonant coupling of spin-flip excitations with phonons in BiFeO3 — •ASEEM RAJAN KSHIRSAGAR and SVEN REICHARDT — Department of Physics and Material Science, University of Luxembourg, Luxembourg

BiFeO3 is a technologically relevant multiferroic perovskite. While a vast literature exists on its electronic, optical, and multiferroic properties, some of its optically active electronic excitations remain to be understood or have been interpreted in ambiguous ways. This applies in particular to features below the absorption onset that feature prominently in resonant Raman scattering [1]. Here we present a detailed study of the electronic structure and resonant Raman spectrum of BiFeO3 from first principles. Using many-body perturbation theory on top of density functional theory, we first analyze and characterize its optical absorption spectrum in terms of excitons and atomic orbitals, focusing in particular on spin-flip excitations that are strongly localized. We then use the state-of-the-art method for the ab initio calculation of resonant Raman intensities [2,3] to analyze the resonant coupling of these finite-spin excitations with phonons. Our results show that these only weakly optically active excitations still leave a clear imprint on the resonant Raman spectrum, making the latter an even more powerful tool to probe "darker" electronic excitations.

HL 25.7   Wed 11:45   POT 251

Coherent Phonons in Halide Perovskite Nanocrystals — •Julian Georg Mann[1], Fei He[1], Quinten Akkerman[1], Tushar Debnath[2], and Jochen Feldmann[1] — [1]Chair for Photonics and Optoelectronics, Nano-Institute Munich and Department of Physics, Ludwig-Maximilians-Universität (LMU), Königinstr. 10, 80539 Munich, Germany — [2]Centre for Nanotechnology, Indian Institute of Technology Guwahati, Guwahati-781039

Halide perovskite nanocrystals are gaining increasing attention in contemporary research due to their promising performance in both light-emitting and solar technologies. We recently showed that photoexcitation of halide-perovskite nanocrystals with ultrashort laser pulses produces coherent phonons (Nat. Comm. 12, 2629 (2021)). We report femtosecond pump-probe spectroscopy studies on the formation and dynamics of coherent phonons in formamidine lead-halide ($FAPbX_3$) nanocrystals in terms of higher harmonic vibrational modes. In addition, we investigate the dynamics of vibrational wave packets in spherical $Cs_2AgBiBr_6$ double perovskite nanocrystals. Here, we observe that optically launched vibrational wave-packets alter spectral positions of excitonic resonances or oscillator strength of particular electronic transitions. Our results show that electron-phonon couplings (polaronic effects) need to be considered to fully understand the optoelectronic properties of halide-perovskite semiconductors.

HL 25.8   Wed 12:00   POT 251

Phonon-driven Intra-exciton Rabi Oscillations in Halide Perovskites — •Katrin Winte[1], Xuan Trung Nguyen[1], Daniel Timmer[1], Davide Ceratti[2], Caterina Cocchi[1], Michael Lorke[3], Frank Jahnke[3], David Cahen[2], Christoph Lienau[1], and Antonietta De Sio[1] — [1]University of Oldenburg, Germany — [2]Weizmann Institute of Science, Israel — [3]University of Bremen, Germany

There is increasing consensus that in halide perovskites (HaPs) the interaction of electronic excitations with the phonon modes of their flexible polar lattice is crucial for the unique optoelectronic and transport properties of these materials. Here we show that coherent low frequency phonon of the lead-halide lattice induce Rabi oscillations between 1s and 2p excitons in $CsPbBr_3$ crystals. Ultrafast two-dimensional electronic spectroscopy reveals an excitonic peak structure oscillating with a 100-fs period up to 2 ps at 20 K. This frequency does not match any phonon modes of the crystals. Only after 2 ps, slow coherent phonon oscillations dominate the dynamics. We rationalize these findings as off-resonant intra-exciton Rabi oscillations induced by the Pb-Br phonon fields of the HaP crystals. We show that the slow motion of Pb-Br sublattice induces electric fields at THz frequencies that are sufficiently strong to drive off-resonant population oscillations between 1s and 2s excitons. Model simulation of the nonlinear optical response support this interpretation. This goes beyond prevailing models for the electron-phonon coupling in HaPs. It suggests that the coupling of characteristic low frequency phonon to intra-excitonic transitions may be the key to control their anharmonic response.

HL 25.9   Wed 12:15   POT 251

Determining (almost) all optoelectronic properties of halide perovskites by transient photoluminescence — •Hannes Hempel[1], Martin Stolterfoht[2], Fangyuan Ye[2], and Thomas Unold[1] — [1]Helmholtz Zentrum Berlin, Germany — [2]Institute of Physics and Astronomy, University of Potsdam, Germany

Time-resolved photo luminescence (trPL) is probably the most common technique to quantify lifetimes of photogenerated charge carriers in semiconductors. However, the usual fitting of exponential decays to estimate lifetimes is a rather crude phenomenological approach since it ignores quenching processes that are not connected to carrier recombination and disregards the absolute amplitude of the luminescence. Here, we present an analysis of injection-dependent absolute trPL transients of bare triple-cation lead halide perovskite thin films. The presented analysis reveals a doping concentration of 3x1013cm-3 and a charge carrier mobility of 0.8 cm2/Vs, which are confirmed by Hall measurements. Further, we determine the injection-dependence of external radiative lifetimes, of the external radiative coefficient, and of the effective charge carrier lifetime. Based on the properties, an implied current-voltage curve is constructed that reveals the potential performance of the material in solar cell. Our trPL-based approach agrees well with the results of injection-dependent photoluminescence quantum yield measurements. However, it is superior in attributing losses, e.g. in the radiative ideality factor or the implied open circuit voltage, to the internal optoelectronic properties and thereby indicates the path to overcome these losses.

HL 25.10   Wed 12:30   POT 251

Characterization of optoelectronic properties of CsSnI3 perovskite thin film as a function of chemical composition. — •Fatima Akhundova, Hannes Hempel, Marin Rusu, Elif Hüsam, Marcus Bär, and Thomas Unold — Helmholtz-Zentrum Berlin

The performance of lead-based halide perovskites as a next generation solar cell rises every year, however toxicity of Pb is a major obstacle for commercialization. Tin is the immediate substitute for Pb in perovskite crystal structure as both metals possess the same electronic configuration. However, Sn-perovskite solar cells have significantly lower efficiencies which is partially caused by poor stability of Sn(II). We report a systematic study of structural and optoelectronic properties of co-evaporated CsSnI3 thin films with regard to lateral compositional gradient. Elemental compositions are confirmed by X-ray fluorescence and X-ray photoelectron spectroscopy techniques. Grazing-incidence X-ray diffraction reveals orthorhombic gamma phase with different preferred orientation for the excess Sn and Cs content. Moreover, Cs-rich regions shows better phase stability than the Sn-rich parts which undergo a phase transition to non-perovskite phase. The optical band gap, work function, and ionization energy are measured as a function of the Cs:Sn ratio to characterize the band diagram. The photoluminescence quantum yield, the charge carrier lifetime and mobility present these properties are rather robust against changes in composition. Our work emphasizes the impact of chemical composition on optoelectronic properties of Sn-based perovskites and demonstrates agile strategy for compositional engineering in materials research.

HL 25.11   Wed 12:45   POT 251

FAIR Cesium Lead Halide Perovskites Data by High-Throughput Investigation of Co-Evaporated Combinatorial Libraries — •Hampus Näsström[1], Pascal Beblo[2], Fatima Akhundova[2], Oleksandra Shargaieva[2], Jose A. Marquez[1], Hannes Hempel[2], Andrea Albino[1], Sebastian Brückner[1], Claudia Draxl[1], Eva Unger[2], and Thomas Unold[2] — [1]Humboldt-Universität zu Berlin — [2]Helmholtz-Zentrum Berlin

Artificial intelligence presents new possibilities in experimental materials research but typically require large well-characterized datasets. High-throughput technologies, including combinatorial synthesis, provide one method for obtaining such datasets. In this work, we show how such a dataset can be created through combinatorial co-evaporation and high-throughput characterization of $Cs_yPb_{1-y}(Br_xI_{1-x})_{2-y}$ perovskites. The evaporated films were investigated with a multitude of contact-less characterization methods such as hyperspectral photoluminescence imaging, time-resolved photoluminescence mapping, and grazing-incidence wide-angle X-ray scattering mapping. The results were combined to estimate the potential of the material in terms of the photovoltaic power conversion efficiency as a function of the Cs to Pb and Br to I ratio. Finally, a generalized data schema for combinatorial thin films was developed, and the data of the 3456 individual samples was disseminated in a Findable, Accessible, Interoperable and Reusable (FAIR) way within the Novel Materials Discovery (NOMAD) laboratory (nomad-lab.eu) that is operated by the NFDI consortium FAIRmat (fairmat-nfdi.eu).

A systematic DFT+U and Quantum Monte Carlo benchmark of magnetic two-dimensional (2D) CrX₃ (X = I, Br, Cl, F) — •Daniel Wines, Kamal Choudhary, and Francesca Tavazza — Materials Science and Engineering Division, National Institute of Standards and Technology (NIST), Gaithersburg, MD 20899, USA

The search for two-dimensional (2D) magnetic materials has attracted a great deal of attention because of the experimental synthesis of 2D CrI₃, which has a measured Curie temperature of 45 K. Often times, these monolayers have a higher degree of electron correlation and require more sophisticated methods beyond density functional theory (DFT). Diffusion Monte Carlo (DMC) is a correlated electronic structure method that has been demonstrated successful for a wide variety of systems, since it has a weaker dependence on the Hubbard parameter (U) and density functional. In this study we designed a workflow that combines DFT+U and DMC in order to treat 2D correlated magnetic systems. We chose monolayer CrX₃ (X = I, Br, Cl, F), with a stronger focus on CrI₃ and CrBr₃, as a case study due to the fact that they have been experimentally realized and have a finite critical temperature. With this DFT+U and DMC workflow and the analytical method of Torelli and Olsen, we estimated an upper bound of 43.56 K for the T_c of CrI₃ and 20.78 K for the T_c of CrBr₃, in addition to analyzing

the spin densities and magnetic properties with DMC and DFT+U. We expect that running this workflow for a well-known material class will aid in the future discovery and characterization of lesser known and more complex correlated 2D magnetic materials.

TREX: an integrated HPC software platform for quantum Monte Carlo calculations — •Claudia Filippi — University of Twente, Enschede, The Netherlands

I will present the software development strategy and current achievements of the European Center of Excellence TREX "Targeting Real chemical accuracy at the EXascale" [1]. TREX focuses on methods at the high-end in the accuracy ladder of electronic structure approaches and, in particular, on quantum Monte Carlo methods which are uniquely positioned to fully exploit the massive parallelism of upcoming architectures. The main objective of TREX is the development of a user-friendly and open-source software suite, which integrates quantum Monte Carlo codes within an interoperable, high-performance platform. Core of our software efforts is the creation of the following two libraries:

TREXIO: A common I/O library and file format for easily exchanging data between applications, facilitating high-throughput computing workflows [2];

QMCkl: A library of computational kernels, written together by quantum Monte Carlo and HPC experts, to perform common CPU-intensive quantum Monte Carlo tasks [3].

HL 26.3 Wed 11:15 TRE Ma
Exciton-phonon coupling in luminescence of indirect band-gap materials — Matteo Zanfrognini[1,2], Fulvio Paleari[1], Daniele Varsano[1], and •Ludger Wirtz[3] — [1]Centro S3, CNR-Istituto Nanoscienze, Modena, Italy — [2]Università di Modena e Reggio Emilia, Modena, Italy — [3]Department of Physics and Materials Science, University of Luxembourg, Luxembourg

Layered, quasi-2D materials, such as hexagonal boron nitride (hBN) are known to display very strong excitonic effects due to the concentration of excitons in two dimensions and due to the relatively weak dielectric screening. If the band-gap of the material is indirect, the dispersion of the lowest lying exciton can have a minimum at a finite wave vector q. Upon absorption of a photon and excitation to a vertical (q=0) exciton, the system will relax to the finite-q exciton. Luminescence then entails the absorption/emission of a phonon with wave vector q. We present a computational approach for phonon-assisted luminescence in the presence of strong excitonic effects using two approaches: (i) a finite-displacement approach for the exciton-phonon coupling and (ii) a diagrammatic approach, calculating the q-dependent exciton-phonon coupling from the exciton eigenvectors and electron/hole-phonon scattering matrix elements. We show that the methodology quantitatively explains recent measurements of different stackings of BN layers. [1]

HL 26.4 Wed 11:30 TRE Ma
A combined G_0W_0/BSE scheme of characterizing photoexcitations in hydroxylated rutile $TiO_2(110)$ — •Savio Laricchia, Andrea Ferretti, Daniele Varsano, and Claudia Cardoso — Centro S3, CNR-Istituto Nanoscienze, 41125 Modena, Italy

In reduced TiO_2, electronic transitions originating from polaronic excess electrons in surface-localized band-gap sta tes (BGS) are known to contribute to the photoabsorption and to the photocatalytic response of TiO_2 in the visible region. Recent state-selective studies using two-photon photoemission (2PPE) spectroscopy have also identified an alternative photoexcitation mechanism contributing to the photoabsorption of the reduced surface (110) of rutile TiO_2. This process involves d-d excitations from BGS arising from surface and subsurface defects, including bridging hydroxyls and oxygen vacancies. Density Functional Theory (DFT) has been used to determine the character of the electronic excited states involved in a $d_{t_{2g}}$-$d_{t_{2g}}$ transitions, but its accuracy is questioned by its theoretical framework: DFT is in principle exact for ground state systems and does not describe interacting photogenerated electron-hole pairs, i.e. the excitons. This has highlighted the need to move beyond the DFT formalism, by working within a many-body perturbation theory (MBPT) framework. It will be shown how a G_0W_0 method, combined with the solution of the Bethe-Salpeter equation (BSE), provides a powerful tool for characterizing from first principles the optical excitations from BGS identified by 2PPE experiments on hydroxylated $TiO_2(110)$.

Scaling the Way for All-Electron XPS Simulations to CalculateAbsolute Binding Energies of Surface Superstructures — •Dylan Morgan[1], Sam Hall[1], Benedikt Klein[1,2], Matthew Stoodley[1,2], and Reinhard Maurer[1] — [1]Department of Chemistry, University of Warwick, United Kingdom — [2]Diamond Light Source, Harwell Science and Innovation Campus, United Kingdom

First principles simulations of x-ray photoemission spectroscopy (XPS) and near-edge x-ray absorption fine-structure (NEXAFS) crucially support the assignment of surface spectra composed of many overlapping signatures. Core-level constrained Density Functional Theory calculations based on the Δ-SCF method are commonly used to predict relative XPS binding energy (BE) shifts but often fail to predict absolute BEs. The all-electron numeric atomic orbital code FHI-aims enables an accurate prediction of absolute BEs, but the legacy code lacked computational scalability to address large systems and robustness with respect to localisation of the core hole. We present a redesign of the core-hole constrained code in FHI-aims that delivers improvements to the scalability and robustness of core-hole constrained calculations in FHI-aims. We demonstrate the improved scaling behaviour and employ the new code to simulate core-level spectroscopic fingerprints of graphene moire superstructures. The code refactorisation forms the basis to expand the code towards improved core hole localisation methods and the rigorous treatment of relativistic effects for core-level spectra beyond the 1s shell.

HL 26.6 Wed 12:15 TRE Ma
Efficient diagonalization of BSE electron-hole Hamiltonian using group theory — •Jörn Stöhler[1,2], Dmitrii Nabok[1], Stefan Blügel[1], and Christoph Friedrich[1] — [1]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, Germany — [2]RWTH Aachen University, Germany

The Bethe-Salpeter equation (BSE) is the state-of-the-art method for the calculation of optical absorption and electron-energy loss spectra including excitonic effects. We solve the BSE by diagonalizing an effective electron-hole Hamiltonian. Often, a high number of **k**-points is needed to converge the BSE spectra, which leads to a large size of the Hamiltonian matrix and makes its diagonalization very expensive. In this work [1], we use the full spatial symmetry group to transform the electron-hole product basis into a symmetry-adapted product basis, which brings the Hamiltonian into a block-diagonal form and speeds up the subsequent diagonalization. The basis transformation is sparse and causes little overhead. We provide an implementation of our method in the FLAPW code Spex and demonstrate speedups of 36, 52, 12 for Si, BN, and monolayer MoS_2, respectively.

We acknowledge financial support by MaX CoE funded by the EU through H2020-INFRAEDI-2018 (project: GA 824143).

Excitonic effects on quadratic optical photoresponse tensors of semiconductors — •Peio Garcia-Goricelaya[1] and Julen Ibañez-Azpiroz[1,2] — [1]Centro de Física de Materiales, University of the Basque Country UPV/EHU, Spain — [2]IKERBASQUE Basque Foundation for Science, Spain

We present a general ab initio scheme for including many-body excitonic effects in the non-linear optical photoresponse up to second order. Our practical implementation starts from the length-gauge formulation of the single-particle non-interacting optical photoresponse tensors [1] that are efficiently calculated using Wannier interpolation [2]. Subsequently, excitonic corrections are included in the many-body interacting current-density response tensors by means of Dyson-like equations derived within TD-CDFT. These equations allow a natural connection with the formalism of the single-particle picture and the Wannier-interpolation scheme respecting the tensorial character of the response. We employ this scheme to assess the impact of excitonic effects on several quadratic optical processes as the second-harmonic generation and the shift-current bulk photovoltaic effect in technologically appealing semiconductors.

Electronic and optical properties of $CoFe_2O_4$ from density functional theory calculations, including many-body effects — •Shohreh Rafiezadeh[1], Vijaya Begum-Hudde[1,2], and Rossitza Pentcheva[1] — [1]Department of Physics University of Duisburg-Essen, Germany — [2]University of Illinois at Urbana-Champaign, USA

$CoFe_2O_4$ is a ferrimagnetic semiconductor that finds application as an anode material in photocatalytic water splitting. We present a comprehensive study of the electronic and optical properties of bulk $CoFe_2O_4$ using density functional theory calculations and many-body perturbation theory to clarify the broad range of reported band gaps both experimentally (0.55-4.1 eV)[1] and theoreti-

cally (0.9-1.90 eV). Starting with different exchange-correlation functionals, we obtain a direct band gap of 1.38 [PBE+(U=4 eV)], 1.69 eV [SCAN+(U=3 eV)], and an indirect gap of 2.02 eV (HSE06). Including quasiparticle corrections within G_0W_0 enhances and renders indirect band gaps for all functionals of 1.78, 1.95 and 2.17 eV, respectively. Excitonic effects are accounted for by solving the Bethe Salpeter equation and result in the lowest threshold for optical transitions at 1.50 eV (SCAN) and 1.61 eV (HSE06), followed by peaks at ∼ 2.0, 3.5 and 5.0 eV, in agreement with experiment highlighting the importance of electron-hole interactions. Support by DFG- within CRC/TRR 247, project B04, and computational time at MagnitUDE is gratefully acknowledged. [1] S. Singh and N. Khare, Sci. Rep. **8**, 6522 (2018).

HL 27: Focus Session: Wissenschaftskommunikation / Outreach (joint session HL/O/TT)

Im wissenschaftlichen Umfeld wird Maßnahmen der Öffentlichkeitsarbeit eine zunehmend größere Bedeutung zugemessen, - aus der Gesellschaft heraus und auch durch die großen Fördereinrichtungen und die DPG. Dabei geht es nicht nur um die Ergebnisse der Forschung, sondern auch darum, Prozesse und Methoden von wissenschaftlicher Arbeit transparent abzubilden – eine Aufgabe, die prinzipiell alle Forschenden übernehmen können. In diesem Symposium sollen erfolgreiche Projekte der Wissenschaftskommunikation, insbesondere aus dem Bereich der Festkörperphysik, vorgestellt werden. In ihrer Gesamtheit sollen sie das Spektrum der Wissenschaftskommunikation hinsichtlich des finanziellen und zeitlichen Aufwands aufzeigen und Methoden für unterschiedliche Zielgruppen vorstellen.

So dient diese Session sowohl als Ideengeber und Inspiration als auch als eine Art Netzwerk-Treffen zum Austausch über die Wissenschaftskommunikation in unterschiedlichen Kontexten.

Time: Wednesday 15:00–18:30   Location: POT 81

Invited Talk   HL 27.1   Wed 15:00   POT 81
experimentamus! Forschendes Lernen von Physik und Chemie in der Grundschule — •Sebastian Schlücker — Universität Duisburg-Essen, Campus Essen
Der Sachunterricht in der Primarstufe ist ein Konglomerat aus allen Natur- und Gesellschaftswissenschaften, erst in der Sekundarstufe findet eine Aufspaltung in die einzelnen Fächer statt. Zudem unterrichten viele Grundschul-Lehrkräfte fachfremd. Auch der Zeitaufwand für die Vorbereitung von Experimenten ist nicht unerheblich. Wie also kann man trotz dieser Hürden kindgerechte physikalische und chemische Experimente bereits in der Grundschule einführen?

Ich berichte aus 10 Jahren Erfahrung mit dem Projekt experimentamus!. Dabei handelt es sich um einen Kanon aus ca. 40 Experimenten für die Klassen 2 bis 4, welcher die Themen Licht, Wärme, Magnetismus, Wasser, Luft, Feuer und Elektrizität mit einem kindgerechten Alltagsbezug abdeckt. Anstelle des darlegenden Lernens wird auf das Forschende Lernen gesetzt: Frage - Hypothese - Experiment - Beobachtung - Erklärung; diese fünf Stationen des wissenschaftlichen Erkenntnisprozesses werden immer wieder durchlaufen. Ganz im Sinne Martin Wagenscheins wird dabei nach der exemplarischen und sokratischen Methode vorgegangen. Die praktische Implementierung umfasst 1. Materialkisten für alle Themen, 2. kompakte und leicht verständliche Informationshefter für die Lehrkräfte, sowie 3. Lernheftchen für alle SuS. Am Ende möchte ich über Erfahrungen und Herausforderungen im Rahmen dieses Projektes berichten und Ideen für eine mögliche weitere Verbreitung vorstellen.

HL 27.2   Wed 15:30   POT 81
Internal interfaces - goals and realisation of a scientific image film — •Ulrich Höfer[1,2] and Michael Dürr[2,3] — [1]Fachbereich Physik, Philipps-Universität Marburg — [2]SFB 1083, www.internal-interfaces.de — [3]Institut für Angewandte Physik, Justus-Liebig-Universität Giessen, Germany
Funded by the German Science Foundation (DFG), a professional film maker has produced an image film about the research conducted in the Collaborative Research Center SFB 1083 "Structure and Dynamics of Internal Interfaces". The six-minute video clip takes the non-specialist on a journey down to atomic scale to show the progress at the forefront of research at solid/solid interfaces. It is not a demanding educational film. Rather, it is a visually stunning piece that looks like science fiction taken straight out of a movie, with tracking shots that take the viewer down to the nanometer scale, with flights through luminous molecules, exotic excitons, and space-filling laser labs. The film also has a very impressive soundtrack. Gustav Holst's (1874-1934) composition "The Planets" was re-orchestrated especially for this film. It is available on the youtube channel of the DFG (https://www.youtube.com/watch?v=_-mDt0NzHrc). Visitors of Chemikum Marburg can watch the German version on a 4K OLED screen, a device actually based on microscopic processes at interfaces investigated by SFB 1083. The idea behind the creation of a professional film, its conceptional design and the necessary steps towards its realization will be outlined.

HL 27.3   Wed 15:45   POT 81
Outreach activities of SFB 1083 @ Chemikum Marburg — •Christof Wegscheid-Gerlach, Luise Cleres, Ina Budde, Karl-Heinz Muth, and Marion Enssle — Chemikum Marburg / SFB1083
The diffusion of concepts, methods, and visions of the SFB 1083 on Structure and Dynamics of Internal Interfaces into the general public is our general goal. To this end project Ö makes use of the institution Chemikum Marburg e.V., whose basic idea is to fascinate the public excited about natural sciences. The experiments offered here, stand for chemical, biological, pharmaceutical, and physical subjects related with daily phenomena or beyond. We will give an overview about the introduction of basic ideas and methods of SFB 1083 to the public as well as the institution Chemikum Marburg. The contents of the individual offers, such as experiments within the regular workspace, the workshops for the Girls' Day and the compilation of special workshops that are offered to give high-school students an understanding of the research content of the SFB 1083 are presented. An additional topic is the linking of basic research to applications for regenerative energy resources. Hydrogen fuel cells are well-known to the general public and rely on functional internal interfaces. An additional workshop which was prepared in cooperation with the district Marburg-Biedenkopf gives an overview about production, storage, and application of hydrogen as a new energy resource. We will also share various occasions at Chemikum Marburg where further outreach activities represent SFB 1083.

Invited Talk   HL 27.4   Wed 16:00   POT 81
Under the Microscope – spotlighting materials and nano science — •Svenja Lohmann and Pranoti Kshirsagar — The Science Talk, Germany
Real Scientists Nano is a science communication project dedicated to materials and nano science. Despite the widespread relevance of materials science to everyday life, we feel that dedicated science communication in this area is much rarer than in other fields. Our aim is to provide a platform for active materials and nano scientists to directly communicate their science and life as a scientist to the public. The use of social media thereby provides a very low threshold to science communication as basically the only requirement is to have an account. We have the goal to showcase the scientific community in all its diversity, and so far (12/2022) had guest scientists from more than 30 countries of origin as well as various fields and career stages. The two main pillars of the Real Scientists Nano project are the @RealSci_Nano Twitter account and the Under the Microscope podcast. Our guest scientists are interviewed for one podcast episode, and subsequently get to tweet from the account for one week following the rotation curation concept. We let curating scientist decide for themselves what they would like to tweet about. The form and content therefore vary greatly. Many of our scientists report from their everyday life, and are for example live-tweeting from a conference, uploading videos or photos from the lab or sending the occasional "stuck in meetings, will return later" tweet. Science communication on social media thus gives the opportunity to open a direct and real-time window into the scientist's life.

Invited Talk   HL 27.5   Wed 17:00   POT 81
Phyphox – A pocketful of physics — •Christoph Stampfer — JARA-FIT and 2nd Institute of Physics, RWTH Aachen University, Germany — Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich, Germany
Most smartphones are used to make phone calls, to write short messages, surf the Internet or check e-mails. However, they can do much more: With the help of the integrated sensors and the free app "phyphox" (abbreviation for Physical Phone Experiments), pupils, students, and teachers and interested others can independently perform and develop physics experiments. For example, the app can use the accelerometer to record pendulum movements and determine the rotational acceleration in a salad spinner, or the air pressure sensor to deter-

mine time-resolved differences in altitude and thus the speed of an elevator. The didactic potential of the app is great, as the students are picked up on ground that is very familiar and attractive to them (smartphones) and are introduced to experimental natural sciences in a playful way and with an extremely low barrier (zero cost, i.e. only one click away). The app helps to get students excited about scientific and technical questions and contexts at an early age. The app is available free of charge for Android and iOS (more information can be found at www.phyphox.org). In my presentation, I will go into the concept of phyphox, introduce the range of functions and show a number of application examples.

Chair PR representative as a doctoral student's secondary task: A field report — •Paula M. Weber, Felix Friedrich, and Manuel Seitz — Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany

Especially in recent years, it has become more important to communicate one's scientific work and methods to the public in order to show that in the scientific world, knowledge can only be created through research and the scientific process. Yet, extra time besides research is often limited and it is thus difficult to get into science communication. In this talk, I would like to present how PhD students can use their interest in science communication to benefit their own research group as a part-time PR representative.

In the first part of my talk, I will report on our efforts to attract new bachelor and master students. This advertising is focused on an audience with a scientific background, such that lab tours and advertising posters may contain scientific language and references. The second part is about communication with the general public, who usually know physics from their school days. Here, I will report on how we presented our research activities at the Night of Science in Physics and at the "Highlights der Physik" in Würzburg.

Working part-time as a PR representative could encourage doctoral students to try their hand at science communication and develop the associated communication skills.

HL 27.7   Wed 17:45   POT 81

Real or Fake - A format in science communication that encourages critical thinking — •Tobias Löffler — Institut für Angewandte Physik Düsseldorf

The outreach format "Real or Fake" aims to train the audience in an critical approach to credible-sounding facts.

It is aimed at the general public and specifically at young people. At the same time, it offers an easy introduction for scientists to audience-oriented communication of science on stage. The format can be performed in front of a live audience or as an interactive online event. It has been proven to work as implemented into science festivals, nights of sciences, as a public individual event and also as part of events with constrained settings - such as outreach events at schools or as part of conferences.

"Real or Fake" was developed in 2017 by scientists around the Berlin March for Science who later founded Besserwissen e.V. with the goal to promote the format and support new organisers. I do cooprate with them since 2019 and have organized more than ten "Real or Fake" events since then.

In my talk, I will present the concept and its origins, give an overview of successful events and show what to do and what support one can get, if one wants to organize a "Real or Fake" event.

Invited Talk   HL 27.8   Wed 18:00   POT 81

Physics for school and the public at the LMU — •Dr. Cecilia Scorza-Lesch — Fakultät für Physik der LMU, München

Germany lives from research and technology. Physics, as the basis of all empirical sciences and technologies, has a very special, fundamental role to play. The Faculty of Physics at LMU, the largest in Germany, comprises nine research areas, three centres and two excellence clusters. In this talk we will present the approach we use to successfully communicate our various topics of modern research, the role of physics in our daily lives and in the fight against global warming to the schools and the public in a participatory way.

HL 28: Focus Session: Breakthroughs in wide-bandgap semiconductor laser diodes II

Time: Wednesday 15:00–16:45   Location: POT 361

Invited Talk   HL 28.1   Wed 15:00   POT 361

Fabrication of AlGaN-based UV-B laser diodes on lattice-relaxed high-quality AlGaN — •Motoaki Iwaya[1], Sho Iwayama[1,2], Tetsuya Takeuchi[1], Satoshi Kamiyama[1], and Hideto Miyake[2] — [1]Meijo Univ., Nagoya, Japan — [2]Mie Univ., Tsu, Japan

Recently, AlGaN-based ultraviolet (UV) light-emitting devices have been achieving remarkable performance. Highly efficient UV light-emitting diodes are finding applications in many fields, such as water and air sterilization. Meanwhile, room-temperature oscillation of laser diodes in the UV-C and UV-B region has also been realized in recent years by current injection. In this presentation, we show our realization of UV-B laser diode. To realize UV-B laser diodes, it is essential to fabricate them on lattice-relaxed AlGaN because the lattice mismatch between AlN and AlGaN active layers is at least 1.2%. We have obtained various methods for improving the quality of lattice-relaxed AlGaN, and would like to report on the methods and effects. As specific methods to fabricate lattice-relaxed high-quality AlGaN, we explain AlGaN fabricated by the spontaneous nucleation method and the AlN nanopillar method. We will also discuss the correlation between lattice defects such as dislocations, V-shaped pits, and hillocks and device properties. And we would like to present the characteristics of UV-B laser diodes fabricated on such AlGaN templates.

Invited Talk   HL 28.2   Wed 15:30   POT 361

Breakthrough technologies to realize room-temperature continuous-wave deep-ultraviolet laser diodes — •Maki Kushimoto — Nagoya University, Nagoya, Japan

AlGaN-based UVC laser diodes operating at wavelengths are expected to be a low-cost, environmentally friendly, and highly efficient laser light source for a variety of applications. Although the pulsed operation of AlGaN-based laser diodes at UV-C wavelengths has been confirmed in the previous studies, continuous wave lasing without cooling was difficult because of the high operating voltage. In this study, we further reduced the threshold gain by improving the optical confinement and improved the threshold current density while lowering drive voltage by modification of device designs. The new design improved the optical confinement factor to the quantum wells from 4% to 6% , which has led to a significant reduction in threshold current density. Furthermore, A reduction in threshold voltage was achieved by reducing the lateral distance between the n- and p-electrodes by tapering the sides of the LD mesa. In the conventional structure, the presence of process-induced crystal defects forced a distance between the n and p electrodes, which was a major factor in increasing the operating voltage. This tapered mesa performs the role of suppressing crystal defects by controlling shear stress of mesa edge. As a result, room temperature CW lasing at a wavelength of 274 nm with a threshold current density of 4.2 kA/cm^2 and a voltage of 8.7 V was successfully achieved.

HL 28.3   Wed 16:00   POT 361

Spectral dynamics of lateral modes and filaments in InGaN broad-ridge laser diodes — •Lukas Uhlig[1], Dominic J. Kunzmann[1], Anna Kafar[2,3], Szymon Grzanka[2,3], Piotr Perlin[2,3], and Ulrich T. Schwarz[1] — [1]Chemnitz University of Technology, Chemnitz, Germany — [2]Institute of High Pressure Physics, Polish Academy of Sciences, Warsaw, Poland — [3]Top-GaN Ltd., Warsaw, Poland.

Blue InGaN broad-ridge laser diodes are versatile, efficient, and compact high power emitters, which are demanded for copper welding, white light generation, and other applications. Compared with standard narrow-ridge laser diodes, in case of the broad-ridge devices the ridge width is increased from around 2 μm to tens of micrometers, leading to lateral multi-mode operation or filamentation.

We investigate a series of devices with ridge widths from 2.4 μm to 20 μm and study their lateral-spectral-temporal behavior as well as high-resolution spectra. With increasing ridge width, we observe the transition from lateral single-mode to multi-mode operation and in the case of the 20 μm wide ridge, filamentation occurs. In the multi-mode regime, the dynamic onset behavior as well as the spectral-lateral mode distribution are governed by competition of lateral and longitudinal modes for gain. Filaments form in the case of strong nonlinear interaction between intensity, charge carrier density, temperature, and refractive index. Using high-resolution spectroscopy, we can clearly differentiate between different lateral modes, which occur in parallel and form multiple longitudinal mode combs.

HL 28.4   Wed 16:15   POT 361

Temperature dependent electroluminescence studies of the carrier transport in multi colour deep ultraviolet light emitting diodes — •Jakob Höpfner[1], Florian Kühl[1], Marcel Schilling[1], Anton Muhin[1], Gregor Hofmann[2], Friedhard Römer[2], Tim Wernicke[1], Bernd Witzigmann[2], and Michael Kneissl[1] — [1]Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany — [2]Lehrstuhl für Optoelektronik, Department EEI, Friedrich-Alexander-Universität, Erlangen-Nürnberg, German

Earlier studies have shown that a drop in current injection efficiency (CIE) is partly responsible for the poor external quantum efficiencies (EQE) of AlGaN-based deep ultraviolet light emitting diodes (DUV-LEDs). In particular, the hole injection and the carrier distribution in the AlGaN multi quantum well (MQW) active region is not well understood. In order to get a better insight we have

performed temperature dependent electroluminescence (EL) investigations of three-fold AlGaN MQW LEDs with two of the QWs emitting at 233 nm and one QW emitting at 250 nm. In addition, the position of the 250 nm QW with the MQW structure was varied. From temperature dependent EL measurements we observe a strong shift in the intensity distribution over wavelength and temperature. We were able to correlate this with a change in the hole injection into the different QWs suggesting an efficient hole transport over the barriers between the QWs at room temperature. These experimental results are also supported by devices simulations and enable us to further improve the LED heterostructure.

HL 28.5   Wed 16:30   POT 361

265 nm LEDs and laser heterostructures with p-type distributed polarization doping AlGaN layers — •Massimo Grigoletto[1,2], Sarina Graupeter[1], Verena Montag[1], Jakob Höpfner[1], Luca Sulmoni[1], Tim Wernicke[1], and Michael Kneissl[1,2] — [1]Technische Universität Berlin, Institute of Solid State Physics, 10623 Berlin, Germany — [2]Ferdinand-Braun-Institut (FBH), Berlin, Germany

Efficient hole injection in AlGaN-based LEDs and lasers emitting in the ultra-violet (UV) spectral range remains a great challenge. Distributed polarization doped (DPD) p-type AlGaN heterostructures have been developed to overcome this hurdle. By introducing a constant piezoelectric polarization charge along compositionally graded $Al_xGa_{1-x}N$ layers a high density of free hole carriers can be established even in the absence of Mg dopants. In this study we have investigated the influence of the DPD design on the structural properties and electro-optic characteristics of AlGaN-based LEDs and laser heterostructures emitting near 265 nm. For efficient hole injection p-type $Al_xGa_{1-x}N$ layers with different Al gradients and thickness have been incorporated and grown by metal organic vapor phase epitaxy. On-wafer measurements of UV-LEDs exhibit forward voltages of 6 V at a dc current of 20 mA and output power of 1 mW comparable to conventionally Mg-doped heterostructures. The LEDs could be operated at high current densities up to 12 kA/cm² in pulsed mode, which shows the DPD is a promising approach for achieving low resistance p-type AlGaN layers with high al mole fractions.

HL 29: Materials and devices for quantum technology I

Time: Wednesday 15:00–18:00   Location: POT 151

HL 29.1   Wed 15:00   POT 151

Mapping of the local valley splitting in a Si/SiGe qubit shuttle device — •Bingjie Chen[1], Mats Volmer[1], Tom Struck[1], Ran Xue[1], Inga Seidler[1], Joachim Knoch[2] und Lars R. Schreiber[1] — [1]JARA-FIT Institute for Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, Germany — [2]Institut für Halbleitertechnik, RWTH Aachen University, Germany

Qubits based on the electron spin in gate-defined ²⁸Si/SiGe quantum dots (QD) are one of the major candidates for the quantum information processing. Due to weak spin-orbit coupling and low hyperfine interaction, their fidelity threshold for quantum error correction is reached. However, valley-state excitations [1-3] have implications for spin dephasing during qubit shuttling [4]. In our experiment, we map the valley splitting energy (E_{VS}) originating from the quantum well confinement at different locations of a qubit shuttle device [5]. We measure their orbital splitting and spin-polarization as a function of various electron fillings and magnetic fields [6]. We fit the local singlet-triplet splitting energy as a lower boundary of the relevant E_{VS}, which is distributed in a range of 11...73 μeV. The correlation length is approximately the QD size and small dependence on the electric field perpendicular to the quantum well is found. [1]Dodson, J.P. ea., arXiv:2103.14702.[2]McJunkin, T. ea., Phys. Rev. B 104, 085406.[3]Hollman, A. ea., Phys. Rev. Applied 13, 034068.[4]Langrock, V. ea., arXiv: 2202.11793.[5]Seidler, I. ea., npj Quantum Inf. 8, 100.[6]Friessen. M. ea., Phys. Rev. B 75, 115318. This work has been funded by the German Research Foundation (DFG) within the project KN 545/28-1.

HL 29.2   Wed 15:15   POT 151

Accessing broad-band quantum dynamics in the low photon regime — •Markus Sifft[1], A. Kurzmann[2], J. Kerski[2], R. Schott[1], A. Ludwig[1], A. D. Wieck[1], A. Lorke[2], M. Geller[2], and D. Hägele[1] — [1]Ruhr University Bochum, Germany — [2]Faculty of Physics and CENIDE, University of Duisburg-Essen, Germany

The analysis of quantum dynamics from measurement records $z(t)$ poses a fundamental challenge in many fields of science and engineering. Measurement records are notoriously difficult to analyze due to inherent or additional background noise, loss of e.g., probe photons, and finite measurement times. We recently introduced quantum polyspectra as a tool to analyze $z(t)$ in terms of higher order spectra whose shapes can be predicted within a quantum master equation approach [1,2]. Here, we solve the problem of analyzing the blinking (charging) dynamics of a semiconductor quantum dot in the regime of low photon rates or high photon loss [3]. The usual telegraph noise of binned photon click events changes to rare single clicks in case of high photon loss. Fitting theoretical quantum polyspectra to their measured counterparts gives full access to the in- and out-tunneling rates γ_{in}, γ_{out} of electrons despite low average photon rates $\gamma_p \ll \gamma_{in} + \gamma_{out}$. We demonstrate the successful evaluation of tunneling rates at up to 99.9 % loss of photons surpassing a previous scheme that handled a 98 % loss using the same data. [1] Hägele et al., PRB 98, 205143 (2018), [2] Sifft et al., PRR 3, 033123 (2021), [3] Sifft et al., arXiv:2109.05862

HL 29.3   Wed 15:30   POT 151

Generation of V_{Si} color centers in 4H-SiC using He and Li focused ion beam — •Christian Gobert[1], Shravan Kumar Parthasarathy[1], Fedor Hrunski[2], Roland Nagy[2], and Patrick Berwian[1] — [1]Fraunhofer Institute for Integrated Systems and Device Technology (IISB), 91058 Erlangen, Germany — [2]Group of Applied Quantum Technologies, University Erlangen-Nuremberg (FAU), 91058 Erlangen, Germany

The silicon vacancy (V_{Si}) color center in 4H-SiC is a promising candidate as a qubit for quantum sensing, communication, and computing, due to its excellent spin and optical properties[1,2], scalability and mature semiconductor technology platform[3]. V_{Si} color centers can be fabricated by means of high energetic irradiation, e.g., using electrons, ions, neutrons, or laser pulses[4]. In this contribution, we report on a direct comparison of 3 different irradiation techniques, i.e. He-Li- and electron irradiation, for the first time on the very same sample material. Characterization is accomplished using confocal photoluminescence (PL) measurements on two perpendicular crystal orientations. We investigate the optical and spin properties of generated V_{Si} color centers and employ PL mappings to judge the scalability of the irradiation technique. To evaluate the quality of the generated V_{Si} color centers, PL excitation spectroscopy (PLE) is applied.

HL 29.4   Wed 15:45   POT 151

1.*Quantum Vector Magnetometry of Magnetic Nanoparticles in Living Tissue — •Andre Pointner[1], Philipp Kunze[2], Regine Schneider-Stock[2], Bernhard Friedrich[3], Christoph Alexiou[3], Rainer Tietze[3], and Roland Nagy[1] — [1]Chair of Electron Devices, FAU Erlangen-Nuremberg — [2]Experimental Tumor Pathology, University Hospital Erlangen — [3]Experimental Oncology and Nanomedicine, University Hospital Erlangen

Developing an understanding of the underlying processes of cancer dissemination is to this day a pressing topic in medical research, due to the lack of observation techniques capable of resolving single cell behavior in living tissue. Widefield imaging with ensembles of nitrogen-vacancy centers (NV-Centers) in diamond as a quantum sensor allows the observation of individual cells by mapping selectively attached superparamagnetic iron oxide nanoparticles (SPIONs) on cells of interest. Application of a magnetic bias field results in a magnetic dipole emitted by the SPIONs, which adds onto the known bias field. The magnetic field causes a lift of the degeneracy of the NV-Centers spin states. Evaluating the spin transitions via optically detected magnetic resonance (ODMR) and comparison to the ground state hamiltonian enables the reconstruction of the magnetic field vector. By applying this measurement scheme pixelwise to a sequence of widefield images of the diamond sample, we calculate the corresponding dipole vector for the SPIONs and map the resulting magnetic field over the field of view. This enables single cell tracking in living tissue inside a homemade integrated widefield microscope over the span of multiple days.

HL 29.5   Wed 16:00   POT 151

Fabrication and pre-characterization of 10 μm long single-electron shuttling devices. — •Max Beer[1], Ran Xue[1], Inga Seidler[1], Jhih-Sian Tu[2], Lino Visser[1], Hendrik Bluhm[1], and Lars R. Schreiber[1] — [1]JARA-FIT Institute for Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, Aachen, Germany — [2]Helmholtz Nano Facility (HNF), Forschungszentrum Jülich, Jülich, Germany

The electron-spin in gate-defined quantum dots in a Si/SiGe quantum well is one of the most promising qubits for scalable quantum computing. Scalability can be achieved by coherent coupling such as conveyor-mode single electron-spin shuttling [1]. Aiming at a shuttle distance of 10 μm, we fabricate a shuttling device with three patterned metal-gate layers forming an array of >140 gates. Al_2O_3 deposited by atomic layer deposition (ALD) isolates the gates, but also induces potential disorder in the quantum well. This disorder can be reduced by

minimizing the oxid thickness [1]. We investigate two strategies: (I) Reduction of oxide thickness towards the ALD limit and (II) replacement of MOS-gates with Pd-Si Schottky-gates wherever applicable. Shuttling devices are selected by a transport measurement-protocol operating at 4.2 K on single electron transistors, which are operated as charge sensors for electron shuttling at 10 mK [2].

Coupling of solid-state quantum emitters to low-loss plasmonic waveguides — •PAUL STEINMANN, HANS-JOACHIM SCHILL, and STEFAN LINDEN — Physikalisches Institut, Universität Bonn, Nussallee 12, 53115 Bonn, Germany
Plasmonic waveguides with integrated single photon emitters (SPEs) offer an attractive platform for nanophotonic quantum circuit applications. Here, we report on the coupling of strain-induced SPEs in an MoSe2 monolayer to low-loss plasmonic waveguides. For this purpose, we used electron beam lithography with the negative-tone resist Medusa82 to fabricate dielectric-loaded surface plasmon polariton waveguides (DLSPPWs) on top of a chemically prepared monocrystalline silver platelet. Additional gratings placed at the ends of the waveguides serve as in- and out-coupling structures. An MoSe2 monolayer was deposited on the centre of one of the waveguides by a dry-transfer technique. Operating at 4 Kelvin, surface plasmon polaritons (SPPs) are launched by a green laser at the in-coupling port of the waveguide. The SPPs travel through the waveguide and lead to the excitation of the monolayer. In addition to the exciton and trion signal, we observe sharp emission lines that we attribute to strain-induced trap states. The second-order correlation function of one of the spectrally filtered emission lines was measured with an HBT setup. The measured value g(2)(0)=0.4 indicates the single-photon nature of the emitter. Our findings indicate that TMDC monolayers can be used as integrated SPEs in efficient plasmonic circuits, and thus further pave the way towards plasmonic-based single photon networks.

HL 29.7   Wed 17:00   POT 151

Sensing of electrolytes with nitrogen-vacancy centers in nanodiamonds — •MAXIMILIAN HOLLENDONNER[1,2], SANCHAR SHARMA[2], DURGA DASARI[3], SILVIA VIOLA KUSMINSKIY[2,4], and ROLAND NAGY[1] — [1]Chair of Electron Devices, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Max Planck Institute for the Science of Light, Staudtstraße 2, Erlangen, Germany — [3]3rd Institute of Physics, University of Stuttgart and Institute for Quantum Science and Technology (IQST), Stuttgart, Germany — [4]Institute for Theoretical Solid State Physics, RWTH Aachen University, Aachen, Germany
Today's batteries suffer from performance losses with increasing cell age which is caused by irreversible degradation processes at a molecular level. To understand these processes, it is important to measure them *in-situ* and *in-operando*. Up to now there exists no sensor which can perform this task with sub-micrometer resolution. We propose to use nanodiamonds containing single NV-centers as such sensors inside the liquid electrolyte of a battery. It has been shown that NV-centers are excellent electric field sensors [1,2]. From theoretical considerations we found out that by performing repeated FID pulse sequences it is not only possible to measure the electric field components generated by the ions inside the electrolyte but also the local ionic concentrations at the position of the nanodiamond with nanometer-resolution.

Interplay of Pauli Blockade with Electron-Photon Coupling in Quantum Dots — •FLORIAN GINZEL and GUIDO BURKARD — Department of Physics, University of Konstanz, D-78457 Konstanz, Germany

Both quantum transport measurements in the Pauli blockade regime and microwave cavity transmission measurements are important tools for spin-qubit readout and characterization. In our work [1] we theoretically investigate how a double quantum dot in a transport setup interacts with a coupled microwave resonator while the current through the DQD is rectified by Pauli blockade. We show that the output field of the resonator can be used to infer the leakage current and thus obtain insight into the blockade mechanisms without additional components such as charge or current sensors for each dot. In the case double quantum dot realized in silicon, we show how the valley quasi-degeneracy can impose limitations on this scheme. We also demonstrate that a large number of unknown double quantum dot parameters including (but not limited to) the valley splitting can be estimated from the resonator response simultaneously to a transport experiment, providing more detailed knowledge about the microscopic environment of the dots. Furthermore, we describe and quantify a back-action of the resonator photons on the steady state leakage current.

Structural and electrical characterization of the InAs/CdSe core/shell NWs — •MANE KALAJYAN[1], MARVIN MARCO JANSEN[1,2], NILS VON DEN DRIESCH[3], ERIK ZIMMERMANN[1], NATALIYA DEMARINA[4], ANTON FAUSTMANN[1], GERRIT BEHNER[1], CHRISTOPH KRAUSE[1], BENJAMIN BENNEMANN[1], JAN KARTHEIN[1], DETLEV GRÜTZMACHER[1,3], THOMAS SCHÄPERS[1], and ALEXANDER PAWLIS[1,3] — [1]Peter Grünberg Institut (PGI-9), Forschungszentrum Jülich, Jülich, Germany — [2]Eindhoven University of Technology, Eindhoven, Netherlands — [3]Peter Grünberg Institut (PGI-10), Forschungszentrum Jülich, Jülich, Germany — [4]Peter Grünberg Institut (PGI-2), Forschungszentrum Jülich, Jülich, Germany
InAs nanowires (NWs) are a well-known basis for field-effect transistors (FETs), light-emitting diodes and lasers, quantum devices and biosensors. The larger band gap material CdSe, having a negligible lattice mismatch to InAs, allows for tailoring the conductive channel at the CdSe/InAs core/shell interface, thus making CdSe an excellent candidate for the InAs surface states passivation.

Here, we present the fabrication, structural, and electrical characterization of a unique InAs/CdSe core/shell NW system. The interface between the core and the shell is proven to be flawless by means of HR-TEM micrographs. Moreover, electrical characterization reveals a high-mobility two-dimensional transport channel in the InAs core. Finally, magnetotransport measurements show clear signs of weak antilocalization. These results make the novel InAs/CdSe hybrid NWs a promising basis for the quantum device applications.

HL 29.10   Wed 17:45   POT 151

Electrical excitation of color centers in phosphorus-doped diamond Schottky diodes — •FLORIAN SLEDZ[1], IGOR A. KHRAMTSOV[2], ASSEGID M. FLATAE[1], STEFANO LAGOMARSINO[1], NAVID SOLTANI[1], SHANNON S. NICLEY[3], ROZITA ROUZBAHANI[3], PAULIUS POBEDINSKAS[3], KEN HAENEN[3], JIN QUN[4], XIN JIANG[4], PAUL KIENITZ[5], PETER HARING BOLIVAR[5], DMITRY YU. FEDYANIN[2], and MARIO AGIO[1] — [1]Laboratory of Nano-Optics, University of Siegen, Germany — [2]Moscow, Russian Federation — [3]Institute for Materials Research (IMO) & IMOMEC, Hasselt University & IMEC vzw, Belgium — [4]Institute of Materials Engineering, University of Siegen, Germany — [5]Institute of Graphene-based Nanotechnology, University of Siegen, Germany
A robust single-photon source operating upon electrical injection at ambient condition is desirable for quantum technologies. Silicon-vacancy color centers in diamond are promising candidates as their emission is concentrated in a narrow zero-phonon line with a short excited-state lifetime of ~1 ns. Creating the color centers in n-type diamond (phosphorus-doped) allows the implementation of a Schottky-diode configuration. This provides a simpler approach than the traditional complex diamond semiconductor junctions e.g., p-i-n. Selective optical excitation allows addressing of single silicon-vacancy color centers while suppressing background from mainly nitrogen-vacancy defects created during Si ion implantation. This paves a way for the realization of the predicted bright electroluminescence of color centers.

Aharonov-Bohm-type oscillations in phase-pure core/shell GaAs/InAs nanowires — •FARAH BASARIC[1,2], ANTON FAUSTMANN[1,2], ERIK ZIMMERMANN[1,2], GERRIT BEHNER[1,2], ALEXANDER PAWLIS[1,2], CHRISTOPH KRAUSE[1,2], HANS LÜTH[1,2], DETLEV GRÜTZMACHER[1,2], and THOMAS SCHÄPERS[1,2] — [1]Peter Grünberg Institut (PGI-9), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]JARA-Fundamentals of Future Information Technology, Jülich-Aachen Research Alliance, Forschungszentrum Jülich and RWTH Aachen University, Germany

Epitaxially grown phase-pure GaAs/InAs core/shell nanowires offer uniformity in their electrical, mechanical and optical properties due to the absence of a crystallographic disorder. Magnetotransport measurements were carried out at variable temperatures and for different gate voltages, under an applied in-plane magnetic field. Pronounced Aharonov-Bohm-type oscillations in the conductance are observed for this nanowire type. In measurements at different gate voltages, significantly higher oscillation amplitudes are observed in comparison to the corresponding measurements on polymorphic core/shell nanowires. Furthermore, measurements at different temperatures show robustness of these

oscillations against high temperatures as a result of reduced disorder. Finally, strong indications of a quasi-ballistic transport regime could be recognized for the phase-pure nanowire type. Obtained results indicate a strong effect of disorder reduction in GaAs/InAs nanowire transport properties, manifested in superior transport properties.

HL 30.2   Wed 15:15   POT 251

Spin valves based on bilayer graphene quantum point contacts — •Eike Icking[1,2], Christian Volk[1,2], Christopher Schattauer[3], Luca Banszerus[1,2], Kenji Watanabe[4], Takashi Taniguchi[5], Florian Libisch[3], Bernd Beschoten[1], and Christoph Stampfer[1,2] — [1]RWTH Aachen University, Germany — [2]Forschungszentrum Jülich, Germany — [3]TU Vienna, Austria — [4]Research Center for Functional Material, Japan — [5]International Center for Materials Nanoarchitectonics, Japan

Bernal bilayer graphene (BLG) is a unique material as it allows opening and electrostatically tuning a sizeable band gap by applying a perpendicular electric field. Recently, charge carriers have been confined successfully in one dimension to form quantum point contacts (QPC) based on split gates separated by a channel of a few hundred nanometers. Moreover, spin-polarized quantum transport through such structures has been demonstrated up to 6 e^2/h using a high in-plane magnetic field. The threshold magnetic field at which the lowest modes become spin-polarized depends on the subband spacing and thus on the width of the split gate channel. In this work, we combine two QPCs of different geometric widths, resulting in different threshold magnetic fields, to spin-polarize the first QPC and use it as a filter for the second QPC. In particular, we report on a spin-valve achieving spin-polarized channels with a total conductance of up to 10 e^2/h.

HL 30.3   Wed 15:30   POT 251

Optical and electrical tuning between the normal insulating and topological insulating phase of InAs/GaSb bilayer quantum wells — •Manuel Meyer[1], Tobias Fähndrich[1], Sebastian Schmid[1], Sebastian Gebert[1], Gerald Bastard[1,2], Fabian Hartmann[1], and Sven Höfling[1] — [1]Technische Physik, Physikalisches Institut and Würzburg-Dresden Cluster of Excellence ct.qmat, Am Hubland, D-97074 Würzburg, Germany — [2]Physics Department, École Normale Supérieure, PSL 24 rue Lhomond, 75005 Paris, France

Topological insulators (TI) based on InAs/GaSb bilayer quantum wells (BQW) are appealing due to their rich phase diagram with a TI and normal insulating (NI) phase[1]. The switching between both phases can be achieved by external electric fields using a top and back gate (TG and BG)[2]. However, especially a fully functional BG is difficult to realize in antimonides due to leakage issues. To overcome this bottleneck we present another tuning knob using optical excitation to switch from the NI to the TI phase over the TI gap[3]. By monitoring the charge carrier densities we can identify the hybridized band structure and in-plane magnetic field measurements evidence the TI gap. Furthermore, a top-gated sample is investigated. Without a back gate we find properties from both phases for magnetotransport measurements which points to a mixing of NI and TI states. This is further indicated by the resistance peak evolutions with temperature for both samples.

Transport in high mobility HgTe heterostructures — •Michael Kick, Lena Fürsst, Johannes Kleinlein, Saquib Shamim, Hartmut Buhmann, and Laurens W. Molenkamp — Experimentelle Physik III, Physikalisches Institut, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany

The Fractional Quantum Hall Effect (FQHE) has not yet been observed in the material system of HgTe. Due to recent progress in MBE growth, routinely charge carrier mobilities of HgTe heterostructures of over $\mu > 1 \cdot 10^6$ cm^2/Vs are obtained which is in the same order of magnitude as in the first reported experimental observation of the FQHE in GaAs/GaAlAs heterostructures. This opens up new prospects for transport investigations into the long time still open question of fractional states in this material system.

In 2-dimensional HgTe quantum wells, transport measurements show well pronounced quantum Hall plateaus for all filling factors, but no indication of any fractional state. High magnetic field measurements show a prolonged $\nu = 1$ plateau and a transition to an insulating state. Intriguingly, the $\nu = 1$ plateau exhibits a transition to an insulating state for filling factor $\nu = 1/2$.

Another possibility to observe the FQHE in HgTe is provided by the 2D surface states of a 3D topological insulator. High mobility layers, $\mu > 1 \cdot 10^6$ cm^2/Vs, of tensil strained HgTe are subject of extensive magneto-transport investigations. First results reveal a good and detailed correspondence to recent k.p band structure calculations for non-interacting electron systems.

Electron Density Depended Giant Negative Magnetoresistance — •Lina Bockhorn and Rolf J. Haug — Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany

Ultra-high mobility two-dimensional electron gases not only show an increasing number of new fractional filling factors, but also an astonishing robust negative magnetoresistance at zero magnetic field [1 -5]. The theoretical description of this negative magnetoresistance is still an open issue due to its complex dependencies on several parameters.

The behavior of the giant negative magnetoresistance is affected by different scattering events, e. g. interface roughness, oval defects, background impurities and remote ionized impurities, which leads to a strong dependence on different parameters. Here, we take a closer look on the temperature dependence of the giant negative magnetoresistance for different electron densities. At low temperatures we observe the predicted temperature dependence of T$^{1/2}$ [6].

HL 30.6   Wed 16:45   POT 251

Massless Dirac fermions on a space-time lattice with a topologically protected Dirac cone — •Michal Pacholski[1], Alvaro Donís Vela[3], Gal Lemut[3], Jakub Tworzydlo[2], and Carlo Beenakker[3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Warsaw University, Warsaw, Poland — [3]Lorentz Institute, Leiden, The Netherlands

The symmetries that protect massless Dirac fermions from a gap opening may become ineffective if the Dirac equation is discretized in space and time, either because of scattering between multiple Dirac cones in the Brillouin zone (fermion doubling) or because of singularities at zone boundaries. Here we introduce an implementation of Dirac fermions on a space-time lattice that removes both obstructions. The quasi-energy band structure has a tangent dispersion with a single Dirac cone that cannot be gapped without breaking both time-reversal and chiral symmetries. We show that this topological protection is absent in the familiar single-cone discretization with a linear sawtooth dispersion, as a consequence of the fact that there the time-evolution operator is discontinuous at Brillouin zone boundaries.

Phase transitions in the two-dimensional Su-Schrieffer-Heeger model — •Changan Li[1], Songbo Zhang[2], Sangjun Choi[1], Jan Budich[3], and Björn Trauzettel[1] — [1]Institute for theoretical physics and astrophysics, University of Würzburg, Wuerzburg, Germany — [2]Department of Physics, University of Zürich, Winterthurerstrasse 190 8057, Zürich, Switzerland — [3]Institute of Theoretical Physics, Technische Universität Dresden, 01062 Dresden, Germany

The 2D Su-Schrieffer-Heeger (SSH) model is endowed with rich topological physics. First we show that the random flux can induce a metal-band insulator transition in the 2D SSH, thus reporting the first example of such a transition. Remarkably, we find that the resulting insulating phase can even be a higher-order topological insulator with zero-energy corner modes and fractional corner charges. Employing both level statistics and finite-size scaling analysis, we characterize the metal-band insulator transition and numerically extract its critical exponent. By proposing another inclined 2D SSH model, a deformed one, we show that a pair of Dirac points protected by space-time inversion symmetry appear in the semimetallic phase. Interestingly, the locations of these Dirac points are not pinned to any high-symmetry points of the Brillouin zone but highly tunable through parameter modulations. Moreover, the merging of two Dirac points undergoes a topological phase transition, which leads to either an anisotropic topological insulating phase or a nodal-line metallic phase.

HL 31.2   Wed 15:15   TRE Ma
Ab initio embedding approach for carbon defects in hexagonal boron nitride: A new platform to probe environmental screening — •Danis Badrtdinov[1], Magdalena Grzeszczyk[2], Alexander Hampel[3], Cyrus Dreyer[3,4], Maciej Koperski[2], and Malte Rösner[1] — [1]Radboud University, Nijmegen, The Netherlands — [2]National University of Singapore, Singapore — [3]Flatiron Institute, USA — [4]Stony Brook University, USA

Correlated defects in layered van der Waals hosts hold high promises for realizing quantum technologies, as they allow for various possibilities to control defect properties, e.g., via altering the host thickness or by changing the substrate material. A quantitative description of the defect ground and excited states taking the details of the impurity environment into account is, however, a considerable challenge for conventional density-functional theory (DFT) based methods as the impurities might be correlated and dielectric environmental screening is not fully accounted for in DFT. To tackle these challenges we apply and extend an embedding approach that treat the defect states within exact many-body theory, while DFT is used as a starting point to describe the bulk host material. We study various carbon defects embedded in hexagonal boron nitride (hBN), allowing us to disentangle all mechanisms responsible for the alteration of defect properties including modifications to the impurity structure and changes in the environmental screening upon thinning down the hBN host. Our new embedding approach paves the way for improved identification of defects in layered materials and to tailor their properties.

HL 31.3   Wed 15:30   TRE Ma
Nonequilibrium electron dynamics in a two-sites Hubbard model — •Jakub Wronowicz and Yaroslav Pavlyukh — Department of Theoretical Physics, Wrocław University of Science and Technology

Electron dynamics in a two-sites Hubbard model is studied using the nonequilibrium Green's function approach using formalism developed in [1]. We focus on the electron dynamics arising in the adiabatic switching scenario. Many-body approximations are classified according to the channel of the Bethe-Salpeter equation in which electronic correlations are explicitly treated. They give rise to the so-called second Born, T-matrix and GW approximations. In each of these cases, the model is reduced to a system of ordinary differential equations, which resemble equations of motion for a driven harmonic oscillator with time-dependent frequencies. We discuss transient solutions for the off-diagonal density matrix. Analytical result for the steady state in second Born approximation is compared with the exact solution. It is further shown numerically that in the large Hubbard-U limit the T-matrix in the particle-hole channel and spin-adapted GW approximations converge to the same solution.

[1] Y. Pavlyukh, E. Perfetto, and G. Stefanucci, *Photoinduced dynamics of organic molecules using nonequilibrium Green's functions with second-Born, GW, T-matrix, and three-particle correlations*, Phys. Rev. B **104**, 035124 (2021).

Time-linear quantum transport simulations with correlated nonequilibrium Green's functions — •Riku Tuovinen[1], Yaroslav Pavlyukh[2], Enrico Perfetto[3], and Gianluca Stefanucci[3] — [1]Department of Physics, Nanoscience Center, University of Jyväskylä, Finland — [2]Department of Theoretical Physics, Wroclaw University of Science and Technology, Poland — [3]Dipartimento di Fisica, Università di Roma Tor Vergata, Italy

We present a time-linear scaling method for open and correlated quantum systems. The method inherits from many-body theory [1] the possibility of selecting the most relevant scattering processes, thereby paving the way for real-time characterizations of correlated ultrafast phenomena in quantum transport. The open system dynamics is described in terms of an embedding correlator from which the transient current can be calculated via the Meir-Wingreen formula [2]. We efficiently implement the method through a combination with recent time-linear schemes for closed systems [3]. Electron-electron and electron-phonon interactions can be treated on equal footing while preserving all fundametal conservation laws. We employ the method by studying transport of correlated electron-hole pairs in semiconductors [4].

Electron-Phonon Interactions from DFPT within an All-Electron Framework — •Sebastian Tillack, Pasquale Pavone, and Claudia Draxl — Humboldt-Universität zu Berlin and IRIS Adlershof, 12489 Berlin, Germany

The interplay between electrons and the motions of nuclei in solids, described in terms of phonons, play a crucial role in the modeling of functional materials, particularly for understanding temperature dependent effects. We present an implementation of density-functional perturbation theory (DFPT) within a full-potential all-electron framework as implemented in the code `exciting` [1]. Our implementation allows one to compute phonons as well as the linear response to external electric fields. We use DFPT calculations to study lattice vibrations and electron-phonon interactions (EPIs) by means of many-body perturbation theory in β-Ga_2O_3. The electron self-energy contribution is computed as a function of temperature from which various properties such as quasi-particle energies, electron linewidths, and spectral functions are derived. We further incorporate many-body electron-electron interactions described by the GW method. Beyond that, our work creates the foundation for a fully *ab initio* study of the effect of EPIs on optical excitations.

Calculation of phonon spectra with the FLAPW method using Density Function Perturbation Theory — •Alexander Neukirchen, Christian-Roman Gerhorst, Gregor Michalicek, Daniel Wortmann, Gustav Bihlmayer, and Stefan Blügel — Peter Grünberg Institute and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany

Computing phonons applying density functional perturbation theory (DFPT) within all-electron DFT methods is a well-known challenge due to the displacement of muffin-tin spheres and sphere-centered basis functions. In this talk, we present our current results of the phonon dispersion based on our implementation of the DFPT approach in the FLEUR code [1] (www.flapw.de), an implementation of the full-potential linearized augmented plane wave (FLAPW) method. We highlight the good agreement of our preliminary results with phonon dispersions obtained with the finite displacement method for which the FLEUR code has been combined with the phonopy tool (www.phonopy.github.io/phonopy/). We discuss the numerical challenges involved in calculating meV quantites on top of large ground state energies typical for all-electron methods and how we addressed them.

This work has been supported by the Helmholtz Postdoc Programme (VHPD-022) and by the MaX Center of Excellence funded by the EU through the H2020-INFRAEDI-2018-1 767 (Grant No. 824143).

Electron-phonon interaction using a localized Gaussian basis set — •Gerrit Johannes Mann, Thorsten Deilmann, and Michael Rohlfing — Institute of Solid State Theory, University of Münster, Germany

Electron-phonon interaction is a crucial mechanism in solid state physics that is responsible for a multitude of phenomena. However, in electronic structure calculations it is usually neglected. We developed an ab-initio implementation on top of density functional theory that combines finite differences calculations with the perturbative Allen-Heine-Cardona framework in order to calculate the temperature-dependent renormalization of the electronic bandstructure due to electron-phonon interaction using a basis set of localized Gaussian orbitals.

This implementation circumvents the limiting problems of previous implementations while maintaining a good agreement with the literature. The calculated Fan-Migdal zero-point renormalization of the direct band gap of silicon amounts to about 15 meV compared to 20 meV in the literature. Also the temperature-dependence of the renormalization agrees similarly well.

Pump-probe spectroscopy on a MoSe2 monolayer — •Max Wegerhoff and Stefan Linden — Physikalisches Institut, Universität Bonn, Nussallee 12, 53115 Bonn, Germany

TMDC monolayers are atomically thin semiconductor materials, which, due to their reduced dimensionality and crystal structure, possess unique optical properties. In particular, they host bound electron-hole pairs, so-called excitons, with binding energies of several 100 meVs.

Here, we report on pump-probe spectroscopy on excitons in a MoSe2 monolayer encapsulated in h-BN. We use spectrally broad probe pulses and a spectrometer to measure the transient differential reflectivity spectra. Based on a mode-locked Ti:Sa laser, a temporal resolution of down to 400fs is achieved. A frequency-doubled OPO can be used to generate non-resonant pump pulses in the visible wavelength range. Furthermore, probe pulses with a bandwidth of up to 70nm can be generated via supercontinuum generation in a photonic crystal fiber. The experiments are performed at 4K in a helium-flow cryostat.

Within the first few picosecond after the pump pulse, we observe a blueshift of the exciton resonance. This shift depends on the wavelength of the pump pulses as well as the polarization of the pump- and probe pulses. Further experiments with an electrically gated heterostructure to control the doping of the monolayer are in progress.

HL 33.2   Wed 17:00   P1

A Model Study of the Phonon-Impact on Absorption Spectra of Moiré Exciton-Polaritons — •Kevin Jürgens[1], Daniel Wigger[2], and Tilmann Kuhn[1] — [1]Institute of Solid State Theory, University of Münster, Germany — [2]School of Physics, Trinity College Dublin, Ireland

The interaction of multiple quantum emitters coupled to a resonant optical field can produce interesting collective behavior. Twisted bilayers of transition metal dichalcogenides are a class of materials, where localized quantum emitters, in this case moiré excitons, can occur. According to their strong localization at the minima of the moiré potential, these excitons have a relatively flat band structure. If the heterostructure is placed into an optical cavity, all excitons interact with the same mode of the resonator, leading to the formation of exciton-polaritons which can interact with lattice vibrations.

We model the moiré excitons in the limit of small densities as bosonic particles that couple to a single quantized cavity mode, resulting in lower and uper polariton states. In addition, each exciton is coupled to the same acoustic phonon bath. The interaction with phonons leads to inter- and intraband transitions between the two polariton branches that strongly depend on the curvature of the polariton dispersion.

We calculate absorption spectra and discuss the influence of phonons on the spectral shape and peak positions, and systematically study the influence of the band structures curvature.

HL 33.3   Wed 17:00   P1

Nonlinear optical processes in the layered magnetic semiconductor CrSBr — •Minjiang Dan[1], Paul Herrmann[1], Julian Klein[2], Zdenek Sofer[3], and Giancarlo Soavi[1] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Jena, Germany — [2]Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, USA — [3]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, 166 28 Prague 6, Czech Republic

CrSBr has recently emerged as a new member in the family of layered magnetic materials, with the distinct advantages compared to CrI_3 of being stable in air and having a high Néel temperature in the bulk form. Recently polarization-resolved Second Harmonic Generation (SHG) has been employed to reveal the layer-dependent magnetic order and symmetry in multilayer CrSBr [1]. In this work, we use nonlinear optical spectroscopy, i.e. SHG and Third Harmonic Generation (THG) and two photon absorption, to investigate the electronic and excitonic resonances in few-layer and bulk CrSBr as a function of the lattice temperature which, modulates the magnetic properties of the material. Our results show large enhancement (>100) in the SHG and THG for specific wavelengths and range of temperatures, pointing towards the existence of resonances from the magnetic dipole response of the system. This sheds light on the excited state landscape of this new material and offers viable insights towards its application in spintronic, magnonic and opto-electronic devices.

HL 33.4   Wed 17:00   P1

The Impact of Inert Conditions During the Fabrication Process on the Optical Properties of MoS_2 Monolayers — •Alina Schubert[1], Michael Kempf[1], Rico Schwartz[1], Patricia Gant[2], Felix Carrascoso[2], Carmen Munuera[2], Andres Castellanos-Gomez[2], and Tobias Korn[1] — [1]Institut für Physik, Universität Rostock, Rostock, Germany — [2]Instituto de Ciencia de los Materiales de Madrid, Madrid, Spain

Transition-metal dichalcogenides (TMDCs) are layered materials that can be thinned down to monolayers. The optical properties of these flakes depend strongly on the cleanliness of the surfaces. Transferring TMDCs with PDMS is simple to perform and allows the fabrication of large monolayers [1]. The objective of this work was to improve the methodology so that sample quality is enhanced without reducing the yield or increasing the effort required for production. For this purpose, a statistic of 20 monolayers was set up, which were half transferred to a SiO_2 substrate at ambient conditions and half transferred in a glovebox [2]. All samples were characterised by photoluminescence (PL) spectroscopy at room temperature and ~4 K. By examining the exciton and trion features in the spectra, it could be shown that only the small difference in the transfer process results in changes of the optical properties that can be attributed to a higher sample quality of the samples produced in the glovebox.

HL 33.5   Wed 17:00   P1

Stokes shift of twisted bilayer WSe2 — •Zihao Liu[1], Yang Pan[1,2], and Dietrich R. T. Zahn[1,2] — [1]Semiconductor Physics, Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany — [2]Center for Materials, Architectures, and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, Chemnitz, Germany

Transition metal dichalcogenides (TMDCs) with a typical layered structure have exceptional optical properties exhibiting a characteristic absorption and emis-

sion at excitonic resonances. The weak van der Waals (vdW) interlayer coupling nature enables the possibility of artificial staking, leading to homo- and heterostructures formation. It was demonstrated in our previous work that the optical properties can be strongly modified by the twisting angle.

Here, WSe2 monolayers (MLs) were obtained by mechanical exfoliation, which were then transferred onto sapphire substrates by a tear-and-stack method to form twisted homo-bilayers with a precision of 0.08°. We then performed optical transmission and photoluminescence (PL) experiments on monolayers, intrinsic bilayers and twisted bilayers to determine the Stokes shift values on a full period (0°-60°) of twisted bilayer WSe2.

HL 33.6　Wed 17:00　P1

Transport and optical characterization of electrically contacted monolayer TMDCs — •Jan-Niklas Heidkamp, Johannes Krause, Swarup Deb, Rico Schwartz, and Tobias Korn — Institute of Physics, University of Rostock, Rostock, Germany

Since Graphene was introduced in 2004, there has been a great interest in other 2D materials as well. Among the most studied is the group of semiconducting transition metal dichalcogenides (TMDCs). The band structure of these crystals changes from an indirect gap in the bulk to a direct gap in the monolayer limit. Herein, a method for contacting monolayer flakes using photolithography and lift-off processes is showcased. Electrical contacts are pre-defined on SiO_2 substrates and thereafter, TMDC flakes are deposited using a deterministic transfer technique. Flakes of the TMDC WS_2 contacted in this way are characterized via gate-dependent photoluminescence measurements and I-V curves.

HL 33.7　Wed 17:00　P1

Enhancing photoluminescence and Raman signals in TMDC monolayers via plasmonic nanostructures — •Johannes Krause, Annika Bergmann, Jan-Niklas Heidkamp, Rico Schwartz, and Tobias Korn — Institute of physics, university of Rostock, Rostock, Germany

Novel 2D thin film materials garnered a great interest in recent years. The family of Transition metal dichalcogenides (TMDCs) among those materials is especially appealing because of the indirect-direct bandgap transition and the possibility to stack different composites of the TMDCs on top of each other to achieve so called heterostructures. Herein, we present a technique to define nanostructures on a SiO_2 wafer using thermal scanning probe lithography. Further, we deposit individual TMDC monolayer flakes on top of the metallized structures via the deterministic transfer technique. We characterize our flakes utilizing photoluminescence and Raman measurements, reporting major enhancements effects (~10x) in PL and minor enhancement (~3x) in Raman signals.

HL 33.8　Wed 17:00　P1

investigation of structural and electronic properties of monolayered MoS2 and graphene compared to the MoS2/graphene heterostructure — •Ateeb Shaban[1], Nebahat Bulut[2], Jakob Kraus[2], Franz Selbmann[1], Jens Kortus[2], and Yvonne Joseph[1] — [1]TU Bergakademie Freiberg, Institute of Electronic and Sensor Materials, Germany — [2]TU Bergakademie Freiberg, Institute of Theoretical Physics, Germany

Graphene and other 2D materials have been shown to have interesting structural and electronic properties. Transition metal dichalcogenides such as molybdenum disulfide (MoS2) and tungsten diselenide (WSe2) have tunable bandgaps that change from indirect to direct when decreasing the number of layers. This property allows for applications such as transistors and sensors. On the other hand, graphene is an ideal channel material. It is used as an electronic sensor in field-effect transistors due to the high sensitivity toward the change in the surrounding environment. These remarkable electronic and structural properties of graphene, being highly susceptible and conductive, have reignited the interest in 2D materials. Subsequently, building variable stacks of 2D van-der-Waals (vdW) structures can open the possibility of designing materials with specific properties across various chemistry's and systems.

In this theoretical work, we analyze and review the properties of MoS2 and graphene individually and study their cumulative effect on the electronic and structural properties of the MoS2/graphene vdW heterostructure using density functional theory.

HL 33.9　Wed 17:00　P1

Rapid hyperspectral imaging of transition metal dichalcogenides and their heterostructures — •Marc Schütte, David Tebbe, Christoph Stampfer, Bernd Beschoten, and Lutz Waldecker — 2nd Institute of Physics A, RWTH Aachen University, Aachen, Germany

Transition Metal Dichalcogenides are two-dimensional semiconductors with many interesting properties for optical applications, such as direct bandgaps in the visible spectral region or optically addressable inequivalent valleys. It is well known, however, that their optical properties can vary spatially by local changes of dielectric screening, doping or strain. Here, we present a measurement setup capable of performing photoluminescence and reflection contrast measurements of 2D heterostructures approximately twenty times faster compared to scanning a focal spot over the sample. The setup is based on simultaneously taking spec-

tra along a line with an imaging spectrometer (push-broom technique), which enables the measurement of multiple spectra simultaneously. The speed of the technique allows for taking images in multidimensional sweeps of parameters, such as gate voltages or magnetic fields.

In this way, the measurements can be conducted by imaging sample regions up to the full size of the heterostructure for each sweep. This allows to distinguish inhomogeneities and enhances the statistical relevance of the data.

HL 33.10　Wed 17:00　P1

Black phosphorus field-effect transistors and its application — •Zahra Fekri[1], Himani Arora[1], Victoria Constance köst[2], Jens Zscharschuch[1], Krzysztof Niewegłowski[2], Kenji Watanabe[3], Takashi Taniguchi[4], Manfred Helm[1,2], Karlheinz Bock[2], and Artur Erbe[1,2] — [1]Helmholtz Zentrum Dresden Rossendorf, Dresden, Germany — [2]Technische Universität Dresden, Dresden, Germany — [3]Research Center for Functional Materials, National Institute for Materials Science, Tsukuba, Japan — [4]International Center for Materials Nanoarchitectonics, National Institute for Materials Science, Tsukuba, Japan

Black phosphorus (BP) has been known as a more favorable material in many applications compared to other 2D materials due to its exceptional properties. However, its sensitivity to air species has restricted its integration into active devices. In this work, we used a few nm thickness BP for developing field-effect transistors (FETs). Lithography-free via-encapsulation scheme allows us to fabricate fully-encapsulated BP-based field-effect transistors and perform reliable electrical measurements. Based on our results, we find that the electronic properties of the via-encapsulated BP FETs are significantly improved compared to unencapsulated devices. We further demonstrated a gas-sensing performance based on the BP FET. Our Preliminary result shows the promising potential of BP for applications in advanced gas-sensing technology.

HL 33.11　Wed 17:00　P1

Stationary and Time-Resolved Luminescence of Organic-Dye/transition metal dichalcogenide Heterostructures — •Julian Schröer, Tim Völzer, Alina Schubert, Rico Schwartz, Stephan Lochbrunner, and Tobias Korn — University of Rostock, Institute of Physics

Thin layers of organic molecules and layered semiconductors build a new compound material with manifolds of interesting applications. The optoelectronic properties of these heterostructures strongly depend on the chosen compounds. Via stationary and time-resolved photoluminescence experiments, we investigate samples of Perylene-Orange (PO) deposited on top of single-layer tungsten diselenide. This joint material exhibits a type-II band alignment, enabling charge transfer processes between the two material layers. Here, we aim to reveal the temperature dependent dynamics of the charge transfer processes. Our work paves the way for a deeper understanding of organic/inorganic heterointerfaces and the functionalization of organics and TMD's in optoelectronic devices.

HL 33.12　Wed 17:00　P1

Quantum transport in twisted bilayer graphene supermoiré heterostructures — Alexander Rothstein[1], Robin Dolleman[1], Christoph Schattauer[2], •Anthony Achtermann[1], Stefan Trellenkamp[3], Florian Lentz[3], Kenji Watanabe[4], Takashi Taniguchi[5], Dante Kennes[6], Florian Libisch[2], Bernd Beschoten[1], and Christoph Stampfer[1] — [1]2nd Institute of Physics, RWTH Aachen University, Germany — [2]Institute for Theoretical Physics, TU Wien, Austria — [3]Helmholtz Nano Facility, Forschungszentrum Jülich, Germany — [4]Research Center for Functional Materials, National for Material Science, 1-1 Namiki, Japan — [5]International Center for Materials Nanoarchitectonics, National Institute for Materials Science, 1-1 Namiki, Japan — [6]Institute for Theory of Statistical Physics, RWTH Aachen University, and Jara Fundamentals of Future Information Technology, Germany

Twisted bilayer graphene hosts a plethora of correlated quantum phenomena, such as superconductivity, correlated insulators and strange metal phases. The unprecedented in-situ gate-tunability of the system allows the study the underlying physics in detail by means of quantum transport experiments. The microscopic details of the van-der-Waals heterostructure, like the presence of competing moiré lattices, heavily influence the exact characteristics of the device. Here, we investigate different conductance regimes in near-magic angle twisted bilayer graphene devices, focusing on the insulating states. We are able to identify the presence of super-moiré lattices in our devices from magneto-transport experiments and compare our results with theory.

HL 33.13　Wed 17:00　P1

Ultrathin 2D gallium selenide devices for optoelectronics — •Marco N. Dembecki, Simon Bernöcker, Michele Bissolo, Eugenio Zallo, and Jonathan J. Finley — Walter Schottky Institute and TUM School of Natural Sciences, Technische Universität München, Am Coulombwall 4, Garching, Germany

The post-transition metal chalcogenides (PTMC, M = [In, Ga], C = [S, Se, Te]) are a group of semiconducting layered materials with a widely tunable band gap and direct-indirect band gap crossover in the few-layer limit. Type II band alignment of PTMC heterostructures makes them good candidates as photoabsorbers [1].

Among PTMCs, GaSe holds promise for optoelectronics, nonlinear optics, and terahertz (THz) generation but its usefulness for devices is inhibited by strong susceptibility to oxidation. Here, we report on the fabrication of dual gated-FET based on fully hBN-encapsulated GaSe multilayers. To preserve the intrinsic properties of the gallium selenide, the encapsulation process was carried out in a controlled nitrogen atmosphere. The gate electrodes are made from few-layer graphene to allow for an optoelectronic investigation. Electrical transport measurements are carried out and a roadmap for future optoelectronic devices will be discussed.

HL 33.14   Wed 17:00   P1

Towards thermoelectric transport measurements in dual-gated bilayer graphene — •Moritz Knaak, Martin Statz, and Thomas Weitz — 1st Physical Institute, Faculty of Physics, University of Göttingen, Friedrich-Hund-Platz 1, Göttingen 37077, Germany

The ratio of the thermal voltage to the corresponding temperature difference is defined as the Seebeck coefficient. As a transport coefficient due to its relation to the density of states (DoS) and its underlying link between entropy and charge transport, the Seebeck coefficient can help to better understand materials with interesting DoS and/or phase transitions. One of these materials is trigonally warped bilayer graphene (BLG), in which Lifshitz transitions can be induced by tuning an out-of plane electric field or the charge carrier density. Near these transitions the DoS is high and electron-electron interaction becomes important. To gain further insights into the emerging correlated phases near these Lifshitz transitions [1] and quamtify the changes in the DoS, we measure the thermoelectric voltage and local temperature difference to extract the Seebeck coefficient. For that we combine a hexagonal boron nitride encapsulated, dual-gated BLG device with graphite gates and contacts together with an on-chip heater next to the BLG. The source and drain contacts are simultaneously used as 4-point-probe on-chip resistance thermometers to determine the local temperature differences. The devices are fabricated utilizing the dry transfer method, e-beam lithography, thermal evaporation of contact leads as well as reactive ion etching.

HL 33.15   Wed 17:00   P1

Niobium-Doping of Atomically Thin Molybdenum Disulfide for Optoelectronic Applications — •Osamah Kharsah, Stephan Sleziona, and Marika Schleberger — Universität Duisburg-Essen, Fakultät für Physik and CENIDE, Germany

Two-dimensional materials are predicted to become a very important disruptive technology, opening the door to a plethora of applications across many fields, especially in the field of optoelectronics. Among these materials, atomically thin molybdenum disulfide (MoS_2) has distinguished itself owing to its electronic properties, good thermal stability, and mechanical durability. However, its intrinsic strong n-type conductivity hinders its implementation. Overcoming this hurdle would allow MoS_2 to be used in structures such as p-n junctions either on its own or in tandem with other 2D materials, with the goal of fabricating the next generation of optoelectronic devices. One approach that could solve this problem is substitutional doping to controllably p-dope MoS_2. We report on the direct growth of niobium-doped monolayer MoS_2, which was characterized by Raman- and photoluminescence spectroscopy. Field-effect transistors, with the as-grown Nb-doped MoS_2, showed n-type transport behavior. After annealing the material in a sulfur atmosphere, this switched to an ambipolar transport behavior, which we attribute to the activation of Nb-doping sites. In addition, the hysteresis of this device exhibited a decrease of 4 orders of magnitude, indicating that the influence of intrinsic defects has been remedied by the annealing process.

HL 33.16   Wed 17:00   P1

Towards strong coupling of confined excitons to a fiber-based microcavity — •Moritz Scharfstädt, Michael Köhl, and Andrea Bergschneider — Physikalisches Institut, Universität Bonn, Wegelerstraße 8, 53115 Bonn, Germany

Excitons in monolayer transition-metal dichalcogenides (TMD) exhibit large oscillator strengths and hence are well-suited for strong light-matter coupling. While for free excitons strong coupling to photonic cavities has been demonstrated in numerous experiments, nonlinearities in those systems are relatively weak. The recently demonstrated quantum confinement of excitons to length scales of about 20nm is a promising route towards enhancing nonlinearities [1].

We want to realize confined excitons with the prospect of embedding them into a high-finesse microcavity and reach the strong coupling regime. To confine the excitons in transverse direction and tune their energy, we develop a specific electric gate configuration. Our microcavity will be fiber-based and tunable at cryogenic temperatures. With this platform we aim for the realization of a quantum emitter in a cavity by harvesting the enhanced nonlinearity combined with a cavity-enabled photon blockade.

HL 33.17   Wed 17:00   P1

Photon assisted tunneling in bilayer graphene double quantum dots — •Tobias Deussen[1], K. Hecker[1,2], L. Banszerus[1,2], A. Schäpers[1], A. Peters[1], S. Möller[1,2], E. Icking[1,2], K. Watanabe[3], T. Taniguchi[4], C. Volk[1,2], and C. Stampfer[1,2] — [1]JARA-FIT & 2nd Institute of Physics, RWTH Aachen — [2]Peter Grünberg Institute, Forschungszentrum Jülich — [3]RCFM, NIMS, Japan — [4]MANA, NIMS, Japan

Spin qubits in semiconductor quantum dots (QDs) are attractive candidates for solid state quantum computation. Singlet-triplet qubits, where the logical qubits are encoded in a two-electron spin system in double quantum dots (DQDs), turned out to be of special interest. In such systems, control over the interdot tunnel coupling and, hence, the exchange interaction is essential. Bilayer graphene (BLG) is an attractive host material for spin qubits due to its small spin-orbit and hyperfine interaction and its gate voltage controllable band gap. Only recently, it has become possible to confine single electrons in BLG QDs and to understand their spin and valley texture. However, microwave manipulation has not been demonstrated, so far. Here, we perform photon-assisted tunneling (PAT) spectroscopy, which relies on resonant microwave excitation of electrons across the interdot transition. We extract a lower bound for charge dephasing, T2*, of about 350 ps. In power-dependent measurements, we explore multi-photon processes. We use PAT as a probe for the interdot tunnel coupling in BLG DQDs and can control and measure the interdot tunnel coupling in a range of several GHz which is suitable for qubit operations.

HL 33.18   Wed 17:00   P1

Coherent coupling dynamics between excitonic complexes in a MoSe$_2$ monolayer — •Daniel Wigger[1], Aleksander Rodek[2], Thilo Hahn[3], James Howarth[4], Takashi Taniguchi[5], Kenji Watanabe[5], Marek Potemski[2,6], Piotr Kossacki[2], and Jacek Kasprzak[2,7] — [1]School of Physics, Trinity College Dublin, Ireland — [2]Faculty of Physics, University of Warsaw, Poland — [3]Institute of Solid State Theory, University of Münster, Germany — [4]National Graphene Institute, University of Manchester, UK — [5]National Institute for Materials Science, Tsukuba, Japan — [6]Laboratoire National desChamps Magnétiques Intenses, CNRS-UGA-UPS-INSA-EMFL, Grenoble, France — [7]Université Grenoble Alpes, CNRS, France

In modern heterostructures of layered van der Waals materials that combine graphene, hBN, and TMDCs it is possible to deterministically control the density of free charge carries in a TMDC monolayer. With this approach and the ultrafast nonlinear four-wave mixing (FWM) spectroscopy technique we study the coherent coupling dynamics between neutral and charged excitons in a MoSe$_2$ monolayer. We demonstrate that the so-called Raman coherence between the two exciton species leads to characteristic quantum beats in the FWM signal. By exploiting 2D-FWM spectra, we can conclude that the bias dependent change of dipole strength between the exciton types is not sufficient to explain the experimental findings. Therefore, we conclude that the tuning of the free carrier density directly affects the coherent coupling between neutral and charged excitons.

HL 33.19   Wed 17:00   P1

Resonant Excitation and Resonant Photoluminescence Detection of Silicon Vacancy Centers in 4H Silicon Carbide for Single Photon Emission — •Fedor Hrunski[1], Mike Gerd Georg Köstler[1], Shravan Kumar Parthasarathy[2,1], Maximilian Hollendonner[1], Andre Pointner[1], Christian Gobert[2], Daniel Scheller[1], and Nagy Roland[1] — [1]Chair of Electron Devices (LEB), Friedrich-Alexander-University, Erlangen, Germany — [2]Fraunhofer Institute for Integrated Systems and Device Technology (IISB), Erlangen, Germany

For today, quantum networks deal with the task of entangling several qubits with each other over a larger distance. Therefore, the resonant excitation of the qubits and the resonant detection of emitted photons by them appears to be an essential component of such a network for coherent spin state control. This work hereby deals with the resonant single photon detection of fluorescence, which is emitted by resonantly exited V2 color centers in 4H-SiC. Therefore, a diode laser modulated by an electro-optical modulator performs a pulsed resonant excitation at one of the A_1 or A_2 spin-conservative optical transitions, while the emitted photons are detected by a superconducting single photon detector. However, due to the chromatic equality of the excitation photons and fluorescent photons, they are distinguished by their polarization.

HL 33.20   Wed 17:00   P1

A standalone fiber-bases quantum sensor using ensembles of NV-Centers in diamond — •Benjamin Pohl, Andre Pointner, and Roland Nagy — Chair of Electron Devices, FAU Erlangen-Nuremberg

Though NV-Center magnetometry with diamonds is widely spread in scientific research, it is rarely used in an industrial context. In order to reduce the complexity of the required hardware we fixate the diamond on the tip of a fiber and miniaturize the system so all the required components can be included in a standalone device for magnetic field determination. The measurement is performed with ensembles of NV-Centers used as an optically controlled [3]quantum sensor in

a confocal setup. Determination of the magnetic field is achieved through optical detected magnetic resonance (ODMR). In the presence of a local magnetic field, the four orientations of the NV-Centers in the diamond crystal results in up to four different Zeeman splits, which allows the evaluation of the local magnetic field vector. The resulting sensitivity to magnetic fields is strongly dependent on the number of collected signal photons on the detector. Therefore, to increase the sensitivity, the collection efficiency is crucial. Detection of the collected photons is realized by an integrated photodiode and the signal is evaluated by a field programmable gate array (FPGA) which also controls the measurement hardware. Such a standalone device will enable measurements in various environments and provide a system for users without insight to optics or quantum technology, thus greatly extending the possible applications for NV-Centers as quantum sensors.

HL 33.21 Wed 17:00 P1

Realization of remote entanglement using vacancy-centers in 4H-SiC — •Michael Baron[1], Maximilian Hollendonner[1], Fedor Hrunski[1], Daniel Scheller[1], Andre Pointner[1], Shravan Kumar Parthasarathy[2], and Roland Nagy[1] — [1]Chair of Electron Devices FAU — [2]Fraunhofer Institute for Integrated Systems and Device Technology IISB

The overall performance of quantum applications, such as quantum sensors, quantum tokens and optical quantum computers, can be highly improved by realizing a quantum network in which these constituents are connected. The emerging field of quantum technologies based on color centers in silicon carbide (SiC) will play an important part in the realization of such distributed quantum networks. As a physical platform silicon vacancy centers inside 4H SiC offer numerous advantages, such as low electrical field sensitivity making the system robust against stray fields, high photon yield in the Zero-Phonon-Line, good spin-coherence time and an already well-matured industrial fabrication knowledge for SiC. My research is concerned with the technical implementation and realization of a heralded single-photon entanglement protocol using V2 silicon vacancy centers in 4H-SiC. The experiment employs two such vacancies residing in independently operated cryostats separated by 2 meters, which are connected in an interferometer-like setup. This allows the creation of entanglement between both V2 centers and thus the creation of a quantum network based on these color centers.

HL 33.22 Wed 17:00 P1

Towards an integrated nanophotonic and electronic spin platform in 4H-SiC — •Daniel Scheller[1], Daniel Häupl[2], Lin Jin[3], Christian Gobert[4], Jannik Schwarberg[1], Jörg Schulze[1], Nicolas Joly[2], Wolfram Pernice[3], and Roland Nagy[1] — [1]Chari of Electron Devices, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany — [2]Max-Planck-Institue for the science of light, Erlangen, Germany — [3]Responsive Nanosystems, University of Münster, Münster, Germany — [4]Fraunhofer IISB, Erlangen, Germany

The solid state spin system of negatively charged silicon vacancies (V_{Si}) V2 in 4H-SiC shows high spectral stability and excellent spin coherence times required for efficient quantum processing. Moreover, silicon carbide provides standardized semiconductor processes enabling the implementation of integrated quantum photonics. However, high-fidelity spin photon coupling and low-loss chip-to-fiber interfaces are necessary to improve experimental rates and, thus, the performance of quantum devices. Recently, high coupling efficiencies of emitted photons from the VSi color center into angle-etched SiC waveguides have been predicted which can be further enhanced by photonic crystal cavities. Further, a low-loss optical interface from on-chip diamond tapered waveguides to tapered optical fibers was shown. Our goal is to combine these properties and implement single VSi color centers into nanophotonic SiC waveguides coupled to tapered fibers for realizing the on-chip entanglement of color centers and two locally separated quantum registers.

HL 33.23 Wed 17:00 P1

Towards Silicon Vacancy centers based quantum repeaters for a distributed quantum computing network in 4H-SiC — •Maximilian Hollendonner[1], Fedor Hrunski[1], Andre Pointner[1], Shravan Kumar Parthasarathy[2,1], Christian Gobert[2], Daniel Scheller[1], and Roland Nagy[1] — [1]Chair of Electron Devices, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Fraunhofer Institute for Integrated Systems and Device Technology IISB, Schottkystraße 10, Erlangen, Germany

For the successful integration of quantum technological systems, like for instance optical quantum computers and quantum sensors [1] into a quantum internet of things it is vital to have quantum repeaters which mediate the exchange of information between various quantum nodes. Due to its excellent optical and spin properties [2], the V_2 silicon vacancy center in 4H-SiC is a promising platform for this task. Within this project we aim at building an interferometer in which after a first 50/50 beam splitter, two single V_2 centers separated by 2 meters are excited by 916nm photons. The single photon emitted by one of the two color centers then enters a second beam splitter, which effectively removes the which-path information and therefore creates a maximally entangled Bell state [3]. Successful demonstration of this entanglement between these two V_2 centers will be a vital step towards realization of a quantum internet of things.

On the positioning accuracy of single quantum emitters in photonic nano-structures embedded through in-situ electron beam lithography — •Jan Donges, Johannes Schall, Imad Limame, Ching-Wen Shih, Sven Rodt, and Stephan Reitzenstein — Technische Universitaet Berlin, Hardenbergstr. 36, 10623 Berlin

The precise integration of single quantum emitters at the target position inside of photonic nano-structures is of upmost importance for their optimum performance. Differences between simulated photon extraction efficiencies and experimentally determined values are often at least partially contributed to a spatial misalignment of the emitter. This is a reasonable assumption considering that for instance in the case of Bullseye cavities simulations yield that the efficiency can drop more than 50% just in case of a 50nm misplacement between structure and emitter. The main problem with this approach so far has been that there is no direct way of determining the emitter position inside the structure. Therefore, all statements about the position were based indirectly on results of photoluminescence (PL) experiments. Here, we present a solution for this issue. Through the simultaneous measurement of the structure via cathodoluminescence and electron microscopy we can directly determine the emitter position inside a photonic structure with. Furthermore, this approach enables us to make a clear statement about the positioning accuracy of in-situ electron beam lithography.

HL 33.25 Wed 17:00 P1

Quantum Polyspectra for an uncompromising and universal evaluation of quantum measurements — •Markus Sifft and Daniel Hägele — Ruhr University Bochum, Faculty of Physics and Astronomy, Experimental Physics VI (AG), Germany

The analysis of a continuous measurement record $z(t)$ poses a fundamental challenge in quantum measurement theory. Different approaches have been used in the past as records can, e.g., exhibit predominantly Gaussian noise, telegraph noise, or clicks at random times. This poster summarizes our latest findings that show that quantum measurements from all cases above can be analyzed in terms of higher-order temporal correlations of the detector output $z(t)$ and be related to the Liouvillian of the measured quantum system. The comparison of temporal correlations via so called quantum polyspectra is based on expressions derived without approximation from the stochastic master equation [1] and automatized without the need for manual post-processing of the detector output. This allows for fitting of system parameters like e.g., tunneling rates in a quantum transport experiment [2]. The very general stochastic master equation approach includes coherent quantum dynamics, environmental damping, and measurement backaction at arbitrary measurement strength. This enables a systematic evaluation of quantum measurements from the realms of conventional spin noise spectroscopy, quantum transport experiments, and, as our newest finding, ultra-weak measurements with stochastically arriving single photons [3]. [1] Hägele et al., PRB 98, 205143 (2018), [2] Sifft et al., PRR 3, 033123 (2021), [3] Sifft et al., arXiv:2109.05862

HL 33.26 Wed 17:00 P1

Detection of half-vortices in confined polariton condensates — •Yannik Brune, Bernd Berger, and Marc Assmann — Department of Physics, TU Dortmund, Germany

A half-vortex describes a rotating quantum fluid carrying a spin dependent topological charge. Theory predicts half-vortices as solutions of the spin dependent GPE. We experimentally demonstrate the existence of half-vortices in an all optical circular confined polariton condensate. Therefore we excite a polariton microcavity across the treshhold using a ringlike excitation profile and observe the polariton emission. Finally, we measure the topological charge of the condensate state, using spin filtered OAM sorting [1], and thereby confirm its half vortex character.

[1]Berger et al., Optics Express 26(24):32248 (2018)

HL 33.27 Wed 17:00 P1

Adaptive Bayesian estimation of an Overhauser field gradient — •Jacob Benestad[1], Jan Krzywda[2], Evert van Nieuwenburg[2,3], Fabrizio Berritta[3], Torbjørn Rasmussen[3], Anasua Chatterjee[3], Ferdinand Kuemmeth[3], and Jeroen Danon[1] — [1]Center for Quantum Spintronics, Norwegian University of Science and Technology, Norway — [2]Leiden Institute of Advanced Computer Science, Leiden University, The Netherlands — [3]Center for Quantum Devices, University of Copenhagen, Denmark

Slow fluctuations of the Overhauser field gradient are an important source for decoherence in singlet-triplet spin qubits hosted in type III-V semiconductors. Single-shot Ramsey experiments are well suited for Bayesian inference of the Overhauser gradient, where smart experiment design and prior knowledge can be leveraged to increase the information gain of a new measurement. This has led to the development of adaptive schemes, where between each measurement

one attempts to determine the optimal next experiment in order to gain the most possible information about an Overhauser field gradient before the qubit decoheres. A real-time exact treatment of this problem at each step is difficult to achieve in an experimental setting. However an approximate treatment using only Gaussian distributions has been shown to give an exponential reduction of the distribution variance and would require only tracking two parameters. We propose a modification of this scheme that should make it more robust for gradients distributed around a mean of zero by evaluating the squared values and performing the Bayesian update scheme on the resulting chi-square distribution.

HL 33.28　Wed 17:00　P1

Zero-phonon line and electron-phonon coupling of the NV center in cubic silicon carbide: first-principles calculations — •Timur Biktagirov[1], Hans Jürgen von Bardeleben[2], Jean-Louis Cantin[2], Wolf Gero Schmidt[1], and Uwe Gerstmann[1] — [1]Universität Paderborn, Paderborn, Germany — [2]Sorbonne Université, Paris, France

The nitrogen-vacancy (NV) center in cubic silicon carbide (3C polytype), the analog of the NV center in diamond, has recently emerged as a solid-state qubit with competitive properties and significant technological advantages [1, 2]. Most applications of NV centers are based on optical spectroscopy of the zero-phonon line (ZPL) and the analysis of the spin states. Thus, we use density functional theory (DFT) calculations to provide thorough insight into the ZPL and the related magneto-optical properties of this center. In the case of NV in diamond, the ZPL is known to be in the visible spectral range [3]. In contrast, we identify the ZPL of the NV center in 3C-SiC at 1289 nm (within the telecom O-band), which is more suitable for device applications due to low transmission losses in optical waveguides. An analysis of the measured phonon sideband reveals the Huang-Rhys factor of 2.85 and the Debye-Waller factor of 5.8 %. Along with exceptionally long low-temperature spin-lattice relaxation times [2], these properties make NV in 3C-SiC a strong competitor for qubit applications.

Design of a microwave resonator for coherent nuclear spin control of ^{13}C and ^{29}Si isotopes near V_2 color centers in 4H-SiC at cryogenic temperatures — •Jan Philipp Ahnfeldt[1], Fedor Hrunski[1], Shravan Kumar Parthasarathy[1,2], Maximilian Hollendonner[1], Daniel Scheller[1], Andre Pointner[1], and Roland Nagy[1] — [1]Chair of Electron Devices, FAU Erlangen-Nürnberg, Erlangen, Germany — [2]Fraunhofer Institute for Integrated Systems and Device Technology (IISB), Erlangen, Germany

One step to meaningful quantum technologies is to scale up the currently developed ones. This can be done by parallelizing several quantum systems through a quantum network. Therefore it is crucial that the network contains quantum memory nodes in which the quantum system used has a long coherence time. This can be ensured by the nuclear spin of the ^{13}C or ^{29}Si isotopes surrounding a silicon vacancy in 4H-SiC. However, due to the low gyromagnetic ratio of a nuclear spin a large magnetic flux is needed for the spin control. Accordingly, a large RF power with a frequency in the upper kHz domain is required. Because the power dissipation causes problems when upscaling these systems, it is important to improve the spin control's efficiency. Hence, a resonator creating a standing magnetic wave polarized perpendicular to the quantization axis of the vacancy seems to be a promising approach. Since it must operate at room and cryogenic temperatures, the resonator must be mechanically stable and needs a wide bandwidth. Therefore, several resonators are investigated which could meet these requirements in a small package of a few cubic centimeters.

Optical Beamsplitter for Orbital Angular Momentum Modes — •Rebecca Aschwanden[1], Bernhard Reineke[2], Lingling Huang[3], Klaus D. Jöns[1], Tim Bartley[1], and Thomas Zentgraf[1] — [1]Department of Physics, Paderborn University, Paderborn, Germany — [2]Institute for Photonic Quantum Systems PhoQS, Paderborn University, Paderborn, Germany — [3]Beijing Institute of Technology, Beijing, China

Metasurfaces consist of periodically arranged antennas of subwavelength dimensions that allow for specifically engineered functionalities and interaction with the incident light beam. They cannot only be used to replace conventional bulk optical elements but also to provide new functionalities. Here, we present the design and fabrication of a dielectric metasurface acting as a beamplitter with multiple output ports for orbital angular momentum (OAM) states. The dielectric metasurface consists of silicon nanofins which are fabricated by electron beam lithography and etching. We show that the metasurface splits the beam containing a superposition of OAM states into four spatially separated output directions.

Integration of free-standing GaAs nanobeam cavities hosting InAs/GaAs QD with LNOI waveguides — •Oscar Camacho Ibarra, Ioannis Caltzidis, Marc Sartison, and Klaus D. Jöns — Paderborn University, Paderborn, Germany

Monolithic integration is the most straightforward approach to incorporate single photon emitters and photonic integrated circuits (PICs). However, this approach limits you to the optical properties of the chosen material platform. Furthermore, the current best emitters on monolithic integration are randomly positioned [1]. Based on this context, hybrid integration, despite also requiring localization, stands out, in this approach different materials are integrated in one PIC, allowing one to exploit the advantages of each different material system (whether they are optical properties of the material or the emitters properties). In our work, we seek to hybridly integrate InAs/GaAs quantum dots embedded in nanobeam cavities with LNOI waveguides. To achieve this, we chose a transfer printing method [2] to place the nanobeam cavities (hosting the emitters) on top of the LNOI waveguides. Therefore, we report on the current progress and challenges for localization and nanofabrication of the free-standing nanobeam cavities.

Observation of quantum Zeno effects for localized spins — •Vitalie Nedelea — Experimentelle Physik 2, Technische Universität Dortmund, 44221 Dortmund, Germany

One of the main dephasing mechanisms for the localized carrier spins in semiconductors is the coupling to the fluctuating nuclear spin environment. Here we present an experimental observation on the effects of the quantum back action under pulsed optical measurements of spin ensemble and demonstrate that the nuclei-induced spin relaxation can be influenced. We show that the fast measurements freeze the spin dynamics and increase the effective spin relaxation time, the so-called quantum Zeno effect. Furthermore, we demonstrate that if the measurement rate is comparable with the spin precession frequency in the effective magnetic field, the spin relaxation rate increases and becomes faster than in the absence of the measurements, an effect known as the quantum antiZeno effect. A theory describing both regimes allows us to extract the system parameters and the strength of the quantum back action.

HL 33.33　Wed 17:00　P1

On-demand strain-induced recombination dynamics in semiconductor quantum wells — Daniel Hensel[1], Daniel Schmidt[3], Fariba Hatami[2], and •Peter Gaal[1,3] — [1]Leibniz-Institut für Kristallzüchtung, 12489 Berlin — [2]Humboldt Universität zu Berlin, 12489 Berlin — [3]TXproducts UG, 22547 Hamburg

Todays technology enables the fabrication of semiconductor structures with a high control over the electronic states. New technologies emerged from the manipulation of these states. To gain full control over the quantum state encrypted in a particle one must control both its lifetime and its coherence. Tailored transient strain pulses provide a new tool for the manipulation of nanoscale quantum objects. The strain-induced deformation of the crystal lattice manipulates the electronic bandstructure via deformation potential coupling. A convenient method to administer strain pulses to a sample are so-called surface acoustic waves (SAW). They are generated electronically by interdigitated circuits (IDT). The experimental control is limited by the ability to generate arbitrary lattice deformations on timescales short compared to the quantum decoherence. The photoacoustic method allows controlling the spatial and temporal shape of the optical excitation and thus shapes the strain pulse. In consequence, arbitrary SAWs can be generated on ultrafast timescales. Time-resolved photoluminescence (TRPL) spectroscopy is used to monitor the strain-induced change in electronic bandstructure. The control of the efficiency of radiative transitions of excitons through the applied strain could be the missing step for the realization of a fast on-demand single photon source.

HL 33.34　Wed 17:00　P1

Fiber-based Open Cavity: a tailored solution for Solid-state Quantum Emitters and their characterization. — •Francesco Salusti[1], Lukas Hanschke[1], Eva Schöll[1], Jonathan Noe[2], Manuel Nutz[2], Michael Förg[2], Thomas Hümmer[2], and Klaus D. Jöns[1] — [1]PhoQS, CeOPP, and Department of Physics, Paderborn University, 33098 Paderborn, Germany — [2]Qlibri GmbH, 80337 Munich, Germany and Fakultät für Physik, Ludwig-Maximilians-Universität, 80799 Munich, Germany

For the realization of bright and reliable quantum light emitters, the integration of these emitters into cavity structures represents an elegant solution. However, in many cases, the fabrication of such photonic structure requires remarkable efforts to precisely match the position and the emission wavelength of the emitter with respect to the cavity mode. The required level of control of the materials, size, and positioning makes the realization of a practical cavity resource intensive. Recent works have demonstrated the possibility to take advance of open cavities to easily tailor the cavity around the specifications of individual emitters, such as 2D flakes and quantum dots. In our collaboration between industry and academia, we show that it is possible to take advantage of a fiber-based de-

vice to realize a tunable cavity at room and cryogenic temperature. In addition to the advantages of in-situ tuning of an optical resonator to specific emitter resonances, the high finesse of the system enables spatially resolved measurements of the absorption coefficient from oxidized 2D material.

HL 33.35   Wed 17:00   P1

Monolithic, heterogeneous and hybrid Integration of quantum emitters — •Marc Sartison, Oscar Camacho Ibarra, Ioannis Caltzidis, Dirk Reuter, and Klaus D Jöns — Institute for Photonic Quantum Systems, Center for Optoelectronics and Photonics Paderborn, and Department of Physics, Paderborn University, 33098 Paderborn, Germany

Modern integrated quantum photonic devices can be built out of a variety of material platforms like Lithium-Niobate on insulator (LNOI), Silicon-Nitride or Silicon with different kinds of quantum emitters like quantum dots, NV centres or emitters hosted in 2D materials. Exploiting the unique material properties several integration approaches were realized that can coarsely be categorized and belong to one of the following types: Monolithic, heterogeneous, and hybrid integration. In our work we give an overview of the different integration methods and compare them in terms of yield and scalability. We discuss the advantages and disadvantages of monolithic, heterogeneous and hybrid integration methods and provide a perspective on the upcoming challenges to realize scalable systems with high yield.

HL 33.36   Wed 17:00   P1

Electrical Stark tuning of multiple waveguides with integrated quantum dots — •Yuhui Yang[1], Shulun Li[1,2], Johannes Schall[1], Chirag Palekar[1], Léo Roche[1], Hanqing Liu[2], Sven Rodt[1], Haiqiao Ni[2], Zhichuan Niu[2], and Stephen Reitzenstein[1] — [1]Institut für Festkörperphysik, TU Berlin, 10623 Germany — [2]Institute of Semiconductors, CAS, 100083, China

Self-assembled quantum dots (QDs) are promising candidates for future photonic quantum technologies owing to their close-to-ideal quantum properties. However, the random spectral and spatial distribution of single QD complicates the controlled integration of single QD into photonic structures using standard nano-processing technologies such as standard electron beam lithography and makes upscaling to complex quantum circuits practically impossible. We overcome these technical issues by combining cryogenic cathodoluminescence (CL) mapping for spectrally selected integration of QDs and the quantum-confined Stark effect for spectral fine-tuning. Two spectrally similar self-assembled QDs in a p-i-n diode membrane are pre-selected and are deterministically integrated into the hybrid structure waveguides using marker-based electron beam lithography. Moreover, the gate voltage-dependent micro photoluminescence spectra reveal the achievement for tuning individual QD in waveguide systems and spectrally overlying them together. Our work demonstrates the high potential of deterministic quantum device processing for the scalable fabrication of complex quantum integrated circuits with multiple single-photon emitters as an attractive platform for future quantum technologies.

HL 33.37   Wed 17:00   P1

Donor Spins in Compressively Strained Silicon — •Basak Cigdem Özcan, David Vogl, and Martin S. Brandt — Walter Schottky Institut and School of Natural Sciences, Technische Universität München, 85748 Garching, Germany

Silicon doped with donors is a promising system for quantum computing applications due to long coherence times, fast spin control and the possibility of scaling as well as integration with conventional microelectronics. In order to achieve

long coherence times, coupling to other nuclear spins should be avoided. This is achieved by using isotopically purified Si-28 samples, which is the naturally more abundant isotope without nuclear spin. The conventional architecture to conduct measurements on doped Si-28 involves the placement of control and read-out gate structures on top of the sample. Such additional structures cause strain near the donors, which makes it important to understand the effect of strain on their spin properties. To study this under controlled strain conditions, we utilize a no-contact capacitive read-out scheme, where optical excitation of donor-bound excitons (DBE) followed by an Auger recombination facilitates spin-dependent excitation, spin polarization and spin-state read-out. Combining infrared optical excitation and microwave pulses, we perform electron nuclear double resonance (ENDOR) experiments, with which we achieve coherent control of nuclear spins of the donors. Here, we investigate the strain-dependent shift of DBE resonance frequencies under uniaxial compressive stress. We acknowledge the financial support of MCQST.

HL 33.39   Wed 17:00   P1

Application of low-cost visible light LEDs in avalanche mode as sensitive photoreceivers in a plastic optical fiber data transmission system — •Heinz-Christoph Neitzert — Dept. of Industrial Engineering (DIIN) Salerno University Fisciano, Italy

Commercial low-cost light emitting diodes have been tested as photoreceivers without and with applied reverse bias voltage. In particular the possibility to operate the devices in the breakdown regime as sensitive avalanche photodiodes has been succesfully tested. High photogain amplification at relatively low breakdown voltage values has been observed. Based on this possibility to operate the LEDs efficiently not only as emitters but also as photoreceivers, a simple half-duplex bidirectional optical transmission scheme, which is based on the plastic-optical-fiber (POF) as transmission medium and green LEDs as receiving/emitting elements has been developed. The choice of the green wavelength range gives the possibility to operate the system at the minimum absorption of the plastic optical fiber

HL 33.40   Wed 17:00   P1

High Resolution Spectroscopy for (Al,In)GaN Laser Diodes — •Dominic J. Kunzmann, Raphael Kohlstedt, and Ulrich T. Schwarz — TU Chemnitz, 09126 Chemnitz, Germany

We investigate laser diodes based on the (Al,In)GaN material system with the help of high-resolution spectroscopy. Therefore, we use two setups, one with a grating spectrometer and a Fabry-Pérot-Interferometer. The grating spectrometer is used to measure the longitudinal mode spectra above and below the threshold current. Below the threshold we perform Hakki-Paoli gain spectroscopy to obtain the internal losses of laser diodes which is getting even more challenging, when the diodes get better and the losses smaller. Above the threshold wavelength shifts with current and temperature can be observed and with these shifts the thermal resistance is available. Additionally for broad ridge high power laser diodes the interplay of different longitudinal mode combs is investigated with the high-resolution spectrometer. The Fabry-Pérot-Interferometer enables us to go to even higher resolutions and to verify single mode behavior of laser sources and to observe much smaller wavelength shifts.

HL 33.41   Wed 17:00   P1

Indium incorporation in thin c-plane GaInN/GaN quantum wells grown via plasma-assisted molecular beam epitaxy — •Farouk Aljasem, Heiko Bremers, Uwe Rossow, and Andreas Hangleiter — Institut für Angewandte Physik & Laboratory for Emerging Nanometrology, Technische Universität Braunschweig, Germany

This work aims to investigate the physical mechanisms of the incorporation of indium atoms in GaInN QW structures with an emphasis on interface properties by growing thin GaInN multiple quantum wells. A comparison of the obtained results using MBE with the results from the previous work using MOVPE offers more information about indium incorporation mechanisms. As well known, the flux of the activated nitrogen in the plasma-assisted molecular beam epitaxy (PAMBE) is independent of the growth temperature. This feature enables the growth of GaInN MQWs at low temperatures and in different growth regimes compared to MOVPE. Fivefold thin GaInN/GaN MQWs are grown via PAMBE in the c-direction using MOVPE-grown GaN templates on sapphire as substrates. The GaInN/GaN MQW samples were grown at different growth temperatures with various III/V ratios and QW thicknesses. MQW thickness ranged between less than half a c-lattice constant and 2 nm with no significant relaxation. To provide a precise understanding of the physical processes during the growth process of GaInN monolayers, the samples were characterized using HR-XRD, AFM, HR-TEM and CW-PL.

HL 33.42   Wed 17:00   P1

Temperature dependent Raman spectroscopy on GaN:Si — •Christina Harms, Jona Grümbel, Martin Feneberg, and Rüdiger Goldhahn — Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Germany

GaN structures are of high interest for optical and electronic applications in current research projects. We investigate the Raman excitations of hexagonal bulk

GaN:Si under temperature variation from 80 K up to 300 K. Seven samples with carrier concentrations ranging between 10^{12} - 10^{19} cm^{-3} were measured using laser excitation of 532 nm. It is shown, that within room temperature measurements both coupled phonon-plasmon-modes (LPP$_\pm$) are visible and follow the prediction of polaritonic excitations. Under variation of temperature the LPP$_+$ mode shows a weak frequency shift with elevated temperature or remains unaffected for low carrier concentrations. Surprisingly, the LPP$_-$ mode shifts towards lower frequencies with increasing temperatures for all samples, which contradicts previous assumptions. A qualitative description of the results and possible interpretations will be presented. Additionally, we also investigated the temperature dependent FWHM of the LPP$_\pm$ mode and the E$_2$ phonon mode. Here, both behaviours match the theoretical and experimental previous research.

HL 33.43   Wed 17:00   P1

Indium incorporation during GaInN quantum well growth: role of underlayer surface morphology — •RODRIGO DE VASCONCELLOS LOURENÇO[1,2], UWE ROSSOW[1], PHILIPP HORENBURG[1], HEIKO BREMERS[1,2], and ANDREAS HANGLEITER[1,2] — [1]Institute of Applied Physics, Technische Universität Braunschweig, Germany — [2]Laboratory for Emerging Nanometrology, Technische Universität Braunschweig, Germany

The control of Indium incorporation is a key factor for the optoelectronic devices in the visible and near UV spectral region. The luminescence efficiency of such devices has been improved by the so-called underlayer, i.e the layer grown just before the active region. We investigate the surface morphology as function of the underlayer (UL) composed of GaN or InAlN. For GaN UL, we find extended, very smooth terraces separated by macrosteps in a range of growth temperature from 770 to 950 °C. Additionally, morphologies associated to the Ehrlich-Schwöbel barrier are not observed. On the other hand, for InAlN UL lattice matched to GaN, evidence for nuclei forming at step edges is observed, which may be due to lower surface mobility of Al compared to Ga or In. In the next step, we want to understand how the underlayer morphology affects the Indium incorporation of GaInN quantum wells.

HL 33.44   Wed 17:00   P1

The impact of laser lift-off on the optical properties of InGaN/GaN LEDs — •STEFAN WOLTER, STEFFEN BORNEMANN, HENDRIK SPENDE, and ANDREAS WAAG — Institut für Halbleitertechnik, Technische Universität Braunschweig, 38106 Braunschweig

InGaN/GaN LEDs are typically grown on sapphire, but sapphire is a disadvantageous material when it comes to electrical or thermal conductivity. This limits the performance, when the LED structure is processed into a device. For this reason, it is useful to transfer the LED structure to another carrier after growth, which can be achieved by laser lift-off (LLO). In this process, a pulsed laser beam is focused on the sapphire/GaN interface, leading to absorption of the laser photons in the GaN layer and subsequent decomposition of GaN near the interface resulting in detachment of the GaN film from sapphire. The usage of ultra short laser pulses can reduce the required laser fluence compared to nanosecond pulses, but has the disadvantage of penetrating deep into the LED structure and possibly even reaching the active region. This leads to a change in the characteristic properties of the LED, which is investigated in this study. For this purpose, in-house grown blue InGaN/GaN LEDs are investigated before and after LLO, which was conducted with sub-bandgap (520 nm) and above-bandgap (347 nm) laser light at a pulse width of 0.4 ps. Temperature-dependent photoluminescence experiments in the temperature range of 6 K to 295 K indicate that the maximum internal quantum efficiency decreases by at least 10 % after LLO. Furthermore, LLO can have an impact on the localization strength of the carriers inside the active region.

HL 33.45   Wed 17:00   P1

haracterization of a semiconductor microstructure analogous to a Venturi pump — •SEVERIN KRÜGER, FABIAN LIEDTKE, PETER ZAJAC, ANDREAS WIECK, ARNE LUDWIG, and ULRICH KUNZE — Ruhr-Universität Bochum, Universitätsstraße 150, 44801 Bochum, Germany

Micro-structuring a high-mobility two-dimensional electron gas allows investigation of the ballistic transport regime for electrons. The electrons in the examined channel structures show edge effects like a minimal resistance at finite currents [1]. Furthermore, the electrons show hydrodynamical behavior and can create a rectifing voltage at the narrow channel, similar to the Venturi-effect [2]. Here, first results of measurements regarding the Venturi analogon with different channel sizes, gate voltages and source-drain currents are presented.

Novel approach to real-space renormalization group analysis of the quantum Hall effect — •NATHAN SHAW and RUDOLF A. RÖMER — Department of Physics, University of Warwick, Coventry, CV4 7AL, UK

Consensus on the value of the critical exponent ν of the plateau-to-plateau transitions in the quantum Hall effect has not yet been achieved. Recent work has highlighted a discrepancy between field theory based predictions and numerical high-precision estimates. A necessarily approximate real-space renormalization group (RG) approach to the Chalker-Coddington model has previously been shown to suggest a critical exponent of $\nu \approx 2.3$. However, most recent numerical estimations suggest that $\nu = 2.58(3)$. In this study, we experiment with varying the analytical form of the scattering matrix elements with the goal of increasing the numerical stability of the fixed point distribution constructed by the RG flow. Using this improved distribution, we recalculate the critical exponent with higher accuracy.

HL 33.47   Wed 17:00   P1

Epitaxial growth of high-density short wavelength InGaAs QDs for low-threshold VCSELs — •SARTHAK TRIPATHI, KARTIK GAUR, CHING-WEN SHIH, IMAD LIMAME, SVEN RODT, and STEPHAN REITZENSTEIN — Inst. for Solid State Phys., Technical Univ. of Berlin, Germany

Self-assembled growth of InGaAs quantum dots by MOCVD is used to form the active region of low-threshold vertical-cavity surface-emitting lasers (VCSELs). In our work, we optimize the QD gain medium for room-temperature lasing at 935-955 nm which is attractive for gas sensing applications. Multiple layers of high-density InGaAs quantum dots are stacked in order to maximize the modal gain. The density of dislocations and point defects in QD heterostructures is strongly reduced by annealing which enables a significant reduction of the spacer thickness (thinner active region) between stacked QD layers without forfeiting their crystalline quality. Surface characterization is performed using atomic force microscopy AFM to determine the QD density. Moreover, during growth optimization photoluminescence studies are conducted to evaluate the optical properties of single and stacked layers of QD emitting in the target wavelength range. In future, the resulting QDs will be integrated in an active region embedded VCSELs with monolithically integrated high contrast grating (MHCG) hybrid structure.

HL 33.48   Wed 17:00   P1

Simulation and fabrication of a WS$_2$-nanobeam cavity with a MoSe$_2$ monolayer as active material — •ARIS KOULAS-SIMOS[1], BÁRBARA ROSA[1], CHIRAG PALEKAR[1], LÉO ROCHE[1], YANG YUHUI[1], FELIX BINKOWSKI[2], SVEN BURGER[2,3], BATTULGA MUNKHBAT[4], and STEPHAN REITZENSTEIN[1] — [1]Institut für Festkörperphysik, Technische Universität Berlin, 10623 Berlin, Germany — [2]Zuse Institute Berlin (ZIB), 14195 Berlin, Germany — [3]JCMwave GmbH, D-14050 Berlin, Germany — [4]Department of Electrical and Photonics Engineering, Technical University of Denmark, 2800 Kongens Lyngby, Denmark

Transition metal dichalcogenides (TMDCs) exhibit extraordinary optical, electrical, and mechanical properties that can be easily tailored for novel integrated photonic applications. Different TMDCs can be combined to form novel nanostructures with highly interesting complex dynamics. Here, we report on the simulation and fabrication of a WS$_2$-nanobeam cavity with a MoSe$_2$ monolayer (ML) as active material. Utilizing a FEM eigenfrequency solver, cavity simulations are performed on a 3D stripe of WS$_2$ with a finite periodic air hole arrangement. The calculated eigenmodes exhibit high Q-factors and tight mode confinement with mode volumes near the fundamental diffraction limit after parameter optimization. The final parameter set is employed in the fabrication process of WS$_2$-nanobeam cavities with a MoSe$_2$ ML embedded in them. This work paves further the way toward the realization of novel nanolaser devices consisting purely of TMDC materials.

HL 33.49   Wed 17:00   P1

Design and optimization of Monolithic High Contrast Grating for tuneable quantum dot VCSEL arrays — •FLORIANA LAUDANI[1], MIKOŁAJ JANCZAK[2], BARTOSZ KAMIŃSKI[3], NIELS HEERMEIER[1], ANNA MUSIAŁ[3], GRZEGORZ SĘK[3], TOMASZ CZYSZANOWSKI[2], SVEN RODT[1], and STEPHAN REITZENSTEIN[1] — [1]Institute of Solid State Physics, Technische Universität Berlin, 10623 Berlin, Germany — [2]Institute of Physics, Lodz University of Technology, 90-924 Łódź, Poland — [3]Department of Experimental Physics, Wroclaw University of Science and Technology, 50-370 Wrocław, Poland

Water vapor measurements are essential for industrial applications to ensure a qualitative processing and control chain and require gas sensors with short response times in a broad wavelength range. In contrast to standard vertical-cavity surface-emitting lasers (VCSELs), devices with monolithically integrated high contrast gratings (MHCGs) can provide a high flexibility with respect to the emission wavelength. We compare reflectivity measurements and theoretical results on GaAs-based MHCGs for a target wavelength around 940 nm. A numerical model based on Plane-Wave Admittance Method solving set of Maxwell equations was used to search for optimal geometric parameters for effective device optimization, allowing a controlled parameter tuning through-

out the fabrication process based on high-resolution electron-beam lithography. Since MHCGs can be custom designed before fabrication, they offer great potential for realizing on-chip tuneable VCSEL arrays, e.g. in a variety of short-range communication systems.

HL 33.50   Wed 17:00   P1

In-plane coupling between a WGM micropillar laser and a ridge waveguide — •Léo Roche[1], Imad Limame[1], Ching-Wen Shih[1], Aris Koulas-Simos[1], Yuhui Yang[1], Sven Burger[2], and Stephan Reitzenstein[1] — [1]Institut für Festkörperphysik (TUB), Berlin, Germany — [2]JCMwave GmbH, Berlin, Germany

Integrated quantum photonic circuits (IQPCs) are very promising can- didates for scalable and flexible on-chip quantum computation and quantum communication hardware. One critical requirement for their realization is the scalable integration of on-demand indistinguishable single-photon emitters. This is potentially possible through the reso- nant excitation of an integrated QD in a waveguide by means of an on-chip integrated coherent light microlaser. Towards this goal, we in- vestigate the coupling and lasing properties of coherent light laterally emitted from a whispering gallery mode (WGM) type micropillar laser evanescently coupled to a single mode ridge waveguide. Using finite element method (FEM) simulations, we predict the pillar dimensions allowing for lasing modes in the typical emission wavelength of InGaAs QD (930nm) and investigate the coupling efficiency and the Q-factor of the pillar-waveguide system for different angular mode number, pillar- waveguide air gap distances and interface types (point-like or pulley coupling). The III-V semiconductor type nanostructures composed of a GaAs cavity with InGaAs QDs and distributed Bragg reflectors are processed using high-resolution electron beam lithography. Simulation predictions and micro-photoluminescence spectroscopy performed on the nanoprocessed devices are compared and discussed.

HL 33.51   Wed 17:00   P1

Relativistic calculation of hyperfine splittings of hydrogen-like atoms with finite-size nuclei — •Katharina Lorena Franzke, Wolf Gero Schmidt, and Uwe Gerstmann — Paderborn University, Warburger Str. 100, 33098 Paderborn

The hyperfine splittings of spin qubits play an important role in quantum information and spintronics application. They allow for readout of the spin qubits, while simultaneously being the dominant mechanism for the detrimental spin decoherence. Their exact knowledge is thus of prior relevance. In this work we show that the formula of Blügel et al. [1] also holds in the full relativistic regime even if finite-size structure of the nuclei are taken into account. For this purpose, different models for the nuclear charge and spin distributions are compared analytically. The calculated hyperfine splittings of H-like alkali atoms up to ^{133}Cs show a good agreement for all nuclei models. For the real one-electron systems ^{1}H, ^{2}H, ^{3}H, ^{3}He$^+$ they are also in very good agreement with available experimental data. Deviations of DFT-predicted hyperfine splittings from experiment are thus actually due to the use of the frozen-core approximation and limitations of the exchange-correlation (XC) functional.

Electro-optic response function of thin Quartz for sampling of high-field THz pulses — •Maximilian Frenzel, Michael S. Spencer, and Sebastian F. Maehrlein — Fritz Haber Institute of the Max Planck Society, Faradayweg 4-6, 14195 Berlin, Germany

As high-field THz sources are currently getting more broadly employed, it becomes increasingly important to characterize intense single-cycle THz fields (> 1 MV/cm) in amplitude and phase without saturation or nonlinearities in the electro-optic detection. After previous attempts of spectrally neutral attenuation, z-cut α-Quartz has been recently found as a suitable electro-optic sampling (EOS) crystal. Nevertheless, its accurate response function, which allows the THz electric field to be exactly determined from the measured EOS signal, is still missing. Here, we employ intense THz fields (0.5 - 4 THz) generated via optical rectification in LiNbO$_3$ to measure EOS in Quartz of various thicknesses between 30 and 150 μm. We find that both EOS peak amplitude and signal shape are significantly thickness-dependent. By modeling the Quartz EOS detector re-

sponse function, we find good agreement between parameter free theory and experiment, thus explaining the measured thickness dependence. Our work will therefore allow accurate measurement of intense THz electric fields wherever conventional EOS materials are facing saturation effects.

Fourier Transform Infrared Spectroscopy of Quantum Dot and Bragg Mirror Layers in Semiconductor Heterostructures — •Nikolaj Lehl, Andreas Wieck, Nathan Jukam, and Amar Alok — Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, Deutschland

A purposefully designed distributed Bragg reflector (DBR) in a semiconductor heterostructure improves this device's photon yield gathered from its quantum dot (QD) layer. In this master thesis the transmission spectra of such semiconductor heterostructure samples are taken using Fourier-transform infrared spectroscopy (FTIR). The molecular beam epitaxy (MBE) grown gallium arsenide (GaAs) based samples include indium arsenide (InAs) QDs, and DBRs made of sequences of GaAs layers and aluminium arsenide (AlAs) layers. The DBR stopband measurements are taken in the near-infrared (NIR) and mid-infrared (MIR) region, in vacuum, under room temperature. Furthermore, it is planned to investigate the QD intersubband transitions implied in the far-infrared (FIR) transmission spectra as a function of applied voltage at liquid nitrogen and liquid helium temperatures. All acquired spectra are compared to the devices' simulated spectra, in order to make a conclusion on the initially expected growth rates and the growth rates resulting from the measurements.

HL 33.55   Wed 17:00   P1

MIR Time-Domain Ellipsometry via 2D Electrooptic Sampling — •Leona Nest, Michael Scott Spencer, Martin Wolf, and Sebastian Maehrlein — Fritz Haber Institute of the Max Planck Society, Department of Physical Chemistry, Faradayweg 4-6, 14195 Berlin, Germany

Terahertz time-domain spectroscopy (THz-TDS) has been established as a powerful tool in fundamental material science as it allows to measure conductivities, dielectric functions, and related phase transitions in e.g. semiconductors, topological insulators, and high-temperature super-conductors. Moreover, THz-TDS is well suited to investigate ultrafast, and thus non-equilibrium, quasi-particle dynamics in such solid- state systems. The time-resolved detection of the electric field provides direct access to complex-valued static and transient material properties. Here, we extend this technique to additionally measure the temporal evolution of the field's polarization for direct determination of complex tensorial material responses. Operating our time-domain ellipsometer in the mid-Infrared (MIR, 15-40 THz) enables anisotropic transmittivity or reflectivity studies in a spectral region where fundamental resonances such as phonons can be found. As a benchmark system, we extract the complex-valued dielectric tensor components of γ-cut α-quartz in the vicinity of its anisotropic 21 THz and 24 THz phonon resonances. Good agreement with free-electron-laser-based studies shows that we developed a versatile table-top time-domain ellipsometer that will be used to also measure non-equilibrium tensorial properties in the near future.

HL 33.56   Wed 17:00   P1

Comprehensive model for the thermoelectric properties of two-dimensional carbon nanotube networks — •Aditya Dash, Dorothea Scheunemann, and Martijn Kemerink — Institute for Molecular Systems Engineering and Advanced Materials, Heidelberg University, Im Neuenheimer Feld 225, 69120 Heidelberg, Germany

Networks of semiconducting single-walled carbon nanotubes (SWCNTs) are interesting thermoelectric materials due to the interplay between CNT and network properties. Here we present a unified model to explain the charge and energy transport in SWCNT networks. We used the steady-state master equation for the random resistor network containing both the intra- and inter-tube resistances, as defined through their 1D density of states that is modulated by static Gaussian disorder. The tube resistance dependence on the carrier density and disorder is described through the Landauer formalism. Electrical and thermoelectric properties of the network were obtained by solving Kirchhoffs laws through a modified nodal analysis, where we used the Boltzmann transport formalism to obtain the conductivity, Seebeck coefficient, and electronic contribution to the thermal conductivity. The model provides a consistent description of previously published experimental data for temperature and carrier density-dependent conductivities and Seebeck coefficients, with energetic disorder being the main factor explaining observed mobility upswing with carrier concentration. For lower disorder, the Lorentz factor obtained from simulation is in accordance with the Wiedemann-Franz law. Suppressed disorder and lattice thermal conductivity can be a key to higher zT.

HL 33.57   Wed 17:00   P1

Electric field assisted transport in photodiodes studied by EBIC and STEM — •Lennart Nolte[1], Christoph Flathmann[1], Tobias Meyer[2], and Michael Seibt[1] — [1]IV. Physical Institute, University of Goettingen, Germany — [2]Institute for Materials Physics, University of Goettingen, Germany

P-i-n diodes consist of an intrinsic layer sandwiched between an n- and p-doped layer. Due to lack of carriers in the intrinsic layer, it shows a high Ohmic resistance and realizes more extended depletion zones compared to a typical p-n junction. This makes p-i-n-diodes particularly interesting for high frequency and high voltage electronic applications in addition to photo detection. In this study, we perform electron beam induced current (EBIC) investigations in cross-section geometry combined with scanning transmission electron microscopy (STEM) in order to study electric field assisted diffusion of excess carriers on a nanometer scale under well-defined experimental conditions. Special focus will be on carrier recombination at surfaces produced by focused ion beam (FIB) preparation.

HL 33.58   Wed 17:00   P1

Investigating the influence of stoichiometry-fluctuations on the electronic properties of ultra-scaled HBTs — •Daniel Dick[1,3], Jörg Schuster[1,2,3], Florian Fuchs[2,3], and Sibylle Gemming[3,4] — [1]Center for Microtechnologies, Chemnitz University of Technology, Chemnitz, Germany — [2]Fraunhofer Institute for Electronic Nano Systems (ENAS), Chemnitz, Germany — [3]Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, Chemnitz, Germany — [4]Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany

Silicon-germanium (SiGe) heterojunction bipolar transistors (HBTs) have found widespread use in high-frequency applications. Scaling of the HBT base layer thickness to 5 nm and below makes an atomistic treatment indispensable as fluctuations of dopant concentrations play a bigger role.

We investigate the effect of scaling on properties such as band gap and carrier effective mass and obtain effective material parameters for use in simulations at a larger scale. The use of semi-empirical methods such as extended Hückel theory enables us to simulate a large number of permutations of the atomic structure and study statistical variation of its properties while first-principles methods such as density functional theory allow us to verify the results. Finaly, using the non-equilibrium Green's function method we investigate the effect of alloy and phonon scattering on transport through such a layer.

HL 33.59   Wed 17:00   P1

Investigation of Transport Phenomena Through Functionalized Single Molecules Using Liquid Mechanically Controllable Break Junctions — •Harpreet Sondhi — FWIO-T, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

The creation of molecular components for use as electronic devices has made enormous progress. In order to advance the field further toward realistic electronic concepts, methods for the controlled modification of the conducting properties of the molecules contacted by metallic electrodes need to be further developed. Here a comprehensive study of charge transport in a class of molecules that allows modifications by introducing metal center/side chain groups into organic structures is presented. Single molecules are electrically contacted and characterized in order to understand the role of the metal center/side chain groups in the conductance mechanism through the molecular junctions. It is shown that the presence of single metal ions/side chain groups modifies the energy levels and the coupling of the molecules to the electrical contacts, and that these modifications lead to systematic variations in the statistical behavior of transport properties of the molecular junctions.

HL 33.60   Wed 17:00   P1

Time-gated coherent two-dimensional spectroscopy on the nanoscale — •Luisa Brenneis, Julian Lüttig, Matthias Hensen, and Tobias Brixner — Institut für Physikalische und Theoretische Chemie, Universität Würzburg, Am Hubland, 97074 Würzburg

The observation of the temporal dynamics of excitons, i.e., electron-hole pairs, is essential for the understanding of fundamental phenomena in nature, e.g., photosynthesis [1]. The method of optical two-dimensional (2D) spectroscopy has proven to be particularly suitable for this purpose. For example, electronic cou-

plings and energy transport phenomena can be directly revealed as cross peaks in a 2D spectrum, i.e., a correlation spectrum of excitation and probe frequency as a function of time. To additionally decipher the spatial dynamics of a system in a nanostructured environment beyond the optical diffraction limit, we have combined 2D spectroscopy with photoemission electron microscopy to realize coherent "2D nanoscopy" [2,3]. Here, using coupled molecular dimers in numerical simulations, we investigate the potential of 2D nanoscopy. In particular, we show how the exciton and biexciton dynamics can be disentangled by resolving the kinetic energy spectrum of photoemitted electrons and by realizing a time gate using an additional ionization pulse.

HL 33.61   Wed 17:00   P1

Negative thermal expansion in HgTe/CdTe heterostructures on ultrafast timescales — •Marc Herzog[1], Matthias Rössle[2], Jan-Etienne Pudell[3], Maximilian Mattern[1], Lukas Lunczer[4], Claus Schumacher[1], Hartmut Buhmann[1], Laurenz Molenkamp[1], and Matias Bargheer[2,3] — [1]Institut für Physik und Astronomie, Universität Potsdam, Germany — [2]Helmholtz-Zentrum Berlin, Germany — [3]European XFEL, Germany — [4]Physikalisches Institut EP3, Universität Würzburg, Germany

Materials that would exhibit an ultrafast negative thermal expansion (NTE) are desirable to generate ultrashort and high-amplitude acoustic waves as unconventional stimulus e.g. in the context of nonlinear acoustics or magnetoelastic effects. Both semimetallic HgTe and semiconducting CdTe exhibt pronounced NTE behaviour in thermal equilibrium below their Debye temperatures $\Theta_D \approx 150$ K owing to a negative Grüneisen parameter and correspondingly negative stress by transverse acoustic (TA) phonons.

Using ultrafast x-ray diffraction we investigate the coherent (sound) and incoherent (heat) lattice response in HgTe thin films on a CdTe substrate to ultrashort laser pulse excitation. While above Θ_D both materials exclusively expand upon excitation, below Θ_D a pronounced NTE is observed. However, the time scale for this NTE to develop is a few 100 ps suggesting a slow excitation of the TA modes. At few-ps time scales, however, a strong expansion of HgTe prevails at all measured excitation densities indicating a fast and dominant positive stress due to non-TA phonon modes and/or hot carriers.

HL 33.62   Wed 17:00   P1

h-BN as a protective encapsulation layer for monolayer graphene — •V. Calvi[1], M. Barnes[1], M. Buscema[1], D. Wehenkel[1], I.M.N. Groot[2], and R. van Rijn[1] — [1]Applied Nanolayers B.V., Feldmannweg 17, 2628 CD Delft, The Netherlands — [2]Leiden Institute of Chemistry, Leiden University, P.O. Box 9502, 2300 RA Leiden, The Netherlands

Graphene surface contamination by polymer residues used in the graphene processing is a key problem for certain device applications. PMMA is used for graphene transfer from a growth substrate to a target substrate. Transfer process leaves polymer residues on the graphene monolayer which causes p-doping. Technique used for the removal of polymer residue is annealing in different gas or vacuum atmospheres. Annealing in oxygen rich environment effectively removes polymer residue, but at the same time also causes damage to the graphene monolayer.

We have investigated stacking a monolayer of h-BN on top of a monolayer of graphene prior to transfer of the graphene. In this way the polymer necessary for the transfer only has direct contact with the surface of the h-BN and graphene would be protected in this way. We compared the damage and cleanliness to both bare graphene and stacked h-BN/graphene by Raman spectroscopy and AFM. We tested different annealing temperatures between 100˚C and 500˚C and found that the graphene is indeed protected from damage from the annealing process by covering it with a layer of h-BN. At the same time, we were able to show that polymer residue is effectively removed at the higher annealing temperatures.

HL 34: 2D Materials V (joint session HL/CPP)

Negative differential resistance with ultra-high peak-to-valley current ratio in tunnel diodes based on two-dimensional cold metals — •Ersoy Sasioglu and Ingrid Mertig — Martin-Luther-Universität Halle-Wittenberg, Institut für Physik, 06120 Halle (Saale)

The negative differential resistance (NDR) effect is of great interest for future memory and logic circuit applications. We propose a novel semiconductor-free NDR tunnel diode concept with ultra-high peak-to-valley current ratio (PVCR) [1]. Our proposed NDR diode consists of two cold metal electrodes separated by a thin insulating tunnel barrier. The NDR effect stems from the unique electronic

band structure of the cold metal electrodes, i.e., the width of the isolated metallic bands around the Fermi level as well as the energy gaps separating higher- and lower-lying bands determine the current-voltage characteristics and PVCR value of the tunnel diode. By proper choice of the cold metal electrodes either Λ-type or N-type NDR effect can be obtained. We employ the nonequilibrium Green's function method combined with density functional theory to demonstrate the NDR characteristics of the proposed diode based on two-dimensional NbS_2/h-BN/NbS_2 vertical and AlI_2/MgI_2/AlI_2 planar heterojunctions. For the lateral tunnel diode, we obtain a Λ-type NDR effect with an ultra-high PVCR value of 10^{16} at room temperature, while the vertical tunnel diode exhibits a

conventional N-type NDR effect with a smaller PVCR value of about 10^4. The proposed concept provides a semiconductor-free solution for NDR devices to achieve desired I-V characteristics.

HL 34.2   Thu 9:45   POT 81

Electrical contact engineering on 2D material through ion implantation and flash lamp annealing — •Kaiman Lin[1,2], Yi Li[1], Manfred Helm[2], Shengqiang Zhou[2], Yaping Dan[1], and Slawomir Prucnal[2] — [1]University of Michigan-Shanghai Jiao Tong University Joint Institute, Shanghai Jiao Tong University, 20024 Shanghai, P. R. China — [2]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany

In recent years, 2D material-based nanodevices have been extensively studied and exhibit highly competitive performance compared with conventional bulk semiconductors. Before they can be fully integrated with existing Si-based technology or offer new platform for novel nanoelectronics, some challenges must be solved. One of the key challenges in 2D devices is the large Schottky barrier at the 2D/metal interface, which limits the charge carrier injection from metal to 2D channel. In this paper, we propose a novel method, which exploits the top metal electrode as the capping layer during the ion implantation process, followed by ms-range flash lamp annealing to repair the defects caused by ion implantation and to activate dopants. Our approach allows to realize effective doping at the interface between multilayer 2D materials and metal electrodes and simultaneously minimize the defect concentration created during the ion implantation process. As a result, the ohmic contact between 2D material and metal electrodes will be realized.

HL 34.3   Thu 10:00   POT 81

Impact of free carriers on exciton and trion diffusion in monolayer WSe2 — •Marzia Cuccu[1], Koloman Wagner[1], Zakhar A. Iakovlev[2], Jonas D. Ziegler[1], Takashi Taniguchi[3], Kenji Watanabe[3], Mikhail M. Glazov[2], and Alexey Chernikov[1] — [1]TU Dresden, Dresden, Germany — [2]St. Petersburg, Russia — [3]National Institute for Materials Science, Tsukuba, Japan

In monolayer transition metal dichalcogenides excitons are tightly bound, mobile at room and cryogenic temperatures, and interact strongly with free charge carriers. However, the role of the exciton-electron interaction in the context of exciton propagation remains unclear. Here, we address this question by demonstrating diffusion of excitons in hBN-encapsulated WSe2 in the presence of a continuously tunable Fermi sea. Using ultrafast microscopy, we reveal a non-monotonic dependence of the exciton diffusion coefficient on the charge carrier density in both electron- and hole-doped regimes. We identify distinct regimes of elastic scattering and quasiparticle formation determining exciton diffusion and highlight the importance of treating exciton-electron scattering in the presence of additional energy and momentum dissipation via phonons. We further show that trions remain mobile even at low temperatures down to 5 K, with an effective trion mobility up to 3000 cm2/(Vs).

HL 34.4   Thu 10:15   POT 81

Electrical Characterization of Thin ZrSe$_3$ Films — •Lars Thole[1], Christopher Belke[1], Sonja Locmelis[2], Peter Behrens[2], and Rolf J. Haug[1] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany — [2]Institut für Anorganische Chemie, Leibniz Universität Hannover, 30167 Hannover, Germany

Two dimensional materials have been of great interest in the past years, because of their huge potential for new applications [1]. While graphene has been extensively researched, a lot of other materials have emerged. One of the most notable groups are the transition metal chalcogenides because of their variety of different compounds. Among these the lesser known transition metal trichalcogenides show unique properties [2].

Here, we have researched the transition metal trichalcogenide ZrSe$_3$ [3]. Its bulk material was produced by a chemical vapor transport method and was then exfoliated to obtain thin films. Electrical measurements show a band gap of 0.6 eV which increases for thinner samples. The material is shown to be an n-type semiconductor by transistor measurements and a mean free path of about 103 nm was determined by looking at different samples with varying thicknesses.

HL 34.5   Thu 10:30   POT 81

Electrically active deep defects in 2D vdW semiconductors — •Michele Bissolo[1], Rongxin Li[1], Masako Ogura[2], Svitlana Polesya[2], Hubert Ebert[2], Eugenio Zallo[1], Gregor Koblmüller[1], and Jonathan J. Finley[1] — [1]Walter Schottky Institute and TUM School of Natural Sciences, Technical University of Munich, Am Coulombwall 4, 85748 Garching, Germany — [2]Department of Chemistry/Phys. Chemistry, LMU Munich, Butenandtstrasse 11, 81377 Munich, Germany

Mid-gap defect states in semiconductors can both potentially degrade the performance of (opto)electronic devices and simultaneously act as a platform for

technologies such as (photo)catalysis and quantum computing. Characterizing the electrically active mid-gap defects in the emerging class of 2D van-der-Waals materials is thus a necessary step in the development of future 2D-based devices. Here, we employ Deep Level Transient Spectroscopy (DLTS) techniques to directly probe deep defects in transition metal dichalcogenides (TMDCs) and group-III monochalcogenides (III-MCs), which have recently gained traction in "more-than-Moore", low-power and renewable energy device applications. Unlike transmission electron or scanning tunneling microscopies, DLTS is both a non-destructive and bulk sensitive technique that provides multiple information on the electronically active defect states, such as concentration, energy and capture cross section. DLTS spectra are collected from few-layer MoS$_2$, MoSe$_2$ and GaSe Schottky diodes in the 10-300 K temperature range with 10 mK stability, and the properties and role of the observed defects are discussed.

15 min. break

HL 34.6   Thu 11:00   POT 81

Ionic based gate control of insulator-to-metal phase transitions on ZrS$_2$ — •Jose Guimaraes[1,2], Dorsa Fartab[1], Marcus Schmidt[1], and Haijing Zhang[1] — [1]Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany — [2]School of Physics and Astronomy, University of St Andrews, St Andrews KY16 9SS, UK

The possibility of tuning the properties of solids, such as their carrier density, allows for the amplification of their potential: In the context of 2D materials, ionic liquid gating provides a highly efficient doping alternative to traditional chemical doping.

Transitional metal dichalcogenides (TMDCs) have emerged as a potential 2D replacement for silicon in many technological applications, however their carrier mobility needs to be vastly increased. Ionic liquid gating enables carrier concentrations of the order of 10^{14} carriers per cm^2 in certain TMDCs, moreover, it allows for the emergence of unique physical phenomena, such as ambipolar behaviour. To realize transistor applications, materials that can be easily switched between p-type and n-type by applying an electric field are essential to minimize circuit size.

Here, an overview of the ionic liquid gating technique is given, including device fabrication and characterization methods, focusing on the TMDCs: ZrS$_2$ and ZrSe$_2$. Being ZrSe$_2$ an oxygen sensitive material, a method of estimating its thickness by its optical image is discussed. Furthermore, experimental efforts reporting ambipolar behaviour in ZrS$_2$ for the first time are presented.

HL 34.7   Thu 11:15   POT 81

Lattice reconstruction in twisted transition metal dichalcogenide heterobilayers — •Wei Li, Thomas Brumme, and Thomas Heine — TU Dresden, Dresden, Germany

Twisted heterostructures of 2D crystals have resulted in a series of high-impact contributions to condensed matter physics, most prominently flat bands and superconductivity in twisted bilayer graphene. But also two-dimensional crystals beyond graphene, such as transition metal dichalcogenides, show strong proximity effects that are affected by twisting. Here, we systematically investigate the structural impact of twist angles on transition metal dichalcogenide van der Waals heterobilayers consisting of MoS$_2$, WS$_2$, MoSe$_2$ and WSe$_2$ monolayers. We find that the significant lattice reconstruction involving in- and out-of-plane displacements strongly depends on the twist angle: from a continuous variation of local stacking alignment at large twist angles to a soliton-domain structure at small twist angles. Especially, starting from either 2H or 3R stacking, two different critical twist angles exist, above which the two constituting layers show dramatically asymmetrical corrugation, in contrast to the symmetry-preserving out-of-plane deformation in twisted homobilayers. We reveal that the development of either the corrugation or the soliton-domain results from the competition between strain energy cost and van der Waals energy gain. Our calculations show that van der Waals heterobilayers develop, besides the well-investigated moiré structures, also systems with large areas of special local stackings arranged in a superlattice, suggesting intriguing electronic properties of these systems.

HL 34.8   Thu 11:30   POT 81

Pump Probe Signatures of Interlayer Excitons in TMDC Heterostructures — •Henry Mittenzwey[1], Manuel Katzer[1], Benjamin Kaiser[2], Veronica Policht[3], Oleg Dogadov[3], Stefano Dal Conte[3], Giulio Cerullo[3], Andreas Knorr[1], and Malte Selig[1] — [1]Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany — [2]Zuse Institute Berlin, Takustraße 7, 14195 Berlin, Germany — [3]Dipartimento di Fisica, Politecnico di Milano, I-20133 Milano, Italy

TMDC heterobilayers are promising candidates for novel optoelectronic applications, since they exhibit long-lived excitonic states with spatially separated electrons and holes located in different layers. The relaxation dynamics of these interlayer excitons and their interplay with intralayer excitons are still under investigation.

Here, we present a microscopic description for the phonon and tunneling induced formation and relaxation of intra- and interlayer excitons in a MoSe$_2$/WSe$_2$ stack. Based on the microscopic dynamics we calculate the pump probe signal for intra- and interlayer transition and their population dynamics including hot exciton bottleneck effects and unbound interlayer occupations.

HL 34.9   Thu 11:45   POT 81

Microscopic picture of interlayer exciton-phonon coupling — Muralidhar Nalabothula, Ludger Wirtz, and •Sven Reichardt — University of Luxembourg, Luxembourg

Excitons play a key role for opto-electronic applications of 2D heterostructures. They also can strongly couple to phonons as evidenced by their imprint on resonant Raman scattering intensities [1,2]. In 2D heterostructures, this sort of strong coupling and its signature Raman scattering offers an ideal setting to learn about exciton-phonon coupling both within and across material layers. Here we focus on the example of monolayer WSe2 and hBN. Its Raman spectrum features the norminally silent out-of-plane optical phonon mode of hBN that becomes active due to symmetry breaking and - most curiously - very strongly enhanced due to resonant exciton-phonon scattering [1]. While the resonant scattering pathways have been identified as involving excitons in WSe2 that couple to the phonons in hBN [1], a microscopic understanding of this interlayer exciton-phonon coupling is still missing. We provide such understanding using the state-of-the-art method for the computation for resonant Raman scattering intensities [2,3], which allows a detailed atomistic and quantum mechanical dissection of the Raman scattering process. Supplemented by a classical picture, our work sheds light on the microscopic mechanism behind exciton-phonon coupling in 2D heterostructures.

HL 35: Focus Session: Transient multi-wave mixing on excitonic resonances

Coherent nonlinear optical spectroscopy and, in particular, transient multi-wave mixing processes provide valuable information for basic research in material science and applications in photonics and quantum technology. It allows one to obtain detailed information about the energy structure and dynamic evolution of quantum systems including excited states which is not possible via linear optical spectroscopy and gives direct access to higher-order correlations among the elementary optical excitations. In addition, multi-wave mixing processes can be used as a powerful tool to coherently control the electronic states of the system and to generate non-classical states of light, which is appealing for the implementation in quantum information devices. Importantly for these studies is that excitons possess high oscillator strength which leads to a significant increase of higher-order mixing under resonant excitation with ultrashort optical pulses. This session will focus on multi-wave mixing processes as a unique tool to uncover the fascinating physics of excitons and many-body correlations in emerging materials such as transition metal dichalcogenides and perovskites and establish novel approaches for the coherent control of excitonic quantum systems with classical and quantum light.

Quantum Dynamics of Polarons in Doped Semiconductor Monolayers — •Xiaoqin Elaine Li[1] and Di Huang[2] — [1]Physics Department, University of Texas at Austin, Austin, TX, U.S.A. — [2]Physic Department, TongJi University, Shanghai, China

When mobile impurities are introduced and coupled to a Fermi sea, new quasiparticles known as Fermi polarons are formed. We study Fermi polarons in two dimensional systems, where many questions and debates regarding their nature persist. The model systems we investigate are doped MoSe2 and WSe2 monolayers. In MoSe2, we find the observed attractive and repulsive polaron energy splitting and the quantum dynamics of attractive polarons agree with the predictions of a simple theory. As the doping density increases, the quantum dephasing of the attractive polarons remains constant, indicative of stable quasiparticles, while the repulsive polaron dephasing rate increases nearly quadratically. In WSe2, two distinct species of attractive polarons exist, singlet and triplet polarons. The singlet (triplet) dynamics are mediated by the Fermi seas in the same (opposite) valley. A long-lived valley polarization component is found and likely related to a reservoir of dark states.

Invited Talk   HL 35.2   Thu 10:00   POT 361

Impact of phonons on time-resolved optical signals from excitons — •Doris E. Reiter — Condensed Matter Theory, TU Dortmund, 44221 Dortmund

A major difference between optical manipulation of atoms and excitons in semiconductors is the interaction of the latter with the vibrational modes of the solid, i.e., the phonons. In particular in nanostructures like quantum dots, the interaction with acoustic phonons is non-monotonous as function of energy, yielding interesting phenomena like phonon sidebands, reappearance of Rabi rotations or phonon-assisted state preparation. When a quantum dot is optically driven exhibiting Rabi oscillations of the exciton, the pure dephasing-type electron-phonon interaction results in polaron formation accompanied by the emission of phonon wave packets. While for the occupation, the phonon influence leads to an exponential damping, optical multi-wave mixing experiments are more sensitive to the quantum dot polarization. Here, the phonons cannot be described by a simple damping, but their interaction can be understood as a relaxation into the lower dressed state. In this talk, we use a simple model of phonons [1] to discuss their impact on time-resolved optical signals in semiconductor quantum dots. We consider the impact of phonon on continuous wave excitation in a pump-probe configuration [1] and on optical photon echo signals, where the model is in excellent agreement with experiments [2]. Ref: [1] Ann. Phys. 533, 2100086 (2021) [2] PRB 106, 205408 (2022).

Hot-Exciton Quantum Dynamics in Zero-Dimensional Structures — •Alfred Leitenstorfer — Department of Physics and Center for Applied Photonics, University of Konstanz, Germany

Electronic quantum processes in intrinsic dimensions of time and space are investigated with femtosecond transient transmission spectroscopy of individual II-VI quantum dots. With our experiments, we are aiming at single-photon amplification for the ultimate control of the quantum statistics of ultrashort light pulses [1]. In these systems, the elementary dynamics of charges and spins is dominated by fundamental aspects such as Coulomb correlations and the Pauli principle [2]. Harnessing a pump-probe microscope optimized for single-electron sensitivity at cryogenic temperatures and high magnetic fields [3], we find extremely asymmetric relaxation characteristics in valence and conduction bands where e.g. femtosecond quantum kinetics of hole-phonon coupling is compatible with persistent spin coherence of hot excitons [4].

Multi-wave mixing applied to explore and control the coherent dynamics of ensembles of semiconductor quantum dots — •Hendrik Rose[1], Stefan Grisard[2], Artur V. Trifonov[2], Rilana Reichhardt[2], Doris E. Reiter[3], Matthias Reichelt[1], Christian Schneider[4,5], Martin Kamp[4], Sven Höfling[4], Manfred Bayer[2], Ilya A. Akimov[2], and Torsten Meier[1] — [1]Paderborn University, Department of Physics & Institute for Photonic Quantum Systems (PhoQS), 33098 Paderborn, Germany — [2]Experimentelle Physik 2, Technische Universität Dortmund, 44221 Dortmund, Germany — [3]Condensed Matter Theory, Technische Universität Dortmund, 44221 Dortmund, Germany — [4]Technische Physik, Universität Würzburg, 97074 Würzburg, Germany — [5]Institute of Physics, University of Oldenburg, 26129 Oldenburg, Germany

Multi-wave mixing provides various possibilities to investigate the ultrafast dynamics of semiconductors. Here, we focus on ensembles of quantum dots where the nonlinear dynamics leads to emission in the form of photon echoes. We show that photon echoes can be temporally controlled by the application of multi-wave mixing [1] and furthermore demonstrate that a damping mechanism based on the spatial shape of the applied laser pulses can be circumvented by pulse shaping [2].

Four-wave mixing at excitonic resonances in the telecom spectral range — •Sebastian Klimmer[1], Artem Sinelnik[1,2], Muhammad Hussain[1], Isabelle Staude[1,2], Habib Rostami[3], and Giancarlo Soavi[1] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Germany — [2]Institute of Applied Physics, Friedrich Schiller University Jena, Germany — [3]Nordita, KTH Royal Institute of Technology and Stockholm University, Sweden

Over the last few decades, nonlinear optical (NLO) processes have become a pillar for novel photonic devices. In particular, four-wave mixing (FWM) effects can be used to generate quantum optical states of light, such as entangled photons. Transition metal dichalcogenides (TMDs) offer significant advantages compared to conventional nonlinear materials, as their strong light-matter interaction and ease of integration into existing photonic platforms[1] make them perfect for enhancing the performance of integrated NLO devices. In addition, their atomic thickness softens phase matching limits, providing a virtually unlimited bandwidth for FWM[2]. This could be exploited to entangle photons from various spectral regions, making them an ideal source for quantum imaging applications[3]. In this work, we study broadband and exciton enhanced FWM in the telecom spectral range in MoS_2, highlighting the capability of TMDs for integrated photonics and communication applications.

Ultrafast dynamics and wave mixing at excitonic resonances in atomically thin semiconductors — •Andreas Knorr, Dominik Christiansen, Florian Katsch, Manuel Katzer, and Malte Selig — Technische Universität Berlin
Atomically thin semiconductors constitute an ideal playground for exciton physics in two dimensions. This involves optically accessible (bright) as well as spin- or momentum-forbidden (dark) excitonic states including intravalley and intervalley excitations. The nonlinear, coherent exciton and wave mixing dynamics induced by short light pulses result from the interplay of strong intrinsic exciton-exciton and exciton-phonon interactions and can be described in a many body Heisenberg equation of motion formalism. Here, we present applications of the theory to:

-exciton-exciton scattering and biexcitons in wave mixing,
-exciton wave function dynamics in time resolved ARPES,
-control of nonlinear excitonic Rabi-oscillations, and
-limits of the boson description of excitons.

Invited Talk   HL 35.7   Thu 12:30   POT 361

Spontaneous parametric down-conversion in semiconductor metasurfaces — •Maria Chekhova — Max-Planck Institute for the Science of Light, Erlangen, Germany — Friedrich-Alexander Universität Erlangen-Nürnberg
Spontaneous parametric down-conversion (SPDC) is the most efficient way to generate pairs of entangled photons for quantum photonics applications such as quantum communication, quantum imaging and sensing, and quantum metrology. Today, several groups are trying to implement SPDC on nanoscale quasi-2D platforms, such as subwavelength crystalline layers and metasurfaces. These ultrathin sources have numerous advantages. They are integrable, ultrafast, ultra-

broadband and, most importantly, multifunctional. Metasurfaces, in addition, can enhance the rate of photon pair generation due to their *geometric* resonances.

In my talk I will show our recent results on the generation of photon pairs in metasurfaces made of gallium arsenide and gallium phosphide. The metasurfaces are structured to support bound states in the continuum (also known as Fano) resonances, with the quality factors Q reaching several hundred. The resonances enhance the spontaneous emission of pairs by a factor on the order of Q if the frequency of one of the photons coincides with the resonance. Due to the ultrasmall thickness of such sources, SPDC can be pumped slightly above their bandgap without considerable effect of absorption. The inevitably high level of photoluminescence can be overcome by time-resolved registration of photon pairs.

HL 35.8   Thu 13:00   POT 361

Time-resolved four-wave mixing spectroscopy of excitons in a $FA_{0.9}Cs_{0.1}PbI_{2.8}Br_{0.2}$ perovskite crystal — •Stefan Grisard[1], Artur V. Trifonov[1], Dmitry N. Dirin[2,3], Maksym V. Kovalenko[2,3], Ilya A. Akimov[1], Dmitri R. Yakovlev[1], and Manfred Bayer[1] — [1]Experimentelle Physik 2, Technische Universität Dortmund — [2]Institute of Inorganic Chemistry, Department of Chemistry and Applied Bioscience, ETH Zürich — [3]Laboratory for Thin Films and Photovoltaics, Empa-Swiss Federal Laboratories for Materials Science and Technology

Formamidinium lead triiodide ($FAPbI_3$) shows outstanding characteristics for future photovoltaic or light emitting devices, suffers however from poor phase stability. Additives such as cesium and bromine help to improve the phase stability, but possibly increase the localization of the charge carriers. In this work, we present time resolved four-wave mixing spectroscopy as a versatile tool to investigate the coherent optical properties of a $FA_{0.9}Cs_{0.1}PbI_{2.8}Br_{0.2}$ crystal. At low temperatures of 1.5K, the coherent optical response is represented by photon echoes due to the strong inhomogeneous broadening of exciton resonances. We find that the coherence time T_2 is surprisingly long (≈100ps), comparable with the lifetime T_1. The spectral dependence of T_2 and T_1 indicate the importance of carrier localization.

HL 35.9   Thu 13:15   POT 361

Multi-photon pump probe of magnetic-field-induced quantum beats in Cu_2O — •Nikita V. Siverin, Andreas Farenbruch, Dietmar Fröhlich, Dmitri R. Yakovlev und Manfred Bayer — TU Dortmund, Dortmund, Germany
Multi-photon processes such as second harmonic generation are suitable for the investigation of exciton symmetries by analyzing the linear polarization angles of the incoming and the outgoing light. We use difference frequency generation (DFG) with two-photon as the optical technique. The initial laser pulse excites an exciton population by a two-photon excitation process. Probe pulse stimulates a DFG photon. Delaying the second pulse in time enables us the measurement of exciton coherence times and quantum beats between several states. There is also an additional degree of freedom compared to the SHG technique in the polarization of the emission channel. We measure the coherence time of yellow series in Cu_2O. By applying a magnetic field up to 10T in Voigt geometry the 1S orthoexciton splits into three states denoted by the quantum number M = -1,0,1. We observe a beating between these three states. By a selection of the linear polarization setting in the emission channel one can deliberately choose to detect single-frequency beats between the M=+1 and M=-1, triple-frequency beats between all three states or only the M=0 state without beats. Beat frequencies scale with magnetic field strength.

Charge carrier mobilities in 2D covalent organic frameworks — •Elif Unsal[1], Alexander Croy[2], Alessandro Pecchia[3], Arezoo Dianat[1], Rafael Gutierrez[1], and Gianaurelio Cuniberti[1] — [1]Institute for Materials Science and Nanotechnology, TU Dresden, Dresden, Germany. — [2]Institute of Physical Chemistry, FSU Jena, Germany. — [3]CNR-ISMN, Rome, Italy

2D COFs are functional porous crystalline structures, which have high chemical and thermal stabilities. Having tunable chemistry and structures are their major properties which make 2D COFs attractive for wide range of applications, such as electro-catalysis, gas storage, and optoelectronic applications[Xiao Feng, 2012, Chem. Soc. Rev.]. Despite the intensive studies on 2D COFs, charge transport properties of most of these materials are still unknown. Here, we present a new approach based on DFTB calculations of the phonon-limited mobility in 2D COFs. We are modelling charge transport properties by combining state-of-the-art electron-phonon coupling calculations and semiclassical Boltzmann transport theory. We are using our own code DFTBephy whose implementation

is based on DFTB+ [Marcus Elstner et al. 1998, Phys. Rev. B: Condens. Matter Mater. Phys.; Marcus Elstner, 2007, J. Phys. Chem. A] and phonopy [Atsushi Togo, 2015, Scr. Mater.] and it interfaces with BoltzTrap2 [Georg K. H. Madsen, 2018, Comput. Phys. Commun.] to calculate transport properties. Our results are benchmarked against state-of-the-art EPW [Samuel Ponce, 2016, Comput. Phys. Comm.] calculations.

Active Dopant Sites in Hyperdoped Si and Ge Investigated by Photoemission — •Moritz Hoesch[1], Mao Wang[2], Slawomir Prucnal[2], Shengqiang Zhou[2], Olena Fedchenko[3], Christoph Schlüter[1], Katya Medjanik[3], Sergey Babenkov[3], Anca Ciobanu[1], Dmitrii Potorochin[1,4], Sanjoy Mahatha[1,5], Markus Scholz[1], Quynh Nguyen[6], Aimo Winkelmann[7], H.-J. Elmers[3], and Gerd Schönhense[3] — [1]DESY Photon Science, Hamburg, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Germany — [3]JGU, Institut für Physik, Mainz, Germany — [4]TU Bergakademie Freiberg, Germany —

[5]UGC-DAE, Indore, India — [6]SLAC, Menlo Park, USA — [7]AGH University of Kraków, Poland

Hyperdoping of silicon and germanium, with dopant concentration well above the thermal solubility limit, is achieved by ion implantation followed by pulsed laser or flash lamp annealing. Here, we probe the materials by photoemission spectroscopy thus revealing the metallic carriers in the valence region as well as core level shifts of the dopant species. The samples are p-doped Ge:Ga and n-doped Si:Te, both well into the metallic regime. The latter shows non-saturating growth of the free carrier concentration with increasing doping [1]. We present experimental determinations of the Fermi surfaces of these materials by soft x-ray ARPES as well as geometrical structure measurements by photoelectron diffraction [2,3].

Rapid Electronic Transport Predictions via the Kubo-Greenwood Formalism — •Florian Fiebig, Matthias Scheffler, and Christian Carbogno — The NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft and IRIS-Adlershof of the Humboldt-Universität zu Berlin

For the first-principles evaluation of electronic heat and charge transport coefficients, the Kubo-Greenwood (KG) formalism [1] represents a more general and accurate alternative to perturbative approaches, [2] since it naturally incorporates all orders of anharmonic and vibronic effects. In practice, however, KG calculations come with a prohibitive computational cost, since ordered crystalline materials typically require both dense reciprocal-space $\mathbf{k}$-grids for the electronic degrees of freedom and large real-space supercells for the vibrational ones. In this work, we propose an adaptive, KG-specific scheme for the $\mathbf{k}$-space sampling that alleviates this issue. It enables the use of very coarse $\mathbf{k}$-grids during the self-concistency cycle, whereas very dense $\mathbf{k}$-grids are used for the evaluation of the KG formula, but only for those Brillouin-zone regions that contribute to the conductivities. As demonstrated for Silicon, this massively reduces the involved computational cost, and hence paves the way towards affordable, fully anharmonic predictions of electronic heat and charge transport coefficients.

Semiconductor to Semimetall Transition in Bi-based Core-Shell Nanowires — Maximilian Kockert[1], Rüdiger Mitdank[1], Mahni Müller[1], Hongjae Moon[2], Jongmin Kim[2], Wooyoung Lee[2], and •Saskia Fischer[1] — [1]Humboldt-Univ. zu Berlin, Germany — [2]Yonsei Univ., Seoul, Korea

The full-thermoelectric characterization of individual core/shell Bi-based nanowires is presented. Compressive strain induced by a TiO_2 shell can lead to a band opening increasing the absolute Seebeck coefficient by up to 30 percent compared to bulk at room temperature [1]. If the strain exceeds the elastic limit the semimetallic state is recovered due to the lattice relaxation. The influence of strain on the temperature dependence of the electrical conductivity, the absolute Seebeck coefficient and the thermal conductivity of bismuth/titanium dioxide (Bi/TiO_2) nanowires with different diameters was measured and compared to bismuth (Bi) and bismuth/tellurium (Bi/Te) nanowires and bismuth bulk. Different nano-contacting methods are discussed.

HL 36.5   Thu 11:00   POT 151

Comprehensive model for the thermoelectric properties of two-dimensional carbon nanotube networks — •Aditya Dash, Dorothea Scheunemann, and Martijn Kemerink — Institute for Molecular Systems Engineering and Advanced Materials, Heidelberg University, Im Neuenheimer Feld 225, 69120 Heidelberg, Germany.

Networks of semiconducting single-walled carbon nanotubes (SWCNTs) are interesting thermoelectric materials due to the interplay between CNT and network properties. Here we present a unified model to explain the charge and energy transport in SWCNT networks. We used the steady-state master equation for the random resistor network containing both the intra- and inter-tube resistances, as defined through their 1D density of states that is modulated by static Gaussian disorder. The tube resistance dependence on the carrier density and disorder is described through the Landauer formalism. Electrical and thermoelectric properties of the network were obtained by solving Kirchhoffs laws through a modified nodal analysis, where we used the Boltzmann transport formalism to obtain the conductivity, Seebeck coefficient, and electronic contribution to the thermal conductivity. The model provides a consistent description of previously published experimental data for temperature and carrier density-dependent conductivities and Seebeck coefficients, with energetic disorder being the main factor explaining observed mobility upswing with carrier concentration. For lower disorder, the Lorentz factor obtained from simulation is in accordance with the Wiedemann-Franz law. Suppressed disorder and lattice thermal conductivity can be a key to higher zT.

HL 36.6   Thu 11:15   POT 151

Thermal mapping of a c-plane oriented GaN membrane — •Mahmoud Elhajhasan[1], Isabell Hüllen[1], Wilken Seemann[1], Jean-François Carlin[2], Ian Rousseau[2], Nicolas Grandjean[2], and Gordon Callsen[1] — [1]Institute of Solid State Physics, University of Bremen, Germany — [2]Institute of Solid State Physics, École Polytechnique Fédérale de Lausanne (EPFL), Switzerland

The thermal characterization of modern semiconductor membranes commonly employed for photonic devices like nanobeam lasers (1D) or photonic crystals (2D), often lacks spatial resolution and appropriate quantification of local temperatures. However exactly these two points are relevant for the detection of e.g., thermal anisotropies, heat leakage, and interfaces providing thermal resistance.

In this contribution, Raman thermometry employing one laser beam (1LRT) is used to quantify the thermal conductivity κ of 250-nm-thick, state-of-the-art, c-plane wurtzite GaN membranes. The same membranes are then probed by two laser Raman thermometry (2LRT) to map the temperature distribution caused by a heating laser via a second probe laser. From such a map, κ is extracted for all in-plane crystal directions, yielding a thermal anisotropy in the c-plane of GaN. Comparing this direct, sub-μm spatially resolved imaging technique to classical Fourier simulations reveals a significant divergence at the heating laser spot pointing to non-diffusive phonon transport.

In conclusion, our comparison of 1LRT and 2LRT measurements provides insight into the applicability of each technique to determine the thermal conductivity of photonic membranes.

Tunable preferable orientation of α-FeSi2 crystallites on silicon surfaces — •Tatiana Smoliarova, Ivan Tarasov, and Ulf Wiedwald — Faculty of Physics and Center for Nanointegration (CENIDE), University of Duisburg-Essen, 47057, Duisburg, Germany

Nowadays, one of the most important applications of silicon (Si) and Si-based functional materials is microelectronics. Silicon forms compounds in the form of solid solutions or intermetallic compounds * silicides. Metallic α-FeSi2 phase can be used as a contact material to silicon or to the semiconducting β FeSi2 phase with good ohmic characteristics.

In this work, we discuss the growth of α-FeSi2 submicron-size crystallites on gold-activated and gold-free p-Si(001), p-Si(110) and p-Si(111) surfaces via molecular beam and reactive epitaxy. The study reveals that the surfactant-assisted mediated epitaxy regulates morphology and the preferable orientation relationship (OR) of the crystallites to Si. According to the X-ray diffraction, strongly preferable ORs are α-FeSi2(001)//Si(001), α-FeSi2(001)//Si(111), α-FeSi2(001)//Si(110) for gold-activated and α-FeSi2(111)//Si(001), α-FeSi2(211)//Si(110), α-FeSi2(112)//Si(111) for gold-free Si substrates. Thus, the orientation control of fabricated α-FeSi2 crystallites can be used for tuning electron transport across the metal/semiconductor interface.

Long-range shuttling of single electron by Si/SiGe conveyor — •Ran Xue[1], Max Beer[1], Jhih-Sian Tu[2], Simon Humpohl[1], Inga Seidler[1], Tom Struck[1], Tobias Hangleiter[1], Hendrik Bluhm[1], and Lars. R Schreiber[1] — [1]JARA-FIT Institute for Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, Aachen, Germany — [2]Helmholtz Nano Facility (HNF), Forschungszentrum Jülich, Jülich, Germany

Electrostatically confined electrons are promising candidates for spin-qubits due to their long coherence in ^{28}Si/SiGe. To scale up qubit numbers and integrate control electronics, we propose to use a 10 μm long quantum bus (QuBus), which requires four control lines independent of the shuttle distance. Providing a propagating sinusoidal potential in a gate-defined 1D channel, adiabatic movement of a quantum dot filled by a single electron representing the qubit has achieved a shuttling fidelity of 99.4 ± 0.02% in a 420 nm long QuBus [1]. Here, we propose and demonstrate the tomography of a single electron shuttling process on

a scaled-up 10 μm long QuBus. The electron is shuttled forth and back over micrometer-scale by a time-reversible pulse composed by only four sine-waves. Our tomography measures the shuttling fidelity and detects shuttling failures such as electron tunneling across pockets of the sinusoidal shuttling potential due to local potential disorder [2].

Telecom C-band photon emission from (In,Ga)As quantum dots generated by filling nanoholes in In0.52Al0.48As layers — •DENNIS DEUTSCH, CHRISTOPHER HENRIK BUCHHOLZ, KLAUS JÖNS, and DIRK REUTER — Universität Paderborn, Warburger Str. 100, 33098 Paderborn

Quantum communication technology requires sources for the on-demand generation of entangled photon pairs, preferably in the optical C-band for long-haul fiber-based communication. Quantum dots grown on InP substrates seem to be an ideal candidate: Here photon pairs can be generated from the biexciton-exciton cascade with emission wavelengths around 1.55 μm. However, the conventional approach of Stranski-Krastanov grown InAs quantum dots leads to several challenges related to the strain driven growth. In this study we report on an alternative approach allowing for unstrained quantum dots by filling of local droplet etched (LDE) nanoholes. The quantum dots are embedded in an $In_{0.52}Al_{0.48}As$ matrix lattice-matched to the InP substrate and grown by molecular beam epitaxy. We show detailed investigations of the hole morphology measured by atomic force microscopy. Statistical analysis of nanoholes shows promising symmetry for a good number of them when etched at optimized temperatures. Furthermore, we see that filling of the holes with $In_{0.53}Ga_{0.48}As$ works under the right growth conditions. By capping the filled holes and performing photoluminescence measurements we observe emission in the O-band up into the C-band depending on the filling height of the nanoholes.

HL 37.3   Thu 10:00   POT 251

Scalable Quantum Memory Nodes using nuclear spins in Silicon Carbide — •SHRAVAN KUMAR PARTHASARATHY[1,2], BIRGIT KALLINGER[1], FLORIAN KAISER[3,4], PATRICK BERWIAN[1], DURGA DASARI[3,4], JOCHEN FRIEDRICH[1], and ROLAND NAGY[2] — [1]Fraunhofer Institute for Integrated Systems and Device Technology (IISB), Erlangen, Germany — [2]Chair of Electron Devices, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany — [3]3rd Institute of Physics and Stuttgart Research Center of Photonic Engineering (SCoPE), University of Stuttgart,70569 Stuttgart, Germany — [4]Center for Integrated Quantum Science and Technology (IQST), Germany

The ultimate motivation of my project is to address the possibility of building a quantum analogue of Internet of Things in order to improve the standards of quantum information processing. A distributed quantum computing network which is capable of achieving this goal, would require large sets of memory nodes. The challenge in this field has been in realizing such memory nodes with features for scalable quantum computing. Solid state spins in 4H-Silicon Carbide (4H-SiC) provides a suitable platform in achieving this goal wherein a controlled generation of highly coherent qubit registers using nuclear spins (^{13}C or ^{29}Si) and silicon vacancy color centers (V_Si^- center) are possible. A numerical model is hence established in order to investigate the influence of material or experimental parameters on number of such controllable nuclear spins. This study would be helpful in finding the optimal parameters to maximize qubits in Quantum Memory Nodes.

HL 37.4   Thu 10:15   POT 251

Coherent Conveyor Mode Shuttling of Electrons and their Spin — •TOBIAS OFFERMANN, TOM STRUCK, LINO VISSER, MATS VOLMER, RAN XUE, HENDRIK BLUHM, and LARS R. SCHREIBER — JARA-FIT Institute for Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, Aachen, Germany

A missing key technology for scaling up electron spin qubits in ^{28}Si/SiGe is a coherent medium-range coupling between two qubits. It would enable a sparse-qubit architecture and makes space for signal-line fan-out and cryogenic electronics tiles integrated on the qubit chip. We present an approach named *conveyor-mode shuttling*, which relies on physically transporting the electron by a propagating wave-potential with simple input signals across an electrostatically defined quantum-channel [1,2]. We will introduce high fidelity single electron shuttling at a velocity high enough to reduce the shuttling time well below the typical spin-dephasing time of natural silicon. We show initialisation of the shuttle device on one end by two electrons in a spin-singlet. Shuttling only one of these electrons, we generate a separated Einstein-Podolsky-Rosen spin-pair. Combining the electrons by shuttling again, we detect their spin-singlet fraction by Pauli-spin blockade and explore the spin-coherence of the shuttling process.

HL 37.5   Thu 10:30   POT 251

Prospects for electrically controlled, directly fiber-coupled circular Bragg gratings as high performance quantum light sources — •LUCAS RICKERT[1], FRIDTJOF BETZ[2], MATTHIAS PLOCK[2], SVEN BURGER[2,3], and TOBIAS HEINDEL[1] — [1]Institut für Festkörperphysik, Technische Universität Berlin, Hardenbergstraße 36, 10623 Berlin, Germany — [2]Zuse Institute Berlin, Takustraße 7, 14195 Berlin, Germany — [3]JCMwave GmbH, Bolivarallee 22, 14050 Berlin, Germany

Semiconductor quantum dots in (hybrid) circular Bragg gratings (hCBGs) have shown seminal performances as bright sources of indistinguishable entangled photons at wavelengths below 900 nm and have also shown significant boosts in performances for telecom wavelength single photons sources. To fully harness their potential for photonic quantum technologies, a direct coupling to single mode fibers (SMFs) for robust quantum light sources as well as designs with gate-contacts allowing for electrical control of the embedded emitters charge environment and spectral Stark-tuning is desirable. In this contribution, we present hCBG-based designs enabling electrical control, which are numerically optimized to show >85% direct fiber coupling efficiencies to SMFs, and Purcell enhancements >20 at operation wavelengths for 930 nm, 1310 nm and 1550 nm respectively. We investigated extensively the impact on performance of deviations in the fabrication using machine-learning algorithms, and show our recent progress in the experimental realization of directly fiber-coupled hCBG single photon sources.

X-ray nanobeam measurements of nanoscale elastic strain in electron shuttling devices — •CEDRIC CORLEY-WICIAK[1], MARVIN H. ZOELLNER[1], IGNATII ZAITSEV[1], COSTANZA L. MANGANELLI[1], EDOARDO ZATTERIN[2], KETAN ANAND[1], AGNIESZKA A. CORLEY-WICIAK[1], FELIX REICHMANN[1], YUJI YAMAMOTO[1], MICHELE VIRGILIO[3], LARS SCHREIBER[4], WOLFRAM LANGHEINRICH[5], CARSTEN RICHTER[6], and GIOVANNI CAPELLINI[1,7] — [1]IHP, Frankfurt(Oder), Germany — [2]ESRF, Grenoble, France — [3]Department of Physics, Università di Pisa, Italy — [4]JARA Institute, RWTH Aachen University, Germany — [5]Infineon Technologies Dresden GmbH und Co.KG, Germany — [6]IKZ, Berlin, Germany — [7]Dipartimento di Scienze, Universita Roma Tre, Italy

Recently, spin qubits housed in electrostatic quantum dots in epitaxial Si/SiGe heterostructures have evolved by the demonstration of multi-qubit algorithms. One key requirement for realizing arrays of qubits with shared gate control is highly homogenous lattice strain in the Si quantum well (QW) hosting the qubits. We leverage Scanning Xray Diffraction Microscopy (SXDM), performed at the beamline ID01/ESRF, to map the strain tensor around several fully CMOS compatible electron shuttling devices for qubit interconnection (QuBus). We observe local modulations of the lattice strain by several 10^{-4}, which are translated into spatially resolved profiles for the energy of the conduction band valley state, showing local fluctuations > 1meV. Thus, our results demonstrate that material inhomogeneities must be considered in the design for scaled quantum processors.

HL 37.7   Thu 11:30   POT 251

Quantum optimal control for conveyor-mode single-electron shuttling in Si/SiGe — •ALESSANDRO DAVID[1], VEIT LANGROCK[2], JULIAN D. TESKE[3], LARS R. SCHREIBER[3], HENDRIK BLUHM[3], TOMMASO CALARCO[1], and FELIX MOTZOI[1] — [1]Institute of Quantum Control (PGI-8), Forschungszentrum Jülich GmbH, Jülich, Germany — [2]Institute of Theoretical Nanoelectronics (PGI-2), JARA-FIT Institute for Quantum Information, Forschungszentrum Jülich GmbH, Jülich, Germany — [3]JARA-FIT Institute for Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, Aachen, Germany

A quantum bus (QuBus) is a promising candidate for the scalability of spin-qubits quantum computers. We consider a gated Si/SiGe quantum well capable of shuttling electrons smoothly by a translating confining potential (conveyor-mode). Dephasing coupling with valley degree of freedom and geometry of the quantum well dictate a maximum shuttling speed to keep the electron state adiabatically in the ground state and avoid excitation of the valley state. In this work we use the position of the electron as a control parameter and we optimise the trajectory of the electron to show how the electron can be shuttled faster and with lower infidelity compared to the adiabatic regime.

HL 37.8   Thu 11:45   POT 251

Determination of optical dipole orientation of quantum emitters in monolayer MoS2 — •ANNA HERRMANN, KATJA BARTHELMI, LUKAS SIGL, MIRCO TROUE, THOMAS KLOKKERS, JONATHAN FINLEY, CHRISTOPH KASTL, and ALEXANDER HOLLEITNER — Walter Schottky Institut and Physics Department, Technische Universität München, Am Coulombwall 4a, Garching bei München, Germany

Single photon emitters in 2D materials are interesting for applications in quantum science and technology. Recently, we demonstrated that defect-based single photon emitters can be site-selectively generated in monolayer MoS2 van der Waals heterostacks by a focused beam of helium ions with an overall positioning

accuracy below 10 nm. The emitters show a luminescence with narrow emission lines around 1.75 eV. To determine the optical dipole orientation of the emitters we discuss the far-field photoluminescence intensity distribution of the defect emission in a back-focal plane geometry. The data is compared to simulations by an analytical model, which describes the dipolar emission pattern in the dielectric environment of the heterostructure. The demonstrated approach allows determining the relative contributions for in- and out-of-plane transition dipole moments of quantum emitters.

HL 37.9 Thu 12:00 POT 251

Interface control of valley splitting in Si-based heterostructures — •Jonas R F Lima[1,2] and Guido Burkard[1] — [1]Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — [2]Departamento de Física, Universidade Federal Rural de Pernambuco, 52171-900, Recife, PE, Brazil

The spin of electrons is a natural two-level system that works as an excellent qubit. The control of the spin of isolated electrons in silicon-based heterostructures is very promising for high performance and scalable qubits. To achieve this, it is very important to predict and control the valley splitting in this system, since a very fast qubit relaxation is obtained, for instance, when the valley splitting becomes equal to the qubit Zeeman splitting. For this reason, different works have investigated the valley splitting in silicon spin qubits, both experimentally and theoretically. In this work we used the effective mass theory, which enables us to obtain the electron envelope function, to predict the valley splitting of silicon-based heterostructures, where we consider fluctuations in the interfaces of the heterostructure. We obtain how the valley splitting can be tuned by the width of the interfaces and compare our results with results obtained by other methods.

HL 38: Functional semiconductors for renewable energy solutions I

Time: Thursday 9:30–11:45 Location: POT 6

HL 38.1 Thu 9:30 POT 6

Energy landscape of B–Si defects calculated by DFT for modelling light-induced degradation in silicon — •Aaron Flötotto[1], Wichard J.D. Beenken[1], Kevin Lauer[1,2], and Erich Runge[1] — [1]Technische Universität Ilmenau, Institut für Physik, Ilmenau, Germany — [2]CiS Forschungsinstitut für Mikrosensorik GmbH, Erfurt, Germany

Boron is a technologically highly relevant p-dopant of silicon. Often, boron does not simply replace a silicon atom, but forms a B-Si pair that shares one lattice site. Several metastable pair configurations exist, with boron being closer to either a more substitutional or a more interstitial position. Using DFT, we calculated all neutral and charged metastable configurations of these defects and – using the Nudged Elastic Band algorithm – the minimal-energy paths between them. The resulting energy minima, barrier heights, and conversion rates will be discussed within the A_{Si}–Si_i model for light-induced degradation (LiD) as suggested by K. Lauer et al. [1].

HL 38.2 Thu 9:45 POT 6

Nanoscale characterization for understanding performance limitations in water splitting photoelectrodes — Lukas Wolz[1], Harishankar Balakrishnan[2], Guanda Zhou[1], Ian Sharp[1], Achim Hartschuh[2], and •Johanna Eichhorn[1] — [1]Walter Schottky Institute, TU München, Am Coulombwall 4, 85748 Garching, Germany — [2]Department of Chemistry, LMU München, Butenandtstr. 5-13, 81377 Munich, Germany

Economically viable systems for photoelectrochemical water splitting are often based of polycrystalline or nanostructured semiconductor thin films. Their nano- to micrometer properties often control critical processes, such as efficiency and stability, of the macroscale system.

Here, we aim at resolving local heterogeneities and at elucidating their effect on light-driven processes of BiVO4 thin films using a correlative nanoscale approach. Scanning nearfield infrared microscopy shows varying absorption from VO4 stretching modes across the film which correlates with local photoconductivity heterogeneities revealed by photoconductive atomic force microscopy. Furthermore, local temperature-dependent current-voltage spectroscopy in controlled gas environment shows that the low intrinsic bulk conductivity limits the electron transport [1], and that adsorbed oxygen acts as surface trap states for electrons [2]. Overall, combining insights from different nanoscale techniques generates a comprehensive picture of charge transport and transfer at the nanoscale, which provides the foundation for the rational design of durable and efficient solar fuel devices.

HL 38.3 Thu 10:00 POT 6

Calibration of low temperature photoluminescence of boron doped silicon with increased temperature precision — •Katharina Peh[1], Aaron Flötotto[1], Kevin Lauer[1,2], Dirk Schulze[1], and Stefan Krischok[1] — [1]TU Ilmenau, Institut für Physik und Institut für Mikro- und Nanotechnologien, 98693 Ilmenau, Germany — [2]CiS Forschungsinstitut für Mikrosensorik GmbH, Konrad-Zuse-Str. 14, 99099 Erfurt, Germany

Low-temperature photoluminescence spectroscopy (LTPL) enables the determination of the dopant concentration of shallow impurities in silicon. We present a method which allows the determination of the boron concentration in silicon in a range from $10^{11} cm^{-3}$ to $10^{17} cm^{-3}$ at temperatures from 4.2 to 20 K with increased temperature accuracy. This method requires only one calibration function for the photoluminescence intensity ratio $I_{B_{TO(BE)}}/I_{I_{TO(FE)}}$. We obtain the

measurement temperature from the intrinsic silicon photoluminescence line of free excitons ($I_{TO(FE)}$) using a fitting method, which distinguish the TO and LO components of the free exciton peak. The determined calibration function is $I_{B_{TO(BE)}}/I_{I_{TO(FE)}} = (5.8 \pm 0.08) \cdot 10^{-18} cm^3 \cdot c_{boron} \cdot e^{(56.7\pm0.7K)/T}$. The obtained exciton binding energy to boron, $E_b = 4.9 \pm 0.1 meV$, agrees well with literature data.

HL 38.4 Thu 10:15 POT 6

Coaxial Nanowire-in-Nanopore Arrays Enabling Anti-Agglomeration and Reliable Length Retention — •Chengzhan Yan, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN Macro-Nano, Technische Universität Ilmenau, 98693 Ilmenau, Germany.

Nanowire arrays, a typical one-dimensional (1D) nanostructure used in energy storage systems, have significantly improved the electrochemical performance by optimizing the active material distribution and promoting the charge transport kinetics in energy storage systems. Notably, nanowire arrays with well-defined arrangements and high aspect ratios are of particular interest. To this end, one prevailing strategy is to combine ordered templates with wet chemical techniques. However, nanowires with high aspect ratios have a more severe tendency to agglomerate because of uneven capillary forces, which leads to poor arrangement reliability and degrades the electrochemical performance. Herein, the ultra-thin honeycomb alumina nanopores are constructed to ensure the structural stability of nanowire arrays, achieving a reliable quadrupling of the length. Based on the integrated nanowire-in-nanopore architecture, MnO2 and polypyrrole are further electrodeposited on these free-standing nanowires to form vertically aligned core-shell 1D nanostructure arrays as cathodes and anodes for micro-supercapacitors (MSCs). Attributed to the high specific surface area and low charge diffusion resistance, these MSCs attain remarkably improved energy density, rate performance and lifespan.

HL 38.5 Thu 11:00 POT 6

Tails states, Voc loss and semiconductor compensation — •Susanne Siebentritt and Omar Ramirez — University of Luxembourg, Laboratory for Photovoltaics

It has been shown for many solar cell absorbers that Voc loss correlates with the Urbach energy, which describes the decay of tail states into the band gap. In chalcopyrites it was furthermore observed that heavy alkali postdeposition treatments reduce both: Urbach energy and Voc loss. This behaviour has been attributed to passivation of grain boundaries. However, recently we have shown, that alkali treatment in single crystalline films without grain boundaries also leads to a reduction of Voc loss and Urbach energies. This behaviour can be traced back to a reduced compensation by increasing the doping level. It is to be expected that a similar mechanism plays a role in polycrystalline films. Part of the dependence of the Voc loss on Urbach energy can be attributed to radiative and non-radiative recombination in and through tail states. However, the dependence is stronger than would be expected from the increased recombination. We now understand that this is due to a simultaneous effect: increasing doping increases Voc and decreases tail states. Thus we propose, that one effect of heavy alkali treatment is due to the observed increase of Na doping inside the grains, because it increases the net-doping, reduces tail states and thereby reduces radiative and non-radiative recombination. All this increases Voc.

HL 38.6   Thu 11:15   POT 6
Dependence of the activation energy of light-induced degradation (LID) in silicon on the illumination intensity — •Kevin Lauer[1,2], Katharina Peh[1], Dirk Schulze[1], and Stefan Krischok[1] — [1]Technische Universität Ilmenau, Institut für Physik und Institut für Mikro- und Nanotechnologien, Ilmenau, Germany — [2]CiS Forschungsinstitut für Mikrosensorik GmbH, Erfurt, Germany

It was found that the activation energy of the dissociation process of the acceptor-iron defects (A_{Si}-Fe$_i$) in silicon depends on the illumination intensity.[1] This implies that besides the thermal energy an additional supply of energy due to e.g. carrier recombination is possible in that defect reaction. To check whether this is also the case for the slow process of the light-induced degradation (LID) in silicon,[2] which can be explained by acceptor-silicon defects (A_{Si}-Si$_i$),[3] we measured the activation energy for the slow LID process for different illumination intensities. No impact of the illumination intensity on the activation energy of the slow LID process could be found indicating a pure thermally activated process.

Photoelectrochemical Catalyst Deposition on III-V Semiconductor Surfaces for Direct Solar Water Splitting — •Erica Schmitt, Moritz Kölbach, Margot Guidat, Marco Flieg, Max Nusshör, Anna-Lena Renz, and Matthias May — Universität Tübingen, Institute of Physical and Theoretical Chemistry, Tübingen, Germany

The conversion of solar electrical energy to chemical energy by the generation of hydrogen is believed to play a key role in the transition towards a sustainable energy system. One approach to generate sustainable hydrogen is the use of III-V photoelectrodes in a highly efficient photoelectrochemical water splitting device. Such fully integrated, monolithic systems have a potentially lower balance of system cost compared to more conventional decoupled PV-electrolysis approaches and have already shown to be highly efficient [1].

The III-V semiconductor-electrolyte interface plays a crucial role in the performance of a photoelectrochemical device. Our work focuses on the photoelectrochemical modification of the semiconductor surface with a suitable catalyst and its stabilization in the harsh environment of an acidic electrolyte under operating conditions while also understanding the underlying physicochemical processes. We present an optimized functionalization process to increase the solar-to-hydrogen efficiency and stability of a photoelectrochemical cell, as well as the electrochemical and spectroscopical characterization using, among other methods, reflection anisotropy spectroscopy. Nailing down charge-density-wave phase-transition temperatures with downfolding approaches — •Arne Schobert[1], Jan Berges[2], Michael Sentef[3], Erik van Loon[4], Sergey Brener[1], Mariana Rossi[3], and Tim Wehling[1] — [1]University of Hamburg, Germany — [2]University of Bremen, Germany — [3]MPSD, Hamburg, Germany — [4]Lund University, Sweden

The coupled dynamics of electrons and nuclei is an extremely complex problem of relevance to multiple branches of sciences. *Ab initio* molecular dynamics (AIMD) simulations are often challenging — especially in large systems, on long time scales, in non-equilibrium or in presence of strong correlation. We can overcome these problems by mapping the full *ab initio* density functional theory (DFT) Hamiltonian onto a low-energy lattice model through downfolding. Three different downfolding strategies based on constraining, unscreening and combinations thereof are compared. The best performing model, which properly accounts for anharmonicity, is combined with path integral molecular dynamics (PIMD). This allows us to nail down the transition temperatures of charge-density waves — for instance in 1H-TaS$_2$.

Structural and electronic properties of the Ba$_8$Au$_x$Ge$_{46-x}$ clathrate: an ab-initio study with cluster expansion — •Peter Weber, Santiago Rigamonti, and Claudia Draxl — Humboldt-Universität zu Berlin, Berlin, Germany

Intermetallic clathrate materials are promising candidates for high-efficiency thermoelectric applications as they can reach very low thermal conductivity. These materials possess a cage-like structure containing guest atoms. Their electronic properties can be tailored by exploiting the idea of the phonon-glass–electron-crystal which allows for reaching a large figure of merit. We study the compound Ba$_8$Au$_x$Ge$_{46-x}$ ($0 \leq x \leq 8$), which has raised interest due to its glass-like thermal conductivity [1]. Using the Zintl concept, a semiconducting state is expected to occur at the charge-balanced composition corresponding to x=5.33. This composition requires a supercell of at least 3 unit cells (162 atoms) which makes a direct *ab initio* study challenging. We tackle this problem by using the cluster expansion method combined with density-functional theory calculations. In this way, we are able to find the atomic ground-state configurations, together with various properties at different temperatures and gold content. These include lattice constants, bond lengths, site occupancies, as well as band gaps and band structures which are compared with available experimental data.

Topical Talk   HL 40.3   Thu 11:00   TRE Ma
New Opportunities for First Principles Simulations of Thousands of Atoms Using Linear Scaling Density Functional Theory — •Laura Ratcliff — University of Bristol, Bristol, United Kingdom

Density-functional theory (DFT) is routinely used to simulate a wide variety of materials and properties, however, standard implementations are cubic scaling with the number of atoms, limiting the system sizes which can be treated. This motivated the development of alternative implementations of DFT, which exploit the nearsightedness principle by using a localised description of the system, leading to algorithms with linear scaling (LS) cost which can treat large systems containing tens of thousands of atoms. One approach, which is implemented in the wavelet-based BigDFT code, uses localised orbitals, also known as support functions, which are optimised to reflect their local chemical environment, and thus constitute an accurate minimal basis set. Beyond reduced computational cost, the localised support function description also facilitates additional developments, such as the ability to automate a fragment-based description. In this talk we will present the formalism behind LS-BigDFT, including some examples of the new types of systems and analyses which are opened up by the ability to treat such large systems. We will also describe recent developments in PyBigDFT, a python-based interface which aims to simplify the usage of LS-BigDFT for complex systems and workflows.

Fully Anharmonic Electronic Transport Coefficients from Temperature-dependent Spectral Functions — •Jingkai Quan, Matthias Scheffler, and Christian Carbogno — The NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft and IRIS-Adlershof of the Humboldt-Universität zu Berlin

The combination of *ab initio* molecular dynamics (aiMD) and band-structure unfolding techniques provides a non-perturbative route to obtain temperature-dependent spectral functions. [1] In contrast to commonly employed perturbative approaches [2], this technique accounts for all orders of anharmonic and vibronic couplings. Building on this non-perturbative formalisms, we here present an approach to obtain electronic transport coefficient such as the electrical conductivity using Kubo's formulation of the fluctuation-dissipation theorem. By this means, all relevant quantities, including electron lifetimes, are obtained from the unfolded, self-consistent wave functions computed during the aiMD runs. We critically benchmark the approach against existing perturbative data for harmonic systems, carefully analyzing to which extent short- and long-range couplings are captured with increasing supercell size. Furthermore, we demonstrate

the advantages of the proposed approach for strongly anharmonic systems, for which perturbative approaches become unreliable.

Accurate prediction of vibrational spectra for solid state systems from ab initio molecular dynamics — •Ekin Esme Bas, Thomas Heine, and Dorothea Golze — Chair of Theoretical Chemistry, Technische Universität Dresden, 01062 Dresden, Germany

We present a highly accurate computational method to calculate vibrational spectra for solid state materials, primarily for covalent-organic frameworks (COFs). IR and Raman spectra are important tools that are frequently used for material characterization. However, the experimental spectra are often difficult to interpret without aid from theory. The computation of IR and Raman spectra is usually based on the harmonic approximation where molecular vibrations can be determined as normal modes from the second derivatives of the electronic energy with respect to the coordinates. Although this method is more straightforward and computationally less expensive, anharmonic modes cannot be captured. Thus, we employ an AIMD (ab initio molecular dynamics) based approach to include vibrational anharmonicities. Power, IR and Raman spectra can then be calculated via a Fourier transformation of the time correlation functions of velocities, dipole moments and polarizability tensors, respectively [1]. We discuss different approaches to compute dipole moments and polarizabilities. We present the power, IR and Raman spectra we calculated for COF-1, and we compare our AIMD based approach to the spectra obtained via harmonic approximation and experiment.

Anharmonic Fingerprints from THz Modes of Polyacene Crystals — •Paolo Lazzaroni, Shubham Sharma, and Mariana Rossi — Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany

Organic molecular crystals exhibit strong lattice anharmonicity, especially in the collective motions that are governed by intermolecular interactions and lie in the low-frequency THz range [1]. Inspired by recent observations that the polarization-orientation (PO) Raman spectra can give exquisite insight into the anharmonic couplings between modes [2], we devise a first-principles framework that can reproduce, explain and give quantitative insight into the type and strengths of mode coupling. This framework is based on machine-learned potentials and polarizability tensors trained on *ab initio* molecular dynamics trajectories [3]. We obtain results through the time-correlation formalism for PO Raman signals, retaining the full anharmonic nature of the potential, and perform a novel analysis of effective temperature-dependent mode couplings from our trajectories. A first-principles Newns-Anderson chemisorption function applied to ultrafast electron transfer — •Simiam Ghan[1], Elias Diesen[1], Christian Kunkel[1], Karsten Reuter[1], and Harald Oberhofer[2] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany. — [2]University of Bayreuth, Bayreuth, Germany

We offer a method to calculate the electronic couplings H_{ad} between an adsorbate and substrate in an ab-initio fashion. The couplings are acquired by projection of the Kohn-Sham Hamiltonian onto a diabatic basis[1]. By averaging over the Brillouin Zone, it becomes possible to calculate a convergent chemisorption function of Newns and Anderson[2], which gives the energetic broadening of an adsorbate frontier orbital upon adsorption. This broadening corresponds to the experimentally-observable lifetime of an electron in the state, which we confirm for the case of core-excited $Ar^*(2p_{3/2}^{-1}4s)$ atoms on a number of transition metal surfaces[3].

We find that the (tunneling) model captures and elucidates aspects of energy-dependence, spin, phase cancellation and k-space in the electron transfer process, in particular suggesting a significant role played by the surface d-bands. Given the prevalence of electronic couplings - and the chemisorption function - in theoretical models, we discuss potential for further applications.

Thermal Conductivities of Ga$_2$O$_3$ Polymorphs: Analysis of Anharmonicity and Anisotropy — •Shuo Zhao, Matthias Scheffler, and Christian Carbogno — The NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft and IRIS-Adlershof of the Humboldt-Universität zu Berlin

Gallium oxide (Ga$_2$O$_3$) is an ultra-wide bandgap material with substantial potential for electronics, e.g., in field effect transistors [1]. In this context, an atomistic understanding of its heat transport characteristics is essential for thermal management. For this purpose, we compute the lattice thermal conductivity of the α-, β-, and κ-polymorphs of Ga$_2$O$_3$ using the *ab initio* Green-Kubo formalism [2,3] that incorporates all orders of anharmonic effects via first-principle molecular dynamics. We discuss the role of anharmonic effects for the different polymorphs and investigate their influence on the anisotropy of the conductivity tensor. Our results provide guiding rules for maximizing and minimizing thermal transport in thin Ga$_2$O$_3$ films.

Strain-induced polymorph conversion in gallium oxide via focused ion beam irradiation — •Umutcan Bektas, Paul Chekhonin, and Gregor Hlawacek — Insitute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany

Monoclinic β-Ga$_2$O$_3$ is chemically and thermally the most stable compound compared to its other polymorphs. It is a promising semiconductor material for power electronics, optoelectronics, and batteries. However, controlling the metastable polymorph phases is challenging, and the fabrication technology at the nanoscale is immature. Our goal is to understand and control the polymorph conversion, so we can establish new fabrication methods of single-phase polymorph coatings, buried layers, multilayers, and different nanostructures in gallium oxide.

Under ion beam irradiation, most semiconductors show transformation from crystalline to amorphous structure due to ion beam induced damage. However, it is observed that, this transformation is suppressed in gallium oxide, and a polymorph conversion is observed instead. Here, we use Gallium and Neon focused ion beams (FIB) from different sources (GFIS, LMIS) to create local strain and induce the polymorph transition. After irradiation, characterization of the exposed areas was conducted by electron backscatter diffraction (EBSD) and atomic force microscopy (AFM). First results indicate that the strain created by the FIB irradiation leads to a local transformation of beta gallium oxide to another polymorph.

HL 41.3   Thu 15:30   POT 81

Comparative Study of Temperature-dependent Bandgap Transitions in Ga2O3 Polymorphs — •Benjamin Moritz Janzen[1], Marcella Naomi Marggraf[1], Moritz Meissner[1], Nils Bernhardt[1], Conrad Valentin Hartung[1], Nima Hajizadeh[1], Felix Nippert[1], and Markus Raphael Wagner[1,2] — [1]Technische Universität Berlin, Institute of Solid State Physics, Germany — [2]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Germany

We employ a combined experimental-theoretical study to investigate the electronic bandgap transitions in Ga2O3 polymorphs as a function of the sample temperature. For this purpose, we apply temperature-dependent UV photoluminescence excitation (PLE) spectroscopy for the β-, κ-, α- and γ-polymorphs in the temperature range between 5 and 300 K and compare the obtained bandgap values with room temperature measurements of the dielectric function as determined by spectroscopic ellipsometry. The obtained temperature dependencies are discussed in conjunction with DFT calculations regarding the effects of electron-phonon coupling.

HL 41.4   Thu 15:45   POT 81

Anisotropic IR active phonon modes and fundamental direct band-to-band transitions in α-(Al$_x$Ga$_{1-x}$)$_2$O$_3$ alloys grown by MOCVD — •Elias Kluth[1], A F M Anhar Uddin Bhuiyan[2], Lingyu Meng[2], Hongping Zhao[2], Rüdiger Goldhahn[1], and Martin Feneberg[1] — [1]Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Germany — [2]Department of Electrical and Computer Engineering, The Ohio State University, Columbus, Ohio, USA

The corundum-like Ga$_2$O$_3$ polymorph α-Ga$_2$O$_3$ is of high research interest as it allows bandgap-engineering by alloying e.g. with α-Al$_2$O$_3$, α-In$_2$O$_3$, α-Ti$_2$O$_3$ and similar materials. Since the corundum-like crystal structure is anisotropic, a direction dependent investigation of the material properties is crucial. m-

plane α-(Al$_x$Ga$_{1-x}$)$_2$O$_3$ thin film samples up to x=0.76, grown on m-plane sapphire substrate by MOCVD have been investigated by infrared (IR) and visible-ultraviolet (UV) spectroscopic ellipsometry. IR ellipsometry yields the anisotropic IR active phonons and their shift to higher wavenumbers with increasing x. Furthermore, with UV ellipsometry, we find the anisotropic dielectric functions up to 6.6eV and the shift of the fundamental direct band-to-band transitions with increasing x. We report an anisotropic bowing parameter for α-(Al$_x$Ga$_{1-x}$)$_2$O$_3$ of b_{ord}=2.7eV and b_{extra}=2.5eV.

Adsorption enhanced photocatalytic degradation of Rhodamine B using GdxBi1-xFeO3@SBA-15 (x= 0, 0.05, 0.10, 0.15) nanocomposites under visible light irradiation — •THOMAS CADENBACH[1] and MARIA JOSE BENITEZ[2] — [1]Universidad San Francisco de Quito, Quito, Ecuador — [2]Escuela Politecnica Nacional, Quito, Ecuador

In the present work show that very high removal efficiency of a variety of organic pollutants by GdxBi1-xFeO3@SBA-15 nanocomposites (x = 0, 0.05. 0.10, 0.15) under visible light irradiation. Specifically, we study the photocatalytic degradation of dyes using the above nanocomposite materials, with pore volume loadings of 5-25%. We compare the obtained catalytic results for the nanocomposite materials to monodisperse BiFeO3 nanoparticles with a particle diameter of 5.5 nm. We find that the best removal performance is achieved by a 10 vol% Gd0.05Bi0.95FeO3@SBA-15 sample, shown by a complete dye degradation in approximately 3h using extremely low concentrations of the actural active photocatalyst. The superior efficiencies of the nanocomposites, which outperformed their parent compounds, i.e. GdxBi1-xFeO3 nanoparticles as well as unfilled SBA-15, are attributable to a synergistic adsorption enhanced photocatalytic degradation process. The possible mechanism in the photodegradation process was investigated and discussed on the basis of trapping experiments.

HL 41.6 Thu 16:30 POT 81

Electrical and thermal transport properties of ZnGa$_2$O$_4$ — JOHANNES BOY[1], RÜDIGER MITDANK[1], ZBIGNIEW GALAZKA[2], and •SASKIA FISCHER[1] — [1]Novel Materials Group, Humboldt-Univ. zu Berlin, Germany — [2]Leibniz-Institute of Crystal Growth, Berlin, Germany

The first full experimental determination of the low-temperature electrical, thermo-electrical [1] and thermal properties [2] of novel highly pure single crystalline ZnGa$_2$O$_4$ is reported. The temperature-dependences of the charge carrier density, mobility, and Seebeck coefficient including phonon drag are discussed between 10 K and 310 K. The thermal conductivity and diffusivity were determined by the so-called 2ω-method. At room temperature the electrical conductivity is 286 S/cm, the mobility 55 cm^2/Vs, the Seebeck coefficient $125\mu V/K$ and the thermal conductivity is 22.9 W/mK. For temperatures above 100 K the phonon transport is limited by phonon Umklapp scattering. At lower temperatures boundary scattering at lattice defects limits the thermal conductivity to 95 W/mK. Therefore, if the cause of boundary scattering is reduced or eliminated, the thermal conductivity of ZnGa$_2$O$_4$ may be increased at low temperatures.

HL 41.7 Thu 16:45 POT 81

Temperature- and Polarisation- Dependant Photoluminescence Excitation Spectroscopy of $\beta - Ga_2O_3$. — •MORITZ MEISSNER[1], NILS BERNHARD[1], FELIX NIPPERT[1], BENJAMIN M. JANZEN[1], CONRAD V. HARTUNG[1], ZBIGNIEW GALAZKA[2], and MARKUS R. WAGNER[1,3] — [1]Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany — [2]Leibniz-Initut für Kristallzüchtung, Berlin, Germany — [3]Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany

The anisotropic, ultra-wide bandgap semiconductor $\beta - Ga_2O_3$ represents a promising candidate for applications in high power electronics. The high anisotropy of the monoclinic crystal structure and the formation of self-trapped excitons has made a precise determination of the bandgap parameters a challenging endeavor. In this work, we apply polarization- and temperature-dependent photoluminescence excitation spectroscopy (PLE) measurements to study the anisotropy of the optical bandgap transitions. The temperature dependence of the PLE spectra between 5K and 300K provides information on the strength of the electron-phonon coupling and zero temperature bandgap energies along the principal axes of the material. The measurements were performed on the three crystal planes (100), (010) and (001) prepared and polished from the same single bulk crystal grown by the Czochralski method. Our results are discussed in comparison with absorption, transmission, and reflectance spectroscopy data in the literature.

HL 42.1 Thu 15:00 POT 151

Cone-shell quantum structures with tunable wave functions — •CHRISTIAN HEYN, AHMED ALSHAIKH, KRISTIAN DENEKE, and ROBERT BLICK — Center for Hybrid Nanostructures (CHyN), University of Hamburg

We discuss the tailoring of the wave functions (WF) in strain-free GaAs quantum structures (QS) fabricated using self-assembled local droplet etching (LDE) during molecular beam epitaxy (MBE). Here, Al droplets are deposited on an AlGaAs surface and drill nanoholes with tunable shape and size. Subsequently, the holes are filled with GaAs to form strain-free QS. Dependent on the process parameters, the QS have the shape of a cone or of a cone-shell. In particular the low-density (about 1x10^7 cm^{-2}) cone-shell QS (CSQS) demonstrate sharp exitonic lines with linewidth down to 25 μeV, a precise control of the emission wavelength from 680...810 nm by the nanohole filling level, a neutral exiton fine-structure splitting below 5 μeV, and nearly perfect single photon emission. To tune the WF in CSQS, a vertical electric field is applied which causes a strong charge-carrier separation. The resulting Stark shift is measured using microphotoluminescence (PL). In combination with simulation results the optical data allow the determination of the QS size and shape. In addition, simulations indicate the transformation of either the electron or the hole WF into a quantum ring. As a further consequence of the field-induced charge-carrier separation, simulations of the exciton-recombination lifetimes predict a variability from nanoseconds up to milliseconds. This suggests CSQS for applications in the field of light storage

HL 42.2 Thu 15:15 POT 151

DNA Origami for low-dimensional electronics — •BORJA RODRIGUEZ-BAREA[1], SHIMA JAZAVANDI-GHAMSARI[1], MADHURI CHENNUR[1], ARCHA JAIN[1], TURKAN BAYRAK[1], JINGJING YE[2], RALF SEIDEL[2], and ARTUR ERBE[1] — [1]Institute of Ion Beam Physics und Material Science, Helmholtz-Zentrum Dresden-Rossendorf, Germany — [2]Peter Debye Institute for Soft Matter Physics, Universität Leipzig, Germany

The increasing demand for energy-efficient products gave rise to electronic fabs looking for new green manufacturing processes. Bottom-up techniques have the potential to reduce economic and environmental costs due to implementing low-dimensional materials with unique properties.

We demonstrated the formation of low-dimensional metallic nanostructures based on the DNA origami technique, which can be considered as building blocks for electronic circuits. DNA templates are used as molds to guide the placement and growth of the metallic 1D nanowires. This solution-based and high-resolution nanofabrication technique complements other nanolithography techniques such as electron-beam lithography and thermal scanning probe lithography. Thus, the shape of the nanostructures can be controlled and measured.

Electronic transport on these assemblies is non-ohmic and deteriorates at low temperatures. Temperature-dependent charge transport measurements reveal the dominating mechanisms along these wires.

HL 42.3 Thu 15:30 POT 151

1D Nanowires on DNA mold-based template — •MADHURI CHENNUR[1], BORJA RODRIGUEZ-BAREA[1], JAZAVANDI-GHAMSARI SHIMA[1], ARCHA JAIN[1], TÜRKAN BAYRAK[1], ULRICH KEMPER[2], JINGJING YE[2], CHRISTOPH HADLICH[2], RALF SEIDEL[2], and ARTUR ERBE[1] — [1]Institute of Ion Beam PhysicsundMaterial Science, HZDR — [2]Peter Debye Institute for Soft MatterPhysics, Universität Leipzig, Germany

Sensors have a fundamental role in improving the world around us. For increasing sensitivity and faster response, new bottom-up approaches are required. DNA nanotechnology allows the creation of nanostructure arrays that can serve the purpose.

We study the controlled growth of 1D metallic nanostructures using DNA origami templates. The DNA nanomolds are folded via staples to obtain the desired conformation. The functionalized template provides the active site for a localized seed nanoparticle attachment, thus allowing metallization by electroless plating. We report continuous Pd and Au 1D nanowires based on this method.

The conductance of the assembled nanostructures through two-probe measurements was investigated. Different origami templates lead to diverse metal morphologies, which influence electronic properties. Temperature-dependent measurements determined the transport mechanism of these nanowires, proving the first step toward an electronic nanosensor.

HL 42.4 Thu 15:45 POT 151

Maximizing Homogeneity of GaAs LDE-QDs on Full Wafer Scale — •Hans-Georg Babin, Timo Kruck, Andreas D. Wieck, and Arne Ludwig — Lehrstuhl für angewandte Festkörperphysik, Ruhr-Universität Bochum, Deutschland

Local droplet etched GaAs quantum dots (LDE-QDs) are a promising candidate for excellent single and entangled photon sources. [1] Taking further steps towards application, this requires structures of increasing complexity, engineering the electronic and photonic environments of the QDs. [2] In previous studies, we showed how properties of GaAs LDE-QDs can be modulate, containing both 737 nm and 795 nm QDs on a single wafer. [3]

However, in device mass production, for example for creating larger quantum networks, it can also be intriguing to maximize the useable area of the produced wafer. This means for the QDs, that the ensemble should be of high homogeneity locally, but also on global wafer scale. Due to the short deposition times of material during LDE this can be challenging due to intrinsic inhomogeneities. We overcome these problems by matching the substrate rotation time with the material deposition time. With this method we receive light emitting QDs on over 96 % of the wafer, with 86 % of the wafer emitting between 792 nm and 802 nm (peak-center). The mean ensemble FWHM of the QD emission is as low as (11.3+-0.4) meV.

Wafer-Scale Epitaxial Modulation of Quantum Dot Densitiy — •Nikolai Bart[1,2], Christian Dangel[2], Peter Zajac[1], Nikolai Spitzer[1], Marcel Schmidt[1], Kai Mueller[2,3], Andreas D. Wieck[1], Jonathan Finley[2], and Arne Ludwig[1] — [1]Ruhr-Universitaet Bochum, Lehrstuhl fuer Angewandte Festkoerperphysik, Universitaetsstraße 150, 44801 Bochum, Germany — [2]Walter Schottky Institut and Physik Department, Technische Universitaet Muenchen, Am Coulombwall 4, 85748 Garching, Germany — [3]Walter Schottky Institut and Department of Electrical and Computer Engineering, Technische Universitaet Muenchen, Am Coulombwall 4, 85748 Garching, Germany

The effect of nanoscale surface roughness on the nucleation of self-assembled InAs quantum dots (QD) is investigated with photoluminescence spectroscopy and atomic force microscopy. We show in-situ control of the roughness modulation by common epitaxial layer-by-layer growth, leaving alternating atomically smooth (rough) surfaces for integer (fractional) completion of a monolayer. We report significant differences in both PL intensity and QD surface density at the critical threshold of nucleation. By varying the underlying GaAs thickness gradients, we create and control 1- and 2-dimensional density modulation patterns on entire 3-inch wafers with modulation periods between a few mm and down to hundreds of μm and densities between 1 and 10 QDs/μm^2.

HL 42.6 Thu 16:45 POT 151

Statistical Analysis of the Spatial Distribution of MBE Grown InAs Quantum Dots on GaAs(100) — •Normen Auler, Akshay Kumar Verma, Ziyang Zhang, and Dirk Reuter — Universität Paderborn, Warburger Str. 100, 33098 Paderborn

Self-assembled InAs quantum dots (QDs) have been intensively studied as model systems for strong three-dimensional confinement over decades and gained considerable interest for applications in quantum technology. The growth by molecular beam epitaxy has been widely studied. In this contribution, we discuss the spatial distribution of InAs QDs grown by solid source molecular beam epitaxy on a GaAs(100) surface for different QD densities. Therefore, we determine the distribution of nearest-neighbor distances from atomic force microscope (AFM) images and compare them to simulated random distributions. We find good agreement under the assumption of a "denuded" zone of ca. 40 nm around each quantum dot center. This means that the QDs are basically randomly distributed as one would expect from the statistical nature of the nucleation process. The diameter of the denuded zone can either be interpreted as the average geometrical diameter of the QDs or the geometrical diameter plus a small distance due to a repelling interaction between QDs mediated by the strain field. We cannot decide this from our experimental data because AFM overestimates the geometrical diameter. For very low quantum dot densities as often required for single dot experiments, it is very difficult to obtain experimental data with statistical significance, whereas simulations can give insight into the spatial distribution.

HL 42.7 Thu 17:00 POT 151

Controlled MOF Growth on Functionalized Carbon Nanotubes — •Marvin J. Dzinnik[1], Necmettin E. Akmaz[1], Adrian Hannebauer[2], Peter Behrens[2], and Rolf J. Haug[1] — [1]Leibniz Universität Hannover, Institut für Festkörperphysik, Appelstraße 2, 30167 Hannover, Germany — [2]Leibniz Universität Hannover, Institut für Anorganische Chemie, Callinstraße 9, 30167 Hannover, Germany

The class of metal organic frameworks (MOFs) is continuously growing. These materials consist of inorganic building blocks, held together by organic linker molecules. Schulze *et al.* [1] showed that adding functionalized multi-walled carbon nanotubes (MWCNTs) to a UiO-66 synthesis drastically decreased the nucleation time. The MOFs preferably grow on the MWCNT until they fully encapsulate it. We demonstrate a mechanism to spatially control the UiO-66 MOF growth on individual carbon nanotubes and deplete the encapsulation. The MWCNTs are drop-casted on a silicon dioxide surface and then locally modified. The samples are then submerged in the synthesis solution. This process leads to a growth of MOF crystals on the MWCNT surface leaving the modified areas depleted. With this method we are able to define lines free of MOF on the length of a single MWCNT down to several hundred nanometres for example to electrically contact the tubes ends.

Invited Talk **HL 43.1** Thu 15:00 POT 251

Superradiance as a witness to multipartite entanglement — •Frederik Lohof[1,2] and Christopher Gies[1,2] — [1]Institute for Theoretical Physics, University of Bremen, Bremen — [2]BCCMS, University of Bremen, Bremen

Generation and detection of entanglement is at the forefront of most quantum information technologies. There is a plethora of techniques that reveal entanglement on the basis of only partial information about the underlying quantum state including, in particular, entanglement witnesses. Superradiance refers to the phenomenon of highly synchronized photon emission from an ensemble of quantum emitters that is caused by correlations among the individual particles and has been connected to the presence of multipartite entangled states. We investigate this connection in a quantitative way and discuss the question, whether or not signatures of superradiance from semiconductor nanolasers, e.g. as revealed by photon-correlation measurements, can be interpreted as a witness to detect entanglement in the underlying state of the emitters.

HL 43.2 Thu 15:30 POT 251

Towards a quantum dot based semiconductor optical amplifier for sensing applications in the telecom O-band — •Philipp Noack, Michael Zimmer, Sergej Vollmer, Michael Jetter, and Peter Michler — Universität Stuttgart, IHFG

Optical methods for gas sensing are of great interest in recent technologies. To facilitate the optical detection of gases, a swept laser source can be realized through a semiconductor optical amplifier (SOA) and a tunable MEMS filter.

MOVPE grown quantum dots (QDs) are a prime candidate for providing gain in such a SOA system because of fast charge carrier recovery times and broad gain spectrum created by the statistical distribution of QD sizes.

To this end, we grow InGaAs QDs on a GaAs substrate. We control the growth parameters, such as material flow and growth time, to produce QDs at high densities. We incorporate a dots-in-well structure to shift the emission into the telecom O-band and to improve charge carrier confinement. To provide sufficient gain in a broad spectrum, we especially investigate the properties of vertically stacked QD layers.

After the optimization of the gain structure we perform optical simulations to find the electric field modes of edge-emitting laser structures. Then we incorporate the investigated QDs into electrically pumped edge-emitting structures and characterize the net modal absorption and net modal gain spectra of the devices as antecedent of the SOA.

HL 43.3 Thu 15:45 POT 251

Optical and quantum optical studies of feedback induced chaotic emission in bimodal VCSELs — •Aris Koulas-Simos, Timo Willburger, Niels Herrmeier, Ching-Wen Shih, Imad Limame, James Lott, and Stephan Reitzenstein — Institut für Festkörperphysik, Technische Universität Berlin, 10623 Berlin, Germany

Vertical Cavity Surface Emitting Lasers (VCSELs) have proven to be a key building block for commercial applications in data communication, automotive sys-

tems and sensing as well as for novel complex neuromorphic photonic platforms. Here, we report on signatures of chaotic emission in bimodal GaAs-based quantum well VCSELs subject to delayed optical feedback. In excitation power-dependent microelectroluminescence studies, a clear lasing transition is evident for the strong mode reflected in the strong s-shape form of the I/O-curve accompanied by an abrupt linewidth narrowing, in contrast to the weak mode which exhibits intensity saturation and rollover at high injection currents. In power-dependent photon autocorrelation measurements, super thermal bunching is observed with $g^{(2)}(0)$ reaching values of 3. Revival peaks with a period equal to the round trip time of the external cavity emerge, indicating that the chaotic emission is induced from the optical feedback. This is further validated from signatures of chaotic emission, directly observed in single-shot intensity measurements with a streak camera.

HL 43.4   Thu 16:00   POT 251

Monolithic 850 nm VCSEL Array for QKD via the decoy state protocol — •Michael Zimmer, Moritz Birkhold, Michael Jetter, and Peter Michler — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart.

In recent years, the need for secure data communication has increased. Here, the usage of quantum key distribution (QKD) offers fundamental advantages over classical key distribution. However, despite its high level of security, QKD comes a long with numerous challenges regarding the application of single photons. In this view, the decoy state protocol offers the possibility to implement QKD using classical light sources such as semiconductor lasers. Here, we present an approach for the realization of a monolithic 850 nm eight VCSEL array capable for QKD via the BB84 and decoy state protocol. Growth of the VCSEL structure takes place by metal-organic vapor-phase epitaxy (MOVPE) on a GaAs substrate. In order to obtain defined light polarization states, each VCSEL features an integrated polarization grating in its light emission window. To allow for operation in the GHz-regime and hence a high key rate generation, the VCSEL are arranged in a co-planar contact design. Electro-optical device characteristics regarding light polarization and high frequency operation are presented.

HL 43.5   Thu 16:15   POT 251

In-situ EBL fabrication of highly homogeneous micropillar laser arrays based on InGaAs quantum dots for neuromorphic computing — •Imad Limame[1], Ching-Wen Shih[1], Sven Rodt[1], Daniel Brunner[2], and Stephan Reitzenstein[1] — [1]Technical Univ. of Berlin, Germany — [2]Univ. Bourgogne Franche-Comté, France

As classical computers are reaching their limit, especially in novel fields such as machine learning and artificial intelligence, cost-effective hardware platforms, and new computing architectures are needed. We combine reservoir computing with a nanophotonic platform in an all-optical computing architecture, taking inspiration from neuroscience. Our approach aims to utilize diffractive coupling between 900 micropillars to create a large-scale processing reservoir. Due to the high number of microlasers and the use of a spatial light modulator, laser arrays with low lasing threshold powers and high spectral homogeneity are required. We develop the necessary nanophotonic platform by optimized growth and in-situ electron beam lithography (EBL) fabrication of micropillar laser arrays. The MOCVD growth focuses on increasing the optical gain of the InGaAs quantum dots, used as the gain medium and on the design of the microresonator to decrease the lasing threshold. The realized devices feature thresholds as low as 20 μW. In the second phase, low temperature in-situ EBL is performed. In this process, first a CL map is recorded to determine the local resonance of the planar microcavity before micropillar with suitable diameter to match a target wavelength are patterned by electron beam lithography. Finally, the resulting micropillar array is investigated via photoluminescence.

HL 43.6   Thu 16:30   POT 251

Multimode lasing in a microdisk nanolaser — •M. L. Drechsler[1], F. Nippert[2], L. Sung-Min Choi[2], M. R. Wagner[2], P. Boucaud[3], S. Reitzenstein[2], and Frank Jahnke[1] — [1]Institute for Theoretical Physics, University of Bremen, Bremen, Germany — [2]nstitute of Solid State Physics, Technische Universität Berlin, Berlin, Germany — [3]CRHEA, Université Côte d*Azur, 06560 Valbonne, France

We investigate the quantum emission properties of a GaN-based microdisk nanolasers with a diameter of 2 μm and β-factor close to unity, pushing the device in the regime of strongly reduced laser threshold. A quantum optical semiconductor laser model based on the cluster expansion technique is used to describe the pump-power dependent emission with one consistent set of material parameters, thereby identifying laser action. Photon correlations quantified by $g^{(1)}(\tau)$ and $g^{(2)}(\tau)$ are an essential tool for this research. Information about the energy spectrum and the detection characteristics of photons is encoded in them. In this device we observe multimode lasing. We show that the mode coupling between well-separated resonator modes has a significant influence on the emission characteristics. Furthermore, we analyze what influence the mode couplings have on photon correlations.

HL 44: Nitrides: Devices

Time: Thursday 15:00–17:00   Location: POT 112

Highly doped GaN:Ge/GaN:Mg tunnel junctions for novel GaN-based optoelectronic devices — •Christoph Berger, Armin Dadgar, and André Strittmatter — Otto-von-Guericke-Universität Magdeburg

We report on low resistive GaN-based tunnel junctions (TJs) implemented into optoelectronic devices grown by metalorganic vapor phase epitaxy. Very high donor concentrations, which are mandatory for low-resistive TJs, are achieved by using germanium instead of commonly used silicon. Fabricated TJ-LEDs show an increased light output by more than 60 % in comparison to conventional LEDs employing indium tin oxide contacts while exhibiting a comparable differential resistance of 1.2×10^{-2} Ωcm^2 at a current density of 100 A/cm^2 and no voltage penalty by the TJ. Higher light output is attributed to a better light extraction efficiency due to V-pits formed within the GaN:Ge layer. We currently apply such tunnel-junctions in edge-emitting laser diodes as well as in vertical-cavity surface-emitting lasers. Furthermore, we will demonstrate cascaded LEDs featuring three tunnel junctions and three pn-junctions stacked on top of each other. Overgrowth of the lower LED sections affects their radiative efficiencies. We investigate different annealing concepts for acceptor activation but also the impact of annealing on the radiative recombination in the InGaN active regions.

HL 44.2   Thu 15:15   POT 112

Mitigating damage induced by strongly ionising radiation in nitride layered structures — •Miguel C. Sequeira[1], Mamour Sall[2], Flyura Djurabekova[3], Kai Nordlund[3], Isabelle Monnet[2], Clara Grygiel[2], Christian Wetzel[4], and Katharina Lorenz[5] — [1]HZDR, Dresden, Germany — [2]CIMAP, Caen, France — [3]University of Helsinki, Finland — [4]RPI, New York, USA — [5]INESC-MN, & IST-Universidade de Lisboa, Portugal

Group-III nitrides are well-known for their high radiation resistance, which brings them to extreme radiation environments. GaN is known for having a high resistance to strongly ionising radiation, such as Swift Heavy Ions (SHI) [1,2]. However, the behaviour of other nitrides under this radiation is not well understood especially when in layered structures (e.g. InGaN/GaN in LED). Here, we inspect how InGaN/GaN quantum wells (QW) resist SHI. We solve the Two-Temperature Model (TTM) using Finite Element Methods to show how the high electronic conductivity of InGaN in a QW acts as a heat sink, reducing the intensity of the ion-induced thermal spike in the entire InGaN/GaN structure. Combining TTM-Molecular Dynamics simulations and Transmission Electron Microscopy images show that the presence of QW significantly decreases the overall radiation damage in a device. The results presented here can lead to new radiation damage mitigation techniques, predict functional changes in devices under long radiation exposure, and ultimately improve device design.

HL 44.3   Thu 15:30   POT 112

A guide on designing high performance porous GaN DBRs — •Matthias Hoormann[1,2], Frederik Lüssmann[1,2], Florian Meierhofer[1,2], Jana Hartmann[1,2], and Andreas Waag[1,2] — [1]Institute of Semiconductor Technology, Technische Universität Braunschweig, Hans-Sommer-Str. 66, 38106 Braunschweig, Germany — [2]Laboratory for Emerging Nanometrology (LENA), Technische Universität Braunschweig, Langer Kamp 6, 38106 Braunschweig, Germany

Recently, porous GaN etching has gained significant attention, due to its broad variety of convenient applications for optoelectronic devices. Specifically, the introduction of nanoporous layers enables the quasi-epitaxial growth of low refractive index GaN-based compounds for applications such as vertical DBR mirror structures.

Whilst classical DBRs are designed in order to satisfy the quarter-wavelength-condition, porous GaN DBRs are subject to a competition between porosity and optimal constructive interference from the layer thicknesses. It is vital to understand the influence of the porosity, as deviations from typical DBR designs might be advantageous for the device performance as inferred from simulations.

In this contribution, we investigate the influence of different designs and etching parameters on the optical performance of a defined layer structure. Particularly, the interdependency between the etched porosity and the design porosity with respect to the optical device performance is investigated. To determine the porosity, a combination of optical measurements, simulations and a gravimetric approach is used.

HL 44.4   Thu 15:45   POT 112

PL enhancement from Mie resonant silicon-rich-nitride nano-disks — •Krishna Koundinya Upadhyayula and Jörg Schilling — Martin Luther Universität Halle-Wittenberg, Halle

PECVD grown silicon-rich-nitride (SRN) exhibits refractive indices up to 3.5 and a broad luminescence in the visible up to near IR wavelengths making it a viable candidate for a photonic platform for bio-sensing at the therapeutic window. After a fundamental study on the origin of this photoluminescence (PL) in SRN using spectral and time resolved PL, we demonstrate the impact of Mie resonances on the luminescence by fabricating single Mie resonant SRN nano-disks with sizes on the order of a few 100nm. Comparing the measured PL-spectra with theoretically modelled transmission and emission spectra from finite element simulations, the observed PL-peaks could be attributed to the coupling of the emitters to electric dipole, magnetic dipole and higher order multipole Mie resonances. Furthermore, we created 2D periodic arrays of such SRN-Mie resonators with periods between 300-500nm and an absolute size of 100mm2 using interference lithography. The fabricated arrays exhibited an up to 27x enhancement of the room-temperature PL compared to that of an unstructured sample increasing further up 54x after hydrogen passivation. Tuning the structure parameters, we identify the remaining impact of the individual Mie-resonances in the spectra and the features caused by the grating/Bragg-resonances of the collective photonic crystal structure. Ongoing time resolved measurements will elucidate the impact of Purcell enhancement on the observed PL due to the Mie resonances.

15 min. break

HL 44.5   Thu 16:15   POT 112

UVC-LEDs grown on HTA-AlN templates with low dislocation densities and high Si doping for strain management — •Tim Mampe[1], Sarina Graupeter[1], Giulia Cardinali[1], Sylvia Hagedorn[2], Tim Wernicke[1], Markus Weyers[2], and Michael Kneissl[1,2] — [1]Technische Universität Berlin, Institute of Solid State Physics, Hardenbergstraße 36, 10623 Berlin, Germany — [2]Ferdinand-Braun-Institut (FBH),Gustav-Kirchhoff-Straße 4, 12489 Berlin, Germany

High temperature annealing (HTA) of AlN layers reduces the threading dislocation density of such layers on sapphire substrates below 10^9 cm^{-2} enabling UVC-LEDs with improved efficiencies. However, the HTA AlN-layers are under high compressive strain after cooling down, which can lead to strain relaxation and defect formation during further LED heterostructure growth. The in-plane lattice constant can be increased by growing a Si-doped AlN layer on HTA-AlN. In this work we investigate the influence of such an AlN:Si-layer on the growth of UVC-LEDs emitting at 265nm on AlN/sapphire substrates with silicon doped as well as undoped AlN layer and different sapphire offcut angles (0.1°, 0.2°, 0.5°). We will discuss the morphology as well as the strain state of AlN and AlGaN layers as well as the electro-optical properties of multi quantum-well (MQW) and LED structures.

HL 44.6   Thu 16:30   POT 112

Intensity fluctuations of infrared and green photodiodes at constant current and its correlation with voltage fluctuations — •Danylo Bohomolov and Ulrich T. Schwarz — Chemnitz University of Technology, Chemnitz, Germany

One important issue for display and sensing applications in LEDs is the fluctuation of light intensity over time. The physical reasons behind this are not fully understood yet, e.g. defect-related blinking is discussed. In addition, it is known that the noise of these devices has a strong correlation with their lifetime. Consequently, the noise of the infrared and green micro-LEDs will be measured here, after which the similarity of their behaviour will be investigated. Standard derivation and corner frequency between flicker noise and thermal noise are chosen as the main comparison parameters. For this purpose, their spectral power density of intensity fluctuations of the emitted light at constant current is investigated. We use a linear controlled precision current source. A large area Si photodiode with amplification capability is used as detector, and the signal is measured using a low-noise transimpedance amplifier and a 24-bit analog-to-digital converter. In parallel, the voltage of the LED is measured to correlate fluctuations in voltage and intensity. We observe oscillations in the frequency range from 1 Hz to 15 kHz. The first measurements of the infrared LEDs showed the presence of 1/f and Johnson-Nyquist noise in this frequency range as expected.

HL 44.7   Thu 16:45   POT 112

Theoretical improvement of 40% in efficiency of AlGaN UV LED using evolution strategies optimization algorithm — •Lucie Leguay and Andrei Schliwa — Institute of Solid-State Physics, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin

Nowadays, LED light sources can be found in many technologies ranging from smart lamps to high-quality screen displays. In particular, ultraviolet (UV) LED light can be used to sterilise surfaces and food, to purify air and water and to detect gas and diseases.

However, the nitride-based existing technology is still lacking efficiency. One way to enhance the performance of such devices is to improve their design with optimization algorithms such as evolutionary algorithms which are inspired by biological evolution.

We report an increase of 40% in the theoretical internal quantum efficiency (IQE) of an AlGaN UV-emitting multiple quantum well nanostructure using an evolution strategies algorithm paired with the simulation sofware nextnano++.

HL 45: Functional semiconductors for renewable energy solutions II

Engineering interfaces in multilayer photoanodes for stable and efficient solar energy conversion — •Katarina-Sophie Flashar, Matthias Kuhl, Gabriel Grötzner, Laura Wagner, Alex Henning, Ian D. Sharp, and Johanna Eichhorn — Walter Schottky Institute and Physics Department, Technical University Munich, Am Coulombwall 4, 85748 Garching, Germany

Photoelectrochemical (PEC) energy conversion is a promising approach for the direct conversion of solar energy into storable chemical fuels. In this context, tantalum nitride (Ta$_3$N$_5$) has attracted considerable interest due to a theoretical photocurrent density limit of 12.9 mA*cm^{-2} and a theoretical solar-to-hydrogen conversion efficiency of 15% under AM 1.5G illumination. However, currently Ta$_3$N$_5$ photoelectrodes suffer from poor stability, such as oxidative decomposition, under the harsh PEC operation conditions. To overcome these limitations, we investigate the protection of Ta$_3$N$_5$ photoelectrodes with ultra-thin catalyst layers deposited via plasma-enhanced atomic layer deposition. In these multilayer architectures, the metal oxide catalyst decreases the activation energy, provides active sites for water oxidation, and promotes charge extraction of photogenerated holes. Here, we use a combination of spectroscopic and microscopic methods to elucidate the impact on interfacial energetics, defect properties, charge transport, recombination, and catalytic reactions. The gained understanding of interfacial properties is applied to design efficient interfaces between semiconductor photoelectrodes and functional catalyst coatings for the realization of highly stable and efficient PEC systems.

HL 45.2   Thu 15:15   POT 6

Discovery of multi-anion antiperovskite as promising thermoelectric materials by computational screening — •Dan Han[1], Bonan Zhu[2], Kieran B. Spooner[2], Stefan S Rudel[1], Wolfgang Schnick[1], Thomas Bein[1], David O. Scanlon[2], and Hubert Ebert[1] — [1]Department of Chemistry, University of Munich, Germany — [2]Department of Chemistry, University College London, United Kingdom

The thermoelectric performance of existing perovskites lags far behind the state-of-the-art thermoelectric materials such as SnSe, PbTe and Bi2Te3. Despite halide perovskites showing promising thermoelectric properties, namely, high Seebeck coefficients and ultralow thermal conductivities, their thermoelectric performance is significantly restricted by low electrical conductivities. Here, we explore new multi-anion antiperovskites by global structure searches, and demonstrate their phase stability by first-principles calculations. Ca6NFSn2 and Sr6NFSn2 exhibit decent Seebeck coefficients and ultralow lattice thermal conductivities (< 1 W m-1 K-1). The weak chemical bonding between the heavy-atom cage-rattler Sn and alkaline-earth metal (Ca and Sr) inducing low-frequency optical modes coupling with heat carrying acoustic phonons in combination with strong bond anharmonicity give rise to ultralow lattice thermal conductivities. Notably, Ca6NFSn2 and Sr6NFSn2 show remarkably larger electrical conductivities compared to halide perovskite CsSnI3. Our exploration of multi-anion antiperovskites X6NFSn2 (X = Ca, Sr) realizes the "phonon-glass, electron-crystal" concept within perovskite structures.

Template realized well-defined nanostructures for energy storage and conversion — •Mo Sha, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Template-based technique provides a perfect approach to realize well-defined arrayed nanostructures within large-scale. We have developed nanostructuring techniques mainly using anodic aluminum oxide templates for fabricating functional nanostructures. The obtained well-defined nanostructures possess large-scale arrayed configuration, high structural density, perfect regularity and cost-effectiveness, and are highly desirable for constructing different nano-devices especially for energy storage and conversion applications, including rechargeable sodium-ion and potassium-ion batteries, supercapacitors, and photo electrochemical devices. The device performances demonstrated that the obtained nanostructures benefit these applications through the precise control over the structural features enabled by the geometrical characteristics of the templates. Optical and Photocatalytic Properties of BiVO$_4$ Nanoplatelets — •Philipp Bootz[1], Bharati Debnath[1], Kilian Frank[2], Markus Döblinger[3], Bert Nickel[2], Jacek Stolarczyk[4], and Jochen Feldmann[1] — [1]Chair for Photonics and Optoelectronics, Nano-Institute Munich, Physics Department, Ludwig Maximilians Universität (LMU), 80539 Munich, Germany — [2]Chair for Soft Condensed Matter, 80539 Munich, Germany — [3]Chair for Functional Nanosystems (Prof. Bein), Department Physical Chemistry, 81377 Munich, Germany — [4]Smoluchowski Institute of Physics, Jagiellonian University, 30-348 Krakow, Poland

Bismuth vanadate (BiVO$_4$) with a bandgap of about 2.4 to 3.1 eV is known as one of the best water-oxidizing semiconductors in the field of photocatalysis. It is a material which can crystallize in three different phases - orthorhombic, tetragonal and monoclinic - and is often used as thin films or micron-sized crystals. In this study, we report a novel solvothermal synthesis method to obtain colloidal BiVO4 nanoplatelets with a lateral size of less than 30 nm. We have performed X-ray diffraction and transmission electron microscopy measurements for their structural characterization. We compare the linear optical properties of the nanoplatelets with their three-dimensional pendants and discuss the microscopic origins for the observed differences. Finally, we present the results of photocatalytic experiments, where a gas chromatograph is used to measure the produced oxygen from water during illumination with light.

beneficial impact of KF post-deposition treatment on optical diode factor and non-radiative recombination of CIGSe absorbers — •Sevan Gharabeiki, Mohit Sood, Valentina Serrano Escalante, Taowen Wang, and Susanne Siebentritt — Department of Physics and Materials Science, University of Luxembourg, 4422 Belvaux, Luxembourg

The efficiency of the solar cells depends on the open circuit voltage (VOC), short circuit current (JSC), and fill factor (FF) which in turn depends on the diode factor. The quasi-Fermi level splitting (QFLS) is the upper limit for VOC and the optical diode factor (ODF) is the lower limit of the diode factor. It has been long known that post-deposition treatment (PDT) with heavy alkalis has a beneficial impact on CIGSe solar cells. An increase in the hole concentration, decrease

in non-radiative recombination, and surface passivation have been reported by many studies. We present the effect of the KF PDT on the CIGSe absorbers with different deposition temperature. Our study shows that the KF PDT increases the (QFLS) and decreases non-radiative recombination for the samples deposited on soda lime glass with high deposition temperature. For the samples with low deposition temperature, the improvement in QFLS is mainly due to an increase in doping level. A combination of QFLS, lifetime and capacitive-voltage measurements were conducted to separate the doping effect from the non-radiative recombination effect. We propose that high concentration of Na is required to get the full effect of KF PDT, i.e. increase in the doping and decrease in the non-radiative recombination.

HL 45.6　Thu 16:45　POT 6

Tuning optical properties of graphitic carbon nitrides for photocatalytic applications — •Julian Hirschmann[1], Bharati Debnath[1], Matthias Kestler[1], Kilian Frank[2], Bert Nickel[2], and Jochen Feldmann[1] — [1]Chair for Photonics and Optoelectronics, Nano-Institute Munich and Department of Physics, Ludwig Maximilians Universität (LMU) — [2]Chair for Experimental Physics Prof. Rädler, Department of Physics, Ludwig Maximilians Universität (LMU)

In the field of photocatalysis, graphitic carbon nitrides have proven to be a promising and cost-effective material. The organic graphene like material built from heptazine or triazole rings enable various photocatalytic applications such as hydrogen evolution and ammonia production.

Graphitic carbon nitrides have a two-dimensional sheet-like structure, which is advantageous for photocatalytic applications. Our refined synthesis process provides a simple way to obtain nanosheets of different thicknesses and varying π-conjugation areas. Their impact on the optical properties such as absorption and photoluminescence are presented. The results are compared with recently published electronic band structure calculations and with more molecularly based exciton models. Finally, photocatalytic measurements have been carried out and the obtained efficiencies are compared with our data from time-integrated and time-resolved optical experiments.

HL 45.7　Thu 17:00　POT 6

Functionalization of TiO2 thin films with gold nanoparticles aiming at plasmonic photocatalysis — •Narmina O. Balayeva[1,2], Lu He[1], Dietrich R.T. Zahn[1,2], and Teresa I. Madeira[1,2] — [1]Semiconductor Physics, Institute of Physics, Chemnitz University of Technology, Reichenhainer Str. 70, 09126 Chemnitz, Germany — [2]Research Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, Rosenbergstraße 6, 09126 Chemnitz, Germany

Developing novel photocatalytic systems with improved charge separation that can exploit visible light is of great interest. Here, we investigated the functionalization of anatase TiO2 thin films with gold nanoparticles (Au NPs) for enhanced photocatalytic activity. The LSPR effect of Au NPs is studied by depositing them either on top of or embedding them beneath TiO2 thin films or mixing them homogeneously into the precursor solution before the films are prepared using the spin-coating technique. An amount of Au NPs relative to TiO2 (0.01 wt% -1 wt%) was employed to study the effect of photocatalytic degradation of acetone using an FTIR-based gas photo-reactor chamber with a set of 6 cool white light-emitting diodes (LED). The structure and morphology of the Au/TiO2 films were characterized with different techniques, i.e., Raman spectroscopy and X-ray diffraction (XRD), X-ray reflectivity (XRR), scanning electron microscopy (SEM), as well as atomic force microscopy (AFM). Spectroscopic ellipsometry (SE) was used for a complementary analysis of thickness, roughness, and, in addition, dielectric properties of the thin films.

Origin of Resistive Switching in SrTiO₃ — •Wahib Aggoune[1], Christian Carbogno[1], Martin Albrecht[2], and Matthias Scheffler[1] — [1]The NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft and IRIS-Adlershof of the Humboldt-Universität zu Berlin. — [2]Leibniz-Institut für Kristallzüchtung, 12489 Berlin.

Memristors may play a key role for the next generation of non-volatile memory devices. They are typically realized using materials that allow to switch between a low- and a high-resistance state. This effect has been recently observed in $SrTiO_3$ thin films, whereby a pronounced dependence of the switching properties on the growth conditions was found [1,2]. To shed light on the underlying atomistic mechanisms, we performed density-functional theory calculations and carefully analyzed the critical effects of different exchange-correlation functionals. We explored the most stable defects (vacancies, interstitial, substitutional) under Ti-*rich* conditions. The study reveals that the formation of a Ti_{Sr} antisite defect is energetically favorable and also induces a spontaneous polarization. It can be further stabilized by an additional nearby Sr-vacancy (Ti_{Sr}+V_{Sr}). Furthermore, such a defect complex increases the observed polarization. We discuss these results with respect to the experimentally observed resistive switching by analyzing the electronic properties and the polarization as well as the energy barriers for switching it.

Second harmonic generation of blue series excitons in Cu₂O — •Andreas Farenbruch[1], Dietmar Fröhlich[1], Heinrich Stolz[2], Dmitri R. Yakovlev[1,3], and Manfred Bayer[1,3] — [1]Experimentelle Physik 2, TU Dortmund, Dortmund, Germany — [2]Institut für Physik, Universität Rostock, Rostock, Germany — [3]St. Petersburg, Russia

Excitons are Coulomb-bound complexes of electrons and holes in semiconductors with a discrete hydrogen-like energy series. The yellow exciton series in Cu_2O involves excitations between the highest valence and lowest conduction band and it presents an ideal platform for investigations of exciton physics with Rydberg states up to a principal quantum number of n=28. Excitations, that involve the same valence band but the second lowest conduction band belong to the so-called blue series. Access in linear optical spectroscopy to these states is hard to achieve due to the high absorption in this spectral range. Optical second harmonic generation (SHG) is therefore a suitable investigation method. By analyzing the measured polarization dependence of the SHG signal and comparing it with group theoretical simulations, the magneto-Stark and Zeeman effects are identified as the SHG mechanisms involved. The 1S, 2S and 2P excitons and magneto-excitons up to n=8 in magnetic fields up to 10 T are detected. By analyzing their magnetic-field shift and polariton effect, key properties such as the energies of the exciton resonances, the Rydberg energy, the band gap, the reduced exciton mass, the anisotropy of the conduction band mass and the exciton radius are obtained for the blue exciton series.

HL 47.3   Fri 10:00   POT 81

Electrical and thermoelectrical properties of the two-dimensional electron gas in polar discontinuity doped BaSnO3/LaInO3 heterostructure — •Fazeel Zohair, Georg Hoffmann, and Oliver Bierwagen — Paul-Drude-Institut für Festkörperelektronik, Hausvogteiplatz 7, Berlin, Germany

Transparent semiconducting oxides (TSOs) are key players for opto-electronic devices, among which high frequency applications benefit from electrical properties of two-dimensional electron gases (2DEGs) . In this contribution we demonstrate the electrical and thermoelectric properties of the 2DEG at the interface between a nonpolar perovskite oxide BaSnO3 and a polar perovskite oxide LaInO3, grown by plasma assisted molecular beam epitaxy. The electrical and thermoelectric properties are analyzed using Seebeck measurements and van der pauw-Hall measurements. Integrating the charge carrier concentrations from both measurements, we were able to deduce the thickness of the charge carrier system.

HL 47.4   Fri 10:15   POT 81

Analysis of thickness distributions for combinatorial pulsed laser deposition — •Clemens Petersen, Holger von Wenckstern, and Marius Grundmann — Universität Leipzig Felix-Bloch-Institut, Leipzig, Deutschland

Recently combinatorial deposition methods have increasingly gained scientists* attention, due to the high experimental throughput and resource-wise efficiency they offer in materials discovery. This enables fast screening of material properties of multinary material systems using just a single sample. By employing pulsed laser deposition with our segmented target approach [1] we successfully realized the deposition of α-$(Al_xGa_{1-x})_2O_3$ with continuous composition spread over the whole composition range on a single 2-inch sapphire wafer [2]. Accom-

panied by the usage of high-throughput measurements such as spectroscopic ellipsometry and x-ray diffraction, the characterization of the material systems' physical properties with high chemical resolution and comparably low efforts becomes feasible. By employing the plasma plume expansion model suggested by Anisimov *et al.* [3] and the resulting spatial material-deposition distribution we calculate binary growth rates as function of position enabling us to predict film thickness and composition locally. Thereby the deposition of group III sesquioxides can be described exceptionally well. We further show that the binary distributions can be used to predict the combinatorial deposition of ternary alloys with high precision. Cloud in cell scheme based stochastic modelling of $BiFeO_3$ memristor for circuit simulations — •Sahitya Yarragolla[1], Nan Du[2,3], Torben Hemke[1], Xianyue Zhao[2,3], Ziang Chen[2], and Thomas Mussenbrock[1] — [1]Chair of Applied Electrodynamics and Plasma Technology, Ruhr University Bochum, Germany — [2]Institute for Solid State Physics, Friedrich Schiller University Jena, Jena, Germany — [3]Department of Quantum Detection, Leibniz Institute of Photonic Technology , Jena, Germany

In recent years, analog memristive devices have been extensively investigated for neuromorphic computing and hardware security applications. It is found that these devices show excellent properties such as long retention time, intrinsic stochasticity, and fast switching. However, the switching mechanism in these devices from the physics point of view is still under discussion. Therefore, in this work, we focus mainly on understanding the resistive switching based on the transport of oxygen vacancies in the interface-type Au/BiFeO₃ (BFO)/Pt/Ti memristive devices using a 1D cloud-in-a-cell model. The proposed model combines the advantages of both 1D concentrated and 3D distributed models in a single model. The model is stochastic and computationally less expensive, making it suitable for circuit simulations. The calculated *I-V* characteristics of BFO memristor using the proposed are in excellent agreement with the experimental results. Furthermore, the response of the BFO memristor to changes in electrical properties, temperature and retention characteristics are analyzed, and the results show reasonable agreement with experimental findings.

Comparing processing strategies for Indium oxide field-effect transistors — •Fabian Schöppach, Clemens Petersen, Holger von Wenckstern, and Marius Grundmann — Felix Bloch Institute for Solid State Physics, Universität Leipzig, Germany

Indium oxide (In_2O_3) combines promising physical properties such as high carrier mobility and transparency in the visible. However, due to its tendency to form an electron accumulation layer on its surface (SEAL), the use of In_2O_3 in active devices is generally difficult. We use the published strategies, compensating Mg doping [1] and oxygen plasma treatment [2], to suppress SEAL formation and allow the films to be used in FET devices. In addition, In_2O_3 as sesquioxide is a very robust material that resists classical patterning processes such as wet chemical etching.

We identified two different fabrication strategies to structure our films laterally: Plasma-assisted etching and using a wet-chemical soluble sacrificial layer. In this work, both strategies are compared regarding additionally necessary processing steps and the final devices' performance. We used In_2O_3 films grown by pulsed laser deposition. For the source and drain contacts, gold was deposited via inert ambient sputtering. Schottky gate diodes were fabricated in a reactive sputtering process, which is a prerequisite for obtaining electrically rectifying contacts to In_2O_3 [3].

Charge carrier diffusion and localization in metal oxide photoabsorbers — •Hannes Hempel, Markus Schleuning, Klaus Schwarzburg, Rainer Eichberger, Roel van de Krol, Moritz Kölbach, Fatwa F. Abdi, and Dennis Friedrich — Helmholtz-Zentrum Berlin, Germany

Long diffusion lengths of photo-excited charge carriers are crucial for high power conversion efficiencies of photoelectrochemical and photovoltaic devices. However, in metal oxids are effects such as (multiple-)trapping, carrier localization and polaron formation can lead to time-varying mobilities and lifetimes that are not accounted for in the conventional analysis. Therefore, here, a generalized analysis is presented that determines the diffusion length directly from the

integral of a photoconductivity transient, regardless of the nature of carrier relaxation. This approach is presented on amorphous silicon, a prototype of disordered materials, and BiVO4, one of the most studied photoanode materials for solar water splitting. Our generalized analysis allows monitoring the temporal evolution of the charge carrier displacement, which converges for both materials after ~100 ns to a diffusion length of a few tens of nanometers. For BiVO4, the

obtained diffusion length is significantly shorter than the typical thin film thickness, which rationalizes the photocurrent loss in the corresponding photoelectrochemical device. Finally, we probe several metal other prominent metal oxide photoabsorbers, namely Fe2O3, FeVO4, CuFeO2, α-SnWO4, BaSnO3, and CuBi2O4, and find sings of carrier localization on the nanometer scale, which limits the charge carrier diffusion.

Time: Friday 9:30–12:00 Location: POT 361

HL 48.1 Fri 9:30 POT 361

Characterizing the nonadiabatic tunneling dynamics in solid-state high harmonic generation — •Ruixin Zuo[1], Xiaohong Song[2], Shuai Ben[2], Weifeng Yang[2], and Torsten Meier[1] — [1]Department of Physics, Paderborn University, Warburger Str. 100, D-33098 Paderborn, Germany — [2]School of Science, Hainan University, Hainan 570288, China

Tunneling is a fundamental quantum process which may result from light-matter interaction. High-harmonic radiation, as an ultrafast phenomenon initiated by the tunneling excitation, carries information about the electronic dynamics in the classically forbidden region. We introduce a quantum trajectory analysis to identify the underlying quantum dynamics governing solid-state high harmonics which improves the understanding of neighboring-atoms collisions [1]. It is revealed that properties of the electron-hole pairs when emerging in the classically allowed region like the group velocity and the relative displacement are dictated by the nonadiabaticity of tunnel ionization and are crucial in determining the subsequent propagation and radiation. Furthermore, we show that the two-color high harmonic spectroscopy validates the quantum trajectory analysis and enables us to probe the tunneling dynamics in strongly driven solid-state systems.

HL 48.2 Fri 9:45 POT 361

Compact, CEP-stable, few-cycle OPCPA for single attosecond pulse generation — •Bastian Manschwetus, Filippo Campi, Thomas Braatz, Sebastian Starosielec, Jan-Heye Buss, Michael Schulz, and Robert Riedel — Class 5 Photonics, Hamburg, Germany

Attosecond technology pathed the way for studying ultrafast electronic processes in atoms, molecules, solids, and complex many body systems. Carrier envelope phase (CEP) stabilization in the few-cycle regime is a key enabler of this technology. A crucial step forward is the demonstration of high-repetition rate optical parametric chirped-pulse amplifier (OPCPA) systems for the generation of phase-stable few-cycle, μJ-level driver pulses for high-harmonic-generation (HHG). In this work, we present an OPCPA providing white light seeded, actively controlled CEP stable, 9 fs pulses around 900 nm center wavelength with 30 μJ pulse energy as a high-harmonic driver for attosecond experiments at 200 kHz repetition rate.

HL 48.3 Fri 10:00 POT 361

Transient Optical Property Changes in Semimetals with Strong Electron-Phonon Coupling — •Fabian Thiemann[1], Germán Sciaini[2], Alexander Kassen[1], Tyler Lott[2], and Michael Horn-von Hoegen[1] — [1]University of Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany — [2]University of Waterloo, 200 University Avenue West, Waterloo, ON N2L 3G1, Canada

Group V semimetals, such as bismuth used in this study, are well known for their strong electron-phonon coupling due to the inherent Peierls distortion of their lattice. In particular, the displacively excited coherent A_{1g} phonon mode plays an important role in ultrafast studies on Bi. With knowledge of the excitation density we used a series of thin Bi films on Si(111) to reconstruct the transient dielectric function in an all optical pump-probe experiment. Though we only access the first half ps of dynamics, we separate the contributions from the excited carrier system and the coherent atomic motion. Our results suggest that we can describe the changes in optical properties caused by the non-equilibrium distribution of carriers still similar to a thermal dependency in equilibrium. In the regime of high excitation densities, we no longer can use the two-band Raman susceptibility approach to describe changes caused by the coherent phonons. We suggest that the light scattering is greatly enhanced by the excited carriers and that recently proposed band shifts in the time domain mainly define this part of changes of the dielectric function.

HL 48.4 Fri 10:15 POT 361

Ultrafast optical control of polariton energy in an organic semiconductor microcavity — •K.E. McGhee[1,2], M. Guizzardi[3], R. Jayaprakash[1], K. Georgiou[1,4], G. Cerullo[3,5], T. Jessewitsch[6], A. Zasedatelev[7], U. Scherf[6], T. Virgili[5], P.G. Lagoudakis[7], and D.G. Lidzey[1] — [1]University of Sheffield, UK — [2]Universität Leipzig, Germany — [3]Politecnico di Milano, Italy — [4]University of Cyprus, Cyprus — [5]Istituto di Fotonica e Nanotecnologia-CNR, Italy — [6]Universität Wuppertal, Germany — [7]University of Southampton, UK

Exciton-polariton condensates are of great interest due to their potential applications in polariton logic devices, nonlinear photonic integrated circuits and quantum simulators. In this work, we have fabricated polariton microcavities designed to allow the dynamic trapping and manipulation of such condensates using ultrashort laser pulses. Using transient pump-probe spectroscopy, we have saturated the electronic transition of a weakly-coupled dye in a cavity containing a second strongly-coupled dye. In doing so, we alter the cavity effective refractive index and therefore the position of the lower polariton branch. We demonstrate a maximum blueshift of this mode of 12 meV, dependent on the pump fluence, and show that this effect is ultrafast, with switch 'on' and 'off' times of less than 1 ps. Utilising this controllable energy shift, it should be possible to dynamically 'write' energy barriers into organic polariton microcavities without affecting the coupling strength. This would allow important studies on interacting polariton condensates for the development of next generation quantum devices.

HL 48.5 Fri 10:30 POT 361

Imaging nanoscale electron dynamics with extreme ultraviolet radiation — •Hung-Tzu Chang[1], Sergey Zayko[1], Jakob Hagen[1], Murat Sivis[1,2], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, 37077 Goettingen, Germany — [2]4th Physical Institute, University of Goettingen, 37077 Goettingen, Germany

Non-equilibrium electronic processes such as electron thermalization, ballistic transport, and spin diffusion, occur at femtosecond time- and nanometer length-scales. While ultrafast spectroscopic methods can trace the temporal evolution of electronic states [1], capturing those dynamics in real space remains challenging. Here we demonstrate time-resolved coherent diffractive imaging using a table-top extreme ultraviolet (EUV) source based on high harmonic generation [2,3], where the sample is first excited by a near-infrared pump pulse and probed with core-level absorption induced by a time-delayed EUV pulse. The valence electron dynamics can be retrieved from the spatially resolved changes of the EUV field amplitude and phase exiting the sample after localized photoexcitation. This technique provides nanometer spatial resolution in addition to the time resolution and element specificity of femtosecond table-top core-level spectroscopy, and paves the way for further understanding of the mechanisms of photophysical processes in condensed matter.

HL 48.6 Fri 11:00 POT 361

Coherent-to-incoherent crossover of photoexcited electron-phonon dynamics in 2D materials — •Enrico Perfetto[1,2] and Gianluca Stefanucci[1,2] — [1]Dipartimento di Fisica, Universita' di Roma Tor Vergata, Via della Ricerca Scientifica 1, 00133 Rome, Italy — [2]INFN, Sezione di Roma Tor Vergata, Via della Ricerca Scientifica 1, 00133 Rome, Italy

We present a first principles nonequilibrium Green's function approach to describe the carrier and nuclear dynamics of 2D materials. Our scheme is based on the simultaneous propagation of the electronic and phononic degrees of freedom and includes the GW, Ehrenfest, and Fan-Migdal self-energies. The method scales linearly with the propagation time, and allows to describe in a conserving fashion the retarded Coulomb screening and the cooling dynamics of hot carriers via phonon emission. Numerical results are provided for a monolayer MoS2 photo-excited above the gap. The intra-valley scattering is responsible for an ultrafast carriers migration toward the band edges already during pumping. Intervalley scattering occurs on a longer timescale, of the order of a few hundreds of femtoseconds. At high carrier density the energy exchange between electrons

and phonons is very efficient, leading to a sizable increase of the lattice temperature within one picosecond. During this processes the electronic coherence is lost. The lattice coherence, instead, survives for much longer. Several hundreds of femtoseconds after the dephasing of the electronic polarization the nuclear displacements still exhibit undamped oscillations.

HL 48.7 **Fri 11:15** **POT 361**

Coherent versus incoherent excitons: Stability, time-dependent ARPES spectrum and Floquet topological phases — •Gianluca Stefanucci[1,2] and Enrico Perfetto[1,2] — [1]Dipartimento di Fisica, Universita' di Roma Tor Vergata, Via della Ricerca Scientifica 1, 00133 Rome, Italy — [2]INFN, Sezione di Roma Tor Vergata, Via della Ricerca Scientifica 1, 00133 Rome, Italy

We consider a band insulator turning into a nonequilibrium (NEQ) exciton superfluid (XS) after resonant pumping. The NEQ-XS is characterized by self-sustained coherent oscillations of the superfluid condensate. We show that the ARPES spectrum from long probe pulses features a subgap excitonic sideband; it originates from the condensate-dressing of the conduction states and it has an intensity proportional to the excitonic wavefunction squared [PRB94, 245303 (2016); PRM3, 124601 (2019)]. Reducing the probe duration below the condensate period the ARPES signal becomes periodic in the impinging time of the probe [PRB101, 041201(R)(2020)]. The stability of the NEQ-XS as the conduction density grows is jeopardized by the increased screening efficiency of the looser excitons. Nonetheless, a proper nonequilibrium self-consistent treatment of screening indicates that NEQ-XS is stable up to relatively high densities [PRB102, 085203 (2020)]. We also show that a p-wave NEQ-XS at high enough density undergoes a Floquet topological transition [PRL125, 106401 (2020)]. Phonon-induced decoherence eventually transforms the XS phase into an incoherent exciton-polaron fluid. During this process the excitonic sideband broadens and red-shifts (Stokes shift) [PRB103, 245103 (2021)]

HL 48.8 **Fri 11:30** **POT 361**

Intermolecular conical intersections in acceptor-donor-acceptor aggregated molecules — •Somayeh Souri[1], Katrin Winte[1], Antonietta De Sio[1], Christoph Lienau[1], Elena Mena-Osteritz[3], Peter Bäuerle[2], Teresa Kraus[3], Fulu Zheng[2], Mohamed Madjet[2], and Sergei Tretiak[4] — [1]University of Oldenburg, Germany — [2]University of Bremen, Germany — [3]Ulm University, Germany — [4]Los Alamos National Laboratory, USA

In molecules, strong coupling between electronic excitations and vibrational modes may result in conical intersections (CoIns) of multidimensional potential energy surfaces. At CoIns different electronic states cross and couple strongly via vibrational modes. This results in large nonadiabatic couplings violating the Born-Oppenheimer approximation. While CoIns are ubiquitous in molecules, not much is known about their occurrence and relevance for intermolecular ultrafast energy and charge transfer dynamics in the solid state. Here, we reveal the existence of intermolecular CoIns in thin films of aggregated acceptor-donor-acceptor-type oligomers by ultrafast two-dimensional electronic spectroscopy (2DES). The 2DES maps show a grid-like peak pattern at early times, followed by a rapid reduction of the peak spacings which transforms into a featureless map after only ~40 fs. We take this abrupt change in the 2DES maps as clear evidence for the passage of the optically launched vibrational wave packet through the intermolecular CoIn in the thin films. Our results, which are confirmed by simulations, suggest new opportunities for guiding the coherent flow of energy and charge in solid-state nanostructures.

HL 48.9 **Fri 11:45** **POT 361**

Potential signatures of hydrodynamic transport captured by THz high harmonic generation — •Tim Priessnitz[1], Thales de Oliveira[2], Liwen Feng[1,3], Min-Jae Kim[1,3], Sergey Kovalev[2], Bernhard Keimer[1], and Stefan Kaiser[1,3] — [1]Max-Planck Institute for Solid State Research, 70569 Stuttgart, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — [3]Institute of Solid State and Materials Physics, Technical University Dresden, 01069 Dresden, Germany

Terahertz high harmonic generation (THz HHG) is a common property of nonlinear systems. Recently it has been used to investigate fundamental principles that govern transport and nonlinear dynamics in novel quantum materials like graphene or Dirac semimetals. However, these studies have not yet been successfully extended to low temperatures where hydrodynamic effects come into play. Optical phenomena such as THz HHG are proposed to provide a more efficient way to probe hydrodynamic effects than previously studied DC transport measurements, which identified the delafossite $PdCoO_2$ as a candidate to observe such properties. Here, we report on THz HHG in thin films of $PdCoO_2$ at low temperatures and we will discuss potential signatures of hydrodynamics, contributing to the ongoing puzzle of low-temperature origins of THz HHG.

Gate-based protocol simulations for quantum repeaters using quantum-dot molecules in switchable electric fields — •Steffen Wilksen, Frederik Lohof, and Christopher Gies — Institute for Theoretical Physics, University of Bremen, Bremen, Germany

Semiconductor quantum dots provide a promising platform for applications in quantum information technologies, such as quantum repeaters, which enable secure quantum communication over long distances. Two quantum dots, separated by a small tunnelling layer, form a so-called quantum dot molecule (QDM), which exhibits properties similar to classical molecules. Their energy levels can be tuned by applying an external electric field, thereby allowing to perform gate operations. We consider QDMs in switchable electric fields towards quantum-repeater realizations. The time dependence that arises from performing gate operations requires a careful treatment of the system-bath interaction. We treat the QDM as an open quantum system using an explicitly time-dependent Redfield master equation approach, accounting for the time dependence of the interaction rates beyond more simple Lindblad approaches. Based on our approach, we investigate the adiabatic and non-adiabatic behaviour of the system for different switching speeds and determine achievable execution times for gate operations with currently existing QDMs.

HL 49.2 **Fri 9:45** **POT 151**

Heterogeneous integration of telecom c-band emitting quantum dots on silicon photonics platform by adhesive bonding — •Ponraj Vijayan, Fiona Braun, Michael Jetter, and Peter Michler — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Universität Stuttgart, Germany

Silicon photonics for telecommunications applications has garnered much attention recently. The optical transparency and the large refractive index contrast of silicon in the telecommunication wavelengths allow the implementation of high-density photonic integrated circuits. The drawback of silicon photonics is that there is no native light source due to the indirect band-gap nature of silicon. Integration of III-V material, which offers outstanding optical emission properties, on silicon provides a potential solution. The direct growth of III-V materials on silicon is the most desired approach because it is economically favourable. However, it is challenging because of large lattice mismatch between

the III-V materials and silicon. An alternate approach for large-scale integration is through heterogeneous integration of thin III-V membrane using adhesive bonding technique. For such integration, it is crucial to have a robust bonding procedure which provides a uniform bonding layer with a desired thickness for efficient light coupling between III-V active layer and the silicon photonic platform. Our group has previously developed InAs QD/InGaAs MMB/GaAs substrate structures for long-distance optical fiber applications [3]. Here, we report on the route to integrate the telecom C-band emitting InAs QD on silicon photonic platform using adhesive bonding.

HL 49.3 **Fri 10:00** **POT 151**

Investigation of optical properties of open-fiber cavities embedding semiconductor quantum dots emitting in the telcom O-band — •Nam Tran[1], Julian Maisch[1], Jonas Grammel[2], Julia Wecker[1], Thomas Herzog[1], Robert Sittig[1], Ponraj Vijayan[1], Michael Jetter[1], Simone L. Portalupi[1], David Hunger[2], and Peter Michler[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen , Center for Integrated Quantum Science and Technology (IQ[ST]) and SCoPE , University of Stuttgart, Stuttgart, Germany — [2]Physikalisches Institut , Karlsruher Institut für Technologie (KIT), Karlsruhe, Germany

Single photon sources operating at telecom wavelength play a central role in quantum information, in particular when long-distance implementations are targeted. Highly promising candidates are semiconductor quantum dots (QD). Cavity quantum electrodynamics is often used to tailor the emission properties and, in case of photon sources, enhance their performances. However, limiting factors like spatial and spectral mismatch can be detrimental to the cavity-emitter interaction. Using tunable fiber cavities can overcome these limitations. Additionally, since the fiber coupling is intrinsically given in these cavities the integration into the already existing fiber network is facilitated. Here, we made a thorough investigation of the optical properties of open fiber cavities embedding semiconductor QDs emitting in the telcom O-band. Moreover, deterministic positioning of individual QDs enables the comparison of the optical properties within and outside the cavity.

HL 49.4   Fri 10:15   POT 151

Higher order effective coefficients in Ge/Si core/shell nanowire devices — •Sebastian Miles[1,2], Piotr Rozek[1,2], Mert Bozkurt[1,2], Dániel Varjas[3], and Michael Wimmer[1,2] — [1]QuTech, Delft University of Technology, Delft 2600 GA, The Netherlands — [2]Kavli Institute of Nanoscience, Delft University of Technology, Delft 2600 GA, The Netherlands — [3]Max-Planck-Institut für Physik komplexer Systeme, 01187 Dresden, Germany

Germanium based nanowires are prominent platforms in mesoscopic physics because of their tunable spin-orbit interaction. This property makes them an interesting candidate for hole-qubit devices or as a platform for Majoranas. Hence, a good understanding of effective models for the relevant degrees of freedom in these devices is of great importance. We revisit the subject of effective Hamiltonians and effective coefficients for efficient nano-device control in Ge/Si core/shell semiconductor nanowires from a perturbation theory perspective. We elaborate on relevant terms and present numerical and semi-analytical results of Lowdin perturbation theory to second order. We discuss the consequences of higher order terms on the effective models of interest for device applications.

30 min. break

HL 49.5   Fri 11:00   POT 151

Interfacing Semiconductor Quantum Dots with Photonic Wire Bonds — •Marco De Gregorio[1], Shangxuan Yu[2,3], Donald Witt[2,3], Becky Lin[2,3], Matthew Mitchell[2], Tobias Huber-Loyola[1], Lukas Chrostowski[2,3], Jeff F. Young[2,4], Andreas Pfenning[1,2], and Sven Höfling[1] — [1]Lehrstuhl für Technische Physik, Julius-Maximilians-Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany — [2]Stewart Blusson Quantum Matter Institute, University of British Columbia, Vancouver, British Columbia V6T 1Z4, Canada — [3]Department of Electrical and Computer Engineering, University of British Columbia, Vancouver, British Columbia V6T 1Z4, Canada — [4]Department of Physics and Astronomy, University of British Columbia, Vancouver, British Columbia V6T 1Z1, Canada

We present first experimental results of an alternative extraction technique of single photons emitted by semiconductor quantum dots. For this purpose, a photonic wire bond is directly attached to the end facet of a waveguide containing In(Ga)As semiconductor quantum dots grown by molecular beam epitaxy and connected to a single-mode optical fiber. We perform above-band and optical resonant excitation of the quantum dot and find that in this configuration, cross-polarization filtering of the single photons can be avoided, while measuring a steady stream of single-photons in fiber. The coupling efficiency can be further improved by optimized mode matching between photonic wire bond and waveguide.

HL 49.6   Fri 11:15   POT 151

Deterministically fabricated InAs quantum dot based single-photon sources at telecom wavelengths — •Monica Pengerla[1], Alkaales Mohanad[2], Ranbir Kaur[2], Jan Donges[1], Lucas Bremer[1], Johannes Schall[1], Sven Rodt[1], Mohamed Benyoucef[2], and Stephan Reitzenstein[1] — [1]Institut für Festkörperphysik, Technische Universität Berlin, Hardenbergstraße 36, D-10623 Berlin, Germany — [2]Institute of Nanostructure Technologies and Analytics (INA), Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Str. 40, 34132 Kassel, Germany

Quantum dot (QD) based single-photon sources are key elements of photonic quantum networks. Most interesting are sources emitting at telecom wavelengths to enable long distance fiber-based quantum communication. Here, we report on deterministically fabricated single-photon sources based on InAs QDs grown on InP substrate. Numerical simulations of such QD heterostructures with backside distributed Bragg reflector reveal photon extraction efficiency exceeding 50% when QDs are integrated into mesa or circular Bragg grating structures. A state-of-the-art electron beam lithography (EBL) system with integrated low temperature cathode luminescence (CL) system allows us to perform in-situ EBL at telecom wavelengths. For noisy CL maps, an advanced approach for machine learning enhanced in-situ EBL to enhance the maps at telecom wavelengths for better integration of QDs into photonic structures is used. Micro-photoluminescence studies reveal the optical properties of the fabricated quantum devices.

HL 49.7   Fri 11:30   POT 151

GaSb Quantum Dots as Emitters of Telecom S-Band Single Photons — •Johannes Michl[1], Giora Peniakov[2], Andreas Pfenning[1], Joonas Hilska[2], Abhiroop Chellu[2], Teemu Hakkarainen[2], Tobias Huber-Loyola[1], Mircea Guina[2], and Sven Höfling[1] — [1]Technische Physik, Julius-Maximilians-Universität Würzburg, Germany — [2]Physics Unit / Photonics Faculty of Engineering and Natural Sciences, Tampere University, Finland

Over the last few years, several semiconductor quantum dot (QD) material platforms like In(Ga)As/ GaAs and InAs/InP have emerged as resources for nonclassical light and spin-photon interfaces in the telecom wavelength range. However, there is not much data on the optical and spin properties of GaSb QDs, despite it being a physically rich system. For example, it is possible to switch between direct and indirect bandgap by controlling the size of the quantum dots. Moreover, due to reduced strain, it is expected to have less quadrupole nuclear interaction resulting in enhanced spin dephasing times, similar to what was recently observed in GaAs QDs in AlGaAs. Here, we investigate the (quantum-) optical properties of GaSb quantum dots which are fabricated by filling droplet-etched nanoholes in an AlGaSb matrix and exhibit photoluminescence (PL) with a narrow linewidth in the telecom S-band. We perform polarization resolved magneto-PL studies to investigate charge complexes in our sample and perform correlation measurements to evaluate the use of GaSb quantum dots as a source of indistinguishable single photons.

HL 50: Materials and devices for quantum technology III

Time: Friday 9:30–13:00   Location: POT 251

HL 50.1   Fri 9:30   POT 251

3D magnetic resonance tomography of nitrogen vacancy centers with sub-10nm resolution — •Mohammad T Amawi[1,2], Andrii Trelin[1], You Huang[1], Georg Braunbeck[2], Francesco Poggiali[1], and Friedemann Reinhard[1] — [1]Institute for Physics, Quantum Technology, University of Rostock, Germany — [2]Physics Department, Technical University of Munich, Germany

We present a device for three-dimensional magnetic resonance tomography with nanoscale resolution, and apply it to image the spatial position of a nitrogen-vacancy center (NV) cluster in bulk diamond. Three orthogonal magnetic field gradients, generated from currents in microfabricated gold conductors, are used to create a position-specific Larmor frequency of the NV ground state spins. Measuring this frequency by pulsed optical-microwave spectroscopy, we determine the position of each NV center in 3D.

I will report on fabrication of the device, based on a liftoff process and maskless lithography, as well as the geometry required to create three orthogonal magnetic fields. The measurement protocol for 3D imaging will be discussed, as well as hardware and software means to reduce the shot-to-shot field variation, caused by electrical noise, down to 0.1%. This level of stability enabled us to demonstrate 3D imaging with around 5 nm spatial resolution. I will conclude with an outlook addressing how the resolution can be further improved by reducing the dimensions of the micro wires, and how it could be extended to image spins deposited on the diamond surface.

HL 50.2   Fri 9:45   POT 251

3D printing as an enabling tool for quantum technologies — •Pavel Ruchka[1], Ksenia Weber[1], Sina Hammer[2], Carlos Jimenez[3], Simon Thiele[3], Johannes Drozella[3], Tim Langen[2], Alois Herkommer[3], and Harald Giessen[1] — [1]4th Physics Institute, Research Center SCoPE and Center for Integrated Quantum Science and Technology, Universität Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany — [2]5th Physics Institute and Center for Integrated Quantum Science and Technology, Universität Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany — [3]Institute of Applied Optics (ITO) and Research Center SCoPE, University of Stuttgart, Pfaffenwaldring 9, 70569 Stuttgart, Germany

Nowadays, a lot of effort is given to making quantum technologies more usable for day-to-day life. This involves many aspects, such as developing quantum computers with a large number of qubits, creating quantum gates with high fidelity, and establishing a large-scale communication links with quantum repeaters. Miniaturizing such quantum devices remains nevertheless a highly relevant issue. For this, the 2-photon polymerization (2PP) based 3D printing comes in handy. In this talk, we present several miniature 3D printed optical and mechanical components, which enable the optical trapping of atoms and coupling quantum emitters and detectors to fibers or chips. These devices have an exceptionally compact footprint and a comparably high efficiency. With the ease of production of such components, 2PP can be scaled for the future requirements of highly compact and efficient quantum devices.

HL 50.3 Fri 10:00 POT 251

Spatially controlled fabrication of telecom single-photon emitters in Si by focused ion beam implantation — •Nico Klingner[1], Michael Hollenbach[1,2], Nagesh Jagtap[1], Lothar Bischoff[1], Ciaran Fowley[1], Ulrich Kentsch[1], Gregor Hlawacek[1], Artur Erbe[1], Nikolay Abrosimov[3], Manfred Helm[1], Yonder Berencen[1], and Georgy Astakhov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, 01328 Dresden, Germany — [2]Technische Universität Dresden, 01062 Dresden, Germany — [3]Leibniz-Institut für Kristallzüchtung (IKZ), 12489 Berlin, Germany

Single photon emitters (SPE) are the starting point and foundation for future photonic quantum technologies. We present the laterally controlled fabrication of single G and W centers in silicon that emit in the telecom O-band. We utilized home built gold-silicon liquid metal alloy ion sources (LMAIS) in a focused ion beam (FIB) system to perform mask-free implantation of 40 keV Si ions from 6 to 500 ions per spot. Analysis and confirmation of SPEs has been done in a home-build cryo-photoluminescence setup. We will demonstrate a success rate of more than 50% and upscaling to wafer-scale. We will also provide an insight and overview on the LMAIS technology and an outlook on other potential applications of FIB implantation. arXiv:2204.13173

HL 50.4 Fri 10:15 POT 251

Plasma studies by optical emission spectroscopy for phosphorus doped diamond — •Felix Hoffmann[1], Nicola Lang[1], Philipp Reinke[2], Peter Knittel[1], and Volker Cimalla[1] — [1]Fraunhofer Institute for Applied Solid State Physics, Tullastraße 72, D-79108 Freiburg, Germany — [2]Quantum Brilliance GmbH, Industriestraße 4, D-70565 Stuttgart, Germany

While p-doping of diamond by Boron is a well-controlled process, n-doping by Phosphorus (P) remains challenging due to its low solubility and big covalent radius in comparison to carbon. The control of plasma conditions and the understanding of its influence on growth parameter is crucial for single crystal diamond growth by microwave plasma assisted chemical vapor deposition (MPCVD) [1]. Hydrogen-methane plasmas with dopant-carrier gases have been analyzed with respect to kinetic gas temperature (of the C2 band) and radical concentration by optical emission spectroscopy (OES) under various experimental conditions such as excitation power, operating pressure and gas concentrations [2]. Here we present results of P-doped diamond growth using the carrier gas trimethylphosphine (TMP) and point out the influence of TMP on plasma properties and its relation to growth parameter of P-doped {111} diamond grown by MPCVD.

HL 50.5 Fri 10:30 POT 251

Modifying dipole selection rules in cuprous oxide Rydberg excitons — •Annika Neubauer and Harald Giessen — 4th Physics Institute, University of Stuttgart

Excitons in cuprous oxide have large binding energies, which implies that different principal quantum number state excitons can be created as they are energetically not spaced too closely to each other nor to the ionization continuum. High principal quantum number Rydberg excitons in cuprous oxide are macroscopic quantum systems with spatial extensions in the several hundreds of nm up to several μm range. This implies, that excitation with a focused light beam leads to a large overlap of light and matter wavefunctions and should lead to an enhanced optical transition.

We are going to show that the dipole selection rules in cuprous oxide Rydberg excitons can be manipulated via excitation with orbital angular momentum light or via the quadrupole field of plasmonic antennas. Both such light fields posses a strong field gradient or an additional angular momentum. This way, different angular momentum quantum number state excitons can be switched on and off, which is attractive for quantum state engineering. The mesoscopic size of cuprous oxide Rydberg excitons also implies that already μm-sized structures lead to mesoscopic quantum size effects. This can be advantageous for the realization of quantum technologies, such as optical switching applications, based on cuprous oxide Rydberg excitons.

HL 50.6 Fri 10:45 POT 251

Strong coupling of a single quantum dot to a tunable plasmonic nanogap antenna at room temperature using a novel scanning probe technique — •Michael A. Becker[1], Hsuan-Wei Liu[1,2], Burak Gurlek[1,2], Korenobu Matsuzaki[1], Randhir Kumar[1], Stephan Götzinger[2,1], and Vahid Sandoghdar[1,2] — [1]Max Planck Institute for the Science of Light, Staudtstr. 2, 91058 Erlangen, Germany — [2]Friedrich Alexander University of Erlangen-Nürnberg, Schloßplatz 4, 91054 Erlangen, Germany

In the strong coupling regime of cavity quantum electrodynamics, the spectrum of an isolated quantum system hybridizes with a mode of a resonator. At room temperature, coupling to the environment leads to a fast dephasing of the transition dipole, and strong near-field enhancements in plasmonic nanoantenna geometries need to be exploited to reach the strong light-matter coupling regime. For an efficient coupling, the antennas need to be placed within a few nanometer with respect to the individual emitters. Here, we exploit our novel and simple press-roll scanning probe technique (PROscan) capable of performing high-precision optical near-field measurements with remarkable stability. We demonstrate an open nanogap antenna that can be tuned in resonance with the exciton transition of a single quantum dot. With this approach, we drive the system from the weak to the strong light-matter coupling regime, evidenced by a vacuum Rabi splitting. Our results elucidate the complex interplay between the nanoantenna's mode volume and the physics of its eigenmode.

HL 50.7 Fri 11:30 POT 251

Optimal quantum control of Si/SiGe spin qubits in a Quantum bus architecture — •Akshay Menon Pazhedath[1], Alessandro David[1], Lars R. Schreiber[2], Hendrik Bluhm[2], Tommaso Calarco[1], and Felix Motzoi[1] — [1]Peter Grünberg Institute-Quantum Control (PGI-8), Forschungszentrum Jülich GmbH, Germany — [2]JARA-FIT Institute for Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, Germany

Quantum bus architecture based on electron spin-shuttling is a promising candidate for scalable quantum computing, as the number of control lines required to control the spin remains constant irrespective of the length of the device. A gated Si/SiGe quantum well with a carefully placed micro-magnet acts as an addressable qubit system in such an architecture. We investigate the feasibility of performing single qubit operations using optimal quantum control techniques. Spin decoherence due to interaction with the valley degree of freedom in the Si/SiGe heterostructure is identified as a potential decay mechanism and optimal pulses are engineered to maximize single qubit state transfer and unitary operation fidelities, so that the operations are compliant with the fault tolerant error threshold.

HL 50.8 Fri 11:45 POT 251

Generating spatially distributed entanglement as a resource for novel quantum computing paradigms on a platform of coupled microcavities — •Marc Bostelmann, Steffen Wilksen, Frederik Lohof, and Christopher Gies — Institute for Theoretical Physics and Bremen Center for Computational Material Science, University of Bremen, Bremen, Germany

Spatially distributed entanglement is important for the realization of novel quantum-photonic applications in quantum computing and quantum machine learning. We consider photonic arrays made from quantum emitters in optically coupled microcavities as hardware platform for entanglement generation. These offer a large degree of tunability with the possibility of site-selective optical excitation. We present a scalable numerical scheme for the determination of excitation parameters to generate different classes of multipartite entangled states, and a quantum bath engineering approach to create entanglement in the steady-state [arXiv:2211.13639].

HL 50.9 Fri 12:00 POT 251

Towards the Development of Cryogenic Integrated Power Management Units — •Alfonso Rafael Cabrera Galicia — Forschungszentrum Jülich GmbH Wilhelm-Johnen-Straße 52428 Jülich

Integrated Circuits (ICs) in cryogenic environments are expected to allow the development of scalable quantum computers consisting of thousands of physical quantum bits (qubits). However, since these ICs require undistorted power supply for optimal performance, the development of Power Management Units (PMUs) capable of cryogenic operation is also needed for the quantum computing systems scalability. To develop such PMUs, it is necessary to understand the cryogenic electrical behavior of its components. Therefore, this talk will present the measurement results obtained from an exploratory cryogenic DC characterization of some of the passive and active components belonging to a commercial 22nm FDSOI IC technology.

HL 50.10 Fri 12:15 POT 251

Physical Integration of Cryogenic Control Electronic Together with a Spin Qubit Sample at mK Temperatures — •Lea-Marie Schreckenberg[1], Patrick Vliex[1], René Otten[2], and Stefan van Waasen[1,3] — [1]Central Institute of Engineering, Electronics and Analytics, Electronic Systems, Forschungszentrum Jülich GmbH, Jülich, Germany — [2]JARA Institute for Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, Aachen, Germany — [3]Faculty of Engineering, Communication Systems, University of Duisburg-Essen, Germany

A universal quantum computer requires the control and read out of millions of physical quantum bits (qubits). Due to wiring limitation in current state-of-the-art dilution refrigerators scaling up to millions of qubits with room-temperature electronics is challenging. Integrated Circuits (ICs) operating next to the qubits will help solving this scalability problem but require novel approaches for cryogenic circuits. This talk will focus on the physical design layer of the integration of a custom-designed 65nm CMOS low-power digital to analog converter (DAC)

for qubit bias together with a spin qubit sample. In total, eight DAC channels are integrated at the mixing chamber stage of a dilution refrigerator and are operated at milli-kelvin temperatures. Additionally, engineering aspects regarding the sample space setup, cryostat wiring and the tight density are pointed out.

HL 50.11   Fri 12:30   POT 251

Design of power efficient digital low-dropout circuit for quantum computers — •Swasthik Baje Shankarakrishna Bhat[1], Alfonso Rafael Cabrera Galicia[1], Arun Ashok[1], Patrick Vliex[1], Andre Zambanini[1], Christian Grewing[1], and Stefan van Waasen[1,2] — [1]Forschungszentrum Jülich GmbH, Germany — [2]Universität Duisburg-Essen

Quantum computing is an approach to enable new computing paradigms with qubits as the computing elements that require individual tuning. A limitation in current setups is the number of controllable qubits. To scale the number of qubits, a close integration of control circuits close to the qubits in the cryogenic environment is required. However, to deal with these cryostats* minimal thermal power budget, ultra-low power dissipation is required, also for biasing circuits.

This contribution presents the design and simulation results of a power-efficient digital low-dropout regulator developed with a commercial 22nm FD-SOI technology. It is expected that the circuit will enable on-chip biasing for future quantum computers based on Cryogenic Electronics operating at 4 K. Unlike its Analog counterpart integrated Digital LDO is not prone to process and mismatches delivering high efficiency at the same time The circuit concept and the system model investigation performed via Matlab-Simulink will be showed, as well as the expected circuit performance.

HL 50.12   Fri 12:45   POT 251

Design of Ultra-Low Power High Speed Communication Interface From Cryogenic to Room Temperature Electronics — •Ege Onat, Jonas Bühler, Christian Grewing, and Stefan van Waasen — Central Institute of Engineering, Electronics and Analytics, ZEA-2: Electronic Systems, Forschungszentrum Jülich GmbH

The objective of this research is to transfer high-speed data from deep cryogenic temperatures to room temperature while aiming for the lowest achievable power consumption in the cryostat. Quantum computers are operated inside dilution refrigerators under deep cryogenic temperatures and they need additional circuitry to ensure fault-free operations. Heating of the qubits caused by additional electronics degrades the system performance. Due to the limited power budget of the dilution refrigerators, each circuit should be designed considering power consumption. In contrast, the higher temperature stage can manage a higher power budget than the stage with the qubits. In this research, low-power data transmission methods for quantum computer applications are investigated and an asymmetric communication interface is designed and implemented. To achieve the asymmetric interface, only a varactor is placed into the cryogenic stage. To measure the capacitance on the room temperature stage, a capacitance readout circuitry is designed. It converts the capacitance into a measurable output such as voltage, frequency, or digital data. By implementing this interface, the data is carried on capacitance rather than voltages, which minimizes the power consumption at the transmitter compared to widely implemented communication interfaces.

HL 51: Nitrides: Preparation and Characterization

Time: Friday 9:30–12:15

Location: POT 112

HL 51.1   Fri 9:30   POT 112

High resistive buffer layers by Fermi-level engineering — •Armin Dadgar, Ralf Borgmann, and André Strittmatter — Otto-von-Guericke-Universität Magdeburg, FNW-IfP, Universitätsplatz 2, 39106 Magdeburg

We present a novel method to increase the resistivity of semiconductor buffer layers by aligning the Fermi level using a donor and an acceptor dopant of which one preferentially is a deep level placed in the lower (acceptor) or upper (donor) half of the energy band-gap. Potential doping sequences in GaN were simulated by nextnano software showing that the average Fermi-level position of alternately donor and acceptor doped layers can be shifted to the midgap position. This shift decreases the free carrier concentration and increases the resistivity as demonstrated for GaN:C / GaN:Si layer stacks. In structures grown by metalorganic vapor phase epitaxy, less charging and hysteresis effects are observed upon polarity changing between electrical contacts placed at surface and substrate. Also, the reduced total deep level concentration improves resistivity under electron and hole injection and the overall breakdown voltage by more than 20 %.

HL 51.2   Fri 9:45   POT 112

yolo-assisted object detection of dislocation-related pits on GaN surfaces using generative adversarial networks — •Mahdi Khalili Hezarjaribi[1,2], Uwe Rossow[1,2], Heiko Bremers[1,2], and Andreas Hangleiter[1,2] — [1]Institute of Applied Physics, Technische Universität Braunschweig, Germany — [2]Laboratory for Emerging Nanometrology, Technische Universität Braunschweig, Germany

In this paper, we present a model for detecting dislocation-related pits on GaN surfaces using SEM images, which strongly relies on the use of synthetic image generation. Pits mark dislocations in the layers and are widely used to assess crystalline quality; therefore, a considerable amount of images containing pits have to be evaluated. For this purpose, a Deep Learning (DL) algorithm is employed to achieve objective results, which are detecting the pits, and hence the dislocations, in SEM images. In order to train the algorithm to efficiently detect the objects, we need a host of SEM images containing pits in multiple sizes, numbers, formations, and noises. Due to the complexity of the microscopic structures and the lack of enough images, we incorporated a group of powerful algorithms called Generative Adversarial Networks to create artificial fake images just like real images and feed them, together with our real images, to our dataset to enrich the volume of the dataset. In the next stage, the YOLO algorithm (version 5) has been employed as the core deep learning algorithm for the object detection process using the above-mentioned dataset to train the network. A minimum average confidence of 86% for detecting real objects has been realized, corresponding to a high probability of detection.

HL 51.3   Fri 10:00   POT 112

Molecular beam epitaxy growth study and characterization of HoN thin films — •Anna Melendez-Sans[1], Vanda M. Pereira[1], Chun-Fu Chang[1], Chang-Yang Kuo[1,2,3], Chien-Te Chen[2], Liu Hao Tjeng[1], and Simone G.

Altendorf[1] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]National Synchrotron Radiation Research Center, Hsinchu, Taiwan — [3]Department of Electrophysics, National Yang Ming Chiao Tung University, Hsinchu, Taiwan

Rare earth nitrides show potential for a wide range of applications due to their strong magnetic moment and semiconducting behavior. However, their synthesis and characterization has proven challenging since they rapidly oxidize when exposed to ambient conditions. Thanks to continuous developments in UHV-based thin film growth methods it is possible to grow high quality rare earth nitride films and, through the characterization of these, gain better insight into these compounds.

Whilst there have been many reports on GdN and SmN, not much is yet known about HoN. Now we present a systematic growth study on HoN thin films synthesized by molecular beam epitaxy (MBE), and using different substrates (MgO, LaAlO$_3$) and growth conditions (substrate temperatures and Nitrogen-gas pressure). These films were subsequently characterized using *in situ* techniques (Reflection high-energy electron diffraction, X-ray absorption and photoelectron spectroscopy) and *ex situ* techniques (X-ray diffraction, Superconducting quantum interference device) in order to evaluate their crystalline, electronic and magnetic structure.

HL 51.4   Fri 10:15   POT 112

Theoretical study on the (Al,Sc)N random alloy — •Jan M. Waack[1,2], Markus Kremer[1,2], Michael Czerner[1,2], and Christian Heiliger[1,2] — [1]Institut für theoretische Physik, Justus-Liebig-Universität Gießen, Germany — [2]Center for Materials Research (LaMa), Justus-Liebig-Universität Gießen, Germany

Aluminium scandium nitride ($Al_xSc_{1-x}N$, (Al,Sc)N or AlScN) is an random alloy. As such, the calculation of physical properties requires specific methods such as the coherent potential approximation (CPA)[1] and special quasi-random structures (SQS)[2]. We compare the CPA in the framework of the atomic sphere approximation (ASA) Korringa-Kohn-Rostoker (KKR) density functional theory (DFT) with the SQS using the plane-wave pseudopotential DFT to calculate the lattice parameters and electronic band structures of the face-centered cubic phase of $Al_xSc_{1-x}N$ (with $0 \leq x \leq 1$).

Using the low computational cost LDA-1/2 quasiparticle method [3] to calculate the electronic band structures within SQS and CPA, we present the first implementation of LDA-1/2 within the KKR DFT. We find that both the lattice parameter and the indirect band gap deviate from Vegard's law.

Thermal Transport in c-plane GaN Membranes Studied by Raman Thermometry — •Wilken Seemann[1], Joachim Ciers[2], Isabell Hüllen[1], Mahmoud Elhajhasan[1], Jean-François Carlin[3], Nicolas Grandjean[3], Åsa Haglund[2], and Gordon Callsen[1] — [1]Institute of Solid State Physics, University of Bremen, Germany — [2]Department of Microtechnology and Nanoscience, Chalmers University of Technology, Gothenburg, Sweden — [3]Institute of Physics, École Polytechnique Fédérale de Lausanne (EPFL), Switzerland

Heating during operation often limits the lifetime or stability of semiconductor devices, like laser structures, e.g., via defect formation or by affecting the refractive index. Understanding how thermal energy is dissipated from the active region of such structures is therefore an important step towards device optimization.

We analyze the in-plane thermal transport in GaN-based membranes. The temperature is probed by the shift and width of Raman modes under heating with a UV laser. This allows for a non-contact characterization without the need for additional processing steps.

By varying the membrane underetching process, we can tune the membrane bottom facet roughness and porosity to study their impact on thermal conductivity κ, due to phonon boundary scattering. A reduction of κ is a sign of phonon frequency filtering, which is a first step towards engineering the phonon dispersion relation in GaN membranes. Controlling this effect, e.g., via the position and sizes of pores, might enable thermal concepts to locally reduce temperature rises.

HL 51.6   Fri 11:00   POT 112

SmN thin films: MBE-growth and spectroscopy studies — •Vanda M. Pereira[1], Anna Melendez-Sans[1], Chun-Fu Chang[1], Chang-Yang Kuo[1,2,3], Chien-Te Chen[2], Liu Hao Tjeng[1], and Simone G. Altendorf[1] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]National Synchrotron Radiation Research Center, Hsinchu, Taiwan — [3]Department of Electrophysics, National Yang Ming Chiao Tung University, Hsinchu, Taiwan

Although the rare earth nitrides have been in the scientific scene for many decades, their poor stoichiometry and reactivity in ambient conditions have severely conditioned their progress. It has been only rather recently that studies on thin films have started to unveil some of their unique characteristics and solve decades-old controversies, but there are still significant gaps left to explore.

Recent studies on the ferromagnetic semiconductor SmN suggest that the 4f bands are involved in electron transport and are crucial to the observed superconductivity in nitrogen-vacancy doped samples. Nevertheless, more concrete experimental evidence is needed.

Here we present a systematic study of SmN thin films grown by molecular beam epitaxy, exploring their crystalline quality and composition as the growth parameters (substrate temperature and nitrogen pressure) are varied. The films were characterized *in situ* making use of photoemission and x-ray absorption spectroscopies, thereby allowing to reliably gain more insight into the electronic structure of this material.

HL 51.7   Fri 11:15   POT 112

Growth of ScN and AlScN by reactive sputter epitaxy — •Florian Hörich, Christopher Lüttich, Ralf Borgmann, Jürgen Bläsing, André Strittmatter, and Armin Dadgar — Otto-von-Guericke University

Spontaneous polarization fields induced by a strained AlGaN/GaN layer structure lead to high-density two-dimensional electron gases which are key to current high-power and high-frequency transistor devices. Recent theoretical and experimental data demonstrated an even higher two-dimensional electron density when AlScN is used [1]. Up to now, growth of Sc-containing materials by conventional MOVPE is hampered by the lack of a suitable Sc precursor. Reactive sputter epitaxy using metallic Al and Sc targets together with ammonia or molecular nitrogen has the potential to fabricate high quality layers at low cost. We will discuss principle growth parameters such as temperature and nucleation conditions for ScN and AlScN on bare Si(111) substrates and on MOVPE grown GaN templates. A large impact of growth temperature is observed on crystal structure and surface morphology. Single-phase crystalline material is obtained at temperatures > 800 ˚C. We find different optimum nucleation conditions for both kind of substrate surfaces. Growth on bare Si(111) surfaces with an initial metallic Sc thickness equivalent to <1 nm drastically improves crystallinity.

For the GaN(0001) template surface, such sequence has no impact. Additionally, sputtering of AlScN and ScN with ammonia results in better structural quality than with nitrogen.

HL 51.8   Fri 11:30   POT 112

On the variation of PL intensity in GaInN/GaN quantum wells with different cladding thicknesses — •Nico Wagner[1], Shawutijiang Sidikejiang[1,2], Philipp Henning[1,2], Rodrigo de Vasconcellos Lourenço[1,2], Heiko Bremers[1], Uwe Rossow[1,2], and Andreas Hangleiter[1,2] — [1]Institute of Applied Physics, Technische Universität Braunschweig, Germany — [2]Laboratory for Emerging Nanometrology, Braunschweig, Germany

The absolute internal quantum efficiency (IQE) of GaInN/GaN quantum wells (QW) at low temperature can be determined using time-resolved photoluminescence (PL) measurements. If the IQE is 100 %, the PL intensity under steady state conditions is expected to be the same for all samples. We can verify that for some samples, but others show different intensities. It turns out that the difference varies for different cladding thicknesses, i.e. the layer between the QW and air. In this work, we present a model calculating the allowed modes inside the sample assuming that all the light is emitted into them if we have 100 % IQE. Due the small critical angle, it is important to determine the small ratio of intensity, which is coupled out and detected. The result yields an oscillating behavior as a function of the cladding thickness and shows a good agreement with the measured samples. It is important to note that this is a consequence of the Purcell effect, i.e. that spontaneous emission depends on the optical environment.

HL 51.9   Fri 11:45   POT 112

Optical properties of ScN films grown by HVPE and sputter epitaxy — •Jona Grümbel[1], Yuichi Oshima[2], Christopher Lüttich[1], Armin Dadgar[1], Martin Feneberg[1], and Rüdiger Goldhahn[1] — [1]Institut für Physik, Otto-von-Guericke-Universität, Universitätsplatz 2, 39106 Magdeburg — [2]Environment and Energy Materials Research Division, National Institute for Materials Science, 1-1 Namiki, Tsukuba, Ibaraki 305-0044, Japan

We investigate the optical properties of rocksalt structured ScN films using spectrocopic ellipsometry and Raman spectroscopy. Two different sets of samples were used for our measurements: (I) ca. 300nm thick ScN grown by sputter epitaxy and (II) $0.4\mu m$ up to $40\mu m$ thick ScN grown by HVPE. The HVPE grown ScN exhibits a very good crystalline structure, so the carrier concentration varies around $10^{18} cm^{-3}$ - $10^{19} cm^{-3}$, while for ScN grown by sputter epitaxy the carrier concentrations can reach $10^{22} cm^{-3}$ or more. Therefrom we obtain detailed information about their impact on optical properties, such as optical transitions, optical phonon modes or luminescence. Using spectroscopic ellipsometry we arrive at the dielectric function of ScN from 0.04eV to 6.5eV. Detailed analysis yields the main transitions regarding to direct bandgaps at X- and Γ-point as it was already shown in earlier theoretical works. Surprisingly, we observe characteristic peaks in a Raman scattering measurement, although first order Raman scattering is forbidden in rocksalt structured crystals. Detailed discussion and a possible interpretation will be presented as well as ScN materials parameters calculated from our measurements.

HL 51.10   Fri 12:00   POT 112

Temperature dependent spectroscopic ellipsometry on cubic GaN — •Jonas Rose[1], Elias Baron[1], Rüdiger Goldhahn[1], Michael Deppe[2], Donat J. As[2], and Martin Feneberg[1] — [1]Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Germany — [2]Department Physik, Universität Paderborn, Germany

Cubic Galliumnitride (c-GaN) is a promising material for designing and fabricating efficient optoelectronic devices, such as green LEDs, and can potentially replace hexagonal GaN for certain applications due to its lack of internal polarization fields. Therefore, the knowlegde and control of the optical properties is essential. Recently, several breakthroughs regarding crystal quality of c-GaN have been achieved by utilizing 3C-SiC as a substrate material. We present our investigation of thin film c-GaN deposited by plasma-assisted molecular beam epitaxy on 3C-SiC/Si substrates in (001) orientation. Temperature dependent spectroscopic ellipsometry between 80 and 300 K yields the optical properties (dielectric function, DF) in this temperature range. Hereby, the influence of the excitonic contribution to the DF is of special interest. Using Elliott's model, we describe the lineshape of the DF around the absorption onset. The obtained transition energies follow Pässler's temperature dependent model. Degenerately doped samples up to 10^{20} cm^{-3} are investatigated as well. A free-carrier dependent behaviour of the absorption onset is observed and explained for different temperatures.

Sessions
– Invited Talks, Contributed Talks, and Posters –

KFM 1: Focus: Domains and Domainwalls in (Multi)Ferroics I

The focus session is dedicated to advanced nanoscale characterization, property engineering, and modelling methods of (multi)ferroic materials. Typical examples may include ferroic domain walls, microstructural levers, or strain effects. Further, applications in novel nanoelectronic devices and nano-related engineering concepts for macroscopic properties of multiferroics are of interest.

Chair: Dr. Jan Schultheiß (University of Augsburg)

Time: Monday 9:00–12:15   Location: POT 51

Invited Talk   KFM 1.1   Mon 9:00   POT 51
Investigations of multiferroic behavior within domains and domain walls of a multiferroic Aurivillius phase system — •Lynette Keeney — Tyndall National Institute, University College Cork, Lee Maltings Complex, Dyke Parade, Cork, Ireland, T12 R5CP

Single-phase multiferroics intertwine ferroelectric and ferromagnetic properties, providing novel ways to manipulate data and store information and provide opportunities for exploring new chemistry and physics. In recent years, my team reported the design of a room temperature multiferroic material with an Aurivillius phase structure demonstrating reversible magnetoelectric switching of ferroelectric domains under the influence of a cycled magnetic field. Our previous work used atomic structure determinations of preferred cation locations to advance comprehension of key mechanisms governing ferromagnetism within multiferroic domains. In this presentation, I will discuss fundamental electronic characteristics at differing bonding environments within this complex layered system. We reveal how crystal field splitting of the titanium cation is influenced by its position within the Aurivillius unit cell, correlating with the extent of tetragonal distortion, octahedral tilting and ferroelectric polarisation within the domains. I will discuss how electrostatic strain and elastic energy variations close to bismuth oxide interfaces and defect regions are not only influential in promoting magnetic cation partitioning and multiferroic behaviour, these also influence the formation of exotic charged domain walls and polar vortex domain walls, further initiating technology prospects for this intriguing multiferroic system.

KFM 1.2   Mon 9:30   POT 51
Understanding sensitivity of ferroelectric domain walls to atmospheric parameters — •Leonie Richarz[1], Jan Schultheiss[1,2], Edith Bourret[3], Zewu Yan[3,4], Antonius T.J. van Helvoort[1], and Dennis Meier[1] — [1]NTNU Norwegian University of Science and Technology, Trondheim, Norway — [2]University of Augsburg, Augsburg, Germany — [3]Lawrence Berkeley National Laboratory, Berkeley, CA, USA — [4]ETH Zurich, Zurich, Switzerland

Ferroelectric domain walls are natural interfaces, separating volumes with different orientation of the spontaneous polarization. The walls can develop completely different electronic properties than the surrounding domains. In ferroelectric oxides, oxygen off-stoichiometry is an additional versatile control parameter, reflected by neutral ferroelectric domain walls in hexagonal manganites: Depending on the oxygen content, their conductance varies from insulating to conducting.

In this work, we change the conductance state of neutral ferroelectric domain walls in high-quality $Er(Mn,Ti)O_3$ single crystals from insulating to conducting by annealing the samples in reducing conditions, e.g., nitrogen. The process can be reversed by annealing under oxidizing conditions, reflecting the outstanding chemical flexibility of the domain walls. The sensitivity to off-stoichiometry can be exploited to utilize the domain walls for sensing applications.

Our results provide new insight into the impact of environmental parameters on the electronic domain wall properties. This is of interest for the development of atmospheric sensors, adding a new direction to the field of domain wall nanotechnology.

KFM 1.3   Mon 9:50   POT 51
Thermal and elastic stability of acceptor dopants in BaTiO3 — •Aris Dimou[1], Aldo Raeliarijaona[2], R. E. Cohen[2], and Anna Grünebohm[1] — [1]Interdisciplinary Center for Advanced Materials Simulation (ICAMS) and Center for Interface-Dominated High-performance Materials (ZGH), Ruhr-University Bochum, Germany — [2]Extreme Materials Initiative, Earth and Planets Laboratory, Carnegie Institution for Science, Washington, DC 20015-1305, USA

The presence of defects, such as vacancies and aliovalent substitutions significantly impacts the functional properties of ferroelectric materials. Defect dipoles formed by acceptor dopants and oxygen vacancies have gained interest after the demonstration of superlative, reversible piezoelectric [1], and electrocaloric [2] responses. But so far a deep understanding of their stability is missing.

We compare the thermal stability of Fe, Cu, and Mn dopants, and explore the impact of biaxial strain on the defect stability by density functional theory and *ab-initio* molecular dynamics. We found the largest barrier for the $Cu_{Ti} - V_O$ defect complexes, and exhibit the enhanced barrier height under compressive biaxial strain.

KFM 1.4   Mon 10:10   POT 51
Probing hidden order in ferroelectric oxide thin films with single crystal diffuse X-ray scattering — •Joohee Bang[1], Nives Strkalj[2], Martin Sarott[1], Morgan Trassin[1], and Thomas Weber[1] — [1]Department of Materials Science, ETH Zurich, Zurich, Switzerland — [2]Department of Materials Science and Metallurgy, Cambridge University, Cambridge, United Kingdom

Ferroelectric thin films have attracted great attention for its rich applications in energy-efficient electronic devices because of functional properties such as high dielectric constants and electrically switchable polarization. Recently, ferroelectric oxide superlattices with complex topologies such as long-range vortex-antivortex arrays of polarization have garnered much interest as they hold promise for alternative device configurations for microelectronics [1]. Here, we report on a newly discovered local order state in ferroelectric superlattices using a complete three-dimensional diffuse X-ray scattering data, which was collected by taking advantage of high-energy synchrotron X-rays in ultra-small grazing incidence geometry. The data was analyzed with the 3D-deltaPDF method [2], which not only gives a three-dimensional view of the disorder, but also the access to weak disorder that was previously not accessible. This work will contribute to understanding structure-property correlations of ferroelectric oxide superlattices and lay groundwork for developing a novel solid-state characterization technique.

15 min. break

Invited Talk   KFM 1.5   Mon 10:45   POT 51
Domains or no Domains in Wurtzite-Type Ferroelectrics — •Simon Fichtner[1,2], Niklas Wolff[1], Tom-Niklas Kreutzer[2], Georg Schönweger[1,2], Adrian Petraru[1], Hermann Kohlstedt[1], Lorenz Kienle[1], and Fabian Lofink[1,2] — [1]Faculty on Engineering, Christian Albrechts University, Kiel, Germany — [2]Fraunhofer ISIT, Itzehoe, Germany

For decades, the wurtzite structure served as a posterchild for pyroelectric, i.e. spontaneously polarized materials which are yet not ferroelectric. The resulting inability to control the dipole ordering after synthetization has largely limited research on wurtzite-type polarization domains and –walls to their suppression. Therefore, the growth of single domain materials of defined polarity has been one of the ultimate goals for the main applications of wurtzite-type semiconductors in the fields of MEMS, RF-, power- and optoelectronics.

Today though, the discovery of ferroelectricity in wurtzite-type solid solutions promises unprecedent possibilities in terms of reconfigurable polarization control in wurtzite-type materials, but also creates the necessity for renewed scientific attention to the domains and -walls of this structure. This contribution aims to provide a vantage point for this attention by giving a glimpse into the literature on this subject and by reporting on our preliminary experimental work on domains in wurtzite-type ferroelectrics. Regarding the latter, transmission electron and piezoelectric force microscopy next to chemical anisotropy studies allow us to draw first conclusions regarding the nucleation, coalescence and distribution of domains in this particular material class.

KFM 1.6 Mon 11:15 POT 51

The role of interfacial stress on the polarization stability of lead-free relaxor ceramics — •Julia Glaum[1,2], Yooun Heo[2], Matias Acosta[3], Pankaj Sharma[2], Jan Seidel[2], and Manuel Hinterstein[2,4] — [1]NTNU, Trondheim, Norway — [2]UNSW Australia, Sydney, Australia — [3]TU Darmstadt, Darmstadt, Germany — [4]KIT, Karlsruhe, Germany

The unique structural, dielectric and electromechanical properties displayed by canonical relaxor systems, make these materials fascinating objects for fundamental studies as well as for industrial applications. Contributors to these unique properties are the multiple crystallographic phases present simultaneously even in individual grains, as well as the ferroelectric-relaxor phase transformation, which can become reversible in the vicinity of the transition temperature.

Here, we report on the thermal evolution of the crystallographic phases in a (Bi1/2Na1/2)TiO3-BaTiO3 relaxor ceramic. This system exhibits two polar phases, with the minority phase embedded into the majority phase. While the majority phase retains a stable poling state with increasing temperature up to the transition to the relaxor state, a gradual de-texturization of the poling state is observed for the minority phase over the whole temperature range. The surface domain structure decays already at significantly lower temperatures than expected from bulk observations. Development of interfacial stresses between majority and minority phases and differences in local stress state between surface and bulk are discussed as driving factors of the phase transition dynamics.

KFM 1.7 Mon 11:35 POT 51

Effect of strain on the 3D domain structure of hexagonal manganites — Nelly Natsch, •Aaron Merlin Müller, Amadé Bortis, Manfred Fiebig, and Thomas Lottermoser — Department of Materials, ETH Zurich, 8093 Zurich, Switzerland

We simulate and visualize the three-dimensional domain structure of strained hexagonal manganites. Due to the improper nature of their ferroelectric order, hexagonal manganites exhibit unconventional vortex domain patterns. In 3D, these vortex domain patterns are characterized by vortex lines, which are 1D topological defects that form arbitrarily oriented loops in bulk materials. We show that when strain is applied in the ab-plane, the domains exhibit an additional stripe-like order that is oriented perpendicular to the ab-plane. In addition, we show that the strain also acts on the vortex lines, forcing them to form closed loops aligned in the same plane as the domain walls. In our simulations, we observe two types of loops: one type that expands and another type that contracts and collapses. We relate both the formation of the stripe-like domains and the evolution of the vortex-line loops to a force acting directly on the vortex lines which is induced by the applied strain. Our numerical investigation is performed with a phase-field model to simulate the domain structure in three dimensions using a Landau-free-energy expansion.

KFM 1.8 Mon 11:55 POT 51

Tracing property-determining structural alterations via scanning electron diffraction — •Ursula Ludacka[1], Jiali He[1], Emil Frang Christiansen[1], Shuyu Qin[2], Manuel Zahn[1,6], Zewu Yan[3,4], Edith Bourret[4], Antonius van Helvoort[1], Joshua Agar[2,5], and Dennis Meier[1] — [1]NTNU, Trondheim, Norway — [2]Lehigh University, Bethlehem, USA — [3]ETH Zurich, Zurich, Switzerland — [4]Lawrence Berkeley National Laboratory, Berkeley, USA — [5]Drexel University, PA, USA — [6]Augsburg University, Germany

Ferroelectricity originates from polar displacements of lattice atoms, suggesting a one-to-one correlation between electronic and structural properties at the atomic level. Scanning electron diffraction (SED), a subcategory of 4D-STEM, in combination with direct electron detection (DED) is a powerful tool for probing functional properties on the atomic scale. We demonstrate the potential and opportunities of this innovative SED approach using improper ferroelectric ErMnO3, an ideal model system as its basic ferroelectric properties, such as local conductivity changes and atomic-scale structure are well understood. By utilizing a convolutional neural network on the SED dataset, we can deconvolve intrinsic scattering phenomena on the atomic level (ferroelectric domains and domain walls) from extrinsic scattering phenomena, such as thickness, bending, or scan distortions. Our results on this topic contain new insights into atomic scale property-structure relations for ferroelectrics. However, the gained knowledge is applicable to complex oxides in general.

KFM 2: Focus: Dislocations in Ceramics: Mechanics, Structures and Functionality (joint session KFM/MA)

Contrasting the common (mis)belief that ceramics are brittle, a new horizon of dislocation engineering in ceramics is being revealed, where dislocations are used to harness the mechanical and electro-functional properties. This session will bring together researchers who are interested in dislocations in ceramics, covering experiments and simulations, to stimulate new ideas for dislocation-based mechanics, characterization, and functionality in ceramics.

Chair: Dr. Xufei Fang (TU Darmstadt), Dr. Till Frömling (TU Darmstadt)

Time: Monday 14:30–17:05 Location: POT 51

Invited Talk KFM 2.1 Mon 14:30 POT 51

Formation of conducting channels along of dislocations in SrTiO₃ — •Christian Rodenbücher[1], Kristof Szot[2], Gustav Bihlmayer[3], and Carsten Korte[1] — [1]Forschungszentrum Jülich GmbH, Institute of Energy and Climate Research (IEK-14) — [2]University of Silesia, Institute of Physics, 41-500 Chorzów, Poland — [3]Forschungszentrum Jülich GmbH, Peter Grünberg Institut (PGI-1), 52425 Jülich, Germany

SrTiO₃ has become one of the most extensively studied metal oxides due to its exceptional electronic properties, which hold promising potential for applications in energy conversion and electronics. A key feature of SrTiO₃ is that its electronic transport properties are closely related to oxygen nonstoichiometry, which can be manipulated via redox reactions. Our nanoscale investigations on crystals and ceramics employing imaging techniques such as local-conductivity atomic force microscopy (LC-AFM) reveal that the reduction process is highly complex and heterogeneous on the nanoscale. Along extended defects such as dislocations there are easy reduction sites where oxygen vacancies are preferentially generated. In this way, filaments with high conductivity evolve around the dislocations in the originally insulating matrix and act as nanoscale short circuits. Upon application of mechanical stress, these filaments can even be moved through the crystal together with the dislocations. These findings not only can explain failure mechanisms in solid oxide electrolytes, but also raise fundamental questions regarding the mechanisms of electronic transport and superconductivity in self-doped transition metal oxides.

KFM 2.2 Mon 15:00 POT 51

Dislocation engineering in oxides at room temperature: understanding the competition between plasticity and cracking — •Xufei Fang — Technical University of Darmstadt, Alarich-Weiss-Str. 2, 64287 Darmstadt, Germany

Dislocations in ceramic oxides are drawing increasing attention owing to their promising physical properties, such as dislocation-tuned electrical conductivity, thermal conductivity, and electro-mechanical properties. However, due to the brittleness of most oxides at room temperature, it remains a great challenge to engineer dislocations without forming cracks, which is a prerequisite for harnessing the functionalities. Here, we demonstrate dislocations can be effectively introduced into various ceramic oxides (SrTiO3, BaTiO3, KNbO3, TiO2) at room temperature by using nanoindentation pop-in stop tests. Interestingly, we find a size-dependent competition between purely dislocation-dominated plastic deformation under a critical tip radius and a concurrent appearance of cracks and dislocations when the tip radius is larger than a certain value. We further extend the deformation scale up to the millimeter regime and identify a reversal of the above size-dependent competition. We will address the underlying mechanisms by examining the dislocation nucleation, multiplication, and motion individually to shed new light on the dislocation mechanics in oxides, particularly at room temperature. Last but not least, the dislocation-tuned electrical and thermal conductivity will be briefly showcased using our developed methods for dislocation engineering.

KFM 2.3 Mon 15:20 POT 51

Tuning dislocations in ferroelectric oxides by cyclic Indentation: dislocation toughening, domain fragmentation and phase stabilisation — •Oliver Preuss, Fangping Zhuo, Enrico Bruder, Christian Minnert, Jürgen Rödel, and Xufei Fang — Department of Materials and Earth Sciences, Alarich-Weiss-Str. 2, 64287 Darmstadt, Technical University of Darmstadt

In light of the growing research interest in dislocation-tuned functionality in ceramics, promising proofs-of-concept have been most recently demonstrated enhanced ferroelectric properties, electrical conductivity, and superconductivity. Yet introducing dislocations into brittle ceramics remains a grand challenge, especially at room temperature. Here, we demonstrate a simple method using a large Brinell indenter to cyclically indent the sample surface to tune the dislocation densities over 4 orders of magnitude (from 10^{10} m^{-2} up to 10^{14} m^{-2}) in

single-crystal $KNbO_3$. A large, crack-free plastic zone (200 μm in diameter) is achieved on the sample surface at room temperature. More interestingly, both damage tolerance and fracture toughness have been improved. The interactions between dislocations and other microstructure features are examined in detail by optical microscopy, electron channelling contrast imaging, piezoresponse force microscopy methods and μ-Raman spectroscopy to shed light on the impact of dislocations on the mechanical properties as well as microstructural evolution. Our findings open new questions that may raise interest for further studies in ductile ceramics such as dislocation-domain wall interaction, domain wall fragmentation and strain-induced phase stabilisation.

Invited Talk   KFM 2.4   Mon 15:55   POT 51
Plastic properties of MgO : Insights from numerical modeling — •Philippe Carrez — Université de Lille, F-59000 Lille, France
Plastic properties of crystalline materials depend not only on the nature of the defects present in the crystal but also and more substantially on their mobilities and mutual interactions. This is typically the case for the creep properties of magnesium oxide (MgO), which has been the subject of numerous investigations over the years. Yet, the atomistic details of dislocation-point defects, dislocation-dislocation or dislocation-grain boundary interactions remain poorly described.

Nowadays, numerical modeling offers the possibility of modeling mechanical properties from the description of the elementary mechanisms of plasticity. As an example, we will discuss the interaction between 1/2<110>{110} dislocations and point defects in MgO. We will show how the edge dislocation core, within a region across the glide planes that expands over several Burgers vector, is a sink for vacancies, and thus enhances the pipe diffusion at moderate temperature. At higher temperature, point-defect absorption or emission along the dislocation lines allow the dislocation climb mechanism and can impact creep properties of MgO. We will thus show how atomic-scale simulations can elucidate the atomic configurations of the various jog configurations structure and give access to their formation energies.

                          KFM 2.5   Mon 16:25   POT 51
Dislocation-tuned Schottky barrier in oxide ceramics — •Mehrzad Soleimany[1,2], Till Frömling[1], Lukas Porz[1], Enrico Bruder[1], Marin Alexe[2], and Jürgen Rödel[1] — [1]Department of Materials and Earth Sciences, Technical University of Darmstadt, 64287 Darmstadt, Germany — [2]Department of Physics, University of Warwick, CV4 7AL Coventry, UK

For decades manipulation of interfaces and point defects in semiconductors have been the main focus of scientists for tuning the functional properties of materials. However, dislocations which are considered as one-dimensional defects, have not only been neglected but also tried to be avoided due to the assumption that they degrade desired properties of semiconductors. Nevertheless, it has recently been shown that this speculation can be challenged and dislocations can even be used to tune the thermal, electrical, and ferroelectric properties of materials, especially when they are introduced in high densities. In this work dislocation densities higher than 4×10^{13} m^{-2} were introduced in a large volume of the n-type and p-type $SrTiO_3$ by mechanical deformation and cyclic loading. That has been confirmed via sample thinning and electron channeling contrast imaging. Utilizing electrochemical impedance spectroscopy and DC electrical measurements, we showed that based on doping, dislocations can reduce the Schottky barrier in the n-type $SrTiO_3$ by a factor of seven and can increase that by a factor of three in the p-type one.

Tailoring ceramic functional properties of YSZ with dislocations — •Till Frömling, Qaisar Muhammad, and Jürgen Rödel — 1Division of Nonmetallic-Inorganic Materials, Department of Materials and Earth Sciences, Technical University of Darmstadt, Alarich-Weiss-Str. 2, Darmstadt 64287, Germany
The defect chemistry of zirconia is usually modified by doping with high levels of yttrium. This induces a very high oxygen vacancy concentration which is responsible for the excellent ionic conductivity. There is a high demand for even better oxygen conductors because this would benefit applications like solid oxide fuel cells and solid state electrolyzers. Nevertheless, a limit has been reached concerning the doping strategy. Therefore, we suggestion to use dislocations as one-dimensional defects. These have so far been mostly disregarded as defects for modification of functional properties but are finding increasing attention recently. However, ceramics are generally brittle and thus not easily plastically deformable. Besides the difficulty of introducing dislocations into ceramics, their exact influence on functional properties is still unclear. Our investigations of yttria-stabilized zirconia show that mechanically introduced dislocations can enhance ionic conductivity significantly. This illustrates the opportunity to tune ceramics beyond what can be achieved by chemical doping.

KFM 3: Instrumentation and Methods for Micro- and Nanoanalysis (joint session KFM/CPP)

The Hitchhiker's Guide to BCARS on Solid-State Single Crystals — •Franz Hempel[1], Lukas König[1], Federico Vernuccio[2], Dario Polli[2], Giulio Cerullo[2], Michael Rüsing[1], and Lukas Matthias Eng[1,3] — [1]Institut für Angewandte Physik, TU Dresden, 01187 Dresden, Germany — [2]Physics Department, Politecnico di Milano, 20133 Milano, Italy — [3]ct.qmat: Dresden-Würzburg Cluster of Excellence - EXC 2147, TU Dresden, 01062 Dresden, Germany
Broadband coherent anti-Stokes Raman scattering (BCARS) is an advanced Raman- spectroscopy technique that offers high-speed hyperspectral imaging and is so far widely applied in the biomedical field. For crystalline materials and their high-precision analysis, however, additional aspects of phase-matching, scattering direction, and background removal delicately need to be taken into account. To prove the reproducibility of BCARS results and pinpoint setup-related influences, we have performed a comparison study using (a) two different setups, and (b) comparing transmission with epi-detection BCARS experiments. A broad set of solid-state crystalline materials with increasing complexity was analyzed, achieving comparable, background-free spectra. Also, each machine allows the specification of optimum laser and setup parameters for inspecting the different samples.

Novel techniques for low-energy positron beam diagnostics. — •Francesco Guatieri, Michael Berghold, and Michael Zimmermann — Heinz Maier-Leibnitz Zentrum (MLZ), Technical University of Munich, Lichtenbergstr. 1, 85748 Garching, Germany
Modern surface analysis techniques based on low-energy positron annihilation require the use of a stable, focused and intense particle beam. Although several techniques are available to beam scientists to measure position, shape and inten-

sity of a positron beam, each comes with its own limitations either in terms of precision, cost or measurement time. We will present two innovative techniques to detect low-energy positrons with the goal of performing beam optimization, each of which improves onto the previous state of the art.

                          KFM 3.3   Mon 15:10   POT 106
Accessible electron microscopy: Adding an EELS workflow to the ChemiTEM project — •Daniela Ramermann, Julia Menten, Elisabeth H. Wolf, and Walid Hetaba — Max-Planck-Institut für Chemische Energiekonversion, Mülheim an der Ruhr
Transmission electron microscopy is a versatile tool for the investigation of micro- and nanostructures as well as chemical and electronic properties. However, TEM experts are needed to perform the majority of analytic measurements, which represents a bottleneck in the throughput of research. To broaden access to TEM investigations for every scientist, the ChemiTEM project[1] has developed workflows for the most used techniques (HRTEM, STEM, EDX). These are implemented in an app and guide the user through every step after only a basic training.

Now a workflow for EELS measurements has been added: For the three most used measurement scenarios, assessing sample thickness, elemental mapping and oxidation state determination, a decision-tree based workflow has been created. A prerequisite is the STEM alignment from the ChemiTEM app. A set of questions about the sample evaluates if EELS measurements using the workflow are possible or a TEM expert is needed. Step-by-step instructions guarantee a standardised measurement and data quality. The workflow can be easily adapted to other microscopes and makes EELS based techniques available to a broader community.

Invited Talk   KFM 4.1   Tue 9:00   POT 51

Towards spatially resolved measurements of thermal transport and electrocaloric effects at the nanoscale in ferroelectric materials — Rebecca Kelly, Olivia Baxter, Fran Kurnia, Amit Kumar, Marty Gregg, and •Raymond McQuaid — School of Mathematics and Physics, Queen's University Belfast, Belfast, U.K.

Scanning Thermal Microscopy (SThM) is a promising Atomic Force Microscopy technique for mapping the thermal properties of materials at the nanoscale. In this talk, I will discuss how SThM could be a powerful tool for studying the role of microstructure on heat flow in ferroelectric materials.

Interest in using ferroic domain boundaries to enable active control of heat flow has been steadily growing over the last decade. However, direct, spatially resolved measurements of domain wall thermal transport have yet to be reported. In the first part of the talk, I will describe our SThM based approach to map spatial variations in thermal conductivity associated with microstructural inhomogeneity. We map the contrast in thermal response of the electrode/dielectric layers of a multilayer ceramic capacitor (MLCC) to demonstrate proof of principle thermal imaging and then use this approach to investigate the thermal transport properties of conducting domain walls in LiNbO3.

In the second part of the talk, I will discuss how SThM can be adapted to measure electric field induced temperature changes in electrocaloric materials with sub-micron spatial resolution. Using our approach, 2D spatially resolved maps of electrocaloric heating and cooling can be generated, here demonstrated in a BaTiO3 based MLCC.

KFM 4.2   Tue 9:30   POT 51

Real time polarization monitoring during growth for the design of artificial layered ferroelectrics — •Ipek Efe[1], Elzbieta Gradauskaite[1], Alexander Vogel[2], Marta D. Rossell[2], Manfred Fiebig[1], and Morgan Trassin[1] — [1]Department of Materials, ETH Zurich, Switzerland — [2]Electron Microscopy Center, Empa, Switzerland

Increasing the complexity of unit cells of ferroelectric oxides beyond the standard perovskite building block supports exotic functionalities such as superconductivity, magnetoresistance, and ferroelectricity. However, integrating complex crystal structures into epitaxial design is challenging, and routes to precisely monitor the non-perovskite systems have yet to be established. Here, we directly access the polarization dynamics of the layered ferroelectric model system Aurivillius $Bi_5FeTi_3O_{15}$ films during growth using in-situ optical second harmonic generation (ISHG). We identify the characteristic Aurivillius antipolar ordering of the dipoles along the growth direction, which leads to an oscillating intensity of the ISHG signal during the layer-by-layer deposition. In combination with reflection high-energy electron diffraction monitoring, we show how the polarization orientation of the films consistently changes from out-of-plane during the growth of perovskite blocks, to fully in-plane upon the completion of the unit-cell with the fluorite-like $(Bi_2O_2)^{2+}$ planes. We demonstrate how direct access to structure-dependent polarization dynamics during growth enables the development of novel layered systems incorporating various functional perovskite blocks into the Aurivillius structure.

KFM 4.3   Tue 9:50   POT 51

3D mapping of grain boundary chemistry in ferroelectrics — •Kasper Hunnestad, Jan Schultheiss, Anders Mathisen, Constantinos Hatzoglou, Antonius Helvoort, and Dennis Meier — Norwegian University of Science and Technology (NTNU), 7491 Trondheim, Norway

In this work, we study the impact of polar order on the local chemistry of charged grain boundaries, which naturally form in polycrystalline pyro- and ferroelectric materials during processing. Analogous to ferroelectric domain walls, these interfaces can develop new physical properties, representing intriguing functional 2D systems. Understanding the origin of the emergent interfacial phenomena, however, is a challenging task, requiring high-resolution imaging of the atomic-scale structure.

Here, we apply atom probe tomography (APT) to study the local chemistry at grain boundaries in ferroelectrics. APT combines high chemical sensitivity and accuracy with three-dimensional spatial resolution, allowing to map and quantify otherwise inaccessible changes in chemical composition. In our polycrystalline model system, $ErMnO_3$, we consistently find an enrichment of erbium and a depletion of oxygen at the grain boundaries. This trend occurs independently of the local charge state of each grain boundary and is unexpected as it implies a local violation of charge neutrality. Our results provide new insight into the defect chemistry at the grain boundaries in polar materials, suggesting pathways for local property engineering in ferroelectric oxides via grain-boundary-selective doping.

Impact of defect dipoles on ferroelectric domain-walls motion — •Sheng-Han Teng and Anna Grünebohm — Interdisciplinary Centre for Advanced Materials Simulation (ICAMS) and Center for Interface-Dominated High Performance Materials (ZGH), Ruhr-University Bochum, Germany

Defect dipoles can alter the polarization switching and the dynamics of domain walls in ferroelectrics [1, 2], which may result in internal bias fields, domain-wall pinning [3] and bowing. In this work, we use *ab initio* based molecular dynamics simulations based on the effective Hamiltonian method [4, 5] to investigate the impact of defect dipoles on the domain-walls motion of tetragonal and orthorhombic phases in $BaTiO_3$. We find that the internal bias induced by defect dipoles may modify the potential energy landscape and leads to a completely different migration path for domain switching, which can pin and possibly even accelerate domain-wall motion.

Revealing hidden ferroelectric domain walls in sub-surface regions and their electronic properties via non-destructive conductance mapping — •Jiali He[1], Manuel Zahn[1,2], Leonie Richarz[1], Ursula Ludacka[1], Erik D. Roede[1], Zewu Yan[3,4], Edith Bourret[4], István Kézsmárki[2], and Dennis Meier[1] — [1]NTNU Norwegian University of Science and Technology, Norway — [2]Universität Augsburg, Germany — [3]ETH Zurich, Switzerland — [4]Lawrence Berkeley National Laboratory, USA

Ferroelectric domain walls hold great promise for next-generation nanoelectronics. In particular, charged domain walls in improper ferroelectrics have triggered conceptually new application strategies. Although it is known that the electronic properties of domain walls are determined by their charge state, orientation, and curvature, non-destructive measurements of these parameters remain a major challenge. We investigate the correlation between electronic surface properties and hidden ferroelectric domain walls in $ErMnO_3$. By recording conductance maps using scanning electron microscopy (SEM) in combination with conductive atomic force microscopy (cAFM) in combination with FIB-nanostructuring, we reveal that domain walls in surface-near regions give rise to distinct variations in surface contrast. The findings are rationalized in a simplified model, linking the contrast variations to the local charged state of the hidden domain walls, their orientation and distance from the surface. Our work introduces novel strategies to analyze the physical properties of ferroelectric domain walls in surface-near regions with nanoscale resolution in a non-destructive way.

KFM 4.6   Tue 11:05   POT 51

Electronic transport at pristine neutral ferroelectric domain walls in lead titanate — •Sabine Körbel[1] and Christophe Adessi[2] — [1]Institute of Condensed Matter Theory and Optics, Friedrich Schiller University Jena, Germany — [2]Institut Lumière Matière, Université Claude Bernard Lyon I, France

Ferroelectric domain walls are intrinsic interfaces that form spontaneously in ferroelectric materials, such as, for example, perovskite oxides. Whereas the ferroelectric perovskite oxide itself is an insulator, ferroelectric domain walls can be electrically conductive, as numerous experiments on different perovskite oxides have shown. This domain-wall conduction could serve, e.g., for charge-carrier transport in future photovoltaic absorbers. We investigated, using ab initio calculations based on Green's functions, the electronic transport along and through neutral ferroelectric domain walls in the prototype ferroelectric perovskite oxide $PbTiO_3$, and determined how the domain walls change the electronic transmission of bulk $PbTiO_3$ and the I-V curves of an ultrathin metal/perovskite/metal sandwich structure. We find that pristine neutral domain walls have a moderate effect on electronic transmission and I-V curve (within about one order of magnitude), much smaller than the experimentally measured conductivity increase at the walls by several orders of magnitude. We suggest that the measured conductivity increase does not directly originate in the electronic structure of the pristine neutral domain walls, but is caused by secondary effects, such as the accumulation of free charge carriers and/or the segregation of charged defects at the walls.

KFM 4.7   Tue 11:40   POT 51

Ferrielectric phase boundaries in antiferroelectric lead zirconate — •Gustau Catalan[1], Krystian Roleder[2], and Ying Liu[3] — [1]ICREA and ICN2, Barcelona, Catalonia — [2]Institute of Physics, University of Silesia in Katowice, Katowice, Poland — [3]ICN2-Institut Catala de Nanociencia i Nanotecnologia, Barcelona, Catalonia

When antiferroelectric PbZrO3 is cooled down from the paraelectric phase, antiferroelectric domains nucleate and grow until they coalesce. Adjacent antiferroelectric domains can differ in the phase sequence of the antipolar arrangement, meaning that there is a polar discontinuity at the domain wall, also known as translational boundary or antiphase boundary. Using high resolution transmission electron microscopy, we have characterized such phase boundaries. We find that their internal structure is ferrielectric, with a basic unit cell that can be described as having two dipoles ion one direction and one in the antiparallel direction. We also find that such translational boundaries can cluster together, forming stripe domains of an incipient ferrielectric phase that can moreover be internally switched. We therefore propose that antiphase boundaries can act as the seed for a low-temperature ferrielectric phase that has been theoretically predicted and which might explain the remnant polarization sometimes observed as triple hysteresis loops in nominally antiferroelectric lead zirconate.

KFM 4.8   Tue 12:10   POT 51

Field Effect Transistor employing the static negative capacitance of a ferroelectric nano-domain nucleus — •Pavel Mokry[1], Vit Kosina[1], and Tomas Sluka[2] — [1]Faculty of Mechatronics, Informatics and Interdisciplinary Studies, Technical University of Liberec, Liberec, Czech Republic — [2]CREAL SA, Ecublens, Switzerland

Miniaturization of conventional field effect transistors (FETs) approaches the fundamental limits beyond which opening and closing the transistor channel require such a gate voltage swing, which causes an unacceptable increase in heat generation. This problem could be reduced by placing a ferroelectric layer between the FET gate electrode and the channel. In this ferroelectric-semiconductor sandwich structure, the gate voltage can be amplified due to the negative capacitance regime of ferroelectrics. However, the original idea of using a bulk ferroelectric for voltage amplification suffers several difficulties. In this work, we provide phase-field simulations of a system that provides static negative capacitance from a nano-domain nucleus. We model the nucleus of a ferroelectric domain with reversed polarization produced by applying the voltage on a small gate electrode. We show that such a nano-domain nucleus represents a reversible system, which follows a unique path during electrical cycling and inevitably crosses a higher energy state characterized by negative static differential capacitance. Phase-field simulations confirm the robustness of this concept offering conveniently small effective negative capacitance and its compatibility with FET technology.

KFM 4.9   Tue 12:30   POT 51

Novel functionalities at twin domain crossings — •Kumara Cordero-Edwards[1,2], Philippe Tückmantel[2], Iaroslav Gaponenko[2], Sahar Saremi[3], Lane Martin[3,4], and Patrycja Paruch[2] — [1]Institut Català de Nanociencia i Nanotecnología, Barcelona, Catalonia. — [2]DQMP, University of Geneva, Geneva, Switzerland — [3]Department of Materials Science and Engineering, University of California, Berkeley, USA. — [4]Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, USA.

In ferroelectrics, domain walls (DWs) are thin interfaces separating regions with different orientations of electric polarization. These interfaces can present physical properties quite different from the surrounding domains, allowing them to be used as active components in future device applications. Recent studies of DWs using scanning probe microscopy (SPM) have focused on mapping their response to different parameters in order to understand their structure-property relationships. In particular, the role of high strain gradients present at ferroelectric twins has been shown to enhance their electrical conduction and can lead to complex rotational polarization textures.

Here, I will present our investigation of ferroelastic twin domains in epitaxial PbTiO3 thin films grown on SrTiO3, explored with SPM. Our results suggest a complex polarization structure around the twin domains, which present an unusual and distinct lateral PFM signal, associated with a distinct current signature. Moreover, twin domain crossings show a unique mechanical response distinct from the surrounding ferroelectric phase, and enhanced electrical conduction.

KFM 4.10   Tue 12:50   POT 51

Three-dimensional imaging of ferroelectric domains using digital holographic tomography — •Pavel Mokry[1,2], Marek Mach[1,2], Pavel Psota[1], and Karel Zidek[1] — [1]Faculty of Mechatronics, Informatics and Interdisciplinary Studies, Technical University of Liberec, Liberec, Czech Republic — [2]Institute of Plasma Physics of the Czech Academy of Sciences, Prague, Czech Republic

The formation and evolution of domain patterns in ferroelectrics are fascinating physical phenomena, which determine to a large extent, the macroscopic properties of ferroelectric samples. Therefore, imaging of ferroelectric domains belongs to the essential characterization techniques of ferroelectric materials. This work demonstrates the three-dimensional (3D) imaging of ferroelectric domains using Digital Holographic Tomography (DHT). Our method is based on the construction of the Digital Holographic Microscope, which allows taking several images of the domain pattern projections from different directions. The 3D image of the ferroelectric domain pattern is then numerically reconstructed using our original method called Curvilinear Filtered Back-projection. Our experimental method has been demonstrated by imagining the domain structure in periodically poled lithium niobate single crystals. The developed method allows fast and accurate 3D observations of ferroelectric domain structures in the whole volume of the ferroelectric single crystals on the centimeter scale. The recent DHM and DHT systems, which allow high-resolution optical imaging and on-chip optical imaging of ferroelectric domain patterns, are demonstrated and discussed.

Electrochemical performance of KTiOAsO$_4$ (KTA) from density functional theory — •Adriana Bocchini, Uwe Gerstmann, Tim Bartley, Hans-Georg Steinrück, Gerald Henkel, and Wolf Gero Schmidt — Universität Paderborn, 33095 Paderborn, Germany

The potassium titanyl phosphate (KTiOPO$_4$, KTP) family has been recently suggested as a promising electrode for alkali-ion batteries [1-3]. Here, we present a study [4] based on density functional theory (DFT) that investigates the electrochemical performance of potassium titanyl arsenate (KTiOAsO$_4$, KTA) as an electrode for potassium-ion batteries (KIBs). K-deficient K$_{1-x}$TiOAsO$_4$ ($x = 0.0-1.0$) and K-doped KTiOAsO$_4$K$_x$ ($x = 0.0-0.5$) is used to model cathode and anode materials, respectively. We show that KTA combines high average working voltages (up to 3.8 V) with a modest volume expansion (shrinkage) upon K (de)intercalation (both below 8%). Nudged elastic band (NEB) calculations are performed to investigate the (de)intercalation dynamics. It is shown that the most favorable K-ion (K-vacancy) diffusion path is located along the [001] di-

rection and is characterized by activation energies lower 0.5 eV. Our results thus suggest a new application of the well-established KTA photonic crystal.

Lithium vacancies concentration in LiNbO$_3$ from first principles — •Christa Fink, Felix Bernhardt, and Simone Sanna — Justus-Liebig-University, Giessen, Germany

Lithium niobate is known as a crystalline material with ferroelectric, piezoelectric, photorefractive, and electro-optical properties and therefore has multiple applications. One of the intrinsic point defects of LiNbO$_3$, the negatively charged Lithium vacancy V'_{Li}, is studied in this contribution from first principles. The isolated defect is investigated using density functional theory to calculate the

temperature dependency of the defect concentration of Lithium vacancies in LiNbO₃ crystals. The defect concentration can be calculated assuming an Arrhenius behavior where the activation energy is given by the Gibbs energy of defect formation. The Gibbs energy itself is a sum of several terms which are all depending on temperature. Since *ab initio* calculations are always performed at $T = 0$ K, a special formalism is used which allows adding a temperature dependency to the standard *ab initio* calculations. This formalism includes several approaches to take temperature into account. In addition, finite-size effects due to computational limitations need to be considered during the calculation of defect formation energies and formation entropies.

KFM 6.3 Tue 17:00 P3

Modelling of CARS — •Leonard M. Verhoff and Simone Sanna — Instutute for theoretical physics, Giessen, Germany

Coherent anti-stokes Raman spectroscopy (CARS) is a widely used method for material characterization which has been recently extended to crystalline solids. Even though it relies on the same vibrational modes as Raman spectroscopy, it yields a much stronger output signal. Being a third order, non-linear optical process, it depends on the material's $\chi^{(3)}$ tensor.

In this contribution, we report on our theoretical modelling of the CARS-signal. In particular, we model the generation of the signal beam by solving the underlying differential equations resulting from Maxwell's equations numerically for LiNbO₃, to extract a frequency-dependent amplitude that is also measured in experiments. The $\chi^{(3)}$ tensor is calculated from first principles using density functional theory before. Exploiting the symmetry of LiNbO₃ crystals, lower order non-linear optical effects can be neglected.

The partial differential equations defining the signal beam are further simplified by assuming plane waves for all involved lasers, including the pump, stokes and probe beam and explicitly using a specific scattering geometry.

KFM 6.4 Tue 17:00 P3

Composition dependent optical properties of LiNb₁₋ₓTaₓO₃ solid solutions — •Felix Bernhardt, Florian Pfeiffer, and Simone Sanna — Justus-Liebig-Universität, Gießen, Germany

Lithium niobate (LN) and lithium tantalate (LT) are ferroelectric crystals with a wide range of applications, extending from piezoelectric sensors [1] to integrated photonics [2]. Their structural similarities enable their combination to LiNb₁₋ₓTaₓO₃ (LNT) solid solutions. As the optical absorption edge of these alloys depend on their composition, one can determine the crystal composition non destructively, e.g. by optical spectroscopy.

Here, we use special quasi-random structures (SQS) to simulate LNT crystals with different compositions. These structures mimic an ideal random alloy, even when periodic boundary conditions are employed.

We calculate the first order dielectric tensor of LNT for different Ta concentrations by using density functional theory (DFT) and the indepnt particle approximation (IPA). Furthermore, we employ the Bethe-Salpeter equation (BSE) on top of quasi-particle calculations in GW-approximation for pure LN and LT to model excitonic effects.

Our calculations show a clear dependence on the absorption edge with respect to the Nb/Ta ratio of the LNT crystals. The inclusion of quasi-particle effects significantly shifts the absorption edge to higher energies. Our results are in good agreement to experimental data.

KFM 6.5 Tue 17:00 P3

Hybrid Functionals for Periodic Systems in the Density Functional Tight-Binding Method — •Tammo van der Heide[1], Bálint Aradi[1], Benjamin Hourahine[2], Thomas Frauenheim[1], and Thomas Niehaus[3] — [1]BCCMS, Univ. of Bremen, Bremen, Germany — [2]SUPA, Dep. of Physics, The Univ. of Strathclyde, Glasgow, G4 0NG, UK — [3]Institut Lumière Matière, Univ. Lyon, Univ. Claude Bernard Lyon 1, CNRS, Villeurbanne, France

Screened range-separated hybrid (SRSH) functionals within generalized Kohn-Sham density functional theory (GKS-DFT) have been shown to restore the correct $1/(r\epsilon)$ asymptotic decay of the screened Coulomb interaction in a dielectric environment (ϵ). Major achievements of SRSH include an improved description of optical properties and correct prediction of polarization-induced fundamental gap renormalization in molecular crystals. The density functional tight-binding method (DFTB) is an approximate DFT that bridges the gap between first principles methods and empirical schemes. While RSH have already been accessible for molecular systems, effort has been made to generalize the theoretical foundation to extended systems beyond the Γ-point. For treating the periodic Fock exchange and its integrable singularity in reciprocal space, we resort to techniques successfully employed by DFT. Starting from the first principles Fock operator, we derive suitable expressions for the DFTB method, using standard integral approximations and their efficient implementation in the DFTB+ software package. Convergence behavior is investigated and demonstrated for the infinite acene series as well as 2D and 3D materials.

KFM 6.6 Tue 17:00 P3

Vibrational and optical properties of LiNbO₃ and LiTaO₃ under uniaxial stress — •Mike Pionteck[1], Ekta Singh[2], Sven Reitzig[2], Michael Lange[2], Michael Rüsing[2], Lukas Eng[2], and Simone Sanna[1] — [1]Justus-Liebig-Universität Gießen, Germany — [2]Technische Universität Dresden, Germany

In ferroelectrics, the bulk material and the domain walls differ strongly in their vibrational and optical properties. X-ray measurements have shown that the domain walls of LiNbO₃ and LiTaO₃ exhibit the structure of compressed bulk material [1]. Consequently, the knowledge of the Raman frequencies as well as the optical response of the bulk material as a function of stress can help to characterize the domain walls.

Our work provides, for the first time, a theoretical description of phonon frequencies under uniaxial stress along Cartesian axes using density functional theory (DFT). The calculations show a roughly linear dependence of the Raman frequencies on the applied stress, which is confirmed by corresponding Raman measurements. This behavior is very similar for LiNbO₃ and LiTaO₃ crystals. In particular, the E TO₅ and TO₆ modes show a strong dependence on uniaxial stress in the x and y direction. As the strain reduces the symmetry of the crystal, we predict degeneracy lifting for the E modes. In addition, we have calculated the linear and nonlinear optical behavior of LiNbO₃. In particular, this includes the second (SHG) and third harmonic generation (THG) coefficients as a function of the applied uniaxial strain. [1] M. Rüsing et al., Phys. Rev. Mat. 2, 103801 (2018).

KFM 6.7 Tue 17:00 P3

Direct growth of iron-based compounds as anodes for potassium ion storage — •Zidong Wang, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Potassium-ion electrochemical energy storage technologies have received much attention in recent years as an alternative to lithium-based energy storage technologies. Iron-based compounds, as a typical transition metal compound, have attracted much attention because of their low cost and high capacity as an anode of batteries. However, poor electrical conductivity and structural instability, which are common in transition metal compounds, hinder their further application in potassium-based energy storage technologies. In this work, the conductivity of electrodes was improved by a strategy of growing iron-based compounds directly on carbon papers, eliminating the binding agent in conventional preparation methods. Also, the directly grown active material can effectively reduce agglomeration during charging and discharging, thus enhancing the stability. The results show that this direct growth strategy can effectively improve the electrochemical potassium ion storage performance of iron-based compounds as a promising high-performance anode.

KFM 6.8 Tue 17:00 P3

Fabrication of reproducible, conductive domain walls in lithium niobate — •Julius Ratzenberger[1,2], Iuliia Kiseleva[1], Peter Hegarty[1], Zeeshan Amber[1], Michael Rüsing[1], and Lukas Eng[1,2] — [1]Institut für Angewandte Physik, Technische Universität Dresden, 01062 Dresden, Germany — [2]ct.qmat: Dresden-Würzburg Cluster of Excellence–EXC 2147, TU Dresden, 01062 Dresden, Germany

In recent years, extensive research on conductive domain walls (CDW) in lithium niobate as possible building blocks for nanoelectronic circuits has been carried out. However, a fundamental understanding of the relationship between poling, and the properties of highly-conductive domains has been missing so to date.

In this work, we systematically investigate the various poling parameters in order to come up with a recipe of how to reproducibly fabricate conductive, hexagonal domains into lithium niobate single crystals. Furthermore, by optimizing the relevant parameters, the CDW is reproducibly enhanced when following the work of Godau et al. [1]. To gain a deeper understanding into the formation of highly-conductive DWs, we apply 3D second-harmonic generation (SHG) microscopy [2] for direct real-space visualization. Our findings provide key insights into the formation of CDW in lithium niobate single crystals.

KFM 6.9 Tue 17:00 P3

Photo-induced transport properties in ferroelectric lithium niobate single crystals and their domain walls — •L. L. Ding[1], E. Beyreuther[1], K. Kempf[1], M. Rüsing[1], and L. M. Eng[1,2] — [1]Institut für Angewandte Physik, TU Dresden, Nöthnitzer Straße 61, 01187 Dresden, Germany — [2]ct.qmat: Dresden-Würzburg Cluster of Excellence - EXC 2147, TU Dresden, 01062 Dresden, Germany

Ferroelectric materials exhibit a spontaneous and stable dielctric polarization, resulting in a variable assembly of domain and domain wall (DW) structures, that have received continuous attention[1]. Furthermore, the multifield-controlled electrical transport offers many prospects for the vivid application of ferroelectrics into electronic devices, such as ferroelectric sensors, memories,

even synaptic circuits[2]. Notably, (external) control of the electronic transport through photons is very desirable since being non-invasive and ultrafast, but has been studied only sparsely. In particular, polarization switching of domains and DWs, bandgap modulation, or DW dynamics, all are susceptible to the photon-electron interaction, thus need fundamental clarifications and profound investigations. Here, we combine scanning probe techniques with analyzing the impact of light irradiation onto lithium niobate (domains and) DWs, and vary both intensity and wavelength to probe the local conductivity. This ansatz thus will improve our in-depth knowledge on the local band structure and energy level distribution within DWs, and will lay the foundation to design integrated electro-optical components thereof. KFM 6.10   Tue 17:00   P3
Thermal Conductivity of CVT Grown FeS2 Crystals Measured by Optothermal Raman Method — •Ayberk Özden[1], Esteban Zuñiga Puelles[2,3], Jens Kortus[1], Roman Gumeniuk[2], and Cameliu Himcinschi[1] — [1]Institut für Theoretische Physik, TU Bergakademie Freiberg, Leipziger Str. 23, 09599 Freiberg, Germany — [2]Institut für Experimentelle Physik, TU Bergakademie Freiberg, Leipziger Str. 23, 09599 Freiberg, Germany — [3]Max-Planck-Institut für Chemische Physik fester Stoffe, Nöthnitzer Str. 40, 01187 Dresden, Germany

In this study, natural mineral and needle-like pyrite crystals grown by chemical vapour transport were selected as model systems and their thermal conductivities were obtained by the optothermal Raman (OTR) method [1]. It is shown that the bulk model used accurately detects differences in the thermal conductivities of mineral and CVT crystals. This difference is attributed to point defects, such as sulphur vacancies or impurity doping. Balkanski-Klemens model analysis showed that three-phonon scattering of Ag and Eg modes and lattice thermal expansion are the dominant anharmonic contributions, while four-phonon scattering is negligible in pyrite-FeS2. Thus, OTR not only provides an easy access to the thermal conductivity of single crystals in their most native form but also sheds light on the underlying phonon scattering mechanisms.

Dynamics of the electrocaloric effect in ferroelectric materials — •Jan Fischer, Daniel Hägele, and Jörg Rudolph — Ruhr-Universität Bochum, Germany

Ferroelectric materials are promising candidates for sustainable and environmentally friendly cooling applications due to their electrocaloric effect (ECE). The reversible temperature change ΔT results from a change of polarization P under adiabatic conditions. However, direct studies of the adiabatic temperature change are experimentally challenging. The vast majority of previous studies has used either indirect methods or slow temperature sensors. Systematic studies of dynamics of the ECE down to short timescales are completely missing.

Here, we present a direct and contactless method to study the dynamics $\Delta T(t)$ of the ECE with mK temperature resolution and μs temporal resolution via the infrared emission of the sample.[1,2] The simultaneous recording of applied electric field $E(t)$ and polarization $P(t)$ transients gives further the opportunity to correlate the caloric with the dielectric properties thus opening new perspectives for a fundamental understanding. The technique also allows for measurements faster than the heat exchange between sample and environment achieving adiabatic conditions. Our method is applicable to a wide range of materials and requires no sophisticated sample processing.

We present measurements on different materials ranging from bulk ferroelectrics over complex relaxor ferroelectrics to thin polymer films.

KFM 6.12   Tue 17:00   P3
Fabrication steps for realization of quantum tokens — •Miriam Mendoza Delgado[1], Julia Heupel[1], Jan Thieme[2], Johann Peter Reithmaier[1], Kilian Singer[2], and Cyril Popov[1] — [1]Institute of Nanostructure Technologies and Analytics (INA), Center of Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Germany — [2]Institute of Physics, Center of Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Germany

Nitrogen-vacancy (NV) color centers in diamond are fluorescent defects which possess "atom-like" properties and can be implemented as single photon sources with high optical stability and quantum yield, even at room temperature. Furthermore, the coherent electron spin of NV can be used as a long lived qubit which can be applied in quantum information technology, e.g. in quantum repeaters or tokens. In order to enhance the photon emission from NV centers and the collection efficiency, they should be incorporated in photonic structures, like nanopillars. The aim of the current work is the fabrication of diamond nanopillars incorporated with NVs and integrated with microwave antennas and electrodes, for the realization of quantum tokens. The fabrication of arrays of monocrystalline diamond nanopillars with diameters between 150 nm and 250

nm, 1 μm height and center-to-center distance of 10 μm consisted of their definition by electron beam lithography and subsequent inductively coupled plasma reactive ion etching with oxygen. Different techniques are implemented for the creation of NVs, which can affect both their density and properties.

KFM 6.13   Tue 17:00   P3
Engineering of Dendrite-Free and Activity-Enhanced Dual-Functional Electrodes for High-Energy Na-CO2 Batteries — •Changfan Xu, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Constructing suitable multifunctional electrodes for dendrite-free anodes and kinetics-enhanced CO2 cathodes is considered one of the most important ways to further advance the practical application of Na-CO2 batteries. Herein, Ru nanoparticles grown on carbon paper (RuCP) are rationally designed and employed as both Na anode and CO2 cathode in Na-CO2 batteries. The outstanding electrical conductivity, superior sodiophilicity, and high catalytic activity of RuCP electrodes can simultaneously contribute to homogenous Na+ distribution and dendrite-free sodium structure, and strengthen discharge and charging kinetics. The morphological evolution confirms uniform deposition of Na on RuCP anode with dense and flat interfaces, delivering enhanced Coulombic efficiency and cycling stability. Meanwhile, Na-CO2 batteries with RuCP cathode demonstrates low overpotentials and excellent cycling stability. Significantly, excellent electrochemical properties are obtained in the full battery (RuCP@Na || RuCP), laying the foundation for practical applications of Na-CO2 batteries.

KFM 6.14   Tue 17:00   P3
Material dependent differences in spectroscopic changes of the transient reflectivity on ultrashort timescales — Jonathan Frank, Julian Mertens, Felix Hoff, and •Matthias Wuttig — 1. Institute of Physics (IA), RWTH Aachen University, Aachen, Germany

Optical spectroscopy is a well-established technique to characterize solids. It can be utilized to distinguish different types of chemical bonding, i.e. separate solids which employ metallic, ionic and covalent bonding. We have tried to understand if these differences in bonding are still visible if the materials are excited with femto-second laser pulses. Femtosecond pump-probe spectroscopy experiments at a fixed pump-pulse wavelength were carried out in an isotropic detection scheme, to investigate the wavelength dependent reflectivity changes of optically excited samples on sub-ps timescales for wavelengths ranging from the visible to the near infrared. The measurements were carried out on various pure metals, chiral topological semimetals and semiconductors. The reflectivity changes, for a given material, vary greatly in duration and magnitude, depending on the probe wavelength. Furthermore, while an initial decrease in the transient reflectivity may be observed at one probe wavelength, an increase may be measured with another. This behavior is intrinsically linked to the excitation of carriers, their subsequent relaxation and their interaction with the lattice. The results for different materials are presented and compared, and trends within a material group evaluated. A possible link to emergent properties, conductivity and dielectric function, is discussed.

KFM 6.15   Tue 17:00   P3
Comparison of Infrared and Raman active phonon modes in Lithium Niobate — •Soham Gharat[1], Susanne Kehr[1], Michael Rüsing[1], and Lukas M Eng[1,2] — [1]Institut für Angewandte Physik, TU Dresden, Nöthnitzer Straße 61, 01187 Dresden, Germany — [2]ct.qmat: Dresden-Würzburg Cluster of Excellence - EXC 2147, TU Dresden, 01062 Dresden, Germany

The isostructural crystal of Lithium niobate is among the most widely used single-crystalline ferroelectric crystal with applications ranging from nonlinear optics [1] and high-speed electro-optic modulators, to high-frequency electronic filters [2]. In this work, we investigate the Lithium niobate crystal using both Raman spectroscopy and Fourier transform infrared spectroscopy (FTIR) [3]. We focus on consistently assigning the phonons in this material system using the two techniques in order to characterize and compare all these vibrational modes and their associated optical response. This work hence serves as a basis for the future study of nanoscopic features in this material, i.e. especially domain walls, by means of nano-FTIR and micro-Raman spectroscopy [4].

KFM 6.16 Tue 17:00 P3

Control of structure and morphology of LiNi0.8Co0.1 Mn0.1 powder before and after calcination — •SLAHEDDINE JABRI[1], MARKUS ROJER[2], GEORG GARNWEITNER[2,3], MARKUS ETZKORN[1,3], and UTA SCHLICKUM[1,3] — [1]Institute of Applied Physics, Technische Universität Braunschweig, 38106 Braunschweig, Germany — [2]Institute for Particle Technology, Technische Universität Braunschweig, 38104 Braunschweig, Germany — [3]Laboratory for Emerging Nanometrology (LENA), Technische Universität Braunschweig, 38106 Braunschweig, Germany

The demand of high energy density of lithium battery cells has strongly increased in the last years to enable long-range electric vehicle applications. Nowadays one focus lies on the optimization of the material composition of LiNi0.8Co0.1Mn0.1 (NMC811) as the promotor cathode material, which has the advantage of high specific capacity. However, the synthesis of high quality NMC811 material is still difficult due to its structure and thermal instability. Here, the NMC811 powder is prepared from acetate precursors in a cheaper and more environmentally synthesis procedure. The structure and the morphology of pre-calcined und calcined NMC811 were investigated using (cross section) Scanning Electron Microscopy (FIB-SEM) and Raman Spectroscopy. Beside the internal structure of single particles, this study provides information about the impurities present in the powder. In addition, the result shows that a compact and ordered layered rhombohedral phase structure of the NMC811 powder is obtained after annealing to 800 and 850 ˚C.

KFM 6.17 Tue 17:00 P3

RbTiPO$_4$F: A novel electrode material? — •YINGJIE XIE, UWE GERSTMANN, WOLF GERO SCHMIDT, and ADRIANA BOCCHINI — Universität Paderborn, 33095 Paderborn, Germany

The development of renewable forms of energy goes hand in hand with the search for efficient energy storages. Battery technologies based on metal ions heavier than Li are discussed as a greener, more efficient, and less expensive energy storage alternative to lithium-ions in batteries. However, because of the larger ionic radii, new electrode materials are required to guarantee, e.g., high energy densities, a fast ion (de)intercalation, and a robust long-term operation. In this context, many recent studies indicate the potassium titanyl phosphate (KTiOPO$_4$, KTP) family as a promising electrode in alkali-ion batteries [1-4].

Here, we investigate the suitability of RbTiPO$_4$F as a cathode for Rb-ion batteries using density functional theory (DFT). Particular attention is paid to the average voltages and the volume shrinkage caused by the deintercalation of Rb atoms from the crystal.

KFM 6.18 Tue 17:00 P3

Nonlinear optical interactions in confined nanostructures — •ZEESHAN HUSSAIN AMBER[1], KAI JÜRGEN SPYCHALA[2], BORIS KOPPITZ[1], LUKAS M ENG[1,3], and MICHAEL RÜSING[1] — [1]Institut für Angewandte Physik, TU Dresden, Nöthnitzer Straße 61, 01187 Dresden, Germany — [2]Department of Physics, University of Paderborn, Warburger Straße 100, 33098 Paderborn, Germany — [3]ct.qmat: Dresden-Würzburg Cluster of Excellence - EXC 2147, TU Dresden, 01062 Dresden, Germany

Nonlinear optical (NLO) micro-spectroscopy is a very power tool for both investigating the material properties and noninvasively visualizing domains and domain walls in ferroelectric materials [1]. Thin film materials are usually supported on substrates leading to interference and reflection related phenomena during -spectroscopy, which make interpretation of experimental results particularly challenging. Here, we report on Second Harmonic (SH) and Third Harmonic (TH) generation experiments on wedge-shaped samples cut out from 5%Mg-doped congruent Lithium niobate single crystals, and compare these findings with numerical [2] and semi-analytical simulations. We find that thin-film interference, reflection and phase matching strongly affect the signal strength in SH/TH generation. The excellent agreement between the simulated and experimental data shows that rigorous theoretical analysis can help identifying genuine material properties through systematically varied sample and setup parameters during NLO analysis.

KFM 6.19 Tue 17:00 P3

Quantitative electrical characterization of conductive ferroelectric domain walls in LiNbO$_3$ — •MANUEL ZAHN[1,2], ELKE BEYREUTHER[1], IULIIA KISELEVA[1], AHMED S. LOTFY[1], MICHAEL RÜSING[1], and LUKAS M. ENG[1,3] — [1]Institut für Angewandte Physik, Technische Universität Dresden, 01187 Dresden — [2]Experimentalphysik V, Zentrum für Elektronische Korrelation und Magnetismus, Universität Augsburg, 86135 Augsburg — [3]ct.qmat: Dresden-Würzburg Cluster of Excellence - EXC 2147, Technische Universität Dresden, 01187 Dresden

Ferroelectric domain wall (DW) conductance can be divided into two separate mechanisms, (a) the injection/ejection of charge carriers across the Schottky barrier formed at the (metal-)electrode-DW junction and (b) the transport of those charge carriers along the DW. Current-voltage (I-U) characteristics recorded at variable temperatures from LiNbO$_3$ DWs are clearly able to differentiate between these two contributions and, moreover, allow us to directly quantify the physical parameters relevant for the two mechanisms (a) and (b) mentioned above. These are, e.g., the resistance of the DW, as well as the saturation current, the ideality factor, and the Schottky barrier height of electrode/DW junction, moreover the activation energies needed to initiate the thermally activated hopping transport along DWs. We will show that this electronic transport along LiNbO$_3$ DWs can be elegantly viewed and interpreted in an adapted semiconductor picture based on a double-diode/double-resistor equivalent circuit model.

KFM 6.20 Tue 17:00 P3

The impact of Schottky barriers when electrically contacting conductive domain-walls in lithium niobate single crystals — •IULIIA KISELEVA[1], ULIANA YAKHNEVYCH[2], JULIUS RATZENBERGER[1], MANUEL ZAHN[1,3], ELKE BEYREUTHER[1], MICHAEL RÜSING[1], HOLGER FRITZE[2], and LUKAS M. ENG[1,4] — [1]Institut für Angewandte Physik, TU Dresden, Nöthnitzer Straße 61, 01187 Dresden, Germany — [2]Institut für Energieforschung und Physikalische Technologien, TU Clausthal, Am Stollen 19 B, Goslar, 38640, Germany — [3]Experimentalphysik V, Universität Augsburg — [4]ct.qmat: Dresden-Würzburg Cluster of Excellence - EXC 2147, TU Dresden, 01062 Dresden, Germany

Conductive domain walls (DWs) in lithium niobate are promising constituents for applications in nanoelectronics, due to their high conductance and ability to be created quasi-on-will through high-voltage poling. However, electrically contacting the DWs leads to the formation of a Schottky barrier between the DW and the electrode material. In this work, we study a variety of different factors affecting the electronic transport across the barrier, e.g. the electrode material, the quality of the lithium niobate surface, and the influence of the applied voltages during the DW conductivity-enhancement procedure. It was found that all these factors have a significant influence on the Schottky barrier formation; moreover, the bulk structure of the DWs is also influenced by the interface's state. Our results demonstrate the importance of reproducible sample surface conditions and identifying promising directions for implementing improved DW conductivity.

KFM 6.21 Tue 17:00 P3

Time-resolved reflectivity measurements of Sb2Se3:Bi2Se3 alloys and Sb2S3 as studied by an ultrafast Optical Tester — •RAMON PFEIFFER, MAXIMILIAN MÜLLER, ERIC LENSKER, and MATTHIAS WUTTIG — Institute of Physics (IA), RWTH Aachen University, 52074 Aachen, Germany

Laser-induced crystallization at a wavelength of 658 nm of alloys of Sb2Se3:Bi2Se3 has shown that the minimum crystallization time decreases with increasing Bi2Se3 content. This is, however, also accompanied by a reduction of the reflectance change upon crystallization. For higher Sb2Se3 contents, on the contrary, a slow and stochastic crystallization process was observed. Since Sb2Se3 has a much higher absorption coefficient at shorter wavelength, more efficient switching is expected with a blue laser diode. A similar consideration is made for Sb2S3 where hardly any light is absorbed below wavelength of about 600 nm. As a blue laser setup is much closer to the absorption maximum of Sb2S3, a better energy input is expected. For this reason, in our optical phase change tester, a blue laser diode (405 nm) has been implemented to investigate the materials mentioned above.

KFM 6.22 Tue 17:00 P3

Simulation Study of the Multi-beam Ptychography Optics and Setup Optimization — •TANG LI, MIKHAIL LYUBOMIRSKIY, and MARTIN SEYRICH — Deutsches Elektronen-Synchrotron DESY, Notkestraße 85, 22607 Hamburg, Germany

Ptychography is a robust computational iterative phase retrieval imaging method using overlapping constraints to decouple the probe and object information. It has the ability to obtain nanometer resolution with a small probe size and efficient overlapping. However, for single beam ptychography, it is inefficient beam usage, where almost 99% of the photon flux is wasted, and time-consuming to collect a nanometer resolution dataset with a large field of view (FOV). Therefore, we propose using a developed multi-beam ptychography (MBP) to relax the sample size limitation and scan duration. The feasible FOV scales with the number of parallel beams.

Although, we demonstrate the feasibility of using six coded probes to reconstruct the sample successfully. It is still not clear what is the up limit for the probe number and the least requirements of the difference between the probes that we still can decouple the probe contribution from the diffraction pattern. Hence these boundaries are explored in this work. It focuses on the forward simulation framework using the MBP setup and investigates the influence of different physical parameters, such as probe distance, probe difference, probe number, noise level influence, etc. This work provides a feasible parametric design for MBP optical and experimental setup, and it also opens the way to further development.

KFM 6.23   Tue 17:00   P3

Loss tangent measurements on an extremely large diamond disc for Brewster angle windows — •Andreas Meier[1], Gaetano Aiello[1], Theo Scherer[1], Sabine Schreck[1], Dirk Strauss[1], Christoph Wild[2], and Eckhard Wörner[2] — [1]Karlsruhe Institute of Technology, Hermann-von-Helmholtz-Platz 1, 76344 Eggenstein-Leopoldshafen, Germany — [2]Diamond Materials GmbH, Hans-Bunte-Straße 19, 79108 Freiburg, Germany

Advanced Electron Cyclotron heating systems for future fusion reactors, such as DEMO, are designed for multi-frequency operation. The favored output window concept of the high power microwave beam is the brewster angle setup, but it requires a disc diameter of 180 mm for the 67.2° angle and the 63.5 mm waveguide. In addition, a thickness of approximately 2 mm is needed to achieve the proper mechanical stability. State of the art microwave plasma reactors are not capable of growing discs of such a size. The maximum available diameter of a polycrystalline CVD diamond disc suited to microwave applications is currently 140 mm.

An extremely large diamond disc with a diameter of 180 mm for RF transmission application was produced by the industrial partner Diamond Materials GmbH. High-resolution loss tangent measurements for several areas of this disc have been realized by using a spherical resonator.

KFM 6.24   Tue 17:00   P3

Analysis of Structural Materials with Coincident Doppler Broadening Spectroscopy Using New Evaluation Software — •Leon Chryssos, Vassily Burwitz, and Christoph Hugenschmidt — Heinz Maier-Leibnitz Zentrum (MLZ), Technical University of Munich, Lichtenbergstr. 1, Garching, Germany

Coincident Doppler Broadening Spectroscopy (CDBS) of the 511 keV electron positron annihilation line not only provides defect sensitive studies of materials, but also elemental signatures at the positron annihilation site. This enables the analysis of foreign atoms in the host matrix, vacancy-solute complexes and precipitates in solids. Using a new data analysis software several structural materials were evaluated at the recently upgraded CDB spectrometer at the NEutron induced POsitron source MUniCh (NEPOMUC). The most important features of the software will be explained. The functionality of the experiment and analysis software will be evaluated using several structural materials including AlCu alloys and W single crystals.

KFM 6.25   Tue 17:00   P3

Improved thermoelectric properties of SnSe through forming a phase employing metavalent bonding — •Nan Lin, Yuan Yu, Tanmoy Ghosh, and Matthias Wuttig — I. Physikalisches Institut (IA), RWTH Aachen University

SnSe only shows high ZT values above 750 K when the structure transforms from the asymmetrical Pnma phase to the higher symmetrical Cmcm phase. As a typical IV-VI compound bonded by p-state electrons, the Cmcm phase SnSe with an improved symmetry is expected to show the same chemical bonding with other rock-salt IV-VI compounds, which could be responsible for its excellent thermoelectric performance. Yet, it is challenging to stabilize the Cmcm phase at room temperature to characterize the bonding indicators. We successfully obtained the high-symmetry rock-salt SnSe phase by growing (SnSe)0.67(AgSbTe2)0.33 (SnSe)0.67(AgBiTe2)0.33, (SnSe)0.67(AgBiSe2)0.33, and (SnSe)0.5(AgSbSe2)0.5 alloys in a Bridgman oven. All cubic SnSe alloys show a unique portfolio of properties including a high optical dielectric constant, a large Born effective charge, and abnormal bond-breaking behavior in laser assisted atom probe tomography. All these characteristics are indicative of the metavalent bonding mechanism while are not found in the pristine SnSe. Concomitantly, zT increases from near 0.1 for the Pnma SnSe to about 1.0 for all the Fm -3m SnSe phases. Our work demonstrates that metavalent bonding could be the origin of many special properties of SnSe including the excellent thermoelectric performance.

KFM 6.26   Tue 17:00   P3

Highly-ordered Ni nanoarrays as an effect current collector for dendrite-free sodium metal batteries — •Mo Sha, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Sodium metal batteries (SMBs) are attracting extensive attention for energy storage field due to its intrinsic high theoretical capacity and low redox potential, as well as its low cost and broad sources. Nevertheless, the inevitable side reactions and uncontrollable dendrite growth block its practical application. 3D confinement strategy demonstrates great potential for stabilizing the Na anode owing to its optimized ion/electron transportation, lower deposition overpotential, and structural stability. A technique via anodized alumina oxide (AAO) templates s is an advanced preparation technique to fabricate various 3D nanostructures. Here, a 3D Ni nano-arrays nanostructure was fabricated with highly-ordered structure, which provides a greater specific surface area, reduces local current density and inhibits of Na dendrite formation. Due to the unique 3D nanostructure, dendrite-free Na deposition and superior electrochemical performance improvements in SMBs have been realized.

KFM 6.27   Tue 17:00   P3

Local control of ferromagnetic domain patterns via structural ordering — •Ahmed Samir Lotfy, Lukas Kuerten, Yooun Heo, Elzbieta Gradauskaite, Morgan Trassin, and Manfred Fiebig — Department of materials, ETH Zürich, Zürich, Switzerland

Controlling domain patterns is closely linked to device functionalities in logic applications. However, the means to engineer domain locations are scarce so far, limiting this functionality. The recent utilization of substrate topography to pre-define the ferroelectric domain patterns by engineering the substrate step spacing via different miscut angles motivates our investigation for a similar control mechanism over ferromagnetic domain patterns. Neodymium gallate (NGO) is our substrate of choice because it is the only oxide among the lanthanide gallates with no structural phase transitions in a very extended temperature range (12-1773K). Therefore, $La_{0.7}Sr_{0.3}MnO_3$ (LSMO) films grown on NGO substrates exhibiting substrate steps were also investigated for such a correlation between the substrate topography and the ferromagnetic domain patterns in LSMO. Strikingly our results show an identical domain pattern to the substrate steps. This correlation might result from the ferroelastic nature of LSMO and could be utilized for ultrahigh-density memory devices.

KFM 6.28   Tue 17:00   P3

How to employ advanced innovation tools to advance soft X-ray nanolithography — •Andreas Späth — Institut für Nanotechnologie und korrelative Mikroskopie (INAM) gGmbH, 91301 Forchheim, Germany — Physikalische Chemie II, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

The Theory of Inventive Problem Solving is becoming increasingly significant in technical engineering and design. The present work illustrates the potential of its most common tools to advance instrumentation in soft X-ray microscopy and nanolithography. The initial setup designed for Focused X-ray Beam Induced Deposition is analyzed in-depth by function modelling to identify harmful or defective interactions between components. These problematic interactions are tracked back to root causes by cause-effect chain analysis. Root causes are often disguised technical or physical contradictions. TRIZ employs abstract innovation principles to solve such contradictions after they are categorized based on the nature of conflicting parameters. Another approach is to transfer harmful/defective interactions into a substance-field model of the problem that can be addressed by suitable substance-field models of potential solutions. The analysis yielded ideas for a significantly improved FXBID setup. The project benefited from funding by DFG (grant SP 1775/1-1).

KFM 6.29   Tue 17:00   P3

X-ray near-edge absorption spectroscopy and X-ray diffraction on thin Al-CrVYN films — •Eric Schneider[1], Nicola Thiering[1], Michael Paulus[1], Finn Ontrup[2], Nelson Filipe Lopes Dias[2], and David Kokalj[2] — [1]Fakultät Physik/DELTA TU Dortmund, 44221 Dortmund, Deutschland — [2]Fakultät Maschinenbau TU Dortmund, Dortmund, Deutschland

In materials science tool coatings are optimized for use at elevated process temperatures. AlCrVYN thin films are promising candidates in this area, as vanadium can form so called Magnéli phases, which reduce the coefficient of friction. The aim of this project is to gain a fundamental understanding of the dependence between deposition parameters, layer structure and oxidation behavior of AlCrVYN coatings. For this purpose, the coating systems were deposited on a WC-Co composite substrate by a hybrid procedure of DC sputtering and high-energy pulse magnetron sputtering (HiPIMS). In addition, different cathode-target combinations will be tested to determine their influence on the structure of the thin films. For the investigation of the samples we used synchrotron radiation at beamline BL9 and BL10 of the synchrotron radiation source DELTA (Dortmund, Germany) to perform XRD and XANES measurements. The samples were annealed ex situ in an oven to temperatures up to 1000°C to study their oxidation behavior. Depending on the process parameters, different oxidation behaviour and residual stresses present in the samples were observed. We thank DELTA for providing synchrotron radiation. This work was supported by the DFG via TO 169/21-1.

KFM 6.30   Tue 17:00   P3

Combine circular economy with analytical facilities, instruments and know-how — •Eric Hirschmann, Maik Butterling, Maciej Oskar Liedke, Ahmed Gamal Attallah, and Andreas Wagner — Zentrum Dresden-Rossendorf, Dresden, Germany

As part of the ReMade@ARI (REcyclable MAterials DEvelopment at Analytical Reserach Infrastructures) project of the Horizon Europe program, we present the Positron Research Infrastructure (pELBE) at the ELBE linear accelerator of the HZDR. PELBE is a collection of methods and instruments that can characterize defects, determine open volumes and investigate open or closed microporous systems using positron annihilation spectroscopy. The ReMade@ARI project is committed to foster the development of innovative, sustainable materials for key components in a wide range of sectors including electronics, batteries, vehicles, construction, packaging, plastics, textiles and food. The project aims to simplify

the use of large-scale research facilities at HZDR or other European sites for both academic and industrial players in the circular economy. The poster will provide a closer look at the outline of the project as well as the positron research infrastructure (pELBE) at HZDR.

KFM 6.31   Tue 17:00   P3

Growth and characterization of $Ni_{37}Co_{13}Mn_{33}Ti_{17}$ single crystals — •David Koch[1], Benedikt Beckmann[1], Gavin Vaughan[2], Oliver Gutfleisch[1], and Wolfgang Donner[1] — [1]Intitute of Material Science, Darmstadt, Germany — [2]European Synchrotron Radiation Facility, Grenoble, France

Since 2015 the „all-d-Heusler"material Ni(Co)MnTi is object of interest due to its magneto-functional applications linked to a martensitic phase transition, like solid state cooling and magnetic shape memory effect. Nevertheless, for many characterization methods single crystals are necessary but not reported in literature so far. Here we report on the growth and preparation of $Ni_{37}Co_{13}Mn_{33}Ti_{17}$ single crystals based on anomalous grain growth. The resulting single crystals are several mm in size, can be used for various experiments and show a reversible martensic phase transition around 200 K. Here, the samples are characterized using magnetometry and various laboratory single crystal diffraction experiments. In addition, we use high energy synchrotron experiments to improve the dynamic intensity range and to reconstruct the whole reciprocal space.

KFM 6.32   Tue 17:00   P3

Metavalent Bonding empowers the High Thermoelectric Performance in Bi2Te3-based Alloys — •Yinghao Tao — I.Physikalisches Institut of RWTH Aachen

Bi-Te-based alloys show outstanding thermoelectric performance near room temperature due to the large Seebeck coefficient, high electrical conductivity, and low thermal conductivity. Even though the excellent properties of these alloys have been recognised for decades, the origin of these favorable characteristics has not been fully revealed. Very recently, a special combination of properties has been found in group IV-VI and V2-VI3 compounds due to an unconventional bonding mechanism, coined metavalent bonding (MVB). Bi2Te3-based alloys also utilize MVB. This raises the question of whether the excellent thermoelectric performance stems from the MVB. In this work, we have prepared single-crystal BixSb1-xTe3 (x=0.5, 0.6, 0.7) samples by Bridgman oven and then measured the transport properties by thermal transport option (TTO) in PPMS. We have also measured the optical properties and the bond-breaking behavior of these compounds using Fourier-transform infrared spectroscopy (FTIR) and atom probe tomography, respectively. These methods prove the metavalent bonding nature in these compounds. Finally, we relate the favorable transport properties to the close relationship between chemical bonding and the electronic band structure. Metavalent compounds are characterized by a large valley degeneracy, a small band effective mass, and strong phonon anharmonicity. All of these attributes lead to high thermoelectric performance.

KFM 6.33   Tue 17:00   P3

First X-ray diffraction measurement from high pressure hydrostatic cells for X-ray scattering applications — •Kevin Lehninger, Eric Schneider, Jaqueline Savelkouls, Michael Paulus, and Christian Sternemann — Fakultät Physik/DELTA, Technische Universität Dortmund, 44221 Dortmund, Germany

Small-angle and wide-angle X-ray scattering (SAXS/WAXS) at moderate pressures are of increasing importance for the investigation of e.g. protein denaturation or stimulus-responsive materials. One of the experimental challenges is the precise pressure control in the pressure range up to 10 kbar while separating the sample volume from the pressure-transmitting medium. To this end, we present two dedicated hydrostatic high pressure cells designed for use at the beamlines BL2 and BL9 of the synchrotron radiation source DELTA, which use water for pressure transmission, and show first measured diffratograms of gold and potassium bromide. The WAXS cell with an opening angle of 60 degrees allows a sample volume with a cross-sectional area of one square millimetre to be exposed to a maximum pressure of 5000 bar. The sample volume is enclosed in a flexible capillary tube capillary tube, which is located between two diamond windows and can have a maximum diameter of 1.5 mm. The SAXS cell can be operated up to a pressure of 10kbar and an opening angle of 20 degrees. Here, the sample volume is contained in a cylinder sealed with polyimide film which is screwed into the high-pressure cell via a sliding system.

KFM 6.34   Tue 17:00   P3

Optical and Spin Properties of NV Center Ensembles in Diamond Nano-Pillars — •Ksenia Volkova[1], Julia Heupel[2], Sergei Trofimov[1], Fridtjof Betz[3], Rémi Colom[3], Rowan W. MacQueen[1], Sapida Akhundzada[4], Meike Reginka[4], Arno Ehresmann[4], Johann Peter Reithmaier[2], Sven Burger[3], Cyril Popov[2], and Boris Naydenov[1] — [1]ASPIN, Helmholtz-Zentrum Berlin, Germany — [2]INA, CINSaT, University of Kassel, Kassel, Germany — [3]Zuse Institute Berlin, Berlin, Germany — [4]IP, CINSaT, University of Kassel, Kassel, Germany

Nitrogen-vacancy (NV) centers in diamond integrated in nano-pillars could be used as tips for scanning probe for magnetic field imaging with high sensitiv-ity and nano-scale spatial resolution. We present the fabrication of diamond nano-pillars with diameters up to 1000 nm in type Ib diamonds with two crystal orientations [100] and [111] using electron beam lithography and inductively coupled plasma reactive ion etching. The NV centers ensembles were created by 6 keV-He ion bombardment and subsequent annealing. Estimated numbers of NVs per pillar to be 4300 ± 300 and 520 ± 120 for the [100] and [111] samples, respectively. Lifetime measurements of the NV's excited state showed two time constants with average values of $\tau_1 \approx 2$ ns and $\tau_2 \approx 8$ ns, which are shorter than a single NV center in a bulk crystal. This is probably due to interaction with defects created by the helium ion bombardment and substitutional nitrogen. Optically detected magnetic resonance contrast was about 5% and average coherence times are T_2 [100] = 420 ± 40 ns, T_2 [111] = 560 ± 50 ns.

KFM 6.35   Tue 17:00   P3

High-speed domain wall imaging using broadband coherent anti-Stokes Raman scattering — •Robin Buschbeck[1], Franz Hempel[1], Sven Reitzig[1], Julius Ratzenberger[1], Lukas König[1], Peter Andrew Hegarty[1], Zeeshan Hussain Amber[1], Michael Rüsing[1], and Lukas Eng[1,2] — [1]Institut für Angewandte Physik, TU Dresden, Nöthnitzer Straße 61, 01187 Dresden, Germany — [2]ct.qmat: Dresden-Würzburg Cluster of Excellence - EXC 2147, TU Dresden, 01062 Dresden, Germany

Spontaneous Raman spectroscopy (SR) is a broadly used and versatile method for the analysis of structures in crystalline materials, such as strain distributions or ferroelectric domain walls. A large disadvantage of this technique are the high acquisition times of up to several seconds per data point to visualize these structures. In this work, we demonstrate the use of a promising alternative, broadband coherent anti-Stokes Raman scattering (B-CARS) and compare this technique with SR at the example of poled Lithium niobate. We demonstrate a more than resulting in a 100 times higher signal-to noise ratio, while maintaining similar intensities. These results promise the use of B-CARS for high-speed spectral imaging in the context of solid-state materials, such as ferroelectrics and their domain walls.

KFM 6.36   Tue 17:00   P3

Low Temperature combined Confocal/AFM microscope for photoluminescence and magnetic resonance experiments — •Elizaveta Starykh, Michael Dotan, and Boris Naydenov — Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany

Measuring small magnetic fields emanating from spins or magnetic nanoparticles, both with high spectral resolution and under diverse conditions has always been an ambitious task. Nanoscale magnetic imaging using nitrogen-vacancy (NV) colour centres in diamond has been proven to be a reliable method due to their unique properties and ability to be effectively manipulated by external magnetic fields. With laser light, it is possible to both initialize and read out the NV spin state, thereby non-destructively determining the magnetic profile of the sample.

With recent developments in technology, it is now possible to fabricate single NVs on the tip of an AFM cantilever and measure a magnetic field map from a sample. Due to the NVs' high sensitivity and susceptibility to the external environment, precise control of many parameters must be observed.

To combine different techniques to perform such complex experiments, we built a confocal setup on top of a attoCUBE closed-cycle cryogenic system. With optical access at the top, microwave and radio frequency control, AFM cantilever and separate temperature control for magnets and sample volume, we can now access a wide range of physical properties of solid-state materials.

KFM 6.37   Tue 17:00   P3

Interatomic Potential for Laser-Excited NV-Centers in Diamond — •Malwin Xibraku, Bernd Bauerhenne, and Martin E. Garcia — Universität Kassel, Heinrich-Plett-Straße 40, 34132 Kassel, Germany

Nitrogen-vacancy-centers (NV-centers) are of interest for quantum computing, sensing and encryption. However, the fabrication of NV-centers is quite challenging. Recently, we have proposed a new fabrication method in which N atoms and vacancies far from each other find each other after femtosecond laser excitation. We simulated this method in a diamond bulk cell, consisting of 288 atoms, using density-functional-theory (DFT) and observed, that it works at very high laser excitations. To include surface effects and consider the electron-phonon coupling it is necessary to perform large-scale moleculardynamics-simulations, with millions of atoms. This is only possible using an interatomic potential, which respects the excitation of the electrons by considering the electronic temperature Te. Here, we present a Te-dependent interatomic potential for laser-excited NV-centers in diamond, which was developed from a large DFT-data set, widely covering the phase space of the system.

KFM 6.38   Tue 17:00   P3

Combined Confocal-AFM setup — •Sergei Trofimov, Klaus Lips, and Boris Naydenov — BerlinJoint EPR Laboratory and Department Spins in Energy Conversion and Quantum Information Science (ASPIN), Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany

Single nitrogen-vacancy (NV) centers in diamond can be utilized for magnetic field sensing with high spatial resolution and high sensitivity. It is even possible to detect spin ensembles or magnetic nanoparticles if they are placed in the vicinity of an NV center. However, precise positioning of such structures is challenging. To tackle this problem AFM cantilevers can be utilized. One can move nanoparticles with a cantilever or attach them to it in order to bring them close to an NV center.

To conduct these experiments a Confocal-AFM setup based on a Park Systems NX12 AFM was built. This setup allows to place a cantilever in the vicinity of an NV center in a diamond sample using a moving sample stage and obtain luminescence maps with laser scanning technique using a set of galvo-mirrors.

To test the setup a diamond plate with NV centers was used to visualize magnetic field lines of a ferromagnetic cantilever. It was shown that the technique can be also applied to image and separately address NV centers that are as close as 10 nm apart. The maximum measured magnetic field strength was 146 ± 2 G when an NV center was 180 ± 10 nm away from the cantilever. A magnetic field gradient at this distance was estimated to be 0.3 G/nm.

KFM 6.39   Tue 17:00   P3
Investigation of ferroelectricity in $BaTiO_3$-relaxors by PFM — •PHILIPP MÜNZER[1], MARKUS KRATZER[1], CHRISTIAN MAIER[3], KLAUS REICHMANN[3], MARCO DELUCA[2], and CHRISTIAN TEICHERT[1] — [1]Institute of Physics, Montanuniversität Leoben, Leoben, Austria
— [2]Materials Center Leoben, Leoben, Austria
— [3]Institute for Chemistry and Technology of Materials, Graz, Austria

$BaTiO_3$ relaxor systems are promising materials for energy storage applications in microelectronic devices. These lead-free dielectrics are thermally stable and suitable for high-temperature operation due to their broad and high permittivity response and low electric coercivity. The relaxor behaviour can be achieved by homo- or heterovalent substitution of Ti^{4+} ions in the perovskite cell, which disrupts the long-range ferroelectric order. We investigated the presence of ferroelectricity in homovalent (Zr^{4+}) and heterovalent (Nb^{5+}) substituted polycrystalline $BaTiO_3$ systems utilizing Piezoresponse Force Microscopy (PFM). We used Single-Frequency-PFM to image the domain structure of the relaxors and conducted polarization switching with a biased tip. Furthermore, local hysteresis loops were recorded utilizing Switching-Spectroscopy-PFM. The results indicate that the grade of ferroelectric disruption is strongly dependent on the amount and type of substitutes.

KFM 6.40   Tue 17:00   P3
Synthesis of depth confined nitrogen vacancy centers in diamond — •KAROLINA SCHÜLE[1], CHRISTOPH FINDLER[1,2], JOHANNES LANG[1,2], and FEDOR JELEZKO[1,3] — [1]Institute for Quantum Optics, Ulm University, Ulm, Germany — [2]Diatope GmbH, Ummendorf, Germany — [3]Center for Integrated Quantum Science and Technology (IQST), Ulm

The negatively charged nitrogen-vacancy center (NV) is a paramagnetic defect (S=1) in diamond which shows coherence times T2 up to milliseconds even at room temperature. The NV is a promising candidate for quantum applications as its spin state can be initialized, read out optically, and manipulated by a microwave field. One way to fabricate NV centers is ion implantation where nitrogen is added into a single crystal diamond layer followed by an annealing process. The depth of the implanted nitrogen can be adjusted by the implantation energy. Larger kinetic energies are leading to deeper NV centers. At the same time, however, the depth distribution gets also broader limiting the degree of depth confinement. This contradicts the goal of homogeneous properties of the NVs beneficial for e.g. NMR applications. Using the method of indirect overgrowth, where implanted nitrogen is buried below a nanometer-thin capping layer of diamond. The resulting depth of the NV centers is decoupled from the implantation ion energy. Here, we show outstanding depth confinement resulting in single NVs which are located at a depth of around 20 nm confined in a range of approx. 1.4 nm. These NV centers are exhibiting a T2 up to ~100 μs.

KFM 6.41   Tue 17:00   P3
Multiphoton imaging of ferroelectric domain structures by means of tunable, high energy fs-pulses — •FIETE BREER[1], FELIX KODDE[1], LAURA VITTADELLO[1], JAN KLENEN[1], MICHAEL RUESING[2], and MIRCO IMLAU[1] — [1]Inst. Physics, Barbarastr. 7, Osnabrück Univ. — [2]Inst. Applied Physics, Nöthnitzer Str. 61, Techn. Univ. Dresden

Multiphoton imaging is a powerful tool for the analysis of polar oxide crystals and has been recently used to reveal previously not expected topologies present in ferroelectric domain walls [https://arxiv.org/abs/2207.01307]. In addition to non-linear optical effects, the system-specific parameters of the optical measuring arrangement in the microscope also determines the detected measurement signals. This includes, for example, the collimation of the infrared excitation light, the direction between excitation and detection, but also the apertures in the beam path of the confocal beam geometry and, therefore, require careful consideration when interpreting experimental results. In this work a Tunable hIGh EneRgy (TIGER) multiphoton microscope [Vittadello et al., Nanomaterials 11, 3193 (2021)] pumped by high energy fs-laser pulses from an optical parametric

amplifier allowing for widefield SHG is used to study ferroelectric domain structures. The results are comparatively evaluated for different measurement setups, discussed and possible consequences for the interpretation of the origin of the SHG signal from widefield and scanning modes are presented. Funded by the DFG (project IM 37/12-1, FOR 5044 and RU 2474/1-1).

KFM 6.42   Tue 17:00   P3
Small-polaron dynamics in lithium niobate tantalate solid solutions studied by means of fs-pump, cw-probe spectroscopy — •NIKLAS DÖMER[1], ANTON PFANNSTIEL[1], MIRCO IMLAU[1], and STEFFEN GANSCHOW[2] — [1]Inst. Physics, Barbarastr. 7, Osnabrück Univ. — [2]Leibniz-Institut für Kristallzüchtung (IKZ), Berlin

The inspection of transport and recombination dynamics of optically generated small polarons with strong coupling enables far-reaching insight into the electronic and microscopic (defect) structure of polar oxide crystals using macroscopic measures. Here, we use the absorption cross-section of small polarons to relate fs-pulse induced transient absorption with the temporal evolution of small polaron number densities, i.e. with the 3D hopping transport of small polarons within a lattice with intrinsic defect structure. For the first time, fs-pump continuous-wave probe spectroscopy is applied to lithium niobate tantalate (LNT, $LiNb_xTa_{1-x}O_3$ with 0≤x≤1) solid solutions. Remarkably, a two-step decay with lifetimes in the order of microseconds and minutes is uncovered, which has not been observed in the widely studied edge compositions lithium niobate (LN, x=1) and lithium tantalate (LT, x=0). This finding is studied over the entire composition range (0≤x≤1) at distinct wavelengths according to the maxima of small polaron absorption features. A microscopic model based on the simultaneous presence of two types of intrinsic antisite defect centers, Nb_{Li} and Ta_{Li}, is deduced to explain two different polaron decay channels. Financial support by the DFG (project IM 37/12-1 and GA 2403/7-1, FOR 5044).

KFM 6.43   Tue 17:00   P3
UV-triggered polymerisation of photosensitive resins via harmonic emission of Bariumtitanate nanocrystals — •EUGEN WOLF and MIRCO IMLAU — Institute of Physics, Barbarastr. 7, Osnabrueck University

Ultraviolet-photosensitive resins are important in various industrial applications like laser-based 3D printing or fibre-reinforced polymers. Spatially localized polymerization becomes possible using laser light at photon energies that are adjusted to the absorption features of the corresponding photoinitiator. A drawback of this approach, however, is the transmission loss of the incident UV light, so that it can be applied only for polymerization of surfaces or thin volumes. To overcome this limitation, the use of infrared light in combination with nanoscaled photocatalytic containers in the resin has been proposed. In this contribution, we present an alternative approach based on the use of harmonic nanocrystals, i.e. to convert the incident infrared to the UV region deep inside the resin. For this purpose, commercially available Bariumtitanate nanocrystals and a regneratively amplified fs-laser system are used. Remarkably, a high reproducibility of the polymerization process as a function of the light propagation coordinate is uncovered. Furthermore, our setup allows for the inspection of the dynamics and shape of the liquid-solid phase front for different laser parameters. We discuss our results taking a simplified model for nonlinear optical emission of nanoparticles stochastically distributed in the resin into account.

KFM 6.44   Tue 17:00   P3
Optical damage and hologram recording in as-grown Lithium-Niobate-Tantalate solid solutions — •SÖREN DOMKE[1], BJOERN BOURDON[1], STEFFEN GANSCHOW[2], and MIRCO IMLAU[1] — [1]Institute of Physics, Barbarastr. 7, Osnabrück Univ. — [2]Leibniz-Institut für Kristallzüchtung (IKZ), Berlin

Lithium niobate tantalate (LNT, $LiNb_xTa_{1-x}O_3$ with 0≤x≤1) solid solutions provide a promising material platform for nonlinear-photonics due to the ability for tuning the optical and electrical properties via composition. However, so far, very little is known about the (nonlinear) optical characteristics and intrinsic defect structure of LNT compared to its edge compositions lithium niobate (LN, x=1) and lithium tantalate (LT, x=0). In this respect, the presence of optical damage, i.e. the transient change of the index of refraction by the action of an incident light beam, is of particular importance as it drastically degrades the components' usability, but can also be used for wave-mixing applications. Originally discovered in LN, we report of our observations of a comparable nonlinear optical phenomenon in nominally undoped LNT samples and present the results of our systematic studies using the recording and reconstruction of elementary holographic gratings. As a particular feature of our finding, the phenomenon shows a transient behavior with a lifetime in the order of tens of hours that can only be erased using white light illumination and/or thermal treatment. The results are discussed in the framework of the photorefractive effect and an intrinsic defect model. Financial support by the DFG (projects IM37/12-1, GA 2403/7-1, FOR 5044).

KFM 6.45   Tue 17:00   P3
Laser induced damage threshold (LIDT) of additively manufactured components in photonics — •MORITZ HUESMANN, YANNIC TOSCHKE, and MIRCO IMLAU — Institute of Physics, Osnabrück University, Germany

Nowadays, desktop additive manufacturing technologies, e.g., 3D-printing based on thermoplastics (filaments), are widely available. They are increasingly finding their way into research laboratories in photonics due to the possibility to manufacture optomechanical components, such as versitale optical adapters, optomechanical mounts and sample holders. While the mechanical properties of the thermoplastics have been studied intensively in literature, nearly nothing is known about the laser damage threshold (LIDT) of these materials. Without this knowledge, the use in optical setups is limited to laser beams with moderate to low average power for safety reasons. In the second step, the damage threshold for PLA and PETG of different color was systematically determined under the exposure with intense femtosecond and nanosecond laser pulses. We discuss the determined LIDT values in the framework of applications in photonics, but also analyze the photophysical processes of the laser-induced damages based on a detailed topographic inspection. Financial support by the BMBF within Open Photonik Pro (project 13N15230, optocubes).

KFM 6.46   Tue 17:00   P3

Temperature dependence of the optical band gap of LNT solid solutions (20–330 K) — •T. Hehemann[1], A. Pfannstiel[1], S. Sanna[2], N. Syvorotka[3], K.-D. Becker[4], S. Ganschow[5], and M. Imlau[1] — [1]Inst. Phys., Osnabrück Univ. — [2]Inst. Phys., Univ. Giessen — [3]Inst. Energy Res., TU Clausthal — [4]Inst. Phys. Theo. Chem., TU Braunschweig — [5]Leibniz-Inst. f. Kristallzüchtung, Berlin

Lithium niobate tantalate solid solutions (LNT, $LiNb_xTa_{1-x}O_3$ with $0 \leq x \leq 1$) represent a promising class of polar oxide materials for photonics due to their favourable linear & nonlinear optical, but also photoelectrical properties. A mandatory basic requirement for customised optical applications is the (precise) knowledge of the optical band edge energy E_{gap}^{opt}. While E_{gap}^{opt} and its relation to the intrinsic defect structure has been well investigated for the edge compositions $LiNbO_3$ (LN, x=1) and $LiTaO_3$ (LT, x=0), nearly nothing is reported for LNT in literature, so far. In particular, there are no data available for the important low temperature region 20–330 K. We here present temperature dependent absorption spectra of LNT in the vicinity of the optical band edge covering the entire composition range ($0 \leq x \leq 1$). The analysis of the data set follows the established fitting routines and reveals, both the composition and temperature dependent shifts of $E_{gap}^{opt}(x, T)$. The former is discussed in the framework of the intrinsic defect structure, while the latter is related with the properties of the electronic structure. All findings are compared with respective shifts widely reported for LN and LT. Financial support by the DFG (projects IM 37/12-1, SA 1948/3-1, FR 1301/40-1, GA 2403/7-1 of the FOR 5044)

KFM 7: Focus: High-resolution Lithography and 3D Patterning

While high-resolution 2D lithography and structuring is relatively matured and also widely applied in industrial processes, work on its 3D variant is mostly focusing on fundamental aspects and process development. At the lower edge of possible 3D feature dimensions, certainly methods such as focused electron beam induced deposition (FEBID), non-linear multi-photon-laser lithography and thermal scanning probe lithography techniques are required. This session will discuss most of these dedicated 3D methods in detail. For the fabrication of complex 2D and 2.5D patterns, advanced electron beam and X-ray methods are continuously developed further. In addition, new methods such as high resolution Talbot lithography for relatively large areas are already entering industrial maturity. This session will also discuss some of the latest developments in this field of binary lithography.

Chair: Dr. Frank Heyroth (Martin-Luther-Universität Halle)

Time: Wednesday 9:00–12:35   Location: POT 51

Invited Talk   KFM 7.1   Wed 9:00   POT 51

Novel device integration – combining bottom-up and topdown approaches — •Artur Erbe — Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — TU Dresden, Germany

Scaling electronic devices to smallest structure sizes well below 10nm will require novel developments for the fabrication of single components. Smallest functional devices can be assembled using chemical methods leading to, e.g., single molecules with electronic functionalities. Reliable contacting of single molecules using metallic contacts is, however, an extremely challenging task that has not been solved so far. We have therefore developed techniques that use self-assembly to create conducting nanostructures to create small, self-assembled circuits that can then be contacted reliably using standard lithographic methods. In this talk, we will show how DNA Origamis can be used for the self-assembly of metallic nanowires, which are contacted using electron beam lithography and electrically characterized. Self-assembly can be used to integrate semiconducting nanoparticles or single molecules for building nanodevices. Further integration of such nanostructures into standard silicon electronics may for example be achieved by connecting these nanodevices to silicon nanowires or transistors based on 2-dimensional materials. We have therefore developed reconfigurable transistors based on these materials using electron beam lithography and further processing (i.e. using a classical top-down approach), which are reconfigurable. With the combination of these transistors with self-assembled nanostructures, a large variety of electronic nanocircuits can be constructed in future applications.

KFM 7.2   Wed 9:30   POT 51

Optical properties of photoresists for femtosecond 3D printing: Refractive index, extinction, luminescence - dose dependence, aging, heat treatment and comparison between 1-photon and 2-photon exposure — •Michael Schmid, Dominik Ludescher, and Harald Giessen — 4th Physics Institute and Research Center SCoPE, University of Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany

Femtosecond 3D printing has emerged as an important technology for manufacturing nano- and microscopic optical devices and elements. Detailed knowledge of the dispersion in the visible and near-infrared spectral range is crucial for the design of these optical elements. Here, we provide refractive index measurements for different UV-doses, aging times, heat treatment and 2-photon exposed structures for the photoresists IP-S, IP-Dip, IP-L, OrmoComp, IP-Visio, and IP-n162. We use a modified and automized Pulfrich refractometer setup, utilizing

critical angles of total internal reflection with an accuracy of 5*10^-4 in the visible and near-infrared spectral range. We compare Cauchy and Sellmeier fits to the dispersion curves and also give Abbe numbers and Schott Catalog numbers of the almost entirely polymerized resists. Additionally, we provide quantitative extinction and luminescence measurements for all photoresists.

KFM 7.3   Wed 9:50   POT 51

3D direct laser writing of miniature optical apertures with highly absorptive photoresist — •Michael Schmid[1,2], Andrea Toulouse[2,3], Simon Thiele[2,3,4], Simon Mangold[1,2], Alois Herkommer[2,3], and Harald Giessen[1,2] — [1]4th Physics Institute, University of Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany — [2]Research Center SCoPE, University of Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany — [3]Institute of Applied Optics (ITO), University of Stuttgart, Pfaffenwaldring 9, 70569 Stuttgart, Germany — [4]Printoptix GmbH, Johannesstraße 11, 70176 Stuttgart

In recent years, 3D direct laser writing and its possible application developed rapidly. Different complex micro-optical systems have been demonstrated, such as multi-lens objectives. However, it is still challenging to integrate microscopic apertures to these systems. We present a novel approach to create 3D direct laser written apertures using an opaque material suitable for 2-photon lithography. This way, it is possible to integrate microscopic apertures into 3D printed micro-optical systems improving the imaging quality. We demonstrate this potential by combining 3D printed black apertures with singlet lenses made of the commonly used photoresist IP-S. A significant contrast improvement of the imaging is achieved. Furthermore, due to the absorption coefficient, it is possible to create thin lenses with the black material enabling the fabrication of optical lens and aperture in one step.

Self-Folding micro cubes of laser-cut templates — •Pierre Lorenz[1], Ye Yu[2], Ronald Franz[3], Joachim Zajadacz[1], Martin Ehrhardt[1], Robert Kirchner[2], Gregory Lecrivain[3], and Klaus Zimmer[1] — [1]Leibniz Institute of Surface Engineering, Permoserstr. 15, Leipzig, 04318, Germany — [2]Institute of Semiconductor and Microsystems, TU Dresden, Nöthnitzer Straße 64, Dresden, 01187, Germany — [3]Helmholtz-Zentrum Dresden-Rossendorf, Institut für Fluiddynamik, Bautzner Landstraße 400, Dresden, 01328, Germany

3D microstructures exhibit manifold applications with compact system integration in mind. Especially self-folding processes of laser-cut 2D templates allow for

fast, flexible, and cost-effective fabrication of 3D structures. A UV ps laser was used for the laser cut of polyimide foil-based 2D templates. Two different folding concepts were tested: water-droplet self-folding and vacuum micro forming (VMF). The VMF concept is based on an array of cavities in a Teflon plate, which work similarly to deep drawing as a guide for the VMF of the 2D templates. In the water-droplet concept, a water droplet was added by a tweezer with a defined volume resulting in self-folding due to the surface tension. Both concepts allow the well-defined folding of sub-mm cubes after optimization of the 2D template geometry. Especially the VMF allows a parallelization and miniaturization of the folding process, which was monitored and analyzed by high-speed imaging.

High resolution and process stability tests on new HSQ based resists — •Nicolas Kunzfeld and Axel Rudzinski — Raith GmbH, Konrad-Adenauer-Allee 8, 44263 Dortmund, Germany

Many new resist providers for hydrogen silsesquioxane (HSQ) based high resolution e-Beam-resist emerged on the market in the last few years.

Until now, the experience with these new resists regarding resolution capabilities, process stability and long term behaviour is very limited.

To expand the experience with these resist, further testing based on statistical methods like a process capability evaluation based on the CpK-Value is required.

This work presents the latest high resolution, process capability and long term stability tests of these HSQ-based resists provided by different resist suppliers.

We achieved isolated single pixel lines with sub 6 nm line width with a CpK-Value of 1 and were also able to get a first impression about the resist behaviour over a time frame of almost 30 days.

4D meso-scale electronics for next generation medical tools and electronic skins — •Daniil Karnauschenko — Research Center MAIN, Technical University Chemnitz, Rosenbergstr. 6, 09126 Chemnitz, Germany

State-of-art mesoscale systems for IoT, e-skins or smart-dust applications, medical or commercial products are essentially 3D architectures, whose geometry plays vital role when providing communication, sensing, actuation and power management functions. Conventional components carrying electronic functions are static, functionally heterogeneous and spatially separated requiring nontrivial sequential assembly and packaging procedures, which hinder further miniaturization and development of next generation mesoscale systems. 3D self-assembled architectures are envisioned to become a driving force for 3D electronic devices designed, microfabricated and self-assembled from planar thin-film structures and self-organized electronic components. Dynamic (4D) parallel assembly operating at mesoscale (1 um - 1 mm) allows offers improved performance while reducing overall manufacturing complexity of devices and components by harnessing the relative ease in which it can produce mesoscopic 3D geometries i.e. origami folded structures and "Swiss-roll" architectures. These architectures and benefits will lead to tighter a system integration e.g. electronic skins and medical tools made out of electronic components including active matrix, capacitors, power sources, coils, sensors, actuators and antennas with reduced costs fabricated from a single wafer.

KFM 7.7   Wed 11:35   POT 51

Two-Photon Polymerization Lithography Structures Characterized via Raman Spectroscopy and Nanoindentation — •Severin Schweiger[1,2], Tim Schulze[1,2], Peter Reinig[1], Simon Schlipf[3], and Harald Schenk[1,2] — [1]Fraunhofer Institute for Photonic Microsystems, Maria-Reiche-Str. 2, Dresden, Germany, 01109 — [2]Brandenburg University of Technology, Platz der Deutschen Einheit 1, Cottbus, Germany, 03046 — [3]Fraunhofer Institute for Ceramic Technologies and Systems, Maria-Reiche-Str. 2, Dresden, Germany, 01109

Additive manufacturing using two-photon polymerization (TPP) lithography has gathered interest in industry and research. Parameter sweeps of cuboid structures fabricated using TPP lithography were investigated to find dependent mechanical material properties across the parameters of the laser power and scan speed. Raman spectroscopy and micro- or nanoindentation were used on the cuboids to find the degree of conversion (DC) of monomer to polymer and the Youngs modulus (E), respectively. The DC and E found for the photoresist IP-Dip was 20 % to 45 % and 1 to 2.1 GPa, respectively. These results were compared to reports found in the literature. The DC and E found for the photoresist IP-Q, was 53 % to 80 % and 0.5 to 1.3 GPa, respectively. The properties found for IP-Q are the current state of knowledge for this photoresist. Many structures fabricated via TPP and based on IP-Q can benefit from this knowledge and the customizability of the material. Examples are evaluated and discussed in the presentation.

Dry film resists: A promising material class for micro-/acoustofluidic chip fabrication — •Andreas Winkler — Group "Acoustic Microsystems", IFW Dresden, Helmholtz str. 20, 01069 Dresden, Germany

Dry film resists (DFRs) promise low-cost and greener microfabrication, and can partly replace conventional technologies for microstructure fabrication being associated with high-energy demands and intense use of toxic and climate-active chemicals. Due to their mechanical stability and superior film thickness homogeneity, DFRs also outperform spin-on resists, such as SU-8, as structural materials, especially when high-resoluted two- and three-dimensional architectures are required such as the case in acoustofluidic chip devices. We investigated various dry film resists in the recent years for their suitability in micro-/acoustofluidic applications. While in general their performance was found to be highly promising and also allowed completely new solutions, properties of commercially available DFRs can vary strongly between individual products and even product charges, and literature on - as well as description of - these materials is still scarce. Here, we introduce this relatively young material class and present selected results regarding technically important effects and limitations, optical properties and performance in acoustofluidic cell separation and aerosol generation.

KFM 7.9   Wed 12:15   POT 51

Artificial Intelligence for high resolution multi-photon lithography — •Julian Hering-Stratemeier[1], Sven Enns[1,2], Nicolas Lang[1], and Georg von Freymann[1,2,3] — [1]Physics Department and State Research Centre OPTIMAS, TUK, 67663 Kaiserslautern, Germany — [2]Opti-Cal GmbH, 67663 Kaiserslautern, Germany — [3]Fraunhofer Institute for Industrial Mathematics ITWM, 67663 Kaiserslautern, Germany

Multi-photon lithography, a.k.a. direct laser writing (DLW), is one of today's most flexible high resolution 3D additive manufacturing technologies. Nevertheless, there are fundamental restrictions, limiting its resolution and structure-conformity: First, the shape of the polymerization-triggering laser focus limits the minimal volume that gets solidified (voxel). Hence, laser focus shape distorting optical aberrations within the beam path worsen the quality of the 3D printed outcome. Second, the physico-chemical properties of the photo resins influence the sharpness and extensions of single voxels, and, therefore, the 3D printed structure quality and resolution as well. Here, we show very first steps (i) towards a fast algorithm for predicting those error-loaded structures. Moreover, we use artificial intelligence (ii) to correct for optical aberrations within the beam path and (iii) to pre-compensate for the photo resin's outcome-worsening properties. Especially correcting aberrations is crucial for, e.g., extending DLW to high resolution STED-inspired DLW which is analogue to the well-known and Nobel price warded STED-microscopy.

KFM 8: Diamond and related dielectric materials

In this session the basics of NV-centers and other defects in diamond were presented. The influence to applications in different fields are obvious. So, there is an influence on dielectric properties of diamond, used e.g. in high power microwave components for fusion applications in the GHz to THz frequency range. Biological diamond applications and applications in quantum photonics are also considered in this field of diamond and related materials.

Optimal Control for Quantum Sensing with NV Centers in Diamond — •Matthias Müller — Forschungszentrum Jülich GmbH

Diamond based quantum technology is a fast emerging field with both scientific and technological importance. The performance relies on unique features like superposition and entanglement and depends on sophisticated mechanisms of control to perform the desired tasks. Quantum Optimal Control (QOC) has proven to be a powerful tool to accomplish this task. I will give a brief overview on the use of QOC for quantum sensing with NV centers in diamond and report on recent applications.

Technical application of CVD Diamond windows in fusion reactor heating systems. — •Peter Späh — KIT, Institute for applied materials, Karlsruhe

The application of CVD diamond windows in fusion experiments often comes along with challenging design requirements. Diamond windows and associated components must be protected properly from harsh environmental conditions. This is particularly the case for the future demonstration power plant reactor (EU DEMO), where sensitive applications shall operate under severe conditions in terms of heat, mechanical loads and radiation.

For the EU DEMO, an EC Heating and Current Drive System (ECH&CD) is under development, where CVD diamond windows together with microwave reflectors (mitre-bends and mirrors), corrugated waveguides, waveguide switches, shutter valves and confinement barrier feed-throughs, will be precisely integrated into a millimetre wave power transmission system. The entire system is installed into massive launching components and reactor building structures. The design takes into account mechanical integrity, dissipation of heat by powerful cooling systems, radiation shielding and the capability to be serviced and maintained by remote handling procedures.

This talk presents the conceptual design and integration of the ECH&CD launching system into the EU DEMO fusion power plant.

KFM 8.4   Wed 15:00   POT 51

Fabrication and Characterization of Thin Single-Crystal Diamond Membranes for Quantum Photonics — •Julia Heupel[1], Maximillian Pallmann[2], Johann P. Reithmaier[1], David Hunger[2], and Cyril Popov[1] — [1]Institute of Nanostructure Technologies and Analytics (INA), University of Kassel, Heinrich-Plett-Str. 40, 34132 Kassel, Germany — [2]Physikalisches Institut, Karlsruher Institute für Technologie (KIT), Wolfgang-Gaede-Str.1, 76131 Karlsruhe, Germany

Due to its exceptional physical and chemical characteristics, single-crystal diamond (SCD) in a form of thin membranes is a promising material for the fabrication of high-quality photonic devices and for envisioned applications in quantum information technologies (QIT). In order to structure SCD membranes with a good quality and thickness of few micrometer or below, it is important to minimize defects originating from polishing (e.g., grooves and pits) or etching procedures (e.g., micro-masking effect). Here we report on the fabrication of thin SCD membranes, exhibiting a low surface roughness down to 0.2 nm by means of inductively coupled plasma reactive ion etching (ICP-RIE). A significant roughness reduction was achieved by using distinct Ar/Cl2 etching recipes as a planarization step before the actual structuring process. These planarized SCD membranes are successfully bonded via van der Waals forces on plane cavity mirrors and optically characterized in a fiber-based Fabry*Pérot microcavity regarding their mode structure and finesse.

Enhanced protein immobilization by nanostructuring of UNCD surface — •Daniel Merker[1], Daniela Bertinetti[2], Rolf Merz[3], Michael Kopnarski[3], Friedrich W. Herberg[2], Johann P. Reithmaier[1], and Cyril Popov[1] — [1]Institute of Nanostructure Technologies and Analytics (INA), Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Germany — [2]Department of Biochemistry, CINSaT, University of Kassel, Germany — [3]Institut für Oberflächen- und Schichtanalytik GmbH, Kaiserslautern, Germany

Investigations of molecular mechanisms related to the formation of the inner clock require detection of coupling factors, e.g. secreted neuropeptides, that mediate synchronization. In this work we study the application of ultrananocrystalline diamond (UNCD) as biosensor for detection of such coupling factors. The crucial part is the feasibility of protein immobilization on UNCD surfaces. From all investigated coupling routs only photochemical attachment of alkenes gave acceptable results when the green fluorescent protein (GFP) was immobilized. A process to create nanostructures was developed to increase the effective surface for protein immobilization. Both functionalization and structuring have beneficial effects on immobilization performance, but especially in combination the immobilization efficacy increases significantly. Lastly, the immobilization of different binding proteins against GFP - antibodies, nanobodies, DARPins - was

investigated, with the last two showing promising results for high specificity and affinity capture of target molecules in a future UNCD biosensor.

Numerical analyses of CVD diamond windows in high power microwave applications — •Gaetano Aiello[1], Andreas Meier[1], Heinrich Peter Laqua[2], Theo Scherer[1], Sabine Schreck[1], and Dirk Strauss[1] — [1]Karlsruhe Institute of Technology, Institute for Applied Materials, 76021 Karlsruhe, Germany — [2]Max Planck Institute for Plasma Physics (IPP), 17491 Greifswald, Germany

Nuclear fusion reactors require electron cyclotron heating and current drive (EC H&CD) systems for plasma heating and stabilization. Chemical vapor deposition (CVD) polycrystalline diamond windows on both the torus and gyrotron sides of the reactors act as confinement and/or vacuum boundaries allowing the transmission of high-power microwave beams. For example, the beam power scenarios of 1.5 MW and 2 MW are the current targets considered respectively in Wendelstein 7-X and European DEMO fusion machines. In this work, with reference to both reactors, the numerical analyses required to verify the thermal and structural performance of the windows are discussed. Experimental measurements of loss tangent in diamond provided inputs for the numerical analyses. Sensitivity studies of the windows with respect to loss tangent and other parameters were also carried out to check the temperature reserve margins of the design.

Simulation study of LC superconducting microresonators for diamond characterization — •Francesco Mazzocchi, Dirk Strauss, and Theo Scherer — Karlsruhe Institute of Technology KIT IAM-AWP, Eggenstein-Leopoldshafen, Germany

The development of high optical quality, ultra-low losses single crystal diamond windows is paramount for the realization of future nuclear fusion facilities like DEMO, given the foresaw increase in power of microwave ECRH systems. Precise determination of the dielectric characteristics (ϵr and tanδ) of these innovative materials have so far relied on techniques involving Fabry-Perot microwave open resonators in various configurations. High Q, superconducting thin film resonators can be effectively used to determine dielectric characteristics of extremely low losses materials like single- and poly-crystalline diamond. Their extremely high-quality factors allow for a substantial increase in resolution in the determination of these parameters when compared to state-of-the-art Fabry Perot open resonators. We hereby report a detailed simulation study of the chosen resonators configurations (Lumped Elements and Circular) that lead to the final design of the devices.

KFM 8.8   Wed 16:35   POT 51

CVD Diamond Disks for ITER ECH windows - dielectric loss characterization and optical inspection — •Sabine Schreck[1], Gaetano Aiello[1], Pablo Estebnez[2], Andreas Meier[1], Theo Scherer[1], Dirk Strauss[1], Christoph Wild[3], and Eckhard Woerner[3] — [1]Karlsruhe Institute of Technology, Institute for Applied Materials, 76021 Karlsruhe, Germany — [2]Fusion for Energy, 08019 Barcelona, Spain — [3]Diamond Materials, 79108 Freiburg, Germany

Diamond disks with a diameter of 70 mm and a thickness of 1.11 mm will be installed into windows of the Electron Cyclotron Heating and Current Drive System (EC-HCD) of the fusion reactor ITER. The bare disks, manufactured by a microwave plasma assisted chemical vapor deposition process, need to ensure high mechanical stability, thermal conductivity and transmission of MW-class microwave beams. Factory acceptance tests of the disks produced by Diamond Materials include a check of dimensional properties and a determination of its dielectric loss. The loss characterization and the comparison with the respective specifications is performed at KIT using dedicated Fabry-Perot resonators, that allow the measurement of the loss tangent at the disk centre and a mapping of it over the disk area. An optical inspection with a digital microscope completes the examination. More than 60 diamond disks need to be qualified prior to their integration into the window assemblies and the application in the ITER EC-system. The disk qualification activities are performed within a contract between F4E and KIT and the talk will present the current status.

KFM 8.9   Wed 16:55   POT 51

CVD Diamond Windows for Electron Cyclotron Resonant Heating in Fusion — •Dirk Strauss, Gaetano Aiello, Andreas Meier, Theo Scherer, and Sabine Schreck — aKarlsruhe Institute of Technology, Institute for Applied Materials, Hermann-von-Helmholtz-Platz 1, 76344 Eggenstein-Leopoldshafen, Germany

Electron cyclotron resonant heating (ECRH) in nuclear fusion combines the injection of multi megawatt power with the possibility to focus the millimeter wave beam to small spot sizes of few centimeters. The ECRH allows efficient plasma heating as well as localized current drive for magneto-hydrodynamic stabilization of e.g. neoclassical tearing modes that create local magnetic islands with a fast loss of plasma confinement. One of the key challenges for high power ECRH systems is the provision of suitable confinement windows.

The low loss tangent, high thermal conductivity and outstanding mechanical properties qualify diamond as the state of the art material for high power millimeter wave heating systems in nuclear fusion devices. Artificial diamond disks are grown by CVD in diameters up to 180mm, sufficient for the usual waveguide diameters.

The principles of ECRH systems will be presented with a focus on the permittivity of diamond, which determines the loss tangent and suitable disk thicknesses. Further concepts and status for small and broadband windows for frequencies of 100-240GHz and beam powers up to 2MW will be discussed.

KFM 9: Microscopy and Tomography with X-ray Photons, Electrons, Ions and Positron

Chair: Prof. Dr. Theo A. Scherer (KIT Karlsruhe)

Time: Wednesday 9:00–13:15   Location: POT 106

FePX$_3$ (X: S, Se): A stable new 2D material for water splitting — •Hafiz Muhammad Zeeshan[1], Sandhya Sharma[1], Elena Voloshina[1,2], and Yuriy Dedkov[1,2] — [1]Centre of Excellence ENSEMBLE3 Sp. z o.o., Wolczynska Str. 133, 01-919 Warsaw, Poland. — [2]Department of Physics, Shanghai University, 99 Shangda Road, 200444 Shanghai, P. R. China.

The interaction of high-quality transition metal trichalcogenides (TMTs) single crystals FePX$_3$ (X: S, Se) with water molecules is studied using NEXAFS and XPS in a wide range of temperature and partial pressure of H$_2$O. The physisorption nature of interaction between H$_2$O and FePX$_3$ is found at low temperatures and relatively small concentrations of water molecules, that is supported by the DFT results. When temperature of the FePX$_3$ samples and partial pressure of H$_2$O are increased, the interaction at the interface is defined by two competing processes - adsorption of molecules at high partial pressure of H$_2$O and desorption of molecules due to the increased surface mobility and physisorption nature of interaction. Our intensive XPS/NEXAFS experiments accompanied by DFT calculations bring new understanding on the interaction of H$_2$O with surface of a new class of 2D materials, TMTs, pointing to their stability and reactivity, that is important for further applications in different areas, like sensing and catalysis.

KFM 9.2   Wed 9:20   POT 106

Solving complex nanostructures with ptychographic atomic electron tomography — •Philipp Pelz — Institute for Micro- and Nanostructure Research, Friedrich-Alexander Universitaet Erlangen, Cauerstr. 3, 91058 Erlangen

Knowledge of the three-dimensional atomic structure of natural and manufactured materials allows us to calculate their physical properties and deduce their function from first principles. Phase-contrast electron microscopy methods like ptychography are ideally suited to solve the 3D atomic structure of nanomaterials containing light and heavy elements. We perform mixed-state electron ptychography from 34.5 million diffraction patterns to reconstruct a high-resolution tilt series of a double wall-carbon nanotube (DW-CNT), encapsulating a complex ZrTe sandwich structure. Class averaging of the resulting reconstructions and subpixel localization of the atomic peaks in the reconstructed volume reveals the complex three-dimensional atomic structure of the core-shell heterostructure with 17 picometer precision.

Optimising the scintillator geometry for positron annihilation spectroscopy - A GEANT4 Simulation — •Dominik Boras — Chair of chemical technology and material synthesis, Würzburg, Germany

To better understand the efficiency and the role of backscattering events of a Positron annihilation lifetime spectrometer, a GEANT4 simulation of the atomic processes is conducted. The gamma quanta from the radioactive decay of 22-Na and from the annihilation positron are detected by a scintillator-photomultiplier combination. In the basic setup of the simulation, as scintillation material plastic

BC422Q- 0.5wt.% was used due to its good energy resolution. Different geometries of the scintillator (box, cone, pyramid and tube) were simulated and their influence on the detection efficiency and the instrument resolution function was investigated. Furthermore, the influence of the measured sample material (density, atomic number) on the scattering of gamma quanta was considered.

KFM 9.5   Wed 10:20   POT 106

Formation and time dynamics of hydrogen-induced vacancies in nickel — •Maik Butterling[1], Luca Chiari[2], Masanori Fujinami[2], Maciej Oskar Liedke[1], Eric Hirschmann[1], Ahmed Gamal Attallah[1], and Andreas Wagner[1] — [1]Institute for Radiation Physics, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Department of Applied Chemistry and Biotechnology, Chiba University, 1-33 Yayoi, Inage, Chiba 263-8522, Japan

The formation of hydrogen-induced defects in nickel was investigated by positron annihilation lifetime spectroscopy and the time dynamics of those defects during room temperature aging was tracked with an unprecedented time resolution of the order of minutes using an ultrahigh-flux slow positron beam. Those measurements showed the formation of a large number of atomic vacancies simply by hydrogen addition at room temperature. It could be proved that they were monovacancy-level defects and that hydrogen was trapped and bound to those vacancies during the hydrogen charge. Room temperature aging, i.e. below the stage III temperature in Ni, and the concomitant hydrogen desorption induced the agglomeration of those monovacancies into large vacancy clusters which remained even after all the hydrogen had desorbed and hydrides had disappeared.

These results [1] constitute the first empirical evidence that vacancy-hydrogen complexes are induced in Ni only by hydrogen charging and demonstrate that hydrogen has a primary role in the formation and stabilization of vacancies even at room temperature.

KFM 9.6   Wed 10:40   POT 106

Electron tomography analysis of Ge/SiGe asymmetrically coupled quantum wells — •Ekaterina Paysen[1], Giovanni Capellini[2,3], and Achim Trampert[1] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany — [2]IHP - Leibniz-Institut für innovative Mikroelektronik, Frankfurt (Oder), Germany — [3]Dipartimento di Scienze, Università degli Studi Roma Tre, Roma, Italy

We present a method for the three-dimensional (3D) characterisation of the morphology and chemical intermixing of buried interfaces in a Ge/SiGe asymmetrically coupled quantum well structure applying electron tomography method based on high-angle annular dark-field (HAADF) scanning transmission electron microscopy. For this purpose, a needle-shaped specimen with a diameter of a few 100 nanometres is prepared with a focused ion beam, from which a tilt series of HAADF projections is recorded. Subsequently, the series is used to calculate a complete 3D image or tomogram of the specimen with the simultaneous iterative reconstruction technique. The analysis of iso-concentration surfaces enables a quantitative determination of morphological quantities such as the root mean square roughness and lateral correlation length individually for each interface. Subnanometre-thin cross-sections from the tomogram are used to measure the chemical interface width with the highest spatial resolution. An advantage of this method is thus the investigation of the interfaces as 3D entities in their buried state on a length scale of a few 100 nanometres without the projection problem.

Weak-signal extraction enabled by deep-neural-network denoising of diffraction data — •Jens Oppliger[1], Michael Marco Denner[1], Julia Küspert[1], Qisi Wang[1], Oleh Ivashko[2], Ann-Christin Dippel[2], Martin von Zimmermann[2], Fabian Donat Natterer[1], Mark Hannes Fischer[1], Titus Neupert[1], and Johan Chang[1] — [1]Physik-Institut, Universität Zürich, Winterthurerstrasse 190, CH-8057 Zürich, Switzerland — [2]Deutsches Elektronen-Synchrotron DESY, Notkerstrasse 85, 22607 Hamburg, Germany

Removal or cancellation of noise has wide-spread applications for imaging and acoustics. In every-day-life applications, denoising may even include generative aspects which are unfaithful to the ground truth. For scientific applications, however, denoising must reproduce the ground truth accurately. We show how data can be denoised via a deep convolutional neural network such that weak signals appear with quantitative accuracy. In particular, we study X-ray diffraction on crystalline materials. We demonstrate that weak signals stemming from charge ordering, insignificant in the noisy data, become visible and accurate in the denoised data. This success is enabled by supervised training of a deep neural network with pairs of measured low- and high-noise data. This way, the neural network learns about the statistical properties of the noise. We demonstrate that using artificial noise (such as Poisson and Gaussian) does not yield such quantitatively accurate results. Our approach thus illustrates a practical strategy for noise filtering that can be applied to challenging acquisition problems.

KFM 9.8 Wed 11:35 POT 106

Positron beams for materials research — •Andreas Wagner[1], Maik Butterling[1], Ahmed Gamal Elsherif[1], Eric Hirschmann[1], Maciej Oskar Liedke[1], and Reinhard Krause-Rehberg[2] — [1]Institute for Radiation Physics, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Martin-Luther-Universität Halle-Wittenberg, Dept.of Physics, 06099 Halle/Saale, Germany

The Helmholtz-Center Dresden - Rossendorf operates several user beamlines for materials research using positron-annihilation energy and lifetime spectroscopy. The superconducting electron linear accelerator ELBE drives several secondary beams including hard X-ray production from electron-bremsstrahlung, which serves as an intense source of positrons by means of pair production. The Monoenergetic Positron Source MePS [1] utilizes positrons with variable kinetic energies ranging from 0.5 to 18 keV for depth profiling of atomic defects and porosities on nm-scales in thin films. High timing resolutions (σt *100 ps) at high average rates (105 s-1) and adjustable beam repetition rates allow performing high-throughput experiments. The MePS facility has partly been funded by the Federal Ministry of Education and Research (BMBF) with the grant PosiAnalyse (05K2013). AIDA was funded by the Impulse- und Networking fund of the Helmholtz-Association (FKZ VH-VI-442 Memriox) and by the Helmholtz Energy Materials Characterization Platform. [1] A. KFM 9.9 Wed 11:55 POT 106

Strain Distribution in Au/ZnO Microstructures for bio-magnetic sensing utilizing Scanning X-Ray Nano Diffraction and Coherent X-Ray Diffraction Imaging — •Philipp Jordt[1], Niklas Wolff[1], Stjepan Hrkac[2], Jorit Gröttrup[1], Sindu Shree[1], Di Wang[3], Anton Davydok[4], Christina Krywka[4,1], Ross Harder[5], Christian Kübel[3], Oleg Shpyrko[2], Rainer Adelung[1], Olaf Magnussen[1], Lorenz Kienle[1], and Bridget Murphy[1] — [1]Kiel University, Germany — [2]UCSD, USA — [3]KNMF, KIT, Germany — [4]Hereon, Germany — [5]XSD, ANL, USA

Magnetic field sensors based on piezoelectric and magnetostrictive materials are a possible path to a new generation of sensors, capable of detecting biomagnetic fields from human physiology at room temperature in an unshielded environment. A huge hurdle are the very low field strengths of these signals. One approach to further enhance the sensitivity is employing the piezotronic effect, which arises from the combination of a piezoelectric material and a Schottky contact. Here, a study on the strain distribution in ZnO nano and microrods coated with gold is presented. Scanning X-ray nano diffraction mapped the 2 dimensional strain distribution across 30-50 μm rods together with insitu current-voltage curves. It is demonstrated that the gold coating and the resulting Schottky contact has a direct impact on the lattice parameters in vicinity of the Au/ZnO interface and further, that the crystal quality of the ZnO is immensely influential on the properties of the Schottky contact. The full 3D strain distribution inside a 1 μm rod was characterized by coherent X-ray diffraction imaging.

Correlation of Mechanical Stress and the Positron Lifetime in Aluminum Alloys — •Lucian Mathes[1], Vassily Vadimovitch Burwitz[1], Adrian Langrehr[1], Maik Butterling[2], Maciej Oskar Liedke[2], Eric Hirschmann[2], Andreas Wagner[2], and Christoph Hugenschmidt[1] — [1]Heinz Maier-Leibnitz Zentrum, TU München — [2]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiation Physics

Positron annihilation lifetime spectroscopy (PALS) is a sensitive technique to analyze the type and concentration of lattice defects on an atomic level. We applied ex-situ and in-situ PALS to plastically deformed technical Al and Al alloys. Thereby we are able to observe the creation and evolution of stress-induced defects in the region beyond the elastic Hook regime of the specimen. The in-situ bulk measurements were performed using a β^+ emitter in a new experimental setup combining tensile tests and PALS at TUM that also allows for investigation of the reversible elastic deformation of samples. The depth-dependent positron lifetime was measured ex-situ at the accelerator-based positron source MEPS at ELBE. For each sample we recorded the tensile stress, and the corresponding stress-strain curves. This allows us to determine the relation between applied stress, strain and mean positron lifetime. Within this contribution, we also discuss the evolution of the defect population with increasing deformation by examining the intensity change of the different positron lifetime components found in the PALS spectra.

KFM 9.11 Wed 12:35 POT 106

Start-to-end simulations of partially coherent X-ray imaging experiments at synchrotron beamlines — •Martin Seyrich — Deutsches Elektronen-Synchrotron DESY, Centre for X-ray and Nano Sciece CXNS, Hamburg, Germany

In the last decade, coherent X-ray imaging techniques, such as ptychography and holography, have grown a large user base at third and fourth generation X-ray light sources. In contrast to conventional microscopy techniques, coherent imaging techniques do not directly project an image on a detector. Instead, the image of the object is retrieved algorithmically from interference patterns, usually under the assumption of a fully coherent illumination.

Real X-ray sources are not perfectly coherent, they can be simulated as stochastic sources emitting an ensemble of waves. These waves can be propagated from the source through the entire beamline ending at the detector. The simulated interference patterns can then be treated with the same phase retrieval algorithms as experimental data.

Here, we present our extensions to existing established simulation software (OASYS / SRW) that permit the user to perform such start-to-end simulations with relative ease. We will present simulated data sets of ptychographic and holographic experiments, and discuss the computational demands of such simulations.

KFM 9.12 Wed 12:55 POT 106

Illumination corrected X-ray near-field microscopy — •Thea Engler[1,2], Johannes Hagemann[1], Christian G. Schroer[1,2], and Mathias Trabs[3] — [1]Deutsches Elektronen-Synchrotron, DESY, Germany — [2]Universität Hamburg, Germany — [3]Karlsruhe Institut of Technology, KIT, Germany

At synchrotron facilities, such as Petra III at DESY, small objects (μm) can be imaged with X-ray propagation-based phase-contrast imaging, i.e. near-field holography (NFH).

Reaching high resolution involves the use of nano-focusing optics. The imperfections of these optics cause aberrations in the illumination of the object and also upon further propagation in the measured hologram of the object. To correct the hologram for these artifacts, a flat-field correction must be applied. Considering a temporally stable beam, the hologram is divided by an empty-beam image, i.e. an image of the illumination without the object. With the common flat-field correction, the hologram is not fully corrected for the illumination function since the division is performed only in intensities in the detector plane.

Instead, the division of illumination and object should be performed in terms of complex wavefields in the sample plane, where the object transmission function physically interacts with the illumination function. Using a simulated dataset, we develop an algorithmic scheme using the recently proposed refractive formulation to take the illumination during the phase retrieval process properly into account.

Materialanalyse von NMC111 Kathodenmaterial aus recycelten Lithium-Ionen-Batterien mittels XRD, AFM und EDX/REM — •Claudia Schöberl, Hanno Käss und Stephan Appel — Hochschule Esslingen, Kanalstraße 33, 73728 Esslingen, Deutschland

In einem industriellen Recyclingverfahren für Lithium-Ionen-Batterien wird Kathodenmaterial von der Trägerfolie mit Wasser abgestrahlt und getrocknet. In einem an der Hochschule Esslingen laufenden Forschungsprojekt wird die so gewonnene Schwarzmasse, die hauptsächlich aus NMC111 besteht, mittels Röntgendiffraktometrie (XRD), Rasterelektronenmikroskopie (REM) und elementanalytischen Methoden untersucht, um Hinweise auf die chemische Zusammensetzung und auf strukturelle Veränderungen zu erhalten. Ziel ist es unter anderem, passende Auswahlkriterien für die Qualität des Recyclingmaterials zu definieren, das nach Verarbeitung erneut in Lithium-Ionen-Batterien eingesetzt werden soll. Dazu zählen, neben dem Rest-Bindemittelgehalt, der Kohlenstoffanteil sowie der Anteil an Fremdelementen wie Kupfer und Aluminium. Das wiedergewonnene, recycelte Aktivmaterial wird bei einem Projektpartner zur Herstellung neuer Kathodenfolien verwendet, die in einer Messzelle elektrisch charakterisiert werden. Mittels Rasterkraftmikroskopie (AFM) werden diese neu präparierten Kathodenfolien an der Hochschule Esslingen untersucht. Mit Hilfe eines speziellen Messmodus, der quantitativen nanoskaligen mechanischen Charakterisierung, wird insbesondere die Korrelation von Strukturmerkmalen und mechanischen Eigenschaften überprüft.

KFM 10.2　Thu 9:20　POT 51

Structural response in NCA-type battery cathodes — •Tobias Hölderle[1,2], Peter Müller-Buschbaum[1,2], and Anatoliy Senyshyn[2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]MLZ, TUM, Garching, Germany

Battery-powered electric drivetrains in electric vehicles (EVs) are heavily limited and constrained to the performance of the energy storage device, i.e. battery. Batteries with higher power/energy densities, capacities, and cycling life are needed to increase EVs' performance and reduce greenhouse gas emissions. Mixed high nickel content $Li_xNi_{0.8}Co_{0.15}Al_{0.05}O_2$ (NCA) cathode material is one of a few today that simultaneously possess high energy and power densities at lower costs. However, NCA materials suffer from poor thermal stability and limited power density. They display capacity fading/efficiency loss due to anti-site defects (cation mixing) in their structure, actively discussed in literature. In order to address the issue of cation mixing, a systematic ex-situ neutron powder diffraction study was done for a series of electrochemically delithiated NCA cathodes. The collected set of structural data was modeled using full-profile Rietveld method and results were discussed in line with observed electrochemical behavior. It is observed that lithium occupancies showed a decreasing character upon charging, independent from transition metal occupancies and indicating an absence of antisite defects (cation mixing) in the commercial NCA material during cell operation.

KFM 10.3　Thu 9:40　POT 51

Dynamic structure evolution of extensively de-lithiated high voltage spinel LNMO — Nicola Jobst[1], •Neelima Paul[2], Premysl Beran[3,4], Marilena Mancini[1], Ralph Gilles[2], Margret Wohlfahrt-Mehrens[1], and Peter Axmann[1] — [1]Accumulators Materials Research (ECM), ZSW Cen-tre for Solar Energy and Hydrogen Research Baden-Württemberg, DE-89081 Ulm, Germany — [2]Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, DE-85747 Garching, Germany — [3]Nuclear Physics Institute CAS, CZ-25068 Rez, Czech Republic — [4]European Spallation Source ERIC, Box 176, SE-221 00 Lund, Sweden

High voltage spinel is one of the most promising next-generation cobalt-free cathode materials for Li-ion batteries. Besides the typical compositional range of LixNi0.5Mn1.5O4 0<x<1 in the voltage window 4.90 to 3.00 V, additional 1.5 mol of Li per formula unit can be introduced into the structure, in an extended voltage range to 1.50 V. Theoretically, this leads to significant increase of the specific energy from 690 to 1190 Wh/kg. However, utilization of the extended potential window leads to rapid capacity fading, voltage polarization that lack a comprehensive explanation. In this work, we conducted potentiostatic entropymetry, operando XRD and neutron diffraction on the ordered stoichiometric spinel LixNi0.5Mn1.5O4 within 0 < x < 2.5 in order to understand the dynamic structure evolution and correlate it with the voltage profile. We were able to provide a conclusive explanation for the additional voltage step at 2.10 V, the sloping voltage profile below 1.80 V, and the additional voltage step at ~3.80 V.

KFM 10.4　Thu 10:00　POT 51

Computational Screening of Oxide Perovskites as Insertion-Type Cathode Material — •Johannes Döhn[1] and Axel Gross[1,2] — [1]Institute of Theoretical Chemistry, Ulm University, Germany — [2]Helmholtz Institute Ulm, Germany

The intermittency of wind and solar power - the solely sustainable energy sources which are considered to be abundantly available - leaves only one consequence: For the transition towards renewable energy systems, efficient and reliable storage technologies are needed. Batteries are one of the most widely used storage devices but current technology based on the transfer of Li-ions faces several challenges including their dependence on critical materials with respect to both, scarcity and toxicity.

In our contribution we will discuss atomic-scale investigations of potential future battery materials carried out using density functional theory (DFT). We employed a high-throughput approach in order to screen the well known material class of oxide perovskites as insertion-type cathode materials and we derived several crucial battery properties including voltage and theoretical energy density for in total 280 compounds. For those candidate materials with promising properties, we evaluated additional features such as the voltage profile and diffusion barriers for ionic transport.

Such in silico investigations significantly narrow down the potential materials space for experimental coworkers and thereby contribute to finding green, cheap and reliable devices for energy storage.

KFM 10.5　Thu 10:20　POT 51

Construction of cobalt oxyhydroxide nanosheets with rich oxygen vacancies as high-performance Lithium-ion Battery anodes — •Yonghuan Fu[1,2], Huaping Zhao[1], Jianhong Liu[2], and Yong Lei[1] — [1]Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — [2]Graphene Composite Research Center, College of Chemistry and Environmental Engineering, Shenzhen University, Shenzhen, P. R. China

Cobalt oxyhydroxide (CoOOH) is a promising anode material for lithium-ion batteries (LIBs) due to its high electronic conductivity and theoretical specific capacity. Herein, CoOOH nanosheets are successfully obtained using a facile one-pot method, and a hierarchical nanoporous structure is formed by oxidizing cobalt hydroxide (Co(OH)2) in NaOH and (NH4)2S2O8 solution. The CoOOH anode shows better electrochemical performance compared to Co(OH)2 and Co3O4 electrodes when applied to LIBs. The hierarchical nanoporous structure and high electronic conductivity of the CoOOH anode contribute to its outstanding initial discharge capacity, high initial coulombic efficiency, and excellent cyclability. Experiments and density functional theory (DFT) calculations confirmed that the high ICE and prominent rate capability of the nanosheets could be ascribed to the rapid and complete conversion reaction of CoOOH upon lithiation/delithiation facilitated by hydroxyl groups and oxygen vacancies. This study provides new insights into the structure-property relationship of transition-metal oxyhydroxide anode materials for LIBs.

KFM 10.6　Thu 10:40　POT 51

The dielectric behaviour of lithium intercalated graphite anodes - as a function of the state of charge — •Simon Annies, Chiara Panosetti, and Christoph Scheurer — Fritz Haber Institut Berlin

The dielectric behaviour of battery materials is a crucial piece of information for understanding atomistic mechanics and modelling diffusion- and charging processes. However, for the most common anode material in today's lithium ion batteries (lithium intercalated graphite), literature results regarding this property are sparse, conflicting and only available for graphite, i.e. the empty state of charge (SOC).

Utilizing our recently developed DFTB parametrization [1] which is based on a machine-learned repulsive potential, we are – for the first time – able to compute the dielectric behaviour of lithium intercalated graphite for the entire range of charge from 0% to 100% - finding a linear dependency from around ϵ_r=7 at 0% SOC to around 25 at 100% SOC. We achieve this by sampling the Coulomb interactions between pairs of Li-ions and vacancies in large cells with varying intercalant concentrations in the adjacent layers.

Our results agree with experiments in the limit of "empty" graphite, as well as for (bilayer-) graphene, which we consider a validation of our approach. With this, we lay an important piece of foundation for the understanding and multiscale modelling of entire charging and discharging cycles of graphite anodes in Li-ion batteries.

KFM 10.7 Thu 11:00 POT 51

Hypothetical t-LGPO as a good ionic conductor, and the influence of Li core electrons on diffusion — Giuliana Materzanini[1], •Nicola Marzari[2,3], and Gian-Marco Rignanese[1] — [1]Modelling Division, Universite catholique de Louvain, 1348 Louvain-la-Neuve, Belgium — [2]Theory and Simulations of Materials (THEOS), Ecole Polytechnique Federale de Lausanne, CH-1015 Lausanne, Switzerland — [3]National Centre for Computational Design and Discovery of Novel Materials (MARVEL), Ecole Polytechnique Federale de Lausanne, CH-1015 Lausanne, Switzerland

Following the computationally found high Li-ion conductivity in tetragonal Li10GeP2O12 (t-LGPO), we study here the role of Li core electrons on Li diffusion in this hypothetical superionic material. We calculate Li diffusivity from two sets of Car-Parrinello canonical molecular dynamics simulations, one using Li pseudopotential with all electrons (1s22s1), and one with just one electron (2s1). The Arrhenius plots show a marked influence of the Li 1s electrons on the Li-ion diffusivity in t-LGPO, being the diffusion coefficient at 600 K one order of magnitude larger, and the activation barrier between 600 and 1200 K 1.5 times smaller, for the Li all-electrons with respect to the Li one-electron calculations. Similar sets of simulations performed for the analogue sulfide material, tetragonal Li10GeP2S12 (LGPS), show, oppositely, that for LGPS the influence of Li 1s electrons on Li diffusivity is minimal. The different response of Li mobility to the explicit treatment of 1s electrons reveals fundamental differences in the ionic conductivity mechanism in these two classes of materials.

Sodiation-induced reactivation of micro-nano flower for ultra-long cycling life sodium-ion batteries — •Yulian Dong, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

A rational micro-nano hierarchical structure is demonstrated to prolong the cycle life of sodium-ion batteries (SIBs) by relieving the volume expansion and preventing active material agglomeration. In this work, micro-nano flower 3D-VSx was fabricated as an anode electrode for SIBs. The advanced features of micro-nano flower and the unique crystal structures of NiAs-type vanadium sulfides synergistically contribute to enhancing the electrochemical kinetics of 3D-VSx, and finally achieved remarking electrochemical performances with an ultra-high capacity (961.4 mAh/g at 2 A/g) and an ultra-long cyclability (more than 1500 cycles). Furthermore, ex situ X-ray diffraction, Raman, and SEM bring to light a gradual reactivation process of 3D-VSx for sodium storage. Fortunately, upon reactivation, the electrochemical impedance of the 3D-VSx anode gradually weakens, and the diffusion-controlled charge storage mode further dominates compared to the capacitively-controlled mode, all of which facilitate the 3D-VSx to maintain a stable sodium storage capability. This work presents a general approach for preparing super-high specific capacity and rate capacity electrode materials for further improving the SIBs performance.

KFM 10.9 Thu 11:55 POT 51

Sodium diffusion mechanism in NASICON solid electrolyte materials studied via quasi-elastic neutron scattering — •Ivana Pivarníková[1,2], Stefan Seidlmayer[1], Martin Finsterbusch[3], Gerald Dück[3], Niina Jalarvo[4], Peter Müller-Buschbaum[1,2], and Ralph Gilles[1] — [1]TUM, MLZ, Garching, Germany — [2]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [3]FZJ, IEK-1, Jülich, Germany — [4]ORNL, Oak Ridge, TN, USA

The sodium superionic conductor materials, also known as NASICON, have been a widely studied class of solid electrolytes for Na-ion based all-solid-state batteries. The aim of this work is to clarify the reason for extremely high conductivity exhibited by Na1+xZr2SixP3-xO12 (0-x-3) and to explain the role of the monoclinic to rhombohedral phase transition for the material with x=2.4, which supposedly occurs at around 170°C. We also investigate the overall temperature dependence of the ionic conductivity in the temperature range of 297-640K. The quasi-elastic neutron scattering (QENS) is used to measure the spatial and temporal dynamic properties of diffusion of Na-ions in the crystal structure. The Na-ion diffusion mechanism can be described by the right choice of the diffusion model. Important parameters, such as diffusion coefficients, activation energies, jump distances between the occupation sites and residence times are extracted from the measured and modelled QENS data. Temperature dependent X-ray diffraction data have been obtained and analysed in order to confirm the results obtained from the QENS data.

KFM 10.10 Thu 12:15 POT 51

3D flower-like MnV12O31 center dot 10H2O as a high-capacity and long-lifespan cathode material for aqueous zinc-ion batteries — •Yan Ran[1], Yude Wang[2], Huaping Zhao[1], and Yong Lei[1] — [1]Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — [2]Yunnan Key Laboratory of Carbon Neutrality and Green Low-carbon Technologies, Yunnan University, 650091 Kunming, China

In this work, MnV12O31 center dot 10H2O (MnVO) synthesized via one-step hydrothermal method is proposed as a promising cathode material for AZIBs. Because its stable layered structure and hieratical morphology provide a large layer space for rapid ion transports, this material exhibits a high specific capacity (433 mAh g-1 at 0.1 A g-1), outstanding long-term cyclability (5000 cycles at current density of 3 A g-1), and sufficient energy density (454.65 Wh kg-1). To illustrate the intercalation mechanism, ex-situ X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FTIR), and X-ray photoelectron spectroscopy (XPS) are adopted, uncovering a H+/Zn2+ dual-cation co-intercalation processes. Besides, density functional theory (DFT) calculation analysis shows that MnVO has a delocalized electron cloud and the diffusion energy barrier of Zn2+ in MnVO is low, which promotes the Zn2+ transport and, consequently, improves the reversibility of the battery upon deep cycling. The results provide key and enlightening insights for the design of high-performance vanadium-oxide-based cathode materials for AZIBs.

eutectic: a game changer — •Sandhya Sharma[1], Hafiz Muhammad Zeeshan[1], Elena Voloshina[1,2], and Yuriy Dedkov[1,2] — [1]Centre of Excellence ENSEMBLE3 Sp. z o. o., Wolczynska Str. 133, 01-919 Warsaw, Poland — [2]Department of Pysics, Shanghai University, 99 Shangda Road, 200444 Shanghai, P.R. China

The world of semiconductors has drastically improved the lifestyle due to its versatile applications. The demand for new efficient semiconductors is increasing day by day, giving birth to the idea of new synthesis methods. Many synthesis techniques have been utilized to engineer band gap of semiconductors to achieve higher efficiency. Here, a perspective on the importance of semiconductor eutectic materials has been presented as one of the future potential candidates, along with the micro (μ) pulling method (as a synthesis method for semiconductor eutectic materials) that not only control factors effecting the devices but also provides variety of options for band gap modification. The efficiency of the present devices in comparison with the eutectic composites has been made, showing the semiconductor eutectic materials as a better candidate for future devices.

KFM 11.2 Thu 14:20 POT 51

Determining the Crystallization Mechanism in Optical Switching Experiments with Electron Backscatter Diffraction — •Maximilian Müller and Matthias Wuttig — I. Institute of Physics (IA), Aachen, Germany

To tailor phase-change materials for computing and data storage applications unraveling the contribution of nucleation and crystal growth to crystallization is essential. Usually, these processes are studied at low temperatures. Subsequently, from the temperature dependence of both processes at low temperature, the role of these processes at high temperatures is extrapolated. This is inherently dangerous if the underlying processes do not follow Boltzmann kinetics.

In this study, crystallization was achieved by short laser pulses with pulse lengths between a few ns to several *s. Afterwards, the resulting grain structure was analyzed by different techniques, including atomic force microscopy and Electron BackScatter Diffraction (EBSD). The grain size distribution is determined by these experiments which helps disentangling the processes of nucleation and growth. Significant differences are observed concerning the nucleation of different compounds. Trends for the nucleation and growth rate as a function of stoichiometry are analyzed and explained based upon systematic changes in bonding.

KFM 11.3 Thu 14:40 POT 51

Vacancies in Prussian White Cathode Materials employing Positron Annihilation Spectroscopy — •Dominik Boras[1], Ida Nielsen[2], Alexander Buckel[3], Tore Ericsson[2], Lennart Häggström[2], Torsten E.M. Staab[1], and William R. Brant[2] — [1]Institute for Functional Materials and Biofabrication, Julius-Maximilians Universität Würzburg, 97070 Würzburg, Röntgenring

11 — [2]Department of Chemistry - Ångström Laboratory, Uppsala University, Box 538, SE-751 21 Uppsala, Sweden — [3]Altris AB, Kungsgatan 70b, SE-753 18 Uppsala, Sweden

We are presenting a novel attempt to characterise Prussian blue analogues. Prussian White samples have been synthesized with different sodium content and, then, characterized by common methods (ICP-OES, TG, SEM) but also by Mösbauer spectroscopy. We prepared there different sample states: fully and half-sodiated as well as de-sodiated. As a new method positron annihilation lifetime spectroscopy (PALS) has been applied to characterize the different samples states. We can state that the methods of PALS gives reasonable results for Prussian White with varying sodium and water content. The relative intensity of the longer positron lifetime component (405ps) is increasing with deceasing sodium content, which is an indication that the positron "sees" less of the open crystal channels filled by movable ions, since those become more and more occupied by intercalated Na-atoms. This first attempt aims to present the potential of PALS to characterise Prussian Blue analogue materials with respect to defects and occupation of of its crystal channels by movable ions.

KFM 11.4　Thu 15:00　POT 51

Disorder engineering for symmetry lowering in Prussian Blue analogues (PBAs) — •Yevheniia Kholina, Thomas Weber, and Arkadiy Simonov — ETH Zürich, Switzerland, Department of Materials, Laboratory for Multifunctional Ferroic Materials

A simple consequence of Neumann's principle is that certain properties can exist in crystals with a certain symmetry. As a result, a lot of materials engineering is focused on designing particular symmetries, which allow the properties of interest. In oxide perovskites as well as their molecular analogues, control of crystal symmetry is achieved by octahedral tilts and cation ordering. In this work we show an alternative way of symmetry lowering, using disorder. We focus on Mn[Co] PBA with the chemical composition $Mn[Co(CN)_6]_{2/3}$. These crystals have 1/3 of $Co(CN)_6$ sites vacant. The structure of such PBAs is believed to be cubic with space group $Fm\bar{3}m$. However, the optical measurements indicate that the crystal is twinned and an actual structure has tetragonal symmetry or lower. We collect single-crystal x-ray diffuse scattering from untwined crystal to probe the local structure and quantitatively characterise defect distribution, using 3D-ΔPDF analysis. The symmetry of the local structure is reduced to tetragonal by local vacancies ordering. The vacancies have stronger correlation along c direction. Such asymmetry is formed because the crystal is growing in this direction. This means the symmetry can be lowered by choosing a specific direction of the crystal growth. We believe this result can be applied to other disordered crystalline materials and be an effective way to lower the symmetry for properties design.

KFM 11.5　Thu 15:20　POT 51

Single crystal growth of the Mott insulator BaCoS2: structure and hole doping — •Haneen Abushammala, Teslin Thomas, Andreas Kryssig, and Anna Boehmer — Experimentalphysik IV, Ruhr-Universitaet Bochum, Universitaetsstrasse 150, 44801 Bochum, Germany

The quasi-2D $BaCoS_2$ is a Mott insulator with a stripe-like antiferromagnetic ordering at T_N=290 K. Both chemical doping or hydrostatic pressure drive the system into a paramagnetic metallic phase. Interestingly, there is no structural transition at the metal-insulator transition of this phase, which offers ideal conditions to investigate the Mott transition in a model multiband system [1].

Nevertheless, $BaCoS_2$ remains little studied, and the interplay of electronic and structural features is still unclear. High-quality single crystals are needed to elucidate this issue. The synthesis of single-crystalline $BaCoS_2$ is challenging owing to its metastability, with a decomposition into Ba_2CoS_3, CoS and S below 850°C. The $BaCoS_2$ phase can only be obtained via quenching from high temperature. Moreover, $BaCoS_2$ melts incongruently, which calls for a flux growth method necessitating separation of the crystals from the flux by the end of the growth. We have successfully grown single crystals of pure and the hole-doped $BaCoS_2$ using a self-flux method with high-temperature flux separation and quench. The structural and anisotropic electrical transport properties are determined and discussed.

KFM 11.6　Thu 15:40　POT 51

Monitoring the S-phase formation in an high-purity Al-Cu-Mg alloy by truncation during heating-up — •Torsten E.M. Staab, Dominik Boras, Sebastian Breitfelder, and Timo Strobl — IFB, Julius-Maximilians Universität Würzburg, 97070 Würzburg, Röntgenring 11

We are presenting a novel attempt to combine in-situ and ex-situ measurements for aluminum alloys. As a model alloy we have chosen an Al-1.7Cu-1.3Mg (at.%) alloy, which has been cast from high purity elements (5N5 Al, 4N Cu and 4N Mg). As basic method DSC (heating ramp: 5 K/min) has been employed to determine different states during S-phase formation: onset, maximum of the exothermal peak, end of exothermal reaction. Sample states were frozen-in by an abrupt truncation of the heating ramp (5 K/min), i.e. cooling quickly to room

temperature. So, the current sample state is frozen-in. After truncation all samples have been measured without further preparation by X-ray diffraction (XRD) and positron annihilation lifetime spectroscopy (PALS). Thus we could correlate exactly different sample states, which is impossible by conventional experiments, i.e. heating to a certain temperature and then holding a certain time. This paves the way to investigate defined and comparable sample states by methods, which require an extensive sample preparation, like TEM or 3DAP, and in-situ methods like DSC or XRD at synchrotron beamlines.

Local structure of titanite CaTiSiO5 — •Arkadiy Simonov — ETH Zürich, Zürich, Switzerland

Titanite, $CaTiSiO_5$, is a multifunctional nesosilicate mineral which recently received attention as a material for building tunable capacitors and oscillators. Near 500K titanite shows a nonlinear dielectric response with positive dielectric tunability and thus its dielectric susceptibility can be efficiently controlled using a voltage bias, moreover capacitors made of this material have unusually low dielectric losses and thus high quality factor [1]. The origin of such a good performance is not currently understood, but one hypothesis is that it is related to an unusual locally antipolar disordered structure which is observed in titanite above 500K in the paraelectric $A2/a$ phase.

In this work we present the analysis of the local structure of titanite in the $A2/a$ phase. We use single crystal diffuse scattering as our probe and analyze it using a non-parametric method based on three dimensional difference pair distribution function (3D-ΔPDF) refinement. We show that despite the $A2/a$ structure is on average paraelectric, locally it is antipolar. It shows Ti^{4+} displacements which have strong ferro correlations along the b direction and weak locally anti-ferro correlations in a and c directions. Such locally antipolar structure can provide a crossover path for the low temperature $P2_1/a$ structure under applied electric field and thus explain the low dielectric losses observed in this material.

Pfaffian invariant identifies magnetic obstructed atomic insulators — •Daniel Varjas[1,2,3,4], Isidora Araya Day[3,4], Anastasiia Varentcova[3], and Anton R. Akhmerov[3] — [1]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Straße 38, 01187 Dresden, Germany — [2]Department of Physics, Stockholm University, AlbaNova University Center, 106 91 Stockholm, Sweden — [3]QuTech, Delft University of Technology, Delft 2600 GA, The Netherlands — [4]Kavli Institute of Nanoscience, Delft University of Technology, P.O. Box 4056, 2600 GA Delft, The Netherlands

We derive a Z_4 topological invariant that extends beyond symmetry eigenvalues and Wilson loops and classifies two-dimensional insulators with a C_4T symmetry. To formulate this invariant, we consider an irreducible Brillouin zone and constrain the spectrum of the open Wilson lines that compose its boundary. We fix the gauge ambiguity of the Wilson lines by using the Pfaffian at high symmetry momenta. As a result, we distinguish the four C_4T-protected atomic insulators, each of which is adiabatically connected to a different atomic limit. We establish the correspondence between the invariant and the obstructed phases by constructing both the atomic limit Hamiltonians and a C_4T-symmetric model that interpolates between them. The phase diagram shows that C_4T insulators allow ±1 and 2 changes of the invariant, where the latter is overlooked by symmetry indicators.

Probing Centrosymmetricity of Emergent Materials by Convergent Beam Electron Diffraction — •S. Subakti[1,2], Y. Wang[3], A. Chakraborty[4], A.K. Srivastava[4], D. Wolf[1], T. Doert[3], M. Ruck[3], S.S.P. Parkin[4], B. Büchner[1,2], and A. Lubk[1] — [1]Leibniz Institute for Solid State and Materials Research Dresden, Helmholtzstraße 20, 01069 Dresden, Germany — [2]Institut für Festkörperphysik, TU Dresden, D-01062 Dresden, Germany — [3]Faculty of Chemistry and Food Chemistry, Technische Universität Dresden, 01062 Dresden, Germany — [4]Department for Nano-Systems from Ions, Spins, and Electrons (NISE), Max Planck Institute of Microstructure Physics, Weinberg 2, D-06120 Halle(Saale), Germany

Many exotic physics present in materials, such as chiral magnetic textures, hinges on the (non)existence of centrosymmetry. Consequently unambigous structural determination beyond x-ray diffraction (XRD), which is to a certain extend blind to centrosymmetry, is indispensable. Here, we present structural investigation of two emergent quantum materials, namely Fe_3GeTe_2 and Rh_2NiSb, by means of convergent beam electron diffraction (CBED). Analyzing the diffraction group symmetries of the CBED patterns in combination with extinction rules and results from XRD analysis, we conclude the space group of these materials. Importantly, both phases are non-centrosymmetric, suggesting possible presence of chiral magnetic textures and multiferroicity.

Nonsymmorphic chiral symmetry and solitons in the Rice-Mele model — •EDWARD MCCANN — Lancaster University, Lancaster, United Kingdom

The charge-density-wave (CDW) phase of the Rice-Mele model in one dimension has alternating onsite energies and constant nearest-neighbor hopping parameters. The chiral symmetry of the CDW wave phase is nonsymmorphic, resulting in a breaking of the bulk topology by an end or a texture in the alternating energies. We consider the presence of solitons (textures in position space separating two degenerate ground states) in finite systems with open boundary conditions. We identify the parameter range under which an atomically-sharp soliton in the CDW phase supports a localized state which lies within the band gap, and we calculate the expectation value of the nonsymmorphic chiral operator for this state, and the soliton electric charge [1]. Finally, we discuss other models with similar, nonsymmorphic nonspatial symmetries.

KFM 11.11   Thu 17:35   POT 51

The Initial Molecular Interactions in the Course of Enthalpy Relaxation and Nucleation in Polyethylene terephthalate (PET) as Monitored by Combined Nanocalorimetry and FTIR Spectroscopy — •WYCLIFFE KIPNUSU[1], EVGENY ZHURAVLEV[2], CHRISTOPH SCHICK[2,3], and FRIEDRICH KREMER[1] — [1]Peter Debye Institute for Soft Matter Physics, Leipzig University, Linnestr. 5, 04103, Leipzig, Germany — [2]Universitat Rostock Institute of Physics, Albert-Einstein_str. 23-24, Rostock, DE 18051, Germany — [3]Kazan, Russia

Fast scanning calorimetry (FSC) and Fourier transform infrared (FTIR) spectroscopy are combined to trace for the same sample the evolution of the calorimetric properties and of the intra- and inter-molecular interactions in polyethylene terephthalate (PET). FSC enables to rapidly quench the sample to amorphous state and to monitor nucleation and crystal growth at isothermal conditions. By Determining the difference IR spectra between a quenched and an annealed sample unravels the the intra- and inter-molecular interactions in detail; (i) as first response already during enthalpy relaxation, the far reaching Coulomb interactions between the polar C=O moieties are active; (ii) in contrast, the ethylene unit and the aromatic ring show a response only, if homogeneous nucleation sets in, while the COC moiety remains uninfluenced; (iii) a hierarchy is observed in the sequence of the response of the different molecular moieties.

Polaronic structures in $LiNbO_3$ and $LiTaO_3$ modelled from first principles — •NILS ANDRE SCHÄFER and SIMONE SANNA — Institute for Theoretical Physics, Justus Liebig University Giessen, Germany

Polaronic defects impact among other properties the optical response of $LiNbO_3$ (LN). Changes in their optical properties are of interest for the applications of LN in optoelectronics. These are relatively well known in LN but in $LiTaO_3$ (LT) less so. In order to improve our knowledge of polaronic structures in LT, we modeled polarons in LN and LT from first principles using the DFT+U method as implemented in VASP.

  We explore different microscopic polaronic structures in both polar oxides with respect to changes in their electronic band structures and optical properties, especially with respect to Jahn-Teller distortions. Similarities and differences between different polaronic defects and both compounds are discussed as well.

Crystal growth and thermal analysis of Li(Nb,Ta)O3 solid solutions — •UMAR BASHIR GANIE — IKZ, Berlin

This work presents the growth and thermal analysis of Lithium Niobate Tantalate (Li(Nb,Ta)O3, LNT) single crystals for different LiTaO3 (LT) mole fractions (xLT), (xLT = nLT/(nLT+nLN)). Our crystal growth experiments show that growth of LNT single crystal over the entire LT mole fraction is not only possible but can be achieved with weaker constituent segregation and therefore higher degree of homogeneity than considered previously. Our differential thermal analysis (DTA) measurements show that the melting temperature increases with increasing fraction of LT and follow the behavior of a (pseudo)binary phase diagram as published previously [1]. Thorough evaluation of the DTA results allows to propose an improved version of the LN-LT phase diagram that is not only thermodynamically stringent but also allows to explain the component distribution observed in LNT single crystals and to design growth experiments yielding crystals of higher homogeneity. We also performed specific heat capacity measurements of single crystals of LNT solid solutions. The aim was to investigate the variation of ferroelectric Curie temperature with composition. We observed that the ferroelectric Curie temperature decreases linearly with growing Ta composition in the LNT solid solution crystals.

KFM 13.3   Thu 10:40   POT 106

Hydrogen Diffusion in LiNbO3 and LiTaO3 — •KOFAHL CLAUDIA[1], DÖRRER LARS[1], SUHAK YURIY[2], YAKHNEVYCH ULIANA[2], FRITZE HOLGER[2], and SCHMIDT HARALD[1,3] — [1]Institut für Metallurgie, AG Festkörperkinetik, TU Clausthal, Germany — [2]Institut für Energieforschung und Physikalische Technologien, TU Clausthal, Germany — [3]Clausthaler Zentrum für Materialtechnik, TU Clausthal, Germany

LiNbO3 and LiTaO3 crystals are technologically important polar metal oxides with exceptional combinations of ferroelectric, piezoelectric, acoustic, optical and ion conductivity properties. The presence and diffusion of H in these materials has an important influence on the materials properties, reducing optical damage, increasing optical birefringence and changing ionic conductivity. The diffusion mechanism is unclear up to now. Therefore, it is of particular interest to study the diffusion of hydrogen. For this purpose, we use two different analytical methods, SIMS (Secondary Ion Mass Spectroscopy) and IRS (Infrared Spectroscopy). For the SIMS measurements, the crystals are loaded with high amounts of H by means of proton-exchange and the redistribution of H is monitored after post-annealing. In contrast, for the IRS experiments, only hydrogen of about 300 ppm, which is introduced by crystal growth in air, is replaced by deuterium during exchange anneals in D2O. The measured diffusion coefficients of the two methods differ from each other, but are higher than Li diffusivities as given in literature. The activation energies are similar. Possible reasons for the differences are discussed.

KFM 13.4   Thu 11:00   POT 106

Acoustic loss in Lithium Niobate-Lithium Tantalate solid solutions with different Nb/Ta ratios at temperatures up to 900°C — •ULIANA YAKHNEVYCH[1], CLAUDIA KOFAHL[2], STEPAN HURSKYY[2], STEFFEN GANSCHOW[3], YURIY SUHAK[1], HARALD SCHMIDT[2], and HOLGER FRITZE[1] — [1]Institute of Energy Research and Physical Technologies, Clausthal University of Technology, Germany — [2]Institute of Metallurgy, Clausthal University of Technology, Germany — [3]Leibniz-Institut für Kristallzüchtung, Berlin, Germany

Lithium niobate-lithium tantalate solid solutions (LNT) are poorly studied materials in modern materials science, which must be seen in the light that they can combine the advantages of the edge compounds lithium niobate (LN) and lithium tantalate (LT). These crystals are expected to exhibit high piezoelectric coefficients and thermal stability. This work focuses on comparing the Q-factor of LN, LT, and LNT as well as on the analysis of loss contributions in samples. Electromechanical losses of the samples were determined using two different approaches, namely noncontacting resonant ringdown spectroscopy and resonant piezoelectric spectroscopy using Pt electrodes. LNT thickness-shear mode (TSM) acoustic resonators exhibit significantly lower loss than LN. The study of the acoustic loss in LNT resonators operated in the TSM showed strong frequency dependent loss increases at temperatures above 450°C. The loss was modelled using independent materials data. Based on the modelling, the above-mentioned loss above 450°C is associated with a conductivity-induced piezoelectric/carrier relaxation mechanism governed by Li migration.

KFM 13.5 Thu 11:35 POT 106

High-temperature stability of electrical and acoustic properties of congruent and near stoichiometric single crystalline LiNbO3, LiTaO3 and LiNb0.94Ta0.06O3 — •Yuriy Suhak[1], Stepan Hurskyy[1], Uliana Yakhnevych[1], Fatima El Azzouzi[1], Claudia Kofahl[2], Harald Schmidt[2], Steffen Ganschow[3], Klaus-Dieter Becker[4], and Holger Fritze[1] — [1]Institute for Energy Research and Physical Technologies, Clausthal University of Technology, Goslar, Germany — [2]Institute of Metallurgy, Clausthal University of Technology, Clausthal-Zellerfeld, Germany — [3]Leibniz Institut für Kristallzüchtung, Berlin, Germany. — [4]Braunschweig University of Technology, Braunschweig, Germany

It is known that the intrinsic properties of LiNbO3, LiTaO3 and, consequently, of Li(Nb,Ta)O3 solid solutions are strongly dependent on lithium stoichiometry. In current work the electrical and acoustic properties of congruent and near-stoichiometric single crystalline Li(Nb,Ta)O3 are studied as a function of temperature by means of impedance spectroscopy and resonant piezoelectric spectroscopy, respectively. The preparation of near-stoichiometric samples was performed by vapor transport equilibration technique (VTE). It is shown, that VTE-treated samples generally exhibit lower conductivity and lower acoustic loss, which implies better thermal stability. The latter was examined by a long-term measurement of electrical conductivity at 500 ˚C in air. After about 330 hours of uninterrupted thermal treatment the conductivity of a congruent LiNb0.94Ta0.06O3 specimen was found to decrease only for about 3 %.

KFM 13.6 Thu 11:55 POT 106

A high-temperature optical spectroscopy study of lithium niobate, LiNbO3 — •Klaus-Dieter Becker[1], Jianmin Shi[1], Piotr Gaczynski[1], Misha Sinder[2], Uliana Yakhnevych[3], Natalia Syvorotka[3], Yuriy Suhak[3], Steffen Ganschow[4], and Holger Fritze[3] — [1]Institute of Physical and Theoretical Chemistry, TU Braunschweig, Braunschweig, Germany — [2]Materials Engineering Department, Ben Gurion University of the Negev, Beer-Sheva, Israel — [3]Institute for Energy Research and Physical Technologies, TU Clausthal, Goslar, Germany — [4]Leibniz Institut für Kristallzüchtung, Berlin, Germany

Optical absorption spectra of chemically reduced LiNbO3 (LN) show broad bands in the vis and NIR region which have been attributed to various types of electron small polarons. At 1000˚C, spectra are dominated by an absorption band at 0.9 eV due to free small polarons, i.e. to electrons localized on niobium ions on regular sites. Band intensity has been found to follow a power-law dependence on oxygen partial pressure PO2 of the form (PO2)^m with m= -0.23(+-)0.02. This m-value is in excellent agreement with the value of -1/4 predicted from point defect thermodynamics of the chemical redox model of LN. The experimental kinetics of reduction and oxidation following a rapid change in oxygen partial pressure have been found to provide a novel route to diffusion of lithium vacancies at high temperatures as well as to that of lithium ions in LN.

KFM 13.7 Thu 12:15 POT 106

Looking undercover - Probing subsurface properties by Piezoresponse force microscopy (PFM) — •Matthias Roeper[1], Samuel D. Seddon[1], Lili Ding[1], Michael Rüsing[1], and Lukas M. Eng[1,2] — [1]Institut für Angewandte Physik, TU Dresden, Nöthnitzer Straße 61, 01187 Dresden, Germany — [2]ct.qmat: Dresden-Würzburg Cluster of Excellence - EXC 2147, TU Dresden, 01062 Dresden, Germany

Piezoresponse force microscopy (PFM) is one of the most widespread methods for investigating and visualizing ferroelectric domain structures at the nanometer length scale, even along all 3 dimensions (3D) [1]. PFM couples to the local dielectric displacement that is present near the sample surface, and hence is also sensitively probing into the bulk of the sample under investigation, i.e. into a subsurface volume with penetration d [2]. In this work, we systematically analyze in both theory and experiment, the contrast and depth resolution capabilities of PFM as a function of the various relevant experimental parameters. PFM tool properties such as the tip radius, ac driving voltage, and ac frequency were optimized, while equally dedicated sample structures incorporating (known) buried features, i.e. ferroelectric domain walls, fabricated into the bulk host at a distance d below the surface, were analyzed Our finding allow to accurately adjust the image contrast to a certain penetration depth d, and thus quantify those local features with high precision.

Domain wall current in lithium niobate single crystals at temperatures up to 370˚C — •U. Yakhnevych[1], M. Kunzmer[1], I. Kiseleva[2], J. Gössel[2], J. Ratzenberger[2], M. Rüsing[2], L.M. Eng[2,3], and H. Fritze[1] — [1]Institut für Energieforschung und Physikalische Technologien, TU Clausthal, Am Stollen 19 B, Goslar, 38640, Germany — [2]Institut für Angewandte Physik, TU Dresden, Nöthnitzer Straße 61, 01187 Dresden, Germany — [3]Dresden-Würzburg Cluster of Excellence - EXC 2147, TU Dresden, 01062 Dresden, Germany

Lithium niobate (LN) ferroelectric crystals with an artificially formed domain structure are widely used in novel electronic devices. So far, a complete picture of the electrical transport mechanism at domain walls is still missing, including its high temperature behavior. This work focuses on the determination of the domain wall conductivity from room temperature up to 370 ˚C. Using 5%MgO:LN, conductive DWs are prepared and enhanced following the procedure by Godau et al. [1]. Direct current measurements using an electrometer amplifier and impedance spectroscopy are applied to locally map the temperature-dependent DW current. A strong dependence of the electrical conductivity on temperature is observed. The activation energy shows distinct values for low-to-medium and high temperatures, respectively, reaching values of ~0.1 eV and ~0.15*eV. For further analysis, the obtained samples should be measured at even higher temperatures. [1] C. Godau, T. Kämpfe, A. Thiessen at al. Ferroelectric domains and domain walls under uniaxial stress * A case study in lithium niobate — Ekta Singh[1], Henrik Beccard[1], Michael Lange[1], Sven Reitzig[1], Zeeshan H. Amber[1], Clifford W. Hicks[3], Julius Ratzenberger[1,2], •Michael Rüsing[1], and Lukas M. Eng[1,2] — [1]Institut für Angewandte Physik, TU Dresden, Nöthnitzer Straße 61, 01187 Dresden, Germany — [2]ct.qmat: Dresden-Würzburg Cluster of Excellence - EXC 2147, TU Dresden, 01062 Dresden, Germany — [3]School of Physics and Astronomy, University of Birmingham, Birmingham B15 2TT, United Kingdom

In material science, mechanical strain has an influence on a multitude of material properties. For ferroelectrics, strain can be achieved via standard techniques, such as lattice-mismatched epitaxial growth of thin films, or hydrostatic pressure. However, these methods are either limited to specific material combinations or non-local investigation techniques. Here, we present an alternative approach [1] to study bulk crystals under the influence of uniaxial strain, using a piezo-actuator-based device that is compatible with various local probe techniques. To demonstrate the operation we present the influence of strain on the vibrational properties probed via micro-Raman spectroscopy [1], as well as the influence of strain on the local conductivity of ferroelectric domain walls probed by scanning con-ductance microscopy [2]. KFM 14.3 Thu 14:40 POT 106

Hall effect in conductive ferroelectric domain walls in BaTiO3 — Henrik Beccard[1], Elke Beyreuther[1], Michael Rüsing[1], Benjamin Kirbus[1], Ekta Singh[1], •Samuel Seddon[1], Petr Bednyakov[2], Jiri Hlinka[2], and Lukas M. Eng[1,3] — [1]Institut für Angewandte Physik, TU Dresden, Nöthnitzer Straße 61, 01187 Dresden, Germany — [2]Institute of Physics, Academy of Sciences of the Czech Republic, Na Slovance 2, 18221 Praha 8, CZR — [3]ct.qmat: Dresden-Würzburg Cluster of Excellence - EXC 2147, TU Dresden, 01062 Dresden, Germany

Two dimensional (2D) electronic systems are essential in cutting-edge nanoelectronic research. Here, conductive ferroelectric domain walls (DWs) are experiencing a concerted research effort for the last decade. Much of the research, however, did focus onto measuring and tuning the electrical DW conductivity [1], with very little investigations reporting on the very fundamental DW properties such as charge carrier density and mobility. Here, we adapted the 4-point van der Pauw [2] geometry to probe these 2D sheets of ferroelectric DWs in BaTiO3, and were able to determine the aforementioned properties. We find large electron mobilities of 400 cm[2] (Vs)$^{-1}$ and decent electron densities [3]. Not only are these results by themselves novel, but also perfectly demonstrate the power of this simple methodology to quantify the charge carrier properties in any low-dimensional system.

KFM 14.4 Thu 15:00 POT 106

Thin Patterned Lithium Niobate Metasurfaces by Parallel Additive Capillary Stamping of Aqueous Precursor Solutions — •Jan Klenen[1], Fatih Alarslan[2], Laura Vittadello[1], Martin Steinhart[2], and Mirco Imlau[1] — [1]Department of Physics, Osnabrück University, Germany — [2]Institute of Chemistry of New Materials, Osnabrück University, Germany

Optical metasurfaces are a rapidly evolving field in the aim to miniaturize optical functionalities and integrated photonics [A. Fedotova et al., *ACS Photonics* **2022**]. However, the large-scale application is still challenging as the preparation of such metasurfaces, i.e., by mechano-chemical wafer thinning or lithographic pattering, is usually complex, time-consuming, and expensive. We try to address this problem and present a novel method of metasurface patterning based on parallel additive capillary stamping of $LiNbO_3$ on an ITO substrate [F. Alarslan et al., *Advanced Engineering Materials* **2021**, 24(6)]. This technique offers the advantage of rapid, easily customizable and cheap structuring of layers with thicknesses on the order of 100 nm. Nonlinear optical investigations performed with the TIGER microscope show a homogeneous second harmonic generation (SHG) of the surface coinciding with the $LiNbO_3$ film structured by hexagonally arranged macropores. The additional implementation of gold nanoparticles at the position of the macropores allows for a drastic enhancement of the SHG by exploiting plasmonic resonances. Financial support by the ERC (project 646742 INCANA) and DFG (projects IM 37/12-1, FOR 5044 and INST 190/165-1) is gratefully acknowledged.

KFM 14.5 Thu 15:35 POT 106

Optical nonlinearities of lithium tantalate solid solutions — •Mirco Imlau, Tobias Hehemann, Sören Domke, Niklas Dömer, Fiete Breer, Felix Kodde, Jan Kleenen, Anton Pfannstiel, and Laura Vittadello — Institute of Physics, Osnabrück University

Optical nonlinearities of optical materials, i.e. the nonlinear material response to incident electromagnetic radiation, are the fundamental physical basis for a number of components in nonlinear photonics, such as nonlinear optical Kerr lenses, saturable absorbers or frequency converters. The properties of optical nonlinearities are closely related to the electronic and atomic structure of the material systems used. Against this background, lithium niobate tantalate (LNT, $LiNb_xTa_{1-x}O_3$ with $0 \leq x \leq 1$) solid solutions are promising because the edge compounds themselves (LN, x=1 and LT, x=0) are already extensively used in photonics' components, but especially because the nonlinear optical properties of LNT may be tailored to the specific requirements of the application via composition. We here present the state-of-the-art knowledge of our studies on optical nonlinearities of LNT over the entire composition range, both, for quasi-instantaneous nonlinear responses (absorption & nonlinear index, frequency conversion) and transient responses (time-resolved transient absorption on the temporal multiscale from femtoseconds to seconds & transient index dynamics). The findings are discussed in the framework of emerging applications in (nano-)photonics, particularly for laser systems of the next generation, and will be compared with LN and LT. Financial support by the DFG (project IM 37/12-1, FOR 5044).

KFM 14.6 Thu 15:55 POT 106

Small polaron absorption centers in lithium noibate-tantalate solid solutions — •Anton Pfannstiel[1], Simone Sanna[2], Yuriy Suhak[3], and Steffen Ganschow[4] — [1]Inst. Physics, Osnabrück University — [2]Inst. Theoretical Physics, University of Gießen — [3]Inst, Energy Research, Technical university of Clausthal — [4]Leibniz-Institut für Kristallzüchtung (IKZ), Berlin

The study of small polarons in ferroelectric lithium niobate (LN) enabled the understanding of various physical phenomena on a microscopic level, like photo-induced coloration or conductivity and led to the formulation of a robust model of polaronic localization centers and energies [O. F. Schirmer *et al* 2009 J Phys.: Condens. Matter **21** 123201]. So far, for lithium tantalate (LT) and the solid solution, lithium niobate-tantalate (LNT) a respective small polaron model is missing in literature.

For this purpose, this study provides polaron self localization energies for LN, LT and LNT crystals of various composition. Thermally reduced crystals are optically bleached at cryogenic temperatures. The resulting small polaron absorption bands are identified through transmission spectroscopy and modeled within the framework of small polaron absorption theory. The determined polaron energies are interpreted against the background of the known defect models for LN and LT but also in conjunction with ab-initio modeling results for carrier self-localization. Financial support by the DFG [projects IM 37/12-1, SA 1948/3-1, SU 1261/1-1, GA 2403/7-1, FOR5044] is gratefully acknowledged.

KFM 14.7 Thu 16:15 POT 106

Nonlinear diffuse fs-pulse reflectometry adopted to LNT solid solutions — •F. Kodde[1], L. Vittadello[1], J. Klenen[1], K. Koempe[2], V. Hreb[3], D. Sugak[3], V. Sydorchuk[4], U. Yakhnevych[5], and M. Imlau[1] — [1]Institute of Physics, Barbarastr. 7, Osnabrück University — [2]Department of Biology and Chemistry, Barbarastr. 11, Osnabrück University — [3]Department of Semiconductor Electronics, Bandery Str. 12, Lviv Polytechnic National University, 79013 Lviv, Ukraine — [4]Institute for Sorption and Problems of Endoecology, NASU, 13 Gen. Naumov St., 03164 Kyiv, Ukraine — [5]Institute of Energy Research and Physical Technologies, Am Stollen 19B, TU Clausthal

Nonlinear diffuse fs-pulse reflectometry is a powerful tool to analyze the spontaneous polarization of polar oxide nano-crystals [Kijatkin *et al.*, Photonics **4**, 11 (2017)]. It profits from the absence of a phase-matching condition for frequency conversion. We present our systematic investigations at the example of nanocrystals of $LiNb_{1-x}Ta_xO_3$ (LNT) solid solutions [Vasylechko *et al.*, Crystals **11**, 755 (2021)], that show a disappearance of the birefringence if the temperature is precisely adjusted [Wood *et al.*, J. Phys.: Condens. Mat. **20**, 235237 (2008)]. Accordingly, we have extended the experimental setup by a temperature controlled pellet holder and determined the harmonic ratio as a function of composition, i.e. Li/Ta-ratio. We find both, a characteristic maximum of the harmonic ratio, and a dependence of the maximum on the composition. Financially supported by the DFG and BMBF [project IM 37/12-1, FOR5044, BMBF, FKZ: 01DK20009].

Members' Assembly of the Magnetism Division

Thu   18:00–19:00   HSZ 04

Sessions
– Invited Talks, Contributed Talks, and Posters –

MA 1: Tutorial: Strategic elements and sustainability (joint session MA/TUT)

Our appetite for resources is insatiable. The path to a climate-neutral society and economy requires the increasingly intensive use of strategy metals such as lithium, cobalt, nickel, but also the group of rare earth elements. This major transformation is not possible without the sustainable use of these so-called critical elements along the entire value chain. In the Tutorial "Strategic elements and sustainability", we have four eminent speakers looking in this context at new developments in batteries, catalysis, thermoelectrics and magnetism.

Organizers: Oliver Gutfleisch (TU Darmstadt) and Heiko Wende (U. Duisburg-Essen).

Time: Sunday 16:00–18:00   Location: HSZ 04

Invited Talk   MA 1.1   Sun 16:00   HSZ 04
Making better batteries? – From Li-ion to Na-ion batteries — •Philipp Adelhelm — Humboldt-University Berlin, Berlin, Germany — Helmholtz-Zentrum Berlin, Berlin, Germany

The shift to electromobility is one of the most important transformations currently taking place in our society. This is associated with a sharp increase in battery production, which on the one hand opens up new opportunities, but on the other hand also has a massive impact on raw material supply and supply chains. In addition, new large markets are emerging, such as stationary energy supply or mobile robotics. Lithium-ion batteries are currently the most attractive technology for this. However, due to the large demand for batteries and the different application scenarios, other technologies are also being pursued. Sodium ion batteries can be produced on the same production lines as lithium ion batteries and are therefore considered a "drop-in" technology. The aim here is to replace not only costly lithium but also other expensive elements such as nickel or copper. Work is therefore being done worldwide on a cell chemistry for sodium ion batteries that works almost as well as lithium ion technology, but at the same time is cheaper and more readily available, or has other specific advantages. The tutorial gives an introduction to sodium ion technology. The motivation and state-of-the art are explained in more detail and material aspects are discussed. In particular, the question is addressed which electrode materials are promising for sodium ion batteries, what is needed to achieve further progress and what actually happens when lithium ions are replaced by sodium ions in a battery.

Invited Talk   MA 1.2   Sun 16:30   HSZ 04
Sustainable Thermoelectric Materials Predicted by Data Mining and Machine Learning — •Kornelius Nielsch — Leibniz Institute of Solid States and Materials Research, Dresden, Germany — Institute of Materials Research at TU Dresden, Germany — Institute of Applied Physcis at TU Dresden, Germany

Generating electricity from temperature differences has proven itself in space. Thanks to this technology, the Voyager probes launched in 1977 are still sending signals today. In the meantime, the car industry and ship producers have become interested in thermoelectrics. The combustion of fossil fuels produces exhaust gas that is up to 1300 ˚C hot. Modern thermoelectric materials are continuously expanding the fields of thermoelectric applications. The experimental search for new thermoelectric materials remains largely restricted to a limited number of successful chemical and structural families, such as chalcogenides, skutterudites and zintl phases. In principle, computational tools such as density functional theory (DFT) offer the possibility of directing experimental synthesis efforts towards very different chemical structures. In practice, however, predicting thermoelectric properties based on first principles remains a difficult endeavour, and experimental researchers do not usually use computations directly to drive their own synthesis efforts. Strategies to bridge this practical gap between experimental requirements and computational tools will be discuss und presented in this tutorial talk. Ref: Energy Environ. Sci. 14, 3559 (2021) and Advanced Theory and Simulations 5, 2200351 (2022)

Invited Talk   MA 1.3   Sun 17:00   HSZ 04
Design strategies for electrocatalysts – an electrochemist's perspective — •Kristina Tschulik — Ruhr-Universität Bochum, Faculty for Chemistry and Biochemistry, Chair for Electrochemistry and Nanoscale Materials — Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Straße 1, 40237 Düsseldorf

The aim to produce highly active, selective, and long-lived electrocatalysts by design drives major research efforts toward gaining fundamental understanding of the relationship between material properties and their catalytic performance. Surface characterization tools enable to assess atomic scale information on the complexity of electrocatalyst materials. Advancing electrochemical methodologies to adequately characterize such systems was less of a research focus point. In this tutorials, we shed light on the ability to gain fundamental insights into electrocatalysis and establish design strategies based on these. Concepts on how to improve mass transport, e.g. by exploiting magnetic fields are highlighted in this respect. Particular attention is paid to deriving design strategies for nanoelectrocatalysts, which is often impeded, as structural and physical material properties are buried in electrochemical data of whole electrodes. Thus, a second major approach focuses on overcoming this difference in the considered level of complexity by methods of single-entity electrochemistry. The gained understanding of intrinsic catalyst performance will ultimately allow us to advance design concepts to transforming "pre-catalysts" in the forseeable future.

Invited Talk   MA 1.4   Sun 17:30   HSZ 04
Green magnetic materials for efficient energy, transport and cooling applications — •Oliver Gutfleisch — TU Darmstadt, Material Science, Functional Materials

High performance hard and soft magnets are key components of energy-related technologies, such as direct drive wind turbines and e-mobility. They are also important in robotics and automatization, sensors, actuators, and information technology. The magnetocaloric effect (MCE) is the key for new and disruptive solid state-based refrigeration. Magnetic hysteresis and its inherent energy product characterise the performance of all magnetic materials. In the 60th position of the periodic table of elements is neodymium - an element that belongs to the rare earth-lanthanides and essential for the above applications. Basic material requirements, figure of merits, demand and supply, criticality of strategic elements and their recycling are explained for both permanent magnets and magnetocalorics referring to the benchmark materials NdFeB and LaFeSi. Every battery needs a magnet. 95% of electric vehicles utilize rare earth magnet-based drive motors, the quantities required global will grow from 5.000 t in 2019 to about 40.000 - 70.000 t per anno in 2030. The material history of neodymium is exciting and complex; monopolistic mining in China under ruinous conditions is just as problematic as our dependence on it. How "green" are the metals for renewable technologies? Who pays which price for it, and when?

MA 2: Skyrmions I

Time: Monday 9:30–12:00   Location: HSZ 02

Invited Talk   MA 2.1   Mon 9:30   HSZ 02
Two-dimensional Skyrmions in the real three-dimensional world — •Nikolai Kiselev — Institute for Advanced Simulation and Peter Grünberg Institute, Forschungsyentrum Jülich, 52425 Jülich Germany

Chiral skyrmions (CSs) emerging in noncentrosymmetric magnetic crystals are a prominent example of topological magnetic solitons – objects possessing properties of ordinary particles. In three-dimensional (3D) bulk samples, CSs usually form vortex-like strings penetrating the whole sample. Although CSs emerge as 3D objects, the two-dimensional (2D) model of a chiral magnet still represents a powerful tool for the theoretical study of CSs. In this talk, I'll present an overview of those phenomena predicted by the 2D model that found its experimental confirmation. In particular, I'll discuss the diversity of CSs with arbitrary topological charge [1] – skyrmions bags, the effect of turning skyrmions inside out [2], and the related phenomenon of skyrmion-antiskyrmion coexistence [3].

The discussion of the above phenomena is supported by a high-resolution transmission electron microscopy experiment. As an illustration of a phenomenon that cannot be described in a simplified 2D model, I'll present the theoretical and experimental study of so-called skyrmion braiding – the emergence of superstructures of skyrmion strings that wind around one another [4].

MA 2.2   Mon 10:00   HSZ 02

Comparing Thiele-model computer simulations and experiments of skyrmion interactions and lattice formation — •Jan Rothörl[1], Yuqing Ge[1,2], Maarten A. Brems[1], Raphael Gruber[1], Mathias Kläui[1], and Peter Virnau[1] — [1]Institut für Physik, Johannes Gutenberg-Universität Mainz — [2]Department of Physics, Chalmers University of Technology, Göteborg, Sweden
Magnetic skyrmions in thin films are often described as quasi-particles evolving according to the Thiele equation. Due to their effective 2D nature, their phase behavior can be compared to phase transitions described by the KTHNY theory. To allow for this analysis, we compare experimental and simulation results for skyrmion lattice formation [1] and determine skyrmion-skyrmion interaction potentials using the Iterative Boltzmann Inversion method [2]. These resulting potentials are then compared to the work describing the dependence of the kind of 2D phase transition on the shape of particle interactions [3].

MA 2.3   Mon 10:15   HSZ 02

Machine learning based skyrmion detection with Kerr microscopy data — Isaac Labrie-Boulay[1], Thomas Winkler[1], Daniel Franzen[2], •Kilian Leutner[1], Alena Romanova[1], Hans Fangohr[3,4], and Mathias Kläui[1] — [1]Johannes Gutenberg University, Mainz, Institute of Physics, Staudinger Weg 7, Germany — [2]Johannes Gutenberg University, Mainz, Institute of Informatics, Staudinger Weg 9, Germany — [3]Max-Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, Germany — [4]University of Southampton, SO17 1BJ, Southampton, United Kingdom
Magnetic skyrmions are topologically stabilized quasi-particles and are a potential enabler for unconventional computing devices [1]. A common method for detecting skyrmions is to use a Kerr microscope. Experimental data is affected by noise, low contrast, intensity gradients, or defects. Therefore, manual data treatment is necessary to evaluate the observations. To automatize Kerr microscopy data analysis, we have used a special type of convolutional neural network, called U-Net, to determine the shapes and positions of skyrmions [2]. Different methods were used to optimize the classification and to detect the skyrmions quickly with high reliability and to minimize manual work [3]. Our approach can also be extended to other magnetic structures, such as stripe domains or vortices.

MA 2.4   Mon 10:30   HSZ 02

Topological Hall effect in Pd/Fe/Ir(111) induced by electron scattering on magnetic skyrmions — •Adamantia Kosma[1], Philipp Rüssmann[2,3], Stefan Blügel[3], and Phivos Mavropoulos[1] — [1]Department of Physics, National and Kapodistrian University of Athens, Panepistimioupolis 15784, Athens, Greece — [2]Institute for Theoretical Physics and Astrophysics, University of Würzburg, 97074 Würzburg, Germany — [3]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany
This work comprises an ab-initio computational study of the topological Hall effect (THE) arising from magnetic skyrmions [1], which are formed in ultra-thin films Pd/Fe/Ir(111) [2]. The investigation of the THE in these systems is of great importance, as it provides a way of electrically detecting magnetic skyrmions. We analyse the resistivity and the Hall angle of the system, which are calculated employing the non-collinear spin-density-functional theory within the full-potential relativistic Korringa-Kohn-Rostoker (KKR) Green function method combined with the semiclassical Boltzmann transport equation [3,4]. We discuss the dependence of the THE on additional electron scattering, modelled as random disorder broadening. Our findings predict a strong dependence of the topological Hall angle on the degree of disorder of a sample. [1] D. Maccariello et al., Nature Nanotechnology, vol. 13, 233-237 (2018). [2] N. Romming et al., Science, vol. 341, 6146, 2013. [3] https://jukkr.fz-juelich.de/. [4] A. Kosma et al., Phys. Rev. B, vol. 102, 144424.

15 min. break

MA 2.5   Mon 11:00   HSZ 02

Observation of the sliding mode of the magnetic texture in Fe/Ir(111) — •Wulf Wulfhekel[1], Hung-Hsiang Hang[1], Louise Desplat[2], Volodymyr Kravchuk[1], Marie Hervé[3], Timofey Balashov[4], Philipp Markus[1], Markus Garst[1], and Bertrand Dupé[5] — [1]Karlsruhe Institute of Technology, Karlsruhe — [2]IPCMS, Université de Strasbourg, Strasbourg — [3]Université Sorbonne, Paris — [4]RWTH Aachen, Aachen — [5]Université de Liège, Liège
The fourfold non-collinear spin texture of Fe on the sixfold surface of Ir(111) is known to be incommensurate along one of the diagonals of the unit cell, while it is commensurate along the other. As the periodicity of the spin texture is only a few atoms, the magnetic energy of the structure experiences the atomic lattice rather strongly. Theoretically, the sliding mode of the spin texture with respect to the crystal lattice becomes gapped in the commensurate direction while it stays soft along the incommensurate one. We report on a combined theoretical and experimental study of the sliding mode along the soft direction excited by microwave fields in the junction of a spin-polarized STM.

MA 2.6   Mon 11:15   HSZ 02

Chemical pressure tuning of a skyrmion lattice with giant topological Hall effect — •Leonie Spitz[1,2], Max Hirschberger[1], Shang Gao[1], Taro Nakajima[1,3], Christian Pfleiderer[2], Taka-hisa Arima[1,4], and Yoshinori Tokura[1] — [1]RIKEN CEMS, Wakoshi, Saitama 351-0198, Japan — [2]Physik-Department, Technical University of Munich, 85748 Garching, Germany — [3]Institute for Solid State Physics, University of Tokyo, Kashiwa 277-8581, Japan — [4]Department of Advanced Materials Science, University of Tokyo, Kashiwa, Chiba 277-8561, Japan
A skyrmion lattice accompanied by a large topological Hall effect was found in the centrosymmetric frustrated triangular lattice magnet Gd_2PdSi_3 [1]. In contrast to non-centrosymmetric compounds, the skyrmion spin-vortices are not stabilized by the Dzyaloshinskii-Moriya interaction, but rather by exchange frustration and the Ruderman-Kittel-Kasuya-Yosida interaction [2,3]. The nanometer-scale size of the skyrmions is a further novelty giving rise to a large emergent magnetic field. We study the effect of isoelectronic doping on Gd_2PdSi_3 to gain a deeper understanding of the material's magnetic and electronic properties. Via alloying we manipulate the lattice constants and polytypism of the structure [4]. We report the impact of chemical pressure tuning on the magnetic order and the topological Hall effect.

MA 2.7   Mon 11:30   HSZ 02

Relationship of charge and spin density waves in the skyrmion compound $EuGa_2Al_2$ — •Steven Gebel[1], Jaime Moya[2], Jochen Geck[1], and Marein Rahn[1] — [1]Institute for Solid State and Materials Physics, Technical University of Dresden, 01062 Dresden, Germany — [2]Department of Physics and Astronomy, Rice University, Houston, TX, 77005, USA
The interplay of spin and charge density waves (SDW/CDW) in rare earth intermetallics is a matter of great interest, since it may reveal a recipe of how to taylor an antiferromagnet to yield certain topological properties. The centrosymmetric skyrmion host series $Eu(Ga,Al)_4$ provides an ideal setting to explore this scenario: The electronic structure can be tuned by chemical and hydrostatic pressure, which induces CDWs, which, in turn, determine a landscape of frustrated itinerant electronic correlations. To clarify the origin and character of such nesting instabilities, we studied subtle structural variations with temperature and pressure, and related them to density functional structure calculations. As magnetic structure determinations of more members of the series become available, this may explain exactly which factors toggle the magnetism's topological character.

MA 2.8   Mon 11:45   HSZ 02

Influence of interlayer Dzyaloshinskii-Moriya interactions on magnetic textures — •Elena Vedmedenko — University of Hamburg
An overview of magnet/non-magnetic metal/magnet trilayers with strong interlayer Dzyaloshinskii-Moriya interactions promoting out-of-plane as well as in-plane chirality between the magnetic layers will be presented [1-2]. Magnetic structuring in systems with the interlayer as well as intralayer Dzyaloshinskii-Moriya interactions will be discussed. An emphasis on the topological stability of those objects will be made.

Voltage-driven giant modulation of magnetism in ferro- and ferri-magnetic alloys — •Xinglong Ye[1,2], Harish Singh[1], Hongbin Zhang[1], Holger Gesswein[3], Reda Chellali[2], Ralf Witte[2], Alan Molinari[2], Konstantin Skokov[1], Oliver Gutfleisch[1], Horst Hahn[2], and Robert Kruk[2] — [1]Department of Material Science, Technical University Darmstadt — [2]Institute of Nanotechnology, Karlsruhe Institute of Technology — [3]Institute of Applied Materials, Karlsruhe Institute of Technology

Controlling magnetism and magnetic properties by small voltages have become one of the core research topics vigorously pursued in magnetoelectric actuation, spintronics and data storage. In magnetically-ordered metals and alloys, however, the voltage effect is usually limited to the scale of atomic layers due to strong electric-field screening. Here, we propose to control their magnetism and magnetic properties by electrochemically-driven insertion/extraction of hydrogen atoms in interstitial sites. Using this approach, we have tuned the magnetocrystalline anisotropy and coercivity of SmCo5 with micrometer-sized particles by more than 1 T by applying voltages as low as 1 V. Consequently, a voltage-assisted and -controlled magnetization reversal has been achieved at room temperature for the first time in permanent magnets. Furthermore, we will show that our electrochemically-driven hydrogen charging can switch the perpendicular anisotropy to in-plane anisotropy in ferrimagnetic thin films with high anisotropy energy, which further exemplifies the universality of our approach in controlling magnetism of rare earth - containing materials.

MA 3.2   Mon 9:45   HSZ 401

Additive Manufacturing of (Pr,Nd)-Fe-Cu-B Permanent Magnets — •Jianing Liu[1], Ruiwen Xie[2], Alex Aubert[1], Lukas Schäfer[1], Holger Merschroth[3], Jana Harbig[3], Ying Yang[4], Philipp Gabriel[4], Anna Ziefuss[4], Stefan Barcikowski[4], Matthias Weigold[3], Hongbin Zhang[2], Oliver Gutfleisch[1], and Konstantin Skokov[1] — [1]Functional Materials, Technical University of Darmstadt — [2]Theory of Magnetic Materials, Technical University of Darmstadt — [3]Institute of Production Management, Technology and Machine Tools, Technical University of Darmstadt — [4]Technical Chemistry I, University of Duisburg-Essen

Additive Manufacturing (AM) of permanent magnets is a new and challenging field in material science and engineering. To obtain a microstructure necessary for high coercivity is by no means straightforward, especially after fast cooling in Laser Powder Bed Fusion (L-PBF). In order to achieve the desired microstructure and hard magnetic properties, we propose the Pr-Fe-Cu-B as a new useful reference alloy system and compare with its Nd-based counterpart. Our studies describe the L-PBF and the subsequent annealing optimization in order to understand the newly established coercivity mechanism. Specifically, we explore the 6-13-1-type grain boundary phase and grow single crystals to understand its magnetism, supported by DFT calculations. Furthermore, grain boundary engineering with nanoparticles shows great potential on grain refinement and uniaxial grain growth during re-solidification during L-PBF. We acknowledge the support of the Collaborative Research Centre/Transregio 270 HoMMage.

MA 3.3   Mon 10:00   HSZ 401

Simultaneous measurements of X-ray absorption, diffraction and bulk properties in HoCo$_2$ — •Katharina Ollefs[1], Gabriel Gomez-Eslava[1], Alex Aubert[2], Konstantin Skokov[2], Alexey Karpenkov[2], Oliver Gutfleisch[2], Fabrice Wilhelm[3], Andrei Rogalev[3], Damian Günzing[1], Johanna Lill[1], Benedikt Eggert[1], and Heiko Wende[1] — [1]Faculty of Physics and CENIDE, University Duisburg-Essen, Germany — [2]Functional Materials, Technical University Darmstadt, Germany — [3]European Synchrotron Radiation Facility, France

Bulk properties and atomistic/local parameters determined by X-ray Absorption Spectroscopy (XAS) or scattering are typically measured on different samples (such as powder) with the same composition. Together with the influence of the different sample environments in different setups this prevents a direct correlation of microscopic and macroscopic observations, especially for materials exhibiting dramatic changes of their properties around phase transitions. Here we present the ULMAG [1] set up. To demonstrate the capability of our technique we measured, a polycrystalline HoCo$_2$ sample. We show the magnetic field dependence of X-ray Magnetic Circular Dichroism (XMCD), stray field, longitudinal and transversal strain and sample temperature. Furthermore we demonstrate the capability to measure XAS/XMCD and diffraction on a single grain inside this material. [1] Aubert, Alex, et al. IEEE Transactions on Instrumentation and Measurement 71 (2022): 1-9. Supported by the DFG CRC TRR 270 HoMMage, the BMBF project ULMAG and the ESRF by beamtime allocation.

MA 3.4   Mon 10:15   HSZ 401

A thorough TEM investigation of B2 ordered FeRh (50/50) alloy — •Esmaeil Adabifiroozjaei[1], Nagaarjhuna Kani[1,2], Robert Winkler[1], Tianshu Jiang[1], Oscar Recalde[1], Alexander Zintler[1], Alisa Chirkova[2], Konstantin Skokov[2], Oliver Gutfleisch[2], and Leopoldo Molina Luna[1] — [1]Advanced Electron Microscopy, Department of Materials- and Earth Sciences, Technical University of Darmstadt, Germany — [2]Functional Materials, Department of Materials- and Earth Sciences, Technical University of Darmstadt, Darmstadt, Germany

Fe50Rh50 alloys are known to have a B2 structure with an antiferromagnetic to ferromagnetic transition at near room temperature. Since this alloy can be considered as betta alloy (CdAu, TiNi, Fe-C, etc), it is expected to present a pre-martensite structure followed by a martensite structure upon cooling at cryogenic temperature. The martensite was also predicted by extensive first principal calculations. However, so far, no evidence has been given regarding the formation of either pre-martensite or martensite structures in the Fe50Rh50 alloy. Here, we use various TEM techniques (including CTEM, HRTEM, STEM (HAADF), and EDS) to investigate the FeRh 50/50 alloy and demonstrate that although the structure of the alloy matches the B2 BCC structure, there is systematic modulation along certain reflexes (100 and 110). We believe that the existence of such ordered modulation along certain directions are indicative of a pre-martensite structure.

MA 3.5   Mon 10:30   HSZ 401

Shaping and functionalizing of Gd for a magnetocaloric cooling application — •Lukas Beyer[1,2], Bruno Weise[1], Julia Kristin Hufenbach[1,2], and Jens Freudenberger[1,2] — [1]Leibniz IFW Dresden, Institute for Complex Materials, Helmholtzstr. 20, 01069, Dresden, Germany — [2]TU Bergakademie Freiberg, Institute of Materials Science, Gustav-Zeuner-Str. 5, 09599, Freiberg, Germany

Magnetic refrigeration based on the magnetocaloric effect aims to substitute conventional cooling solutions, still, shaping and use of magnetocaloric materials remains challenging [1]. A combination with so-called thermal switches could improve the heat transport resulting in higher operating frequencies and therefore, an increase in the power density of magnetic cooling [2]. This could be beneficial for battery thermal management systems [3]. In this work we studied the influence of mechanical deformation on Gd while producing Gd-substrates that could be combined with fast thermal switches by ElectroWetting On Dielectric. We prepared Gd-substrates via cold-rolling and strip casting and investigated these in regards of sufficient surface quality and substrate dimensions. Heat treatments have been performed to restore the magnetocaloric effect after deformation. By means of magnetic and heat-capacity measurements we calculated the isothermal entropy and adiabatic temperature change and proved the recovery of the magnetocaloric effect in Gd-substrates. [1] J. S. Brown, et al.;Appl. Therm. Eng. 64 (2014). [2] A. Kitanovski, et al.;Int.J. Refrig. 33 (2010). [3] J. Kim et al.;Appl. Therm. Eng. 149 (2019).

MA 3.6   Mon 10:45   HSZ 401

Large Room Temperature Anomalous Transverse Thermoelectric Effect in Kagome Antiferromagnet YMn6Sn6 — •Subhajit Roychowdhury[1], Andrew M. Ochs[2], Satya N. Guin[1], Kartik Samanta[1], Jonathan Noky[1], Chandra Shekhar[1], Maia G. Vergniory[1], Joshua E. Goldberger[2], and Claudia Felser[1] — [1]Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany — [2]The Ohio State University, Columbus, 43210 Ohio, United States

Kagome magnets possess several novel non-trivial topological features owing to the strong correlation between topology and magnetism, that extends to their applications in the field of thermoelectricity. Conventional thermoelectric (TE) devices use the Seebeck effect to convert heat into electrical energy. In contrast, transverse thermoelectric devices based on the Nernst effect are attracting recent attention due to their unique transverse geometry, which uses a single material to eliminate the need for a multitude of electrical connections compared to conventional TE devices. In this study, we obtain a large anomalous transverse thermoelectric effect of ~ 2 microV K-1 at room temperature in a kagome antiferromagnet YMn6Sn6 single crystal. The obtained value is larger than that of state-of-the-art canted antiferromagnetic (AFM) materials and comparable with ferromagnetic systems. The large anomalous Nernst effect (ANE) can be attributed to the net Berry curvature near the Fermi level.

MA 3.7   Mon 11:15   HSZ 401

Tailoring of thermal hysteresis in Ni-Mn-Sn shape memory alloys via microstructure design — •Franziska Scheibel[1], Chistian Lauhoff[2], Johannes Puy[1], David Koch[1], Philipp Krooss[2], Thomas Niendorf[2], and Oliver Gutfleisch[1] — [1]Technische Universität Darmstadt, Darmstadt, Germany — [2]Universität Kassel, Kassel, Germany

Ferromagnetic shape memory alloys (FSMA) like Ni-Mn-Sn undergo a magneto-structural transition and show giant multicaloric properties. Thus, these materials are excellent for caloric refrigeration as an energy efficient, environmentally friendly and safe alternative for vapor compression cooling. However, tailoring of the inherent thermal hysteresis is essential for material development [1].

The hysteresis can be influenced by the microstructure (grain configuration and size, texture, defects, or internal stress) [2]. In this study, the grain size and arrangement have been modified by powder-based processing using spark-plasma sintering and additive manufacturing technique to tailor both the microstructure and the thermal hysteresis at the same time. The understanding of the relation between grain-size, texture, grain arrangement and multiple external stimuli is essential to develop materials with first-order magneto-structural transition transformation for multicaloric cooling.

This work was supported by the ERC Advanced Grant "Cool Innov" and the SFB-TRR270 "HoMMage".

Impact of disorder on the vibrational and magnetic properties of Ni-Mn-(Sn,In) Heusler alloys — •Olga N. Miroshkina[1], Benedikt Eggert[1], Johanna Lill[1], Benedikt Beckmann[2], David Koch[2], Katharina Ollefs[1], Francesco Cugini[3], Massimo Solzi[3], Mojmir Šob[4], Martin Friák[4], Oliver Gutfleisch[2], Heiko Wende[1], and Markus E. Gruner[1] — [1]University of Duisburg-Essen, Duisburg, Germany — [2]Technical University of Darmstadt, Darmstadt, Germany — [3]University of Parma, Parma, Italy — [4]Czech Academy of Sciences, Brno, Czech Republic

Ni-Mn-Z with Z=In,Sn Heuslers are promising magnetocaloric systems to be employed in the magnetic cooling devices. In this respect, it is important to understand the influence of the main group element on the vibrational and magnetic properties of these materials. By combining large-scale density functional theory calculations with ^{119}Sn-NRIXS and Mössbauer spectroscopy, we disentangled the vibrational contributions of the Sn atoms in Ni_2MnSn. We found the evidence that inversion of optical modes at Γ involving the displacement of Ni and the heavier Z atoms predicted previously for other Ni-Mn-based Heuslers is also a property of Ni_2MnSn, while deviation between experimental spectra and simulations might be explained by site-disorder [1]. In turn, the variation of Z in combination with chemical disorder can be employed to control the magnetization of the transition metal sublattice [2]. This work is funded by DFG within CRC/TRR 270.

MA 3.9   Mon 11:45   HSZ 401

Tailoring thermal hysteresis and microstructure of Ni-Mn-based Heusler alloys for multicaloric cooling applications — •Andreas Taubel[1], Franziska Scheibel[1], Lukas Pfeuffer[1], Benedikt Beckmann[1], Navid Shayanfar[1], Tino Gottschall[2], Konstantin Skokov[1], and Oliver Gutfleisch[1] — [1]TUDarmstadt, Material Science, 64287 Darmstadt — [2]Dresden High Magnetic Field Laboratory (HLD-EMFL), HZDR, 01328 Dresden

Refrigeration based on the magnetocaloric effect (MCE) attracts a lot of attention since it can be more energy efficient and environmentally friendly than current vapor compression technology. The concept uses a solid-state magnetic material that heats up and cools down cyclically when exposed to a changing magnetic field. The problem of thermal hysteresis for efficient materials with a first-order phase transition can be overcome by applying stress as a second stimulus [1].

In this work, we develop Ni-Co-Mn-In and Ni-Co-Mn-Ti Heusler alloys towards using them in a novel multi-stimuli cooling concept. We investigated the influence of different microstructures from chemical variation and different processing routes on the magnetocaloric and elastocaloric performance of these materials [2,3]. The introduction of secondary phases significantly enhances the mechanical stability.

We acknowledge funding by ERC (Adv. Grant Cool Innov, GrantNo. 743116) and by DFG (CRC HoMMage, ID 405553726 *TRR 270)

MA 3.10   Mon 12:00   HSZ 401

Influence of Cu addition and chemical order on the thermomagnetic properties of Ni-Mn-Ga-based films — •Lukas Fink[1,2,3], Kornelius Nielsch[2,3], and Sebastian Fähler[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, D-01328 Dresden, Germany — [2]Leibniz IFW Dresden, Institute for Metallic Materials, D-01171 Dresden, Germany — [3]TU Dresden, Institute of Materials Science, D-01062 Dresden, Germany

One way to harvest low-grade waste heat is a microscale thermomagnetic generator (TMG), which uses magnetocaloric films as active material. The high surface-to-volume ratio of thin films enables a fast heat transfer, increasing the cycling frequency and power density compared to bulk devices. Selecting the optimal active material is decisive for the efficiency of a TMG since it will determine the temperature regime and the cycling frequency. Recently Ni-Mn-based Heusler alloys were proposed as they can be prepared by standard thin-film technologies.

Here we use combinatorial growth of Cu alloyed Ni-Mn-Ga films and subsequent heat treatment for systematic optimization of thermomagnetic properties. We examine the key thermomagnetic properties like 1) the working temperature T^* and 2) the performance $\frac{\Delta M}{\Delta T}$ and correlate them with common properties like 3) crystal structure, 4) 1st and 2nd order transition and 5) spontaneous magnetization. Within our research, we can disentangle the effects of valence electron number e/a and chemical order. This work is funded by the DFG (FA453/14).

Topological information device operating at the Landauer limit — •Ahmet Mert Bozkurt[1,2,3], Alexander Brinkman[4], and Inanc Adagideli[3,4] — [1]QuTech, Delft University of Technology, 2600 GA Delft, The Netherlands — [2]Kavli Institute of Nanoscience, Delft University of Technology, 2600 GA Delft, The Netherlands — [3]Faculty of Engineering and Natural Sciences, Sabanci University, Orhanli-Tuzla, Istanbul, Turkey — [4]MESA+ Institute for Nanotechnology, University of Twente, The Netherlands

We propose and theoretically investigate a novel Maxwell's demon implementation based on the spin-momentum locking property of topological matter. We use nuclear spins as a memory resource which provides the advantage of scalability. We show that this topological information device can ideally operate at the Landauer limit; the heat dissipation required to erase one bit of information stored in the demon's memory approaches $k_B T \ln 2$. Furthermore, we demonstrate that all available energy, $k_B T \ln 2$ per one bit of information, can be extracted in the form of electrical work. Finally, we find that the current-voltage characteristics of the topological information device satisfy the conditions of an ideal memristor.

MA 4.2   Mon 9:45   HSZ 403

Controlling 3D spin textures by manipulating sign and amplitude of interlayer DMI with electrical current — •Fabian Kammerbauer[1], Won-Young Choi[1], Freimuth Frank[1,2], Robert Frömter[1], Yuriy Mokrousov[1,2], and Mathias Kläui[1] — [1]Institute of Physics, Joahnnes Gutenberg University, Staudingerweg 7, 55128 Mainz, Germany — [2]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany

The recently discovered interlayer Dzyaloshinskii-Moriya interaction (IL-DMI) in multilayers with perpendicular magnetic anisotropy favors a canting of spins in the in-plane direction [1]. It could thus stabilize exciting spin textures such as

Hopfions. A key requirement for nucleation is to control the IL-DMI and so, we investigate the influence of an electric current on the strength of the IL-DMI, as previously found for FMI. The IL-DMI is quantified using out-of-plane hysteresis loops while applying a static in-plane magnetic field at varied azimuthal angles. We observe a shift in the azimuthal dependence with increasing current, which is concluded to originate from the additional in-plane symmetry breaking introduced by the current flow. Fitting the angular dependence we demonstrate the presence of an additive current-induced term [3]. With this, an easily accessible possibility to manipulate 3D spin textures by current is realized.

Nonequilibrium dynamics in a spin valve with noncollinear magnetization — •Rudolf Smorka[1], Pavel Baláž[2], Michael Thoss[1], and Martin Žonda[3,1] — [1]University of Freiburg, Germany — [2]Institute of Physics of the Czech Academy of Sciences Prague, Czech Republic — [3]Charles University Prague, Czech Republic

Manipulation of magnetization by electric currents enables novel functions for spin-transfer torque devices. We study the nonequilibrium spin dynamics and spin-transfer torques in noncollinear spin-valve heterojunctions using a mixed quantum-classical Ehrenfest approach.

In an isolated valve for short spacer layers and weak spin-electron couplings, magnetization dynamics of the ferromagnetic layers is in agreement with the macrospin approximation. For large spacer layers, our quantum-classical approach predicts electron-induced spin relaxation. For intermediate electron-spin couplings, a change in the localization character of the electronic eigenstates from metallic-like to insulator-like leads to a reduced indirect exchange interaction between spins mediated by the conduction electrons. In a spin valve coupled to leads, spin relaxation times differ by several orders of magnitude depending on whether the DC bias is introduced by shifting the electrochemical potentials of both leads symmetrically about the equilibrium Fermi level of the spin valve (reminiscent of a gate-tunable junction) or by shifting the chemical potential of only one lead (as realized in a scanning tunneling microscope geometry).

Nonrelativistic spin currents in altermagnets — •Rodrigo Jaeschke-Ubiergo, Jairo Sinova, and Libor Šmejkal — Institut für Physik, Johannes Gutenberg Universität Mainz, D-55099 Mainz, Germany

Altermagnetism has emerged recently as a third basic collinear magnetic phase [1], in addition to ferromagnets and antiferromagnets. Conventional antiferromagnets exhibit two sublattices with opposite magnetic moment related by translation or inversion. In altermagnets the magnetic sublattices are connected by a rotation or a mirror operation. The particular symmetry causes that altermagnets display time-reversal (T) symmetry breaking and spin split band structure even in absence of spin-orbit coupling [2]. In this work, we study the spin conductivity tensor in altermagnets by using spin group theory formalism [1]. We also use Kubo's linear response to calculate the spin conductivity tensor in all the altermagnetic spin point groups models. Additionally, we identify and sort 200 altermagnetic candidates into spin conductivity tensor classes. We will discuss some spin point groups that allow for a transverse spin current in detail. This is the case of spin splitter current in RuO_2 [3,4], which is a nonrelativistic effect that conserves spin unlike in general magnetic spin Hall effect in noncollinear magnets. Moreover, the spin conductivity tensor is symmetric and T-odd, which makes it different from the conventional spin Hall effect. [1] Šmejkal et al., PRX, 12, 031042 (2022). [2] Šmejkal, et al. Sci.Adv 2020. [3] Gonzalez- Hernandez, et al. PRL 2021. [4] Šmejkal, et al. PRX 12, 011028 (2022).

Quantification and modulation of intrinsic spin transport in 5d transition metals — •Akash Bajaj, Reena Gupta, Andrea Droghetti, and Stefano Sanvito — School of Physics and CRANN, Trinity College Dublin, Dublin 2, Ireland

Spin-Hall effect (SHE) enables charge-to-spin conversion in heavy transition metals, such as Ta and Pt, with strong spin-orbit coupling (SOC) strengths. It has been extensively studied as a viable mechanism for the development of next-generation spintronics-based non-volatile memory devices. Numerous experimental and first-principles approaches have been devised to quantify the charge-to-spin conversion efficiency i.e., the spin-Hall angle (SHA), for the SHE. However, such approaches unavoidably involve interface contributions and, in general, extrinsic effects such as disorder and impurities, which are known to be less dominant than the bandstructure-only intrinsic contribution in such heavy metals. In this work, we use density functional theory combined with a bond-current-based non-equilibrium Green's functions approach to quantify the intrinsic SHAs of bulk elemental and thin-film models of 5d transition metals. We then computationally demonstrate a strategy for modulating the SHA within the same device, using Pt and Au as contrasting examples. Our computational work

not only provides a quantitative estimation of the intrinsic SHAs for these materials, but also enables its theoretical understanding aimed towards the development of higher performance and power-efficient spintronics-based non-volatile memory devices.

MA 4.6 Mon 10:45 HSZ 403

Influence of Disorder at Insulator-Metal Interface on Spin Transport — Mahsa Alsadat Seyed Heydari, Wolfgang Belzig, and •Niklas Rohling — Department of Physics, University of Konstanz

Motivated by experimental work showing enhancement of spin transport between yttrium iron garnet and platinum by the thin antiferromagnetic insulator NiO [1] between them, we consider spin transport trough the interface of a nonmagnetic metal and a ferro- or antiferromagnetically ordered insulator. The spin transport is carried by spin-polarized electrons in the metal and by magnons in the insulator. Spin current can be generated by a spin accumulation in the metal due to the inverse spin Hall effect, a microwave field exciting magnons in the insulator, or by a thermal gradient (spin Seebeck effect). The spin current can be computed using Fermi's Golden Rule [2]. For a perfectly clean interface, the in-plane momentum is conserved for the electron-magnon scattering events which govern the spin transport through the interface. We calculate how disorder-induced broadening of the scatting matrix elements with respect to the in-plane momentum influences the spin current. As a general result, we observe that for many experimental setups, one should expect a rather small effect of interface disorder on the measured spin current.

MA 4.7 Mon 11:00 HSZ 403

Long-range orbital-Hall torques in Nb(or Ru)/Ni Heterostructures — Arnab Bose[1], Fabian Kammerbauer[1], •Rahul Gupta[1], Dongwook Go[2], Yuriy Mokrousov[1,2], Gerhard Jakob[1], and Mathias Kläui[1,3] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, 55128 Mainz, Germany — [2]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — [3]Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, NO-7491 Trondheim, Norway

We report a large orbital Hall torque (OHT) generated by Nb and Ru via strong dependence of torques on the ferromagnets, Ni, in Nb(Ru)/Ni heterostructures. We found the sign reversal of the damping-like torque in Nb/Ni. Moreover, the long-range orbital transport in the ferromagnet was revealed by the thickness dependences of Ni in Ni/Nb(or Ru) heterostructure, which are markedly different from the regular spin absorption in the ferromagnet that takes place within a few angstroms and thus it uniquely distinguishes OHT from the spin Hall torque. The experimentally measured effective orbital-Hall conductivities are found to be $6.1 \times 10^4 \frac{\hbar}{2e}$ $(\Omega m)^{-1}$ and $5.86 \times 10^4 \frac{\hbar}{2e}$ $(\Omega m)^{-1}$ for Nb and Ru, respectively, which is an order of magnitude higher than their measured spin Hall conductivities, as also confirmed by the density functional theory. This study opens a plethora of possibilities to further engineering the torques, utilizing the orbital degree of freedom.

MA 4.8 Mon 11:15 HSZ 403

Layer-resolved spin-orbit torque assisted magnetization dynamics in Pt/Co heterostructure — •Harshita Devda[1], András Deák[1], Leandro Salemi[3], Levente Rózsa[1], László Szunyogh[2], Peter M. Oppeneer[3], and Ulrich Nowak[1] — [1]Universität Konstanz, Konstanz, Germany — [2]Budapest University of Technology and Economics, Budapest, Hungary — [3]Uppsala University, Uppsala, Sweden

It is well known that the spin-orbit torque (SOT) mechanism is more reliable for current induced magnetization dynamics than the spin-transfer torque. The key phenomenon behind the SOT in heavy metal/ferromagnet (HM/FM) bilayers is attributed to the spin Hall effect (SHE) and the spin Rashba-Edelstein effect (SREE). However, the exact mechanism is still under debate. So far various works have studied the SOT-driven magnetic behavior in different magnetic systems, but the layer-resolved understanding of the SOT effect in the HM/FM bilayer due to spin-orbit coupling (SOC) in heavy metal is still lacking. We focus on current-induced magnetization dynamics in a Pt/Co bilayer assisted by the SOC in Pt. We use a multiscale model which links ab initio calculations with atomistic spin dynamics simulations. We implement a linear-response formalism to compute the electrically induced magnetic moments, caused by SHE in bulk and SREE at the interface, and utilize these in atomistic spin dynamics simulations. We analyse the layer-resolved behavior of both field-like and damping-like torques in FM and determine how they affect magnetization dynamics in ferromagnets.

Spin and orbital Edelstein effect in a bi- and trilayer system with Rashba interaction — •Sergio Leiva[1], Jürgen Henk[1], Ingrid Mertig[1], and Annika Johansson[2] — [1]Martin Luther University Halle-Wittenberg, Halle, Germany — [2]Max Planck Institute of Microstructure Physics, Halle, Germany

The spin Edelstein effect has proved to be a promising phenomenon to generate spin polarization from a charge current in systems without inversion symmetry. In recent years, current-induced orbital magnetization, also called the orbital Edelstein effect, has also been predicted for several systems with broken inversion symmetry [1-6].

In the present work, we calculate the current-induced spin and orbital magnetization for a bilayer and a trilayer system with Rashba interaction for the interface and the free-standing slab configurations. We use the modern theory of orbital magnetization [7] and the Boltzmann transport theory. We found a significantly larger orbital than spin effect, with a strong dependence on the model parameters, such as effective mass and spin-orbit coupling per layer. This dependence allows us to enhance and even revert the sign of the orbital effect.

Optical detection of the orbital Hall effect in a light metal Ti — •Young-Gwan Choi[1,2], Daegeun Jo[3], Kyung-Hun Ko[1], Dongwook Go[4,5], Kyung-Han Kim[3], Hee Gyum Park[6], Changyoung Kim[7,8], Byoung-Chul Min[6], Uri Vool[2], Gyung-Min Choi[1,9], and Hyun-Woo Lee[3,10] — [1]DOES, SKKU, Suwon, Korea — [2]MPI-CPfS, Dresden, Germany — [3]Physics, POSTECH, Pohang, Korea — [4]PGI and IAS, FZJ and JARA, Julich, Germany — [5]GSE Mainz, Mainz, Germany — [6]Center for Spintronics, KIST, Seoul, Korea — [7]Physics, SNU, Seoul, Korea — [8]CCES, IBS, Seoul, Korea — [9]CINAP, IBS, Suwon, Korea — [10]APCTP, Pohang, Korea

Electrical generation of the angular momentum current enables the development of novel memory devices, similar to spin current generation. Recently, it has been theoretically proposed that the orbital angular momentum (OAM) current can be driven by a charge current, called as the orbital Hall effect (OHE). Here we report evidence of the OHE, measured by magneto-optical Kerr effect microscopy. We detect large Kerr signals in one of the 3d transition metals, Ti, in which the high orbital Hall conductivity is predicted. We also find that the large OAM is accumulated by the OHE with a relaxation length ~70 nm. Moreover, we present the torque results in Ti/Ni. The high torque efficiency shows that the OAM injection allows for the electrical control of the magnetization. We also propose magnetic imaging using a nitrogen-vacancy scanning probe to measure OAM accumulation directly. Our results can pave the way for a deep understanding and provide techniques for generating and detecting orbital transport.

MA 4.11   Mon 12:00   HSZ 403

Spin and orbital Edelstein effects at oxide interfaces — •Annika Johansson[1], Börge Göbel[2], Sara Varotto[3], Srijani Mallik[3], Ingrid Mertig[2], and Manuel Bibes[3] — [1]Max Planck Institute of Microstructure Physics, Halle, Germany — [2]Martin Luther University Halle-Wittenberg, Halle, Germany — [3]Unité Mixte de Physique, CNRS, Thales, Université Paris-Saclay, Palaiseau, France

The spin Edelstein effect (SEE) provides charge-spin interconversion in nonmagnetic systems with broken inversion symmetry [1,2]: An external electric field generates a charge current as well as a homogeneous spin density. Further, a finite current-induced magnetization originating from the electrons' orbital moments can be generated, which is called orbital Edelstein effect (OEE) [3-5]. In this talk, the SEE and OEE at SrTiO$_3$- and KTaO$_3$-based two-dimensional electron gases are discussed within a semiclassical Boltzmann approach [6-8]. The OEE is predicted to exceed its spin counterpart by one order of magnitude, which can be understood by a band-resolved analysis of the SEE and OEE. Further, we suggest design rules for Rashba-like systems to enhance spin-charge interconversion efficiencies.

Anisotropic anomalous Hall effect in altermagnetic Mn$_5$Si$_3$ — •Miina Leiviskä[1], Rafael Lopes Seeger[1], Helena Reichlová[2,3], Ismaïla Kounta[4], Libor Šmejkal[5,3], Javier Rial[1], Sebastian Beckert[2], Antonín Badura[6,7], Isabelle Joumard[1], Dominik Kriegner[2,3], Eva Schmoranzerová[6], Jairo Sinova[5], Tomáš Jungwirth[3], Sebastian Goennenwein[7], Lisa Michez[4], and Vincent Baltz[1] — [1]Univ. Grenoble Alpes, CNRS, CEA, Grenoble INP, IRIG-SPINTEC, F-38000 Grenoble — [2]Institute of Solid State and Materials Physics, TU Dresden, Dresden, Germany — [3]Institute of Physics, Czech Academy of Sciences, Prague, Czechia — [4]Aix-Marseille University, CNRS, CINaM, Marseille, France — [5]Institute for Physics, Johannes Gutenberg University Mainz, Mainz, Germany — [6]Department of Chemical Physics and Optics, Faculty of Mathematics and Physics, Charles University, Prague, Czechia — [7]Department of Physics, University of Konstanz, Konstanz, Germany

The altermagnetic epitaxial films of Mn$_5$Si$_3$ exhibit anomalous Hall effect (AHE) despite the vanishing net magnetization [1]. This can be explained by non-relativistic time-reversal symmetry breaking, which allows for momentum-locked alternating spin-splitting of the bands [2]. Here, we investigate the anisotropy of the AHE by varying both the external field and the current channel orientations. In both cases, we observe unconventional, anisotropic behaviour that deviates from the typical behaviour of ferromagnets.

MA 4.13   Mon 12:30   HSZ 403

Observation of nonreciprocal magnon Hanle effect — •Janine Gückelhorn[1,2], Sebastián de-la-Peña[3], Matthias Grammer[1,2], Monika Scheufele[1,2], Matthias Opel[1], Stephan Geprägs[1], Juan Carlos Cuevas[3], Rudolf Gross[1,2,4], Hans Huebl[1,2,4], Akashdeep Kamra[3], and Matthias Althammer[1,2] — [1]Walther-Meißner-Institut, BAdW, Garching, Germany — [2]Physik-Department, School of Natural Sciences, TUM, Garching, Germany — [3]IFIMAC and Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, Madrid, Spain — [4]Munich Center for Quantum Science and Technology, München, Germany

The realization of the magnon Hanle effect, which is based on the precession of magnon pseudospin about the equilibrium pseudofield, via electrically injected and detected spin transport in an antiferromagnetic insulator demonstrates its high potential for devices and as a convenient probe for the underlying spin interactions in antiferromagnets. Here, we observe a nonreciprocity in the magnon Hanle signal measured in hematite (α-Fe$_2$O$_3$) using two spatially separated platinum electrodes as spin injector/detector [1]. Interchanging their roles was found to alter the detected magnon spin signal. The recorded difference depends on the applied magnetic field and reverses sign when the signal passes its nominal maximum at the so-called compensation field. We explain these observations in terms of a spin transport direction-dependent pseudofield. The latter leads to a nonreciprocity, which is found to be controllable via the applied magnetic field.

MA 4.14   Mon 12:45   HSZ 403

Spontaneous anomalous Hall effect arising from an unconventional compensated magnetic phase in a semiconductor — •Dominik Kriegner[1,2], Ruben Dario Gonzalez Betancourt[1,2,3,4], Jan Zubáč[1,3], Rafael Julian Gonzalez Hernandez[5], Kevin Geishendorf[4], Gunther Springholz[6], Kamil Olejník[1], Jakub Železný[1], Libor Šmejkal[7], Andy Thomas[2,4], Helena Reichlová[1,2], Sebastian Tobias Benedikt Goennenwein[8], and Tomas Jungwirth[1,9] — [1]Institute of Physics, AV ČR, Prague, Czech Republic — [2]IFMP, TU Dresden — [3]Charles University, Prague — [4]IFW Dresden — [5]Universidad del Norte, Barranquilla, Colombia — [6]JKU Linz, Austria — [7]JGU, Mainz — [8]University of Konstanz — [9]University of Nottingham, United Kingdom

The anomalous Hall effect, commonly observed in metallic magnets, has been established to originate from the time-reversal symmetry breaking by an internal macroscopic magnetization in ferromagnets or by a non-collinear magnetic order. Here we observe a spontaneous anomalous Hall signal in the absence of an external magnetic field in an epitaxial film of MnTe, which is a semiconductor with a collinear antiparallel magnetic ordering of Mn moments and a vanishing net magnetization. The anomalous Hall effect arises from an unconventional phase with strong time-reversal symmetry breaking and alternating spin polarization in real-space crystal structure and momentum-space electronic structure.

MA 5: Thin Films: Magnetic Coupling Phenomena / Exchange Bias

Time: Monday 9:30–11:00 Location: POT 6

MA 5.1 Mon 9:30 POT 6

Study of Amorphous CoFeB Film Interfaced with Heavy Metals using Magnetic Circular Dichroism in Hard X-Ray Photoemission — •A. Gloskovskii[1], C. Schlueter[1], M. Singh[2], S. K Vayalil[2], M. Gupta[3], V. R. Reddy[3], and A. Gupta[2] — [1]Photon Science, Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]Physics Department, University of Petroleum and Energy Studies, Dehradun, India — [3]UGC-DAE Consortium for Scientific Research, Indore, India

Heterostructures consisting of HM/CoFeB/HM (HM=Heavy Metal) are important for the development of low power spintronics, thanks to the phenomena like Interfacial Dzyaloshinskii-Moriya Interaction, spin Hall effect etc. The HM interface layers can significantly affect the magnetic properties as well as thermal stability of the CoFeB layer. In the present work, magnetic circular dichroism in hard X-ray photoemission (MCD-HAXPES) has been used to elucidate the possible difference in the electronic structure of Fe and Co atoms and the effect of interfacing HM layer on the same. Multilayers: Si(substrate)/HM 20nm/ $Co_{40}Fe_{43}B_{17}$ 10nm/HM 3nm/Al 3nm (HM=Mo, W) were deposited using magnetron sputtering. CoFeB layer is amorphous in nature. MCD-HAXPES measurements were done at beamline P22 of PETRA III, Hamburg, using 6 keV X-rays, falling at a grazing angle. The maximum asymmetry is found to be 39% for Fe and 23.6% for Co. Co spectrum has an additional weak shoulder at 4 eV from the main 2p line. This may be an indication of a correlation-induced satellite of majority spin nature in Co.

MA 5.2 Mon 9:45 POT 6

Ferromagnetic springs in exchange biased trilayers — •Sapida Akhundzada[1], Lukas Paetzold[1], Arne Vereijken[1], Christian Janzen[1], Thomas Saerbeck[2], and Arno Ehresmann[1] — [1]Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Kassel, Germany — [2]Institut Laue-Langevin, Grenoble, France

Exchange springs or magnetic helices, consisting of multilayered thin film systems, exhibit spiral spin configurations during magnetization reversal [1]. By combining magnetically soft/hard bilayers [2] or exchanged biased ferromagnetic/antiferromagnetic layer systems [3], comparably short domain walls can be engineered, making these systems interesting for fundamental as well as applied research [1]. Here we show how magnetic order can be induced in exchange biased trilayer systems consisting of a single ferromagnetic layer embedded between two antiferromagnetic layers. The exchange coupling between the ferromagnet and one antiferromagnet is modified by light helium ion bombardment [4] leading to a trilayer system in which the exchange bias at the two ferromagnet/antiferromagnet interfaces points in different directions. The trilayer system is characterized by angular-resolved vibrating sample magnetometry revealing the existence of the spiral domain state in the designed layer system.

Mesoscale Dzyaloshinskii-Moriya interaction in corrugated ultra-thin asymmetric magnetic layers — •Shahrukh Shakeel, Oleksii M. Volkov, Pavlo Makushko, Eduardo Sergio Oliveros Mata, Denise Erb, Shengqiang Zhou, Juergen Fassbender, and Denys Makarov — Helmholtz-Zentrum Dresden-Rossendorf e. V., 01328 Dresden, Germany

Asymmetrically sandwiching thin magnetic layers with perpendicular anisotropy and Dzyaloshinskii-Moriya interaction (DMI) produces chiral nontrivial textures, e.g. skyrmions and chiral domain walls, which exhibit unexplored application potential in logic and memory devices [1]. Conversely, extrinsic DMI is observed by breaking local inversion symmetry appearing in curvilinear structures of conventional materials [2]. Here, employing ion beam irradiation of SiO2 substrates we fabricate corrugated ultra-thin Cr2O3/Co/Pt asymmetric layer stacks with different geometric parameters. By means of magnetometric and transport measurements, we demonstrate the appearance and controllability of mesoscale DMI [3] by tuning geometric and material parameters of the system.

MA 5.4 Mon 10:15 POT 6

Polycrystalline exchange-biased bilayers: Magnetically effective versus structural antiferromagnetic grain volume distribution — •Maximilian Merkel, Meike Reginka, Rico Huhnstock, and Arno Ehresmann — Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Str. 40, D-34132 Kassel

The macroscopic magnetic characteristics of polycrystalline exchange-biased antiferromagnet/ferromagnet bilayers are generally determined by a complex interplay of several parameters that describe the structural and magnetic properties of the material system. [1] We demonstrate the possibility to determine averaged microscopic parameters from macroscopic magnetic quantities measured by vectorial Kerr magnetometry in comparison to an elaborate model. In particular, we estimated the magnetically effective antiferromagnetic grain size distribution, finding that it differs significantly from the structural one. [2] This indicates, that the antiferromagnetic order, being essential for the interface exchange coupling to the ferromagnetic layer, extends only over a part of the grains' structural volumes.

Spin current generation in ferrimagnetic heterostructures — •Felix Fuhrmann[1], Sven Becker[1], Akashdeep Akashdeep[1], Zengyao Ren[1,2], Mathias Weiler[3], Gerhard Jakob[1,2], and Mathias Kläui[1,2,4] — [1]Institute of Physics, University of Mainz, Germany — [2]Graduate School of Excellence "Materials Science in Mainz" (MAINZ), Germany — [3]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Technische Universität Kaiserslautern, Germany — [4]Center for Quantum Spintronics, Norwegian University of Science and Technology, Trondheim, Norway

With growing demand for more energy-efficient information technology, the utilization of magnons as information carriers entails potential advantages [1]. To successfully develop magnon-based devices, there are several requirements for the applied materials to meet. The insulating ferrimagnet Yttrium Iron Garnet $(Y_3Fe_5O_{12}$, YIG) and related garnets are good candidates with outstanding low damping and large magnon propagation lengths [1]. Our heterostructures of YIG and Gadolinium Iron Garnet $(Gd_3Fe_5O_{12}$, GIG) were grown by pulsed laser deposition. We observe a ferromagnetic coupling between the Fe sublattices of the two layers, leading to complex magnetic response to external magnetic fields and a nontrivial temperature dependence [2]. We investigate the spin current generation by means of the spin Seebeck effect and spin pumping at ferromagnetic resonance. SQUID magnetometry and spin Hall magnetoresistance measurements support our observations [2]. [1] A. Chumak et al., Nat. Phys. 11, 453 (2015). [2] S. Becker et al., Phys. Rev. Appl., 16, 014047(2021).

MA 5.6 Mon 10:45 POT 6

In-situ monitoring of the electric-field induced switching process in Fe_3O_4/Nb:STO heterostructures — •Yifan Xu[1], Mai Hussein Hamed[1,2], Connie Bednarski-Meinke[1], Asmaa Qdemat[1], Steffen Tober[1], Emmanuel Kentzinger[1], Ulrich Rücker[1], Oleg Petracic[1], and Thomas Brückel[1] — [1]Jülich Centre for Neutron Science (JCNS-2) and Peter Grünberg Institut (PGI-4), JARA-FIT, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — [2]Faculty of Science,Helwan University,11795 Cairo,Egypt

The ability to tune magnetic oxide phases via redox reactions across their heterointerfaces could lead to useful spintronic and memristive device applications. By applying a small electric field, oxidation/reduction occurs at the heterointerface and leads to a reversible phase transition. In this talk, we present the preparation and characterization of epitaxial (001)Fe_3O_4 thin films grown on TiO_2-terminated (001)Nb:STO via pulsed laser deposition. Using magnetometry, we detect the Verwey transition; a strong indicator of the oxygen content in the Fe_3O_4 films. We observe the disappearance in the Verwey transition temperature with an applied positive electric field. This could be explained by oxygen diffusion through the interface which then leads to a reversible phase transition from Fe_3O_4(magnetite) to γ-Fe_2O_3(maghemite). Using ex-situ x-ray diffraction, we observe an additional Fe_3O_4(111) peak in the out-of-plane direction influenced by the applied voltage. Interestingly, by grazing-incidence small-angle X-ray scattering, we observe a change in the magnetite domain size for the sample after applying the electric field.

MA 6: Focus: Dislocations in Ceramics: Mechanics, Structures and Functionality (joint session KFM/MA)

Contrasting the common (mis)belief that ceramics are brittle, a new horizon of dislocation engineering in ceramics is being revealed, where dislocations are used to harness the mechanical and electro-functional properties. This session will bring together researchers who are interested in dislocations in ceramics, covering experiments and simulations, to stimulate new ideas for dislocation-based mechanics, characterization, and functionality in ceramics.

Chair: Dr. Xufei Fang (TU Darmstadt), Dr. Till Frömling (TU Darmstadt)

Time: Monday 14:30–17:05   Location: POT 51

Quantitative theories of magnetic interactions in solids — •Attila Szilva[1], Yaroslav Kvashnin[1], Evgeny A. Stepanov[2], Lars Nordström[1], Olle Eriksson[1], Alexander I. Lichtenstein[3], and Mikhail I. Katsnelson[4] — [1]Uppsala University — [2]Institut Polytechnique de Paris — [3]Universität Hamburg — [4]Radboud University

The talk will summarize the review paper Quantitative theories of magnetic interactions in solids, by focusing on the derivation of the LKAG formula and the extension of the formalism for the case of non-collinear magnets. A first version of the paper can be read here: https://arxiv.org/abs/2206.02415. The paper reviews the method of explicit calculations of interatomic exchange interactions of magnetic materials. This involves exchange mechanisms normally refereed to as Heisenberg exchange, Dzyaloshinskii-Moriya interaction and anisotropic symmetric exchange. The connection between microscopic theories of the electronic structure, such as density functional theory or dynamical mean field theory, and interatomic exchange, is given in detail.

MA 7.2   Mon 15:15   HSZ 02
Magnetic Anisotropy and Ground States of α-RuCl$_3$ — •Seung-Ju Hong[1] and Cheol-Hwan Park[1,2,3] — [1]Department of Physics and Astronomy, Seoul National University, Seoul 08826, Korea — [2]Center for Correlated Electron Systems, Institute for Basic Science, Seoul 08826, South Korea — [3]Center for Theoretical Physics, Seoul National University, Seoul 08826, South Korea

In this talk, I will talk about the magnetic anisotropy of the Kitaev candidate α-RuCl$_3$. This material gained much attention due to its proximity to Kitaev spin liquid. Thus, there are many kinds of research that computed the anisotropic exchange parameters from first principles.

However, in our work, we conducted an unprecedented number of *ab initio* calculations with constrained density functional theory and total energy fitting. We both examined the monolayer and multilayer systems and computed the intra/inter-layer exchange parameters. Then, from Monte Carlo simulations, we compute the thermodynamical quantities. From these computations, we obtained a non-trivial results.

MA 7.3   Mon 15:30   HSZ 02
Modification of Magnetic Anisotropy at Organic-Inorganic Interfaces — •Anita Halder, Sumanta Bhandary, David O'Regan, Stefano Sanvito, and Andrea Droghetti — School of Physics and CRANN, Trinity College, Dublin 2, Ireland

The adsorption of nonmagnetic organic molecules on ferromagnetic materials offers an opportunity to tune their magnetic properties for promising applications in high-density data storage and spintronic devices. In this work, we report the manipulation of the magnetocrystalline anisotropy (MCA) of Co slabs through the adsorption of small molecules, such as benzene, cot etc. We consider a simple model based on 2nd-order perturbation theory to explain the modification of MCA due to molecular adsorption in a qualitative way. Further, we have used Density Functional Theory and the magnetic force theorem to calculate magnetic anisotropy. The results indicate that molecular adsorption tends to favour perpendicular MCA at surfaces by reducing in-plane MCA of the slab. A detailed analysis of various atom-resolved quantities demonstrates that the underlying physical mechanism is the metal-molecule interfacial hybridization, and, in particular, it is related to the chemical bond between the molecular p$_z$ and the surface d$_{z^2}$ orbitals. Generalizing the same argument, we also show that the complex molecules C$_{60}$ and Alq$_3$ deposited on fcc-Co induce a similar modification of the in-plane MCA, and we related the results to recent experimental observations.

MA 7.4   Mon 15:45   HSZ 02
Strain dependence of magnetism in transition-metal phosphorus trichalcogenides — •Yang-Jun Lee[1,2,3], Tae Yun Kim[2], and Cheol-Hwan Park[1,2,3] — [1]Department of Physics and Astronomy, Seoul National University, Seoul 08826, Korea — [2]Center for Correlated Electron Systems, Institute for Basic Science, Seoul 08826, Korea — [3]Center for Theoretical Physics, Seoul National University, Seoul 08826, Korea

Few-layer transition-metal phosphorus trichalcogenides (TMPX3) are two-dimensional (2D) antiferromagnetic materials, which have recently attracted attention because they can realize interesting 2D magnetic phenomena; they are considered materials whose magnetism can be described by the Heisenberg model, Ising model, or XY model depending on the transition metal ion. In this talk, we present the strain effects on the magnetism of TMPX3 compounds obtained from first principle calculations. Also, we will talk about the change in the symmetry and the magnetic model due to the strain.

MA 7.5   Mon 16:00   HSZ 02
Microscopic Insights for Beyond Room-Temperature Ferromagnetism in Two-Dimensional Fe5-xNixGeTe2 — •Sukanya Ghosh[1], Soheil Ershadrad[2], and Biplab Sanyal[3] — [1]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden — [2]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden — [3]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden

The FenGeTe2 (n=3-5) (FGT) systems belong to the class of two-dimensional (2D) van der Waals (vdW) materials, promising candidates to explore magnetism in low-dimension with potential applications in spintronics. These systems are special due to their tunable structural, electronic and magnetic properties. Among the existing members of FGT family, Fe5GeTe2 has room temperature ferromagnetism with several intriguing properties. With the inclusion of dynamic electron correlation effect, our DFT+DMFT study shows how the spin moments, exchange interactions and Curie temperature (TC) of 2D Fe5-xGeTe2 can be varied significantly by substitutional doping with Ni. More importantly, the highest TC ~400 K is achieved for 20% doping concentration, beyond which the ferromagnetic order gets gradually suppressed. Our DFT+DMFT results are in good agreement with the experimental reports on bulk Fe5-xNixGeTe2 [1]. Moreover, we investigate the microscopic mechanisms responsible for the observed trend of TC in Fe5-xNixGeTe2 monolayer as an interplay between specific magnetic exchange interactions.

MA 7.6   Mon 16:15   HSZ 02
Efficient calculation of exchange interactions in magnetic materials — •Tae Yun Kim[1,2,3] and Cheol-Hwan Park[1,2,3] — [1]Center for Correlated Electron Systems, Institute for Basic Science, Seoul 08826, Korea — [2]Department of Physics and Astronomy, Seoul National University, Seoul 08826, Korea — [3]Center for Theoretical Physics, Seoul National University, Seoul 08826, Korea

Accurate description of the total energy of a magnetic system as a function of the local magnetic moments has always been a matter of importance, since it allows one to access the relevant low-energy excitation of the system, i.e. the magnon, which governs the low-temperature thermodynamics and remains important even at temperatures as high as the Curie temperature [1]. In this contribution, I will talk about an efficient way of calculating exchange interactions based on a constrained density functional theory method that captures accurately the magnetic total energy surface. As a concrete example, our ab-initio results on a magnetic system with substantial Dzyaloshinskii-Moriya interactions will be presented and be compared with that reported from previous studies to confirm the validity of our scheme.

MA 7.7 Mon 16:30 HSZ 02

Magnetic phases and stability of MPS4 — •Beatriz Costa Guedes[1], Thomas Brumme[2], Andrea Leon[3], and Thomas Heine[2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Chair of Theoretical Chemistry, Technische Universität Dresden, Dresden, Germany — [3]Physics Faculty, Pontificia Universidad Católica de Chile, Santiago,Chile

The discovery of magnetic van der Waals materials provided a new playground for studying different aspects of magnetic interactions in reduced dimensions. Some interesting materials in this regard are the transition metal phosphorous chalcogenides MPS3 and CrPS4 (M = Mn, Fe, Co, and Ni), which are semiconductors exhibiting novel magnetic properties such as an intriguing dependence of the magnetic ordering on the transition metal (M). CrPS4 is particularly interesting because it exhibits a magnetic transition from antiferromagnetic (AFM) to ferromagnetic (FM) ordering in the monolayer limit, analog to the CrI3 compound, which is, in contrast, not stable in air. In this research, we study the stability and the electronic properties of the whole MPS4 family using density functional theory with a special focus on magnetic properties. Our results reveal a rich magnetic phase diagram with a complex electronic and magnetic dependence on M. They can be semiconductors, metals, or half-metals with AFM, FM, and non-magnetic configurations. We explain this behavior by discussing the interplay among structure, magnetism, and Coulomb interaction. By comparing it with the MPS3 system, we find some keys to understanding the magnetic properties of the MPS4 family.

MA 7.8 Mon 16:45 HSZ 02

Effect of Coulomb interaction on the magnetic properties of orthorhombic monolayer CrSBr — •Alexander Rudenko — Radboud University, Nijmegen, The Netherlands

Two-dimensional CrSBr is a recently discovered semiconducting spin-3/2 ferromagnet with the Curie temperature around 140 K. Unlike many other known 2D magnets, CrSBr has an orthorhombic lattice, giving rise, for instance, to spatial anisotropy of the magnetic excitations within the 2D plane. Theoretical description of CrSBr within the spin Hamiltonian approach turns out to be essentially nontrivial due to the complex character of the magnetic anisotropy resulting from low crystal symmetry. Here, we employ the Green's function formalism combined with first-principles calculations to systematically study magnetic properties of monolayer CrSBr. We find that the magnetic anisotropy and thermodynamical properties of CrSBr depend strongly on the Coulomb interaction and its external screening. In the free-standing limit, the system is close to an easy-plane magnet, whose long-range ordering is partially suppressed. On the contrary, in the regime of large external screening, monolayer CrSBr behaves like an easy-axis ferromagnet with more stable magnetic ordering. Our findings suggests that 2D CrSBr is an excellent platform for studying the effects of substrate screening on magnetic ordering.

Cu(VO)2(AsO4)2 with ferromagnetic V-V and antiferromagnetic Cu-V interactions — •Victoria Ginga[1,2], Alexander Tsirlin[1], and Oleg Siidra[2] — [1]Universität Leipzig, Felix Bloch Institute for Solid State Physics, Linnestraße 5, 04109 Leipzig — [2]St. Petersburg, Russia

Recent years have seen an increased interest in studying the magnetic properties of mineral-like compounds. The Cu(VO)2(AsO4)2 obtained by the CVT reaction method reproducing exhalative conditions has a new type of structure, which is characterized by layers formed by two [1+4+1]V4+-tOeq-[1+4+1]V4+ and one [1+4+1]V4+-vOeq-[1+4+1]V4+ linkages of V-centered octahedra. Arsenate groups decorate vanadate layers via corner-sharing with the VO6 octahedra, while single CuO6 octahedra are connecting vanadate layers into a framework via edge-sharing. Our ab initio calculations show that the magnetism of Cu(VO)2(AsO4)2 is dominated by the antiferromagnetic Cu-V coupling JCu-V = 257 K and the ferromagnetic V-V coupling JV-V =-277 K. This high energy scale is not uncommon in both Cu2+ and V4+ oxide compounds with

the edge-shared octahedral geometry. Our results show the formation of unusual interaction geometries through the mixing of different spin-1/2 ions in the crystal structure. Experimental and computational results of the study of the Cu(VO)2(AsO4)2 with two distinct spin-1/2 magnetic ions will be presented.

MA 7.10 Mon 17:15 HSZ 02

SU(4) magnetism on a triangular moiré superlattice — •Lasse Gresista[1], Dominik Kiese[2], Michael Scherer[3] und Simon Trebst[1] — [1]Institute for Theoretical Physics, University of Cologne, Germany — [2]Center for Computational Quantum Physics, Simons Foundation Flatiron Institute, New York, USA — [3]Institute for Theoretical Physics III, Ruhr- University Bochum, Germany

The discovery of correlated insulating states in several graphene based moiré heterostructures such as trilayer graphene aligned with hexagonal boron nitride (TG/h-BN) has renewed the interest in strongly coupled electron systems where spin and orbital (or valley) degrees of freedom are intertwined. Considering the strong coupling limit, the localized degrees of freedom in such systems may be described by generators of SU(4) instead of the conventional SU(2) spin operators. Here, we study such an SU(4) 'spin-valley' model on a triangular lattice at a filling of two electrons (or holes) per moiré unit cell, with interactions that strongly break the SU(4) symmetry down to $SU(2)_{spin} \otimes U(1)_{valley}$. This is, e.g., relevant for the flat band physics of TG/h-BN within the topologically trivial regime. Using a pseudo-fermion functional renormalization group approach and semi-classical Monte Carlo calculations, we are able to distinguish parameter regimes showing no magnetic order, suggesting a spin-valley liquid or other quantum disordered ground state, and a multitude of classically ordered phases including ferromagnetic, antiferromagnetic, incommensurate and stripe order that manifests in different sectors of the coupled spin-valley space.

MA 7.11 Mon 17:30 HSZ 02

YSrFeCrO6 as a Robust Ferromagnetic Semiconductor with Large Photovoltaic Efficiency — •Avijeet Ray, Paresh C. Rout, and Udo Schwingenschlögl — Physical Sciences and Engineering Division (PSE), King Abdullah University of Science and Technology (KAUST), Thuwal 23955-6900, Saudi Arabia

Semiconducting ferromagnetic transition metal oxides play a key role in spintronics applications. Employing first-principles calculations, we predict the existence of the double perovskite Y_2FeCrO_6 and study its properties. While both rock-salt (RS) and layered (L) structures are found to be dynamically stable, the L structure turns out to be energetically favorable. We determine the magnetic phase diagram under hydrostatic pressure. We find that the RS structure is dynamically stable and energetically favorable over the L structure in the case of $YSrFeCrO_6$ (hole doping by substitution of Y by Sr). $YSrFeCrO_6$ realizes a ferromagnetic ordering with a magnetic moment of 7 μ_B per formula unit, which is promising for spintronics applications. In addition, the ferromagnetic ordering is not compromised by hydrostatic pressure from −10 to 16 GPa. While the L structure of Y_2FeCrO_6 is an indirect bandgap semiconductor, the RS structure of $YSrFeCrO_6$ shows a direct bandgap of 0.90 eV (spin-orbit coupling taken into account in the calculation). We obtain a large spectroscopic limited maximum efficiency of 26% for $YSrFeCrO_6$, which is suitable for photovoltaic applications.

MA 7.12 Mon 17:45 HSZ 02

Magnetic Anisotropy of α-RuCl3 — •Seung-Ju Hong[1], Tae Yun Kim[2], and Cheol-Hwan Park[1,2,3] — [1]Department of Physics and Astronomy, Seoul National University, Seoul 08826, Korea — [2]Center for Correlated Electron Systems, Institute for Basic Science, Seoul 08826, South Korea — [3]Center for Theoretical Physics, Seoul National University, Seoul 08826, South Korea

α-RuCl3 has gained much attention due to its proximity to Kitaev spin liquid. In this talk, we will discuss the magnetic anisotropy of α-RuCl3. We performed first-principles calculations on the magnetic anisotropy of α-RuCl3. We will compare the results of our first-principles calculations with available previous experimental and theoretical studies.

MA 8: Ultrafast Magnetization Effects I

Invited Talk MA 8.1 Mon 15:00 HSZ 04

Optical control of antiferromagnetism — •Christian Tzschaschel — Department of Chemistry and Chemical Biology, Harvard University, USA

Antiferromagnets are a promising class of materials for novel spintronic applications. The absence of a net magnetization not only leads to a robustness of the magnetic state against magnetic fields but may also enable faster and potentially more energy efficient switching dynamics compared to their ferromagnetic counterparts. However, probing and controlling an antiferromagnetic state, in particular on ultrafast timescales, is a major challenge of antiferromagnetic spintronics.

Here, we will exploit magneto-optical and inverse magneto-optical effects to control antiferromagnetism. For example, the inverse Faraday effect, whereby circularly polarized light acts as a magnetic field in a material, allows us to selectively excite specific magnon modes in fully compensated antiferromagnets. The excitation mechanism can be based on a rotation of the antiferromagnetic vector or the generation of a net magnetization in the material. We will show that excitation mechanisms that induce a net magnetization exhibit a significantly higher efficiency. Moreover, we uncover a new inverse magneto-optical effect that allows us to deterministically induce an antiferromagnetic state in a magneto-electric antiferromagnet.

Our results demonstrate a high degree of optical control of antiferromagnetism, where we use light as both a probe and a handle to act on an antiferromagnetic state. We thus move closer to achieving a fundamental requirement for future ultrafast opto-spintronic devices.

MA 8.2   Mon 15:30   HSZ 04

Accelerating write/erase cycles in all-optical magnetization switching — •Felix Steinbach[1], Nele Stetzuhn[1], Daniel Schick[1], Dieter Engel[1], Unai Atxitia[2], Clemens von Korff Schmising[1], and Stefan Eisebitt[1,3] — [1]Max Born Institute for Nonlinear Optics and Short Pulse Spectroscopy — [2]Dahlem Center for Complex Quantum Systems and Fachbereich Physik — [3]Institut für Optik und Atomare Physik, Technische Universität Berlin

All-optical switching of magnetic order presents a promising route toward faster and more energy efficient data storage. However, a realization in future devices is ultimately dependent on the maximum repetition rates of optically induced write/erase cycles. Here, we present two strategies to minimize the temporal separation of two consecutive femtosecond laser pulses to toggle the out-of-plane direction of the magnetization of ferrimagnetic rare-earth transition metal alloys. First, by systematically changing the heat transfer rates using either amorphous glass, crystalline silicon, or polycrystalline diamond substrates, we show that efficient cooling rates of the magnetic system present a prerequisite to accelerate the sequence of double pulse toggle switching. Second, we demonstrate that replacing the transition metal iron by cobalt leads to a significantly faster recovery of the magnetization after optical excitation allowing us to approach terahertz frequency of write/erase cycles with a minimum pulse-to-pulse separation of 7 ps [1].

Variation of magnetic model parameters during ultrafast demagnetisation — •S. Polesya, S. Mankovsky, and H. Ebert — Department Chemie, Ludwig Maximilian University, Munich, Germany

Recent developments in time-dependent density functional theory (TD-DFT) paved the way towards investigating the ultrafast demagnetisation caused by a strong laser pulse on an *ab initio* level. However, the relaxation processes after a pump pulse still require to use phenomenological models that allow to account for different types of relaxation mechanisms on the basis of model parameters, that can be calculated from first principles. A stumbling block for such schemes is that the electronic structure is strongly out of equilibrium after the laser pulse and changes with time due to the relaxation. In the present work, we explore whether the parameters which determine the magnetization dynamics in this time regime can indeed be described on a first-principles level. This concerns first of all the exchange coupling, magnetic anisotropy and the Gilbert damping parameters that have been calculated for several transition metals using the spin-polarized relativistic Korringa-Kohn-Rostoker method. To account for the time evolution of the system, the calculations have been performed employing the TD-DFT potentials and occupation numbers generated by the Elk code [http://elk.sourceforge.net] for different time steps during the laser pulse and shortly after it, i.e. in the non-relaxed situation. In all cases a strong modification of the parameters compared to the equilibrium situation is found.

MA 8.4   Mon 16:00   HSZ 04

Temperature- and density-dependent spin-resolved coupling parameters in the μT-model — •Christopher Seibel, Sebastian T. Weber, Tobias Held, Sanjay Ashok, Hans Christian Schneider, and Baerbel Rethfeld — Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau

Since the first ultrafast demagnetization experiment by Beaurepaire *et al.* in 1996, many models have been developed. They reach from complex kinetic descriptions to simpler temperature-based models. The former consider the microscopic interactions between the individual (quasi-)particles involved and allow to extract coupling parameters of the individual interactions. These parameters can enter temperature-based models and depend on the nonequilibrium distribution, (quasi-)temperature, densities and the spin-dependent density of states [1,2,3]. However, these coupling parameters are often assumed to be constant in temperature-based models.

In this work, we investigate the influence of transient coupling parameters, like the electron-phonon coupling parameter, on the magnetization dynamics. The spin-resolved coupling parameter is calculated using complete Boltzmann collision integrals and depends on the transient temperatures and densities of the individual subsystems.

Investigating the interplay of local electron correlations and ultrafast spin dynamics in fcc Ni at the European XFEL — •Tobias Lojewski — University of Duisburg-Essen

---

The interplay between exchange interaction, electron hopping and local Coulomb repulsion is of great interest as it influences the magnetic order in the 3d transition metals. We report the investigation of the electronic structure in fcc Nickel on the time scale of these interactions by combining the femtosecond time-resolved spectroscopic analysis of Nickel X-ray absorption spectra, measured at the SCS instrument of the European XFEL, with *ab initio* TD-DFT. We find a transient broadening and redshift of the $L_{2,3}$-edge absorption spectra, which we relate to electron repopulation and correlation-induced electronic structure modifications, demonstrating a time-dependent interaction between band formation, exchange interaction and Coulomb repulsion.

Laser-induced spin polarization on ultrafast time scales — •Oliver Busch, Franziska Ziolkowski, Ingrid Mertig, and Jürgen Henk — Institut für Physik, Martin-Luther-Universität, D-06099 Halle

In ultrafast spin dynamics one focuses often on demagnetization. However, the incident laser pulse should produce spin-polarized excited electrons – an effect ubiquitous in spin- and angle-resolved photoemission [1]. This laser-induced spin polarization certainly affects the ultrafast dynamics.

We study systematically the laser-induced spin polarization and its effect on the electron dynamics in Co/Cu heterostructures, modeled within our theoretical framework EVOLVE [2]. The spin polarization depends strongly on polarization and angle of incidence of the femtosecond laser pulse, similar to photoemission [3]. Moreover, we find a significant spatial dependence, which underlines the importance of inhomogeneities in ultrafast spin dynamics.

Finite-size effects in [Fe/MgO]n heterostructures on ultrafast timescales — •Moumita Kundu[1], Nico Rothenbach[2], Tobias Lojewski[2], Andrea Eschenlohr[2], Markus Gruner[2], Katharina Ollefs[2], Carolin Schmitz-Antoniak[3], Klaus Sokolowski-Tinten[2], William Windsor[4], Laurenz Rettig[4], Rossitza Pentcheva[2], Heiko Wende[2], Ulrich Nowak[1], and Uwe Bovensiepen[2] — [1]University of Konstanz, Konstanz, Germany — [2]University of Duisburg-Essen, Duisburg, Germany — [3]TH Wildau, Wildau, Germany — [4]FHI Berlin, Berlin, Germany

The analysis of magnetization dynamics on ultrafast timescales provides insight into microscopic interactions of magnetic moments with the charge and lattice degrees of freedom in solids. Here we analyze the finite size effect of ferromagnets on ultrafast timescales for [Fe/MgO]$_n$ heterostructures. Using femtosecond time-resolved XMCD, measured at the Femtoslicing facility, BESSY II, we observe an increasing laser-induced demagnetization at time delays > 0.5ps as the Fe layers get thinner, and it can be clearly distinguished from the primary ultrafast demagnetization occurring at < 0.5ps. Atomistic spin simulations are used to investigate the thickness dependence of the ultrafast magnetization dynamics in iron thin films, modeled using an extended Heisenberg-type Hamiltonian in the stochastic Landau-Lifshitz-Gilbert equation, coupled with the 2-temperature model. Comparing with our measurements, we conclude that finite size effects are the dominating factor for the different demagnetization rates due to a reduced spin-spin coordination at the interfaces.

MA 8.8   Mon 17:00   HSZ 04

A real-space tight-binding approach to ultrafast spin dynamics in inhomogeneous systems — •Franziska Ziolkowski, Oliver Busch, Ingrid Mertig, and Jürgen Henk — Martin Luther University Halle-Wittenberg, Halle, Germany

In laser-induced ultrafast spin dynamics a spin current is generated at a magnetic-nonmagnetic interface, whose orgin and properties are still under debate. To better understand the microscopic processes and the role of the interface we are developing the theoretical framework *evolve* [1].

In a real-space tight-binding model the electron system is optically excited by a femtosecond laser pulse and coupled to a bosonic bath. The time evolution of the density operator yields occupation numbers, demagnetization profiles as well as spin- and orbital-resolved occupation flows.

Our simulations confirm the importance of interfaces for ultrafast transport phenomena and demagnetization processes. We identify a reflow from Cu d orbitals across the interface into Co d orbitals as an important contribution to

demagnetization. This refilling manifests itself as a minority-spin current proceeding several layers into the Cu region.

Moreover, we investigate the influence of pulse parameters such as polarization and photon energy.

MA 8.9   Mon 17:15   HSZ 04

Measuring the spin-flip scattering rates in the demagnetization transient state of ferromagnets — •Régis Decker[1], Artur Born[1,2], Kari Ruotsalainen[1], Karl Bauer[1], Robby Büchner[1,2], Robert Haverkamp[1,2], Annette Pietzsch[1], and Alexander Föhlisch[1,2] — [1]Institute Methods and Instrumentation for Synchrotron Radiation Research PS-ISRR, Helmholtz-Zentrum Berlin für Materialien und Energie Albert-Einstein-Strasse 15, 12489, Berlin, Germany. — [2]Institut für Physik und Astronomie, Universität Potsdam, Karl-Liebknecht-Strasse 24-25, 14476, Potsdam, Germany

In crystalline ferromagnets, one of the main microscopic mechanisms of spin relaxation is the electron-phonon driven (Elliott-Yafet) spin-flip scattering. To deduce the spin-flip scattering rate, we exploit the stringent atomic symmetry selection rules of X-ray Emission Spectroscopy (XES) and observe the quantifiable change in the decay peak intensities in static XES spectra when changing the temperature, *i.e.* the phonon population. We deduce the temperature-dependent spin-flip scattering rate for Ni [1]. In FeNi alloys, we evidence a thresholding the Elliott-Yafet mechanism linked to the intra- and intersublattice exchange energies [2]. In Gd, we show an Elliott-Yafet mechanism for the itinerant 5d electrons and its absence for the localized 4f electrons [3].

Electron-magnon interactions and Elliot-Yafet Spin Flips in a Two Band Stoner Model — •Felix Dusabirane, Kai Leckron, Bärbel Rethfeld, and Hans Christian Schneider — Physics Department & Research Center OPTIMAS, RPTU Kaiserslautern, Germany

We study electronic scattering dynamics in ferromagnets due to electron-magnon and electron-electron scattering. We also include an electron-electron spin-flip process, i.e., an electronic Elliott-Yafet mechanism and study the dynamics due to the interplay of the different scattering processes on the magnetization on ultrafast timescales. For the ferromagnetic band structure, we employ a model system consisting of two Stoner-exchange split bands and electron-magnon interaction, as can be obtained using a Heisenberg model where magnons (and electrons) are treated as bosons (and fermions). Electron-electron and electron-magnon scattering dynamics are studied with Boltzmann scattering integrals. We show that the spin-flip electron-electron scattering together with electron-magnon scattering generates non-equilibrium magnons, leading to a pronounced magnetization change that is mostly due to magnon generation and only to a very limited extent to a change in the spin polarization of the electrons. The effect of electron spin-flips and time dependent spin splitting will also be discussed.

MA 8.11   Mon 17:45   HSZ 04

Nonequilibrium Magnons from Hot Electrons in Antiferromagnetic Systems — Marion Barbeau[1], Mikhail Titov[2], Mikhail Katsnelson[2], and •Alireza Qaiumzadeh[1] — [1]Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, NO-7491 Trondheim, Norway — [2]Radboud University, Institute for Molecules and Materials, 6525 AJ Nijmegen, The Netherlands

We describe a *nonthermal* magnon activation mechanism in antiferromagnetic (AFM) systems via locally equilibrated *spin-unpolarized* hot electrons excited by an ultrafast intense laser pulse. We employ a quantum kinetic equation that takes into account a direct electron-magnon scattering channel in either bulk AFM metal or at the interface of the AFM/normal-metal heterostructure. The mechanism is responsible for the nonequilibrium population of AFM magnon modes on a subnanosecond timescale, which are formed shortly after the local thermalization of hot electrons by Coulomb interactions. Nonequilibrium magnon populations can be additionally manipulated by applying an external magnetic field. Our work paves the way toward spin dynamics control in AFM systems via the ultrafast manipulation of out-of-equilibrium magnon excitations [1].

Spin functional renormalization group for dimerized quantum spin systems — Andreas Rückriegel, •Jonas Arnold, Raphael Goll, and Peter Kopietz — Institut für Theoretische Physik, Universität Frankfurt, Max-von-Laue Straße 1, 60438 Frankfurt, Germany

We investigate dimerized quantum spin systems using the spin functional renormalization group approach proposed by Krieg and Kopietz [Phys. Rev. B **99**, 060403(R) (2019)] which directly focuses on the physical spin correlation functions and avoids the representation of the spins in terms of fermionic or bosonic auxiliary operators. Starting from decoupled dimers as initial condition for the renormalization group flow equations, we obtain the spectrum of the triplet excitations as well as the magnetization in the quantum paramagnetic, ferromagnetic, and thermally disordered phases at all temperatures. Moreover, we compute the full phase diagram of a weakly coupled dimerized spin system in three dimensions, including the correct mean field critical exponents at the two quantum critical points.

MA 9.2   Mon 15:15   HSZ 401

Magnetic correlations in the presence of disorder in the Hubbard model — •Fabio Pablo Miguel Méndez-Córdoba[1,2,3], Joseph Tindall[4], Dieter Jaksch[2,5], and Frank Schlawin[2,3,6] — [1]Departamento de Física, Universidad de Los Andes, A.A. 4976, Bogotá, Colombia — [2]Universität Hamburg, Luruper Chaussee 149, Gebäude 69, D-22761 Hamburg, Germany — [3]The Hamburg Centre for Ultrafast Imaging, Luruper Chaussee 149, Hamburg D-22761, Germany — [4]Center for Computational Quantum Physics, Flatiron Institute, 162 5th Avenue, New York, NY 10010 — [5]Clarendon Laboratory, University of Oxford, Parks Road, Oxford OX1 3PU, UK — [6]Max Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, Germany

By selectively modifying hopping integrals in the triangular Hubbard model at half filling [1], we show that it is possible to change the ground state's spin angular momentum magnetization. We further demonstrate that this change does not appear in the corresponding effective Heisenberg model. The latter does not predict any magnetic coherence between distant sites [2]. Instead, higher-order interactions are required to anticipate the symmetry breaking that leads to the lifting of the degeneracy present in the Heisenberg model. Our results can be understood as an extension of Lieb's theorem to non-bipartite lattices [3].

Subsequent Mott transitions and magnetic ground state in NiS_2 — •Jonas A. Krieger[1], Fabio Orlandi[2], Mikel I. Iñurrieta[3], Iñigo Robredo[3], Zaher Salman[4], Niels B. M. Schröter[1], Maia Garcia-Vergniory[3], Stuart S. P. Parkin[1], and Leslie Schoop[5] — [1]Max Planck Institute of Microstructure Physics, Halle, Germany — [2]Rutherford Appleton Laboratory, Didcot, UK — [3]Donostia International Physics Center, San Sebastián, Spain — [4]Paul Scherrer Institute, Villigen, Switzerland — [5]Princeton University, Princeton, USA

We present muon spin spectroscopy (μSR) measurements on the antiferromagnetic Mott insulator NiS_2. This compound features two subsequent magnetic phase transitions around 38.9K and 29K associated with the opening of a Mott gap. From the zero field and rotation dependence of transverse field μSR spectra we confirm the magnetic space group 205.33 in the 38.9K to 29K phase, determined from neutron diffraction [1]. We refine the muon stopping sites by using ab-initio density functional theory (DFT) and show that the resulting 8c and 24d muon sites can fully explain the observed μSR precession frequencies. A disproportionate temperature evolution of the two frequencies associated with these sites points to the presence of a strong temperature dependence in the muon hyperfine coupling strength due to concomitant changes in the electronic structure. We then use the number of μSR frequencies in combination with complementary neutron diffraction results to identify the magnetic ground state.

Magnetocrystalline anisotropies and quantum phase transitions in the cubic chiral magnets $Mn_{1-x}Fe_xSi$ and $Mn_{1-x}Co_xSi$ — •Vivek Kumar, Andreas Bauer, Marc Andreas Wilde, and Christian Pfleiderer — Physik-Department, Technische Universität München, D-85748 Garching, Germany

In the archetypical cubic chiral magnet MnSi, an extended regime of topological non-Fermi liquid behavior emerges without quantum criticality as magnetic order is suppressed by means of hydrostatic pressure [1]. Substitutional doping with iron or cobalt also results in the suppression of magnetic order, where quantum critical behavior is masked by the influence of disorder [2]. Recent small-angle neutron scattering studies suggested that in this context magnetocrystalline anisotropies may subtly but decisively influence the magnetic textures, however, no quantitative information was available [3]. Here, we report a study of a series of single crystals of $Mn_{1-x}Fe_xSi$ and $Mn_{1-x}Co_xSi$ by means of

cantilever torque magnetometry. An analytic description that takes into account the tetrahedral point group of the cubic chiral magnets allows us to quantitatively infer anisotropy constants up to sixth-order in spin-orbit coupling and discuss their evolution as a function of temperature, magnetic field, and dopant concentration x.

MA 9.5 Mon 16:15 HSZ 401

Investigating the CMR Effect in EuCd$_2$P$_2$ by Means of Nonlinear Transport and Fluctuation Spectroscopy — •Marvin Kopp[1], Charu Garg[1], Sarah Krebber[1], Kristin Kliemt[1], Cornelius Krellner[1], Sudhaman Balguri[2], Fazel Tafti[2], and Jens Müller[1] — [1]Institute of Physics, Goethe-University Frankfurt, Frankfurt (Main), Germany — [2]Departments of Physics, Boston College, USA

The colossal magnetoresistance (CMR) effect has inspired extensive studies for decades and is still the subject of intense research due to its central place in the physics of correlated electron systems as well as its potential relevance for applications. Unlike the prototypical CMR compounds based on mixed valence and double exchange in manganites or a structural Jahn-Teller distortion and ferromagnetic ordering, we focus on EuCd$_2$P$_2$, that exhibits a strikingly large (10^4 %) negative MR significantly above its antiferromagnetic ordering temperature T_N = 11 K. Initial reports suggest that strong magnetic fluctuations within the layered structure could be responsible for the drastic change of resistance in the magnetic field [1]. In this work, we aim to investigate these fluctuations using higher harmonic resistance and resistance fluctuation (noise) spectroscopy. Higher harmonic measurements are sensitive to the small changes in magnetoelectric coupling caused by the postulated forming of magnetic clusters (polarons), often hidden in standard resistance measurements. The dynamics of these magnetic clusters is studied using resistance noise spectroscopy as a function of temperature and magnetic field. [1] Adv. Mat., 2021, 33, 2005755.

MA 9.6 Mon 16:30 HSZ 401

Investigating the electronic charge and magnetic spin dynamics in the ferromagnetic semiconductor HgCr$_2$Se$_4$ using resistance fluctuation (noise) spectroscopy — •Charu Garg[1], Zhilin Li[2], Youguo Shi[2], and Jens Müller[1] — [1]Institute of Physics, Goethe University, 60438 Frankfurt (M), Germany — [2]Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190

The n-type HgCr$_2$Se$_4$ has been reported to exhibit a pronounced semiconductor-to-metal transition below and a CMR effect at the ferromagnetic transition at T_C = 107 K. Our recent study of charge carrier dynamics [Phys. Rev B 105, 064404 (2022)] suggests isolated magnetic polarons forming at $T > 2T_C$ which coalesce at T_C. In this talk, we discuss new results highlighting the strong correlation between the magnetic and electronic degrees of freedom that can lead to complex exchange pathways. Likely due to competing AF and FM interactions, we observe a distinctly slow decrease in resistance below the CMR transition. The striking dynamics of a distinct two-level fluctuations superimposed on 1/f-type noise corroborates a slowing down of charge carrier and/or magnetic dynamics. Further, below 20 K, a strong upturn in resistance and simultaneously in resistance noise down to 500 mK is observed and is speculated to be linked to the emergence of spiral type magnetic order. Our results demonstrate that the presence of pronounced electron-spin correlations plays a key role in the unconventional temperature dependence of resistance and CMR effect in this spinel.

MA 9.7 Mon 16:45 HSZ 401

Field-induced magnetic excitations in phases II and II$'$ of Ce$_3$Pd$_{20}$Ge$_6$ — •Federico Mazza[1], Jakob Lass[2], Daniel Mazzone[2], Stewart Ross[3], Eun Sang Choi[4], Martin Nikolo[5], Xinlin Yan[1], Andrey Prokofiev[1], Silke Paschen[1], and Dmytro S. Inosov[6] — [1]TU Wien, Austria — [2]PSI, Villigen, Switzerland — [3]ISIS, Didcot, UK — [4]Florida State University, Tallahassee, USA — [5]St. Louis University, USA — [6]TU Dresden, Germany

Ce$_3$Pd$_{20}$Ge$_6$ is known for its unique quantum phase transitions between antiferromagnetic ordering phase III and ferroquadrupolar phases II and II$'$. Using torque magnetometry at subkelvin temperatures, we were able to map the phase diagram in field and momentum space, here we find the crossover between phases III-II$'$ at 1.5 T and II$'$-II at 8 T. In addition, with inelastic neutron scattering we investigate dispersive collective excitations with a strong magnetic field dependence for **B** ∥ (110), revealing a magnon soft mode (Goldstone mode) at (001) for phase III and (111) for phases II and II$'$. At 4 meV we discover the presence of two (CEF) excitations exhibiting a weak dispersion best seen in the (HH1) direction. They are degenerate in the absence of magnetic field but split progressively as the field is increased.

MA 9.8 Mon 17:00 HSZ 401

Magnetoelastic coupling in the skyrmion lattice magnet GdRu$_2$Si$_2$ — •Lukas Gries[1], Daniel Mayoh[2], George Wood[2], Geetha Balakrishnan[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Department of Physics, University of Warwick, United Kingdom

We present high-resolution thermal expansion and magnetostriction studies on the centrosymmetric skyrmion-hosting tetragonal magnet GdRu$_2$Si$_2$ in high magnetic fields up to 15 T. Our data show magnetoelastic coupling associated with the onset of long-range antiferromagnet order in form of pronounced anomalies in thermal expansion and magnetostriction. We extract the uniaxial pressure dependencies of the different phase boundaries and discuss them in terms of spin-lattice coupling. Our data suggest additional phases in magnetic field and allow us to complement the previously published magnetic phase diagram.

MA 9.9 Mon 17:15 HSZ 401

Charge dynamics of heavy fermions near their quantum critical point — •Renjith Mathew Roy[1], Run Yang[1], Sooheyon shin[2], Seulki Roh[1], and Martin Dressel[1] — [1]1. Physikslisches Instiut, Universität stuttgart, Germany — [2]Laboratory for Multiscale Materials Experiments, Paul Scherrer Institut, Switzerland

Using infrared spectroscopy, we investigate the evolution of hybridization strength between the localized magnetic moments and itinerant electrons in heavy fermionic compound CeRh(In1-xSnx)5, with three different Sn concentrations, Sn 4.4%, Sn 6.9%, and 9.8% respectively. CeRhIn5 has an antiferromagnetic ground state, which is suppressed with Sn doping revealing a quantum-critical region. From our optical conductivity result, we report an enhancement of hybridization strength with increasing Sn concentration, and the observation of a non-Fermi liquid behaviour near the quantum critical point. The phase characterization was performed by magnetic susceptibility and resistivity measurements, which also support the non-Fermi liquid behavior observed near the quantum critical point.

MA 9.10 Mon 17:30 HSZ 401

Local structure of disordered Fe$_{60}$V$_{40}$ and the impact on its magnetism — •Simon Rauls[1], Benedikt Eggert[1], Shadab Anwar[2], Damian Günzing[1], Philipp Klassen[1], Tom Helbig[1], Rantej Bali[2], and Heiko Wende[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen — [2]Helmholtz-Zentrum Dresden-Rossendorf

Control of the structural order and nearest-neighbour interactions can provide a path to modify application relevant magnetic properties, such as the Gilbert damping. The binary alloy Fe$_{60}$V$_{40}$ shows an amorphous to polycrystalline phase transition, which can be triggered by annealing or ion irradiation. This phase transition also is a transition from a paramagnetic phase towards a ferromagnetic phase with very low Gilbert damping of ~0.002 [1], which makes the material a promising candidate for the fabrication of embedded magnetic nanostructures in a single irradiation step. We want to highlight the results of our structural and magnetic investigations on Fe$_{60}$V$_{40}$ thin films, using EXAFS, magnetometry and Mössbauer spectroscopy, in order to understand the interconnection between the evolving ferromagnetism and nearest-neighbour interactions along the ion-irradiation induced phase transition.

Benchmark study of symmetry-adapted ML-DFT models for magnetically doped topological insulators — •Johannes Wasmer[1], Rubel Mozumder[1], Philipp Rüssmann[1,2], Ira Assent[1,3], and Stefan Blügel[1] — [1]Forschungszentrum Jülich, Germany — [2]University of Würzburg, Germany — [3]Aarhus University, Denmark

We present a benchmark study of surrogate models for impurities embedded into crystalline solids. Using the Korringa-Kohn-Rostoker Green Function method [1], we have built databases of several thousand calculations of single impurities (monomers) embedded into different elemental crystals, as well as magnetic transition metal impurity dimers embedded in the topological insulator Bi$_2$Te$_3$. We predict the converged monomer impurity electron potential and the isotropic

exchange interaction of the impurity dimer in the classical Heisenberg model. From these surrogates, we intend to build transferable models for larger systems in the future, which will accelerate the convergence of our DFT codes. The study compares various recent E(3)-equivariant models such as ACE and MACE [2] in terms of performance and reproducible end-to-end workflows.

High thorughput magnetic topological materials search II — •Iñigo Robredo[1,2], Yuanfeng Xu[3,4], Andrei Bernevig[2,3], Claudia Felser[1], Nicolas Regnault[3,6], Luis Elcoro[5], and Maia G. Vergniory[1,2] — [1]MPI CPFS Dresden — [2]DIPC — [3]Princeton University — [4]Zhejiang University — [5]Basque Country University — [6]Sorbonne Université

The development of topological quantum chemistry has proven to be a game changing tool for predicting topological phases in realistic materials, both nonmagnetic and magnetic. Building on the work of previous studies, in this work we expand the family of magnetic insulators and semimetals with non-trivial topological properties. We analyzed 408 magnetic structures from the Bilbao Crystallographic Server magnetic database, whose crystal and magnetic structures have been experimentally reported. To take into account the localized nature of magnetic elements, we perform electronic structure calculations and topological diagnosis as a function of the Hubabrd U parameter. This results in a topological phase iagram for each material as a function of the Hubbard interaction potential. We provide full details of the materials, which can be readily grown to explore their new topological phenomena.

MA 10.3 Mon 15:30 HSZ 403
Manipulating topological feature of massive Dirac particle with scalar potential — •Sumit Ghosh[1,2], Yuriy Mokrousov[1,2], and Stefan Blügel[1] — [1]PGI-1, Forschungszentrum Jülich, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, Germany

Topology is one of the central aspect of modern spintronics. Different physical observables as well as transport properties that originates from the nontrivial topology of the system shows significant robustness against different external perturbation. Manipulating the topology of a system on the other hand is a highly non-trivial task since it requires tuning the internal degrees of freedom. In this presentation we are going to present an intrinsic mechanism to manipulate the topological feature and associated transport properties by using scalar potential. We systematically demonstrate how a scalar potential can invert the mass term of a massive Dirac particle which subsequently leads to the change of the topological index. We further demonstrate how this mechanism can be exploited to control the formation of edge states which can control the transport properties. This study thus provides a better understanding of the origin of the topological properties as well as a simple way to manipulate them. [https://arxiv.org/abs/2204.06412]

MA 10.4 Mon 15:45 HSZ 403
Mapping out the topological phase diagram of FeSn — Soumya Sankar[1], Ruizi Liu[2], Xuejian Gao[1], Qifang Li[3,4], JiaChang Zheng[1], Caiyun Chen[1], Chengping Zhang[1], Kun Qiang[2], Zi Yang Meng[3,4], Kam Tuen Law[1], Qiming Shao[1,2], and •Berthold Jäck[1] — [1]HKUST, Clear Water Bay, Kowloon, Hong Kong SAR — [2]HKUST, Department of Computer Science and Electrical Enginerring, Clear Water Bay, Kowloon, Hong Kong SAR — [3]Hong Kong University, Department of Physics, Pokfulam Road, Hong Kong SAR — [4]University of Tokyo, Department of Physics, Hongo, Bunkyo City, Tokyo

Metallic kagome magnets exhibit a flat band and a Dirac point in their electronic structure and long-range magnetic order. The combination of these properties creates favourable conditions to search for strongly correlated and topological electronic states. The near-ideal kagome band structure of the inter metallic kagome series X1Y1 offers opportunities to study the interplay between strong electronic correlations, topology, and magnetism.

We have used molecular beam epitaxy and electronic transport measurements to study the interplay of magnetism and band topology in thin films of antiferromagnetic FeSn. We will present results from a magnetic field and temperature dependent study of the anomalous Hall effect. Combining these measurements with magnetic Monte-Carlo simulations and theoretical model calculations, we map out the topological phase diagram of FeSn over a large temperature range.

We acknowledge support by the GRC, and the Croucher Foundation.

Investigation of the magnetic topological insulator family (MnPn2Te4) (Pn2Te3) n, (Pn=Bi, Sb) by μSR and NMR — •Manaswini Sahoo[1,2], Anna Isaeva[1], Bernd Büchner[1], and Roberto De Renzi[2] — [1]Leibniz IFW Dresden, Dresden, Germany — [2]University of Parma,Parma, Italy

Time-reversal symmetry breaking in a topological insulator (TI) opens a surface gap and distinguishes chiral quantum states that could eventually be exploited

in electrically controlled spintronic devices. The recent discovery of layered van der Waals materials opens a new approach to achieve this.(MnBi2Te4) (Bi2Te3) n is one of the first such examples, where the increasing number n of TI layers controls the magnetic dimensionality of the material. These compounds do display the quantum anomalous Hall effect, where spontaneous magnetization and spin-orbit coupling lead to a topologically non-trivial electronic structure. In the case of (MnBi2Te4) (Bi2Te3) n, Zero Field μSR shows more than one internal field at the muon site with the majority one decreasing in value when n is increased. The muon spin precessions display very fast relaxations of static inhomogeneous nature. Whereas in the sister compound MnSb2Te4, Zero Field μSR shows a broader distribution of magnetic field at the muon due to larger intermixing between Mn/Sb in the sample. Importantly, the weak Transverse Field shows a sharp magnetic transition at the same Tc, with a clear relaxation peak due to critical fluctuations, taking place in the whole volume of the material. This local information from μSR together with NMR is crucial to correctly interpret macroscopic magnetization data.

MA 10.6 Mon 16:30 HSZ 403
Magnetic dilution effect and topological phase transitions in antiferromagnet $Mn_{1-x}Pb_xBi_2Te_4$ — •Yueh-Ting Yao[1], Tiema Qian[2], Tay-Rong Chang[1,3,4], and Ni Ni[2] — [1]Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan — [2]Department of Physics and Astronomy and California NanoSystems Institute, University of California, Los Angeles, California 90095, USA — [3]Center for Quantum Frontiers of Research and Technology (QFort), Tainan 701, Taiwan — [4]Physics Division, National Center for Theoretical Sciences, Taipei 10617, Taiwan

The interplay between magnetism and topology have taken the central stage of modern condensed matter physics in the past three years. The fine control of magnetism and topology in a magnetic topological insulator is crucial for realizing various novel magnetic topological phases, such as axion insulator, magnetic Weyl semimetals, etc. In this work, we investigate the evolution of magnetism and band topology in $Mn_{1-x}Pb_xBi_2Te_4$ via angle resolved photoemission spectroscopy (ARPES), first-principles calculations, and electronic transports. We present the comprehensive phase diagram by controlling Pb content and magnetism in this alloy system. Moreover, we provide the first topological crystalline insulator with non-trivial glide mirror Chern number in MnBi2Te4-family materials, which is protected by non-symmorphic symmetry arise from antiferromagnetic (AFM) configuration. Our work provides a fruitful platform with continuously tunable magnetism and topology for investigating emergent phenomena and pave a way towards potential new applications of nanoelectronics.

MA 10.7 Mon 16:45 HSZ 403
Thermal Hall Effect of Magnon-Phonon Hybrid Quasiparticles in a Fluctuating Heisenberg-Kitaev Antiferromagnet — •Robin R. Neumann[1], Alexander Mook[2], Jürgen Henk[1], and Ingrid Mertig[1] — [1]Martin Luther University Halle-Wittenberg, Halle (Saale), Germany — [2]Johannes Gutenberg University, Mainz, Germany

Magnons, the quantized excitations of localized spins, and phonons, the quantized excitations of the lattice, are two types of quasiparticles that are responsible for heat transport in magnetic insulators. However, phonons by themselves do not contribute to the *transverse* heat current induced by a temperature gradient, i.e., the thermal Hall effect (THE). Magnons, on the other hand, may exhibit a Berry curvature, a magnetic field in reciprocal space, that leads to an intrinsic THE.

In this talk, I address the THE in a Heisenberg-Kitaev antiferromagnet subjected to a magnetic field. The applied field drives the system from a zigzag antiferromagnetic to a spin-flop state. The magnon-driven THE indicates the magnetic phase transition by a sign change at the critical field. Furthermore, when the magnetoelastic interaction is considered, the phonon and magnon bands hybridize and additional Berry curvature at the avoided crossings emerge. Depending on the strength of the spin-phonon coupling, this may lead to an overall reversal of the THE while the field-induced sign change at the critical field remains mostly robust. These results showcase that magnon-phonon hybridization can be pivotal for the interpretation of transport experiments.

MA 10.8 Mon 17:00 HSZ 403
Limitations of the Bulk-Boundary Correspondence in Topological Magnon Insulators due to Magnon-Magnon Interactions — •Jonas Habel[1], Johannes Knolle[1], Alexander Mook[2], and Josef Willsher[1] — [1]Technical University of Munich, Germany (Theory of Quantum Matter and Nanophysics) — [2]Johannes Gutenberg University Mainz, Germany

Magnon excitations in ordered quantum magnets can exhibit topological band structures characterized by non-zero Chern numbers. Such magnonic Chern insulators are widely believed to host protected chiral edge modes due to the bulkboundary correspondence, in analogy to electronic Chern insulators. However, in contrast to electrons, magnons are bosons and can thus be subject to exotic number-non-conserving many-body interactions, enabling potentially strong spontaneous decays at zero temperature.

To assess their effect on the chiral edge magnons, we study a topological honeycomb-lattice ferromagnet with Dzyaloshinskii-Moriya interactions using many-body perturbation theory. We discover that non-harmonic terms of the spin-wave expansion may lead to severe lifetime reduction of edge modes and their delocalisation into the bulk. For sufficiently strong interactions, the spectral weight of the chiral edge magnons vanishes entirely. These findings indicate that topological magnon bands within the harmonic framework do not necessarily give rise to protected edge modes in the full spin theory, suggesting limitations of the bulk-boundary correspondence in this case.

Topological defects in a multiferroic antiferromagnet — •AURORE FINCO[1], ANGELA HAYKAL[1], STÉPHANE FUSIL[2], PAWAN KUMAR[1], PAULINE DUFOUR[2], ANNE FORGET[3], DOROTHÉE COLSON[3], JEAN-YVES CHAULEAU[3], MICHEL VIRET[3], NICOLAS JAOUEN[4], VINCENT GARCIA[2], and VINCENT JACQUES[1] — [1]Laboratoire Charles Coulomb, Université de Montpellier, CNRS, Montpellier, France — [2]Unité Mixte de Physique, CNRS, Thales, Université Paris-Saclay, Palaiseau, France — [3]SPEC, CEA, CNRS, Université Paris-Saclay, Gif sur Yvette, France — [4]Synchrotron SOLEIL, Gif-sur-Yvette, France

We report on the formation of topological defects emerging from the cycloidal order at the surface of bulk $BiFeO_3$ crystals [1]. Combining reciprocal and real-space magnetic imaging techniques, we first observe, in a single ferroelectric domain, the coexistence of regions in which the antiferromagnetic cycloid propagates along different wave vectors. We then show that the direction of these wave vectors is not strictly locked to the preferred crystallographic axes but rather rotates continuously. At the junctions between the magnetic domains, we observe topological line defects identical to those found in a broad variety of lamellar physical systems with rotational symmetries. Our work establishes the presence of these magnetic objects at room temperature in the multiferroic antiferromagnet $BiFeO_3$, offering new opportunities in terms of robustness and electrical control towards their use in spintronic devices.

Domain structures of stressed free-hanging magnetic thin films — DHAVALKUMAR MUNGPARA[1], •ALEXANDER SCHWARZ[1], FEDERICO MASPERO[2], RICCARDO BERTACCO[2], NICOLA MANCA[3], LEONÈLIO CICHETTO JR.[3], and LUCA PELLEGRINO[3] — [1]INF, University of Hamburg, Jungiusstr. 11, 20355 Hamburg — [2]CNR-IFN, Piazza Leonardo da Vinci 32, 20133 Milano, Italy — [3]CNR-SPIN Corso F. M. Perrone 24, 16152 Genova, Italy

This work has been conducted as part of the OXiNEMS project, which aims to realize a miniaturized all-oxide hybrid sensor able to detect magnetic fields in the fT-regime. Our envisaged design encompasses a superconducting pick-up loop with a constriction and a magnetically sensitive resonator placed directly above.

To achieve a high sensitivity, the resonator must have a high Q-value, which is accomplished by a large in-plane stress. To obtain magnetic sensitivity, the resonator itself can be magnetic, or a magnetic thin film element is grown on top of a non-magnetic resonator. Of course, the magnetic sensitivity of the whole device depends on the magnetic properties of the resonator. Therefore, we investigated the domain structure of two promising resonator candidates using magnetic force microscopy: 100 nm thick Co rectangles on non-magnetic silicon nitride trampoline resonators and 100 nm thick magnetic $La_{0.7}Sr_{0.3}MnO_3$ trampoline resonators.

The OXiNEMS project (www.oxinems.eu) has received funding from the European Union's Horizon 2020 research and innovation program under Grant Agreement No. 828784.

Stability and dynamics of SO(3) solitons in magnetically frustrated systems — •RICARDO ZARZUELA — Institut für Physik, Johannes Gutenberg Universität Mainz, D-55099 Mainz, Germany

In recent years frustrated magnets have resurged in condensed matter due to their striking spin transport properties [1,2] and ability to host three-dimensional magnetic solitons, such as Shankar skyrmions [3] or Anderson-Toulouse vortices [4]. The latter emerge in the corresponding SO(3)-order parameter (describing the spin-spin correlation of the system), have potential use in topological computing and high-density memory storage, and coexist with those conventional magnetic solitons encoded in the total magnetization field (e.g., domain walls and baby skyrmions). We discuss the stability of these SO(3) solitons for several phenomenological models for a magnetically frustrated platform and, within a collective variable approach, we also explore their dynamics in the presence of spin-transfer torques and topological defects.

Interaction of antiferromagnetic domain walls with crystal defects — •OLEKSANDR V. PYLYPOVSKYI[1,2], ARTEM V. TOMILO[1], NATASCHA HEDRICH[3], KAI WAGNER[3], BRENAN J. SHIELDS[3], TOBIAS KOSUB[1], RENÉ HÜBNER[1], JÜRGEN FASSBENDER[1], DENIS D. SHEKA[4], PATRICK MALETINSKY[3], and DENYS MAKAROV[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V., 01328 Dresden, Germany — [2]Kyiv Academic University, 03142 Kyiv, Ukraine — [3]University of Basel, Basel CH-4056, Switzerland — [4]Taras Shevchenko National University of Kyiv, 01601 Kyiv, Ukraine

Understanding behavior of magnetic texture in antiferromagnetic nanostructures and thin films is crucial for the design of novel magnetic data storage and logic devices. Here, we derive the boundary conditions for the Néel vector in a two-sublattice antiferromagnet (AFM) and apply them to describe the shape of the domain walls [1,2] and skyrmions [2] in confined samples. In general, the surface of a 3D domain wall behaves as an elastic ribbon which bends in response on the topographic features of the single crystal Cr_2O_3 [1]. In presence of the Dzyaloshinskii-Moriya interaction, topologically non-trivial AFM textures possess broadening near the surface. In thin films, the sample's granularity becomes crucial. We present a model of a granular AFM and, by comparison with Nitrogen Vacancy magnetometry of 200-nm-thick Cr_2O_3 films, estimate the inter-grain exchange strength. The grain boundaries act as strong pinning sites for the AFM texture. [1] N. Hedrich et al., Nat. Phys. 17, 574 (2021); [2] O. Pylypovskyi et al., Phys. Rev. B 103, 134413 (2021).

Evaluation of phase images obtained by electron holography for three-dimensional spin-textures — •MORITZ WINTEROTT[1,2] and SAMIR LOUNIS[1,2] — [1]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich & JARA, D-52425 Jülich, Germany — [2]Faculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany

Three-dimensional (3D) spin-textures, similarly to their 2D counterpart (skyrmions), are attracting widespread interest, especially because of their potential application as magnetic bits for energy-efficient storage devices. Thereby, a major challenge is their identification. Here we focus on electron holography, where phase images are reconstructed in order to recognize 3D spin-textures. The phase image consists of an electronic and a magnetic contribution, with the latter being assumed to emerge from the stray field, and thus should vanish for antiferromagnets, while the former is conjectured to be inert to the magnetic texture. Here we demonstrate that the electronic phase image carries non-trivial magnetic information induced by spin-mixing and spin-orbit mechanisms. We calculate and compare systematically the strength of both electronic and magnetic phase images employing the optimized forward model [1] and a tight-binding scheme combined with multiple-scattering theory. We explore the impact of spin-orbit interaction, exchange splitting and hopping.

X-ray holographic imaging of magnetic surface spirals in FeGe lamellae — •LUKE A. TURNBULL[1], MATTHEW T. LITTLEHALES[1], MURRAY N. WILSON[1], MAX T. BIRCH[2], HORIA POPESCU[3], NICOLAS JAOUEN[3], JOEL VEREZHAK[4], GEETHA BALAKRISHNAN[4], and PETER D. HATTON[1] — [1]Department of Physics, Durham University, Durham, DH1 3LE, UK — [2]Max Planck Institute for Intelligent Systems, 70569 Stuttgart, Germany — [3]Synchrotron SOLEIL, Saint Aubin, BP 48 91192 Gif-sur-Yvette, France — [4]Department of Physics, University of Warwick, Coventry, CV4 7AL, UK

Isotropic helimagnets are known to host a diverse range of chiral magnetic states. In 2016, F.N. Rybakov et al. theorized the presence of a surface-pinned stacked spin spiral phase [F.N. Rybakov et al., 2016 New J. Phys. 18 045002], which had yet to be observed experimentally. The phase is characterized by surface spiral periods exceeding the host material's fundamental winding period, L. In this talk we present experimental evidence for the observation of this state in lamellae of FeGe using resonant x-ray holographic imaging data and micromagnetic simulations. We find images of FeGe lamellae, exceeding a critical thickness of 300 nm (4.3L), exhibit contrast modulations with a field-dependent periodicity of

x<1.4L, consistent with theoretical predictions of the stacked spiral state. The identification of this spiral state carries significant implications for the stability of other coexisting spin textures in chiral helimagnets, and indicates the utility in considering magnetic systems in three-dimensions.

MA 12: Skyrmions II

Coexistence of distinct skyrmionic spin textures — •Börge Göbel[1], Jagannath Jena[2], Stuart Parkin[2], and Ingrid Mertig[1] — [1]Institut für Physik, Martin-Luther-Universität Halle-Wittenberg — [2]Max-Planck-Institut für Mikrostrukturphysik, Halle

The field of skyrmionics has attracted great research interest, as skyrmions – whirl-like nano-objects – are very stable which makes them potential carriers of information in future data storage devices. However, their integer topological charge causes two shortcomings of skyrmion-based racetrack storages: The skyrmions do not move parallel to a current and multiple skyrmions attract and repell each other.

In this talk, I present several alternative nano-objects that go beyond conventional skyrmions [1]. We discuss via simulations, Lorentz transmission electron microscopy measurements [2,3] and Hall transport measurements [4] that skyrmions, antiskyrmion and topologically trivial bubbles [5] can coexist. They can even appear fractionally near the sample's edges [6]. The interplay of Dzyaloshinskii-Moriya and dipolar interactions leads to interesting coexistence and deformation phenomena that may even be utilized for neuromorphic applications.

Magnetic Néel Domain Walls and Skyrmions in La0.7Sr0.3Mn1-xRuxO3 Multilayers — •Arsha Thampi[1], Jörg Schöpf[2], Daniel Wolf[1], Ionela Lindfors-Vrejoiu[2], and Axel Lubk[1,3] — [1]Leibniz Institute for Solid State and Materials Research Dresden, Helmholtzstraße 20, 01069 Dresden, Germany — [2]Physics Institute, University of Cologne, 50937 Cologne, Germany — [3]Institute of Solid State and Materials Physics, TU Dresden, 01069 Dresden, Germany

Magnetic domain walls (DWs) in ferromagnetic thin films exhibit a rich variety of configurations and corresponding dynamic properties depending on parameters like film thickness, defect density, magnetocrystalline anisotropy, exchange stiffness, and Dzyaloshinskii*Moriya interaction (DMI). Here, we study epitaxial ferromagnetic multilayer devices of La0.7Sr0.3Mn1-xRuxO3, consisting 8 nm thick manganite layers with varying Ru/Mn content, in order to engineer symmetric and antisymmetric exchange interaction and magnetic anisotropy across the multilayer stack. We particularly map the DW states as a function of temperature and external out-of-plane magnetic fields employing high-resolution magnetic imaging in the Transmission Electron Microscopy (TEM). Lorentz TEM and transport of intensity phase reconstruction is used to characterize the magnetic domains and DWs formed as a function of temperature and perpendicular magnetic field strength. High-resolution magnetic field mapping of La0.7Sr0.3Mn1-xRuxO3 multilayer system demonstrates the possibility to engineer chiral Néel domain walls and skyrmions.

MA 12.3   Tue 10:00   HSZ 02

In-situ correlation of the anomalous Hall effect with the occurrence of topological and non-topological magnetic phases in $Mn_{1.4}PtSn$ — •Darius Pohl[1], Andy Thomas[2], Sebastian Schneider[1], Dominik Krieger[3], Yejin Lee[2], Praveen Vir[4], Claudia Felser[4], Moritz Winter[1,4], and Bernd Rellinghaus[1] — [1]Dresden Center for Nanoanalysis (DCN), cfaed, TU Dresden — [2]Leibniz Institute for Solid State and Materials Research Dresden — [3]Institute of Solid State and Materials Physics, TU Dresden — [4]Max Planck Institute for Chemical Physics of Solids, Dresden

Topologically protected (anti-)skyrmions are potential future information carriers, since they can be electrically manipulated and detected, e.g., by measuring their Hall signature. Hall measurements are usually conducted on samples with different geometries as compared to those used for Lorentz TEM magnetic imaging. In magnetic phases which are strongly influenced by dipole-dipole interactions, such comparisons are problematic. We devised an experimental setup that bridges this gap and allows for the conduction of in-situ Hall measurements in a TEM. Besides proof-of-principle experiments on thin Ni films, our new setup allows us to follow in detail the field dependence of the Hall voltage while simultaneously monitoring the magnetic phases in $Mn_{1.4}PtSn$. This provides valuable insights into the existence and nature of an intensely debated electrical signature of skyrmionics structures. Financial support by DFG through SPP 2137 is gratefully acknowledged.

Room temperature stabilization of skyrmionic spin textures in synthetic antiferromagnets — •Mona Bhukta, Takaaki Dohi, M-A. Syskaki, Robert Frömter, and Mathias Kläui — Institut für Physik, Johannes Gutenberg-Universität Mainz, Staudingerweg 7, 55128 Mainz, Germany

Magnetic skyrmions [1] are twisted spin configurations, which show a non-zero skyrmion Hall angle when driven by current due to their topological nature[2], which is detrimental for applications. Skyrmions in synthetic antiferromagnet(SAFs), suppress this effect owing to an overall zero topological charge. Recent observations of skyrmions in SAFs have opened the possibility for using skyrmions as a candidate for logic operations in data storage devices [3]. Here, we investigate different, more exotic spin textures beyond skyrmions in a SAF consisting of CoFeB/Ir/CoFeB multilayers by using scanning electron microscopy with polarization analysis (SEMPA). The surface sensitivity of SEMPA is especially effective on SAFs enabling us to investigate the topological spin textures even in a fully compensated composition. We report merons and antimerons in the SAF that are stable at zero magnetic fields and room temperature. Micromagnetic simulations of the investigated SAF stacks have been carried out to understand the way of stabilization of these exotic spin textures as well as to explore the possible emergence of three-dimensional (3D) spin structures in the SAF multilayer system. Evidence for Chiral Soliton Lattice formation in the Antiskyrmion compound $Mn_{1.4}PtSn$ — •M. Winter[1,2,3], M. Rahn[4], D. Wolf[3], S. Schneider[2], M. Valvidares[5], C. Shekar[1], P. Vir[1], B. Achinuq[6], H. Popescu[7], T. Helm[8], G. Van der Laan[9], T. Hesjedal[6], B. Rellinghaus[2], and C. Felser[1] — [1]MPI CPfS, Dresden, Germany — [2]DCN, TU Dresden, Germany — [3]IFW, Dresden, Germany — [4]IFMP, TU Dresden, Germany — [5]ALBA Synchrotron, Barcelona, Spain — [6]Clarendon Laboratory, University of Oxford, UK — [7]Synchrotron SOLEIL, Saint-Aubin, France — [8]HZDR,Dresden,Germany — [9]Diamond Light Source, Didcot, UK

The Antiskyrmion (aSks) compound $Mn_{1.4}PtSn$ has a rich magnetic phase diagram that strongly depends on strength and orientation of an external magnetic field as well as on the history of its application. We conducted combined experiments of resonant elastic x-ray scattering (REXS) and Lorentz transmission electron microscopy (LTEM) on an identical lamella of Mn1.4PtSn. Our complementary approach allows for an unambiguous correlation of the real space magnetic textures in Mn1.4PtS, i.e., helices, non-topological (NT) bubbles and aSks as determined by LTEM and transitions between them with their corresponding k space scattering patterns obtained by REXS. The octupole vector magnet of the REXS setup enabled us to gain extended information on the dependence of the phase diagram of $Mn_{1.4}PtSn$ on the direction of the external magnetic field, revealing the interplay of chiral soliton lattices, NT bubbles, the conical phase and aSks. Part of this work is gratefully supported by DFG within SPP 2137.

MA 12.6   Tue 10:45   HSZ 02

Spin dynamics of skyrmion lattices in a chiral magnet resolved by microfocused Brillouin light scattering — Ping Che[1], •Riccardo Ciola[2], Markus Garst[2], Volodymyr Kravchuk[2], Arnaud Magrez[1], Helmuth Berger[1], Thomas Schönenberger[1], Henrik M. Rønnow[1], and Dirk Grundler[1] — [1]École Polytechnique Fédérale de Lausanne, Switzerland — [2]Karlsruhe Institute of Technology, Germany

Chiral magnets provide an innovative framework to study non-collinear spin textures and their associated magnetization dynamics. They include helical and conical magnetic textures that are spatially modulated with a wavevector k_h as well as the topologically non-trivial skyrmion lattice (SkL) phase. So far, different techniques have been used to probe the magnetization dynamics of the latter SkL phase in the small wavevectors limit, $k \ll k_h$, as well as for $k > k_h$. Here, we show that Brillouin light scattering (BLS) is ideally suited to probe the complementary range of wavevectors $k \lesssim k_h$. We analysed bulk spin waves in the SkL phase of Cu_2OSeO_3. We provide parameter-free predictions for the BLS cross section and compute both the resonances and their spectral weights. The theoretical results are compared to a BLS experiment in the backscattering geometry that probe magnons with a wavevector $k = 48 rad/\mu m < k_h = 105 rad/\mu m$. The clockwise, counterclockwise and breathing modes are clearly resolved. Due to the finite wavevector of the magnon excitations, finite spectral weight is theoretically predicted also for other resonances. Experimentally, at least one additional resonance is clearly identified.

MA 12.7   Tue 11:00   HSZ 02
Modelling thermal transport in spiral magnets — •Margherita Parodi[1,2] and Sergey Artyukhin[2] — [1]University of Genova, Italy — [2]Italian Institute of Technology, Genova, Italy

Magnetic memory and logic devices, including prospective ones based on skyrmions, inevitably produce heat. Thus, controlling heat flow is essential for their performance. Here we study magnon contribution to thermal conductivity in the most basic non-collinear magnet with a spin spiral ground state. Non-collinearity leads to anharmonic terms, resulting in magnon fusion and decay processes. These processes determine the magnon lifetime which can be used to estimate thermal conductivity in single mode approximation. However, by solving the full Boltzmann equation numerically, we find much higher thermal conductivity. This signifies that heat is carried not by individual magnons but by their linear combinations, called relaxons. The thermal conductivity is found to be increasing with the diminishing twist angle, consistent with recent experiments. The results pave the path to understanding magnetic thermal transport in other non-collinear magnets.

MA 12.8   Tue 11:15   HSZ 02
Enhanced Skyrmion Diffusion by Periodic Excitation — •Raphael Gruber, Maarten Brems, Jan Rothörl, Tobias Sparmann, Fabian Kammerbauer, Iryna Kononenko, Maria-Andromachi Syskaki, Peter Virnau, and Mathias Kläui — Institut für Physik, Johannes-Gutenberg Universität Mainz, 55099 Mainz, Germany

Magnetic skyrmions are chiral, quasi-particle spin structures that are considered as promising candidates for data storage, logic and non-conventional computing devices. When thermal excitation of the spins overcomes the variations in the energy landscape of a sample, skyrmions exhibit thermal motion as recently reported [1]. For non-conventional computing, diffusion is essential and its speed is key. Although pinning slows down diffusion, a finite effect of pinning is even required in order to ensure the system's complexity and non-linearity for non-conventional computing [2]. Using magneto-optical Kerr microscopy, we demonstrate that we can drastically increase the diffusion coefficient of micrometer-sized skyrmions in magnetic thin films by excitation with oscillating magnetic fields. The faster motion is traced back to a reduction of the effective pinning since the skyrmion pinning is strongly size-dependent [3]. Our findings thus pave the way to a significant increase of both performance and reliability of skyrmion devices, especially in non-conventional computing.

MA 13: Focus Session: New Perspectives for Adiabatic Demagnetization Refrigeration in the Kelvin and sub-Kelvin Range (joint session TT/MA)

Efficient cooling into the Kelvin and sub-Kelvin range is a long-standing challenge relevant to both fundamental research and future quantum technologies. The standard cooling cycle based on vapor compression exploits expensive and rare helium. Low-temperature physicists world-wide are presently looking for cheaper and accessible alternatives, not to mention the need of compact cooling technology for desktop quantum technology, or special requirements for applications such as space missions and scanning tunneling microscopes. One of the key candidates is adiabatic demagnetization refrigeration (ADR). ADR is based on magnetic solids with a huge magnetocaloric effect and requires no helium. Even if paramagnetic salts are known and used for ADR applications for almost a century, there is an ongoing quest for materials with better magnetocaloric and mechanical properties, thermal conductivity, and vacuum compatibility. In this symposium, new fundamental ideas and the recent successful design and characterization of quantum materials for improved ADR will be highlighted. These materials exploit collective phenomena in correlated electron systems, such as the concept of geometrically frustrated magnetism to push the entropy to low temperatures, as well as heavy-fermion, and quantum-critical states.

Self-cooling molecular spin quantum processors — •Marco Evangelisti[1], Fernando Luis[1], Elias Palacios[1], David Aguilà[2], and Guillem Aromí[2] — [1]INMA, CSIC & Universidad de Zaragoza, Spain — [2]Dept. Química Inorgànica, Universidad de Barcelona, Spain

Cryogenic refrigeration is crucial for a wide range of emerging applications in the field of quantum technologies. Indeed, thermal energy must be minimized to avoid the excitation of vibrational motions that could disturb quantum operations. Synthetic chemistry provides a sophisticated methodology for the design and synthesis of materials displaying a wide variety of properties. Molecular materials are capable of excellent and unique characteristics that can be exploited either for caloric cooling[1] or spin-based quantum computing[2]. However, these features are not yet being implemented as such to act together within the same material, that is, at the molecular scale. Here, we show that a spin qubit (or qudit) can be brought into proximity with a spin centre that acts as a cooler. To this end, we make use of rare-earth-based asymmetric molecular dimers. A chemically engineered structural asymmetry introduces different coordination environments for each metal ion, operating similarly as for molecular quantum gates reported by some of us[3]. This strategy allows selecting individually both constituent ions, leading to e.g. the direct observation of the cooling of a single Er(III) ion qubit, or a Tm(III) electronuclear spin qudit, driven chiefly by the demagnetization of a single Gd(III) ion located within the same molecule.

Triangular rare-earth borates for milli-Kelvin adiabatic demagnetization refrigeration — •Philipp Gegenwart — Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg

Adiabatic demagnetization refrigeration (ADR) is a classical cooling technique with renewed recent attention as alternative to costly and elaborate ^{3}He/^{4}He dilution refrigeration. Established water containing ADR salts suffer from chemical instability which requires delicate treatment to avoid degradation and ensure good thermal contact. Water-free KBaYb(BO$_3$)$_2$ is an excellent alternative with high entropy density that allows ADR to below 20 mK [1]. Sintered pellets with silver powder admixture to ensure good thermal coupling are easy to manufacture, inexpensive and long-term stable even upon heating up to 700°C, enabling also ultra-high vacuum applications. KBaYb(BO$_3$)$_2$ belongs to a family of rare-earth-based borates with triangular arrangement of magnetic moments. We discuss the impact of geometrical frustration and structural randomness on its low-temperature properties and demonstrate the enormous tunability of cooling power and operating temperature by chemical substitution.

A millikelvin scanning tunnelling microscope in ultra-high vacuum with adiabatic demagnetisation refrigeration — •Ruslan Temirov — Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany — University of Cologne, Institute of Physics II, Cologne, Germany

Scanning tunnelling microscopes (STMs) operating in ultra-high vacuum (UHV) and low-temperature conditions are used widely for imaging and precise manipulation of surface nanostructures. A growing interest in studies of quantum-coherent phenomena in such nanostructures stimulates the development of STMs that operate at very low millikelvin temperatures. This contribution presents the design of a first-ever UHV STM cooled by adiabatic demagnetisation refrigeration (ADR) to below 30 mK. The use of ADR makes the STM design modular and helps it to reach a remarkable degree of mechanical stability. Tunnelling spectra collected on an atomically clean superconducting Al(100) surface reveal that the electronic temperature of the tunnelling junction is less

than 80 mK. The inelastic electron tunnelling spectroscopy of an individual electron spin performed in magnetic fields of up to 8 Tesla validates the STM capabilities for quantum nanoscience research.

ADR cryostats in low temperature physics and their applications — •Doreen Wernicke — Entropy GmbH, Gmunder Str. 37a, 81379 München

Entropy GmbH is a company founded in 2010 in Munich, Germany, specializing
in the development and manufacture of low temperature cryostats. All Entropy cryostats are based on closed-cycle pre-cooling to temperatures below 3K. Further cooling stages such as ADR units, Joule-Thomson stages, and dilution refrigerators including electronics and software are proprietary developments. The modular design of all cryostats offers the possibility of adaptation to many different experiments and applications. One of Entropy's most common products are the ADR cryostats. The presentation will explain the principle of ADR cooling and features such as base temperature and holding time at operating temperature. Applications for low temperature device operation such as various types of superconducting detectors (TES, MKIDs, SQUIDs, SNSPDs) and Qubit characterization will be presented to demonstrate the performance and limitations of adiabatic demagnetization refrigeration.

Frustrated dipolar materials for low-temperature magnetic refrigeration — •Mike Zhitomirsky — Institute of Interdisciplinary Research, CEA-Grenoble, France

Low-temperature refrigeration is crucial for emergent quantum-information technologies and other scientific applications that outstretch from space telescopes to medicine. This growing demand fuels an interest in alternative low-temperature techniques including the adiabatic demagnetization refrigeration. The existing ADR technologies for the sub-Kelvin range utilize dilute paramagnetic salts of Cr and Fe magnetic ions, which have limited efficiency at higher temperatures. I shall discuss general directions of the ongoing search of prospective refrigerant materials by exploring collective effects in systems of interacting magnetic moments as opposed to noninteracting moments in paramagnetic salts. Specifically, I focus on geometrically frustrated magnets with a residual ground-state degeneracy as well as on dipolar magnets. I present new experimental and theoretical results obtained recently in Grenoble for two dipolar materials: $Yb_3Ga_5O_{12}$, which is a spin-1/2 dipolar ferromagnet on a hyper-Kagome lattice, and $GdLiF_4$, which exhibits a hidden magnetic frustration. The striking properties of the latter material including a fractional magnetization plateau demonstrate importance of new magnetocaloric materials not only for applied but also for basic research in magnetism.

MA 13.6   **Tue 12:15**   **HSZ 03**
ADR based sub-Kelvin cryostats for applied quantum technologies — •Pau Jorba[1], Felix Rucker[1], Steffen Säubert[1], Alexander Regnat[1], Jan Spallek[1], and Christian Pfleiderer[2] — [1]kiutra GmbH, Flößergasse 2, D-81369 München, Germany — [2]Physik-Department, Technische Universität München, D-85748 Garching, Germany

In view of the increasing demand for the cooling of quantum electronic devices, the development of scalable cooling solutions that provide low temperatures independent of rare helium-3 will be mandatory for the adoption and commercial use of next-generation quantum technologies. We present novel ADR based sub-Kelvin cryostats[1] specifically developed for the characterization and operation of quantum devices. We address how known challenges of ADR systems such as limited hold time and magnetic stray fields can be overcome. Specifically, we describe how continuous sub-Kelvin cooling and wide-range temperature control can be achieved by combining multiple ADR units and mechanical thermal switches. We also present a novel sample loader mechanism[2] that allows taking advantage of the solid-state nature of ADR and to cool samples from room temperature to 100 mK in less than 3 hours.

ADR below the ordering temperature in triangular $KBaGd(BO_3)_2$ — •Noah Winterhalter-Stocker[1], Alexander Bellon[1], Fabian Hirschberger[1], Sebastian Bachus[1], Sebastian Erdmann[1], Alexander Tsirlin[1,2], Yoshifumi Tokiwa[1,3], Anton Jesche[1], and Philipp Gegenwart[1] — [1]Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg, D-86159 Augsburg, Germany — [2]Felix Bloch Institute for Solid-State Physics, Leipzig University, D-04103 Leipzig, Germany — [3]Advanced Science Research Center, Japan Atomic Energy Agency, Tokai, Ibaraki 319-1195, Japan

Compared to the triangular ADR magnet $KBaYb(BO_3)_2$ [1] the isotructural sister compound $KBaGd(BO_3)_2$ with spin 7/2 moments has a three times enhanced magnetic entropy density of 192 $mJK^{-1}cm^{-3}$. We report a low-temperature magnetic and thermodynamic investigation of polycrystalline $KBaGd(BO_3)_2$ down to 50 mK. Specific heat indicates an antiferromagnetic phase transition at 263 mK, strongly broadened due to randomness and frustration, that becomes suppressed beyond 0.5 T. Further increase of magnetic field shifts the available entropy of R log 8 towards high temperatures. Interestingly, ADR of a pellet utilizing the same setup as used in [1] reveals a minimal temperature if T_{min}=122 mK that is more than twice below T_N along with a hold time of more than 8 hours. The combination of minimal temperature and entropy density in $KBaGd(BO_3)_2$ is outstanding among known ADR materials.

MA 13.8   **Tue 12:45**   **HSZ 03**
Magnetocaloric properties of $(RE)_3Ga_5O_{12}$ (RE=Tb, Gd, Nd, Dy) — Markus Kleinhans[1], Klaus Eibensteiner[1,2], Jon Leiner[1], •Christoph Resch[1], Lukas Worch[1], Marc Wilde[1], Jan Spallek[1,2], Alexander Regnat[1,2], and Christian Pfleiderer[1] — [1]Physik Department, Technical University Munich, D-85748 Garching, Germany — [2]kiutra GmbH, Rupert-Mayer-Str. 44, D-81379 Munich, Germany

We report the characteristic magnetic properties of several members of the rare earth garnet family, $Gd_3Ga_5O_{12}$ (GGG), $Dy_3Ga_5O_{12}$ (DGG), $Tb_3Ga_5O_{12}$ (TGG), and Nd_3Ga5O_{12} (NGG), and compare their relative potential utility for magnetocaloric cooling, including their minimal adiabatic demagnetization refrigeration (ADR) temperatures and relative cooling parameters. A main objective of this work was to find potential improvements over the magnetocaloric properties of GGG for use in low temperature ADR cryostats. Using Tb^{+3} and Dy^{+3} in the RE-site oers, in principle, a higher saturation magnetization and Nd^{+3} gives a lower de Gennes factor and therefore potentially low transition temperature. Our results show that $Dy_3Ga_5O_{12}$ yields an optimal relative cooling parameter (RCP) at low applied fields and a low transition temperature, which would allow for the design of more efficient ADR cryostats.

MA 13.9   **Tue 13:00**   **HSZ 03**
Study of the large rotational magnetocaloric effect in $Ni(en)(H_2O)_4SO_4 \cdot 2H_2O$ — •Róbert Tarasenko, Petro Danylchenko, Erik Čižmár, Vladimír Tkáč, Alexander Feher, Alžbeta Orendáčová, and Martin Orendáč — Institute of Physics, Faculty of Science, Pavol Jozef Šafárik University, Park Angelinum 9, 041 54 Košice, Slovakia

The title compound $Ni(en)(H_2O)_4SO_4 \cdot 2H_2O$ (en = ethylenediamine) has been identified as a spin-1 paramagnet with the nonmagnetic ground state introduced by the easy-plane anisotropy D/k_B = 11.6 K with E/D = 0.1 and negligible exchange interactions $J \approx 0$. We present an experimental study of the rotational magnetocaloric effect (MCE) in single crystals at temperatures above 2 K, associated with adiabatic crystal rotation between the easy plane and hard axis in magnetic fields up to 7 T. The experimental observations are completed with *ab* initio calculations of the anisotropy parameters. Theoretical simulations of the rotational MCE in the $S = 1$ paramagnet were performed and the simulations were compared with experimental data. A large rotational magnetic entropy change ≈ 16.9 $Jkg^{-1}K^{-1}$ has been achieved in 7 T. The adiabatic rotation of the crystal in 7 T starting at the initial temperature of 4.2 K leads to the cooling of the sample down to 0.34 K, which suggests the application of this material in low-temperatures cooling. Our simulations show that $S = 1$ Ni(II)-based systems with easy-plane anisotropy can have better rotational magnetocaloric properties than costly materials containing rare-earth elements.

Antiferromagnetism-driven two-dimensional topological nodal-point superconductivity — •Roberto Lo Conte[1], Maciej Bazarnik[1,2], Eric Mascot[1], Krisztián Palotás[3], Levente Rózsa[4], László Szunyogh[3], André Kubetzka[1], Dirk K. Morr[5], Kirsten von Bergmann[1], and Roland

Wiesendanger[1] — [1]Department of Physics, University of Hamburg, Germany — [2]Institute of Physics, Poznan University of Technology, Poland — [3]Department of Theoretical Physics, Budapest University of Technology and Economics, Hungary — [4]Department of Physics, University of Konstanz, Germany — [5]Department of Physics, University of Illinois at Chicago, USA

In the recent years, pioneering studies have been carried out on magnet/superconductor hybrid systems[1-4], motivated by their potential to host emergent quantum phases such as topological superconductivity. Here, we present the discovery of a topological nodal-point superconducting phase in antiferromagnetic manganese (Mn) monolayer islands on superconducting niobium (Nb) via low temperature spin-polarized STM[5]. Low-energy edge modes are found to separate the topological phase from the trivial one. The relative spectral weight of the edge modes depends on the edge's atomic configuration, which is a fingerprint of the discovered topological state. [1]S. Nadj Perge et al., Science 346, 602(2014). Structure–Property Relationship of Reversible Magnetic Chirality Tuning — •Jing Qi[1], Paula M. Weber[1], Tilman Kisslinger[2], Lutz Hammer[2], M. Alexander Schneider[2], and Matthias Bode[1] — [1]Julius-Maximilians-Universitaet Wuerzburg — [2]Universitaet Erlangen-Nuernberg

The Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction mediates collinear magnetic interactions via the conduction electrons of a non-magnetic spacer, resulting in a ferro- or antiferromagnetic magnetization in magnetic multilayers [1]. Recently it has been discovered that heavy non-magnetic spacers are able to mediate an indirect magnetic coupling that is non-collinear and chiral. This Dzyaloshinskii-Moriya-enhanced RKKY (DME-RKKY) interaction causes the emergence of a variety of interesting magnetic structures, such as skyrmions and spin spirals [2]. Here, we show by spin-polarized STM that the interchain coupling between manganese oxide chains on Ir(001) can reproducibly be switched from chiral to collinear antiferromagnetic by increasing the oxidation state of MnO_2 while the reverse process can be induced by thermal reduction. The underlying structure–property relationship is revealed by low-energy electron diffraction intensity (LEED-IV) analysis. Density functional theory calculations suggest that the magnetic transition may be caused by a significant increase of the Heisenberg exchange which overrides the DMI interaction upon oxidation.

Lifting the frustration of higher-order exchange interactions in ultrathin films — •Felix Nickel[1], Soumyajyoti Haldar[1], Roland Wiesendanger[2], Stefan Heinze[1], and Kirsten von Bergmann[2] — [1]Institute of Theoretical Physics and Astrophysics, University of Kiel — [2]Department of Physics, University of Hamburg

The 3Q state – a three-dimensional spin structure on a two-dimensional lattice predicted about 20 years ago [1] – has been observed in a Mn monolayer on Re(0001) using spin-polarized scanning tunneling microscopy (SP-STM) [2]. The 3Q state is a superposition of three symmetry equivalent spin spirals with the same period and can be stabilized by higher-order exchange interactions (HOI) such as the biquadratic or four-spin interactions [1,2]. Recently, it has been suggested based on density functional theory (DFT) calculations that the 3Q state in Mn/Re(0001) is significantly distorted due to topological chiral magnetic interactions [3]. Here, we show using DFT that the competition of biquadratic, four-spin, and topological chiral interactions can be tuned in Mn/Re(0001) by single atomic adlayers of Pd or Rh. Thereby, the frustration of HOI present in Mn/Re(0001) is lifted which results in the occurrence of the ideal 3Q state. SP-STM experiments confirm the predicted 3Q ground state of Pd/Mn/Re(0001) and Rh/Mn/Re(0001) and reveal differences to Mn/Re(0001).

Conical spin-spirals at a ferromagnet's surface: experimetal observations — •Patrick Haertl[1], Gustav Bihlmayer[2], Markus Leisegang[1], Stefan Bluegel[2], and Matthias Bode[1] — [1]Universität Würzburg, Germany — [2]Forschungszentrum Jülich and JARA, Germany

The spin-orbit–driven Dzyaloshinskii-Moriya interaction (DMI) can lead to chiral spin structures in magnetic systems with broken inversion symmetry [1]. The purely interfacial origin of DMI generally results in a reciprocal scaling with the magnetic layer thickness [2]. Here we report on the observation of a conical spin-spiral state at the surface of epitaxial Gd(0001) films grown on W(110). In a recently performed spin-polarized scanning tunneling microscopy (SP-STM) investigation of the thickness-dependent domain structures of Gd/W(110) we confirmed the existence of a spin reorientation transition (SRT) [3] from in-plane to out-of-plane magnetized films at a critical thickness $\Theta_{crit} \approx (100 \pm 20)$ AL [4]. In the vicinity of this SRT, we identify striped regions with a periodicity of about 2 nm. The application of an external magnetic field induces a rearrange-

ment of the stripes, thereby unambiguously confirming its magnetic origin. The experimental observations are discussed on the basis of density functional theory (DFT).

Conical spin-spirals at a ferromagnet's surface: a theoretical analysis — •Gustav Bihlmayer[1], Patrick Härtl[2], Markus Leisegang[2], Matthias Bode[2], and Stefan Blügel[1] — [1]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, D-52425 Jülich, Germany — [2]Universität Würzburg, Germany

The properties of surface layers of a magnetic material can differ substantially from those of the bulk material. A prominent example is the Dzyaloshinskii-Moriya interaction (DMI), resulting from inversion-symmetry breaking at the surface, but also the magnetic anisotropy and the exchange interactions are locally modified. Gd(0001) is here a well-investigated model surface but despite its sensitivity of exchange interactions to the local environment, experimental data indicated that it behaves as homogeneous Heisenberg system [1]. Recent observations of spin-spirals at the surface of epitaxial Gd(0001) with spin-polarized scanning tunneling microscopy let us re-investigate this system. Density functional theory (DFT) calculations show that not only a sizable DMI can be found at the Gd(0001) surface but also the exchange interactions are modified to drive the system locally towards a conical spin-spiral state. Since the magnetic anisotropy and the exchange interactions with the ferromagnetic bulk material disfavor non-collinear magnetic states, only slight modifications of the exchange interactions make these spirals visible. We explore the phase diagram numerically and with the help of atomistic spin-dynamics simulations.

Non-collinear spin structure of trilayer Mn films on W(001) — •Tim Drevelow[1], Paula M. Weber[2], Jing Qi[2], Matthias Bode[2,3], and Stefan Heinze[1] — [1]Institute of Theoretical Physics and Astrophysics, University of Kiel, Leibnizstraße 15, 24098 Kiel, Germany — [2]Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — [3]Wilhelm Conrad Röntgen-Center for Complex Material Systems (RCCM), Universität Würzburg, Am Hubland, 97074 Würzburg, Germany

The spin structure of Mn films on the W(001) surface depends sensitively on the number of atomic layers. It has been shown that a Mn monolayer exhibits a spin spiral driven by the Dzyaloshinskii-Moriya interaction (DMI) [1] while the Mn double layer possesses an antiferromagnetic checkerboard state and vanishing Mn moments at the interface [2]. Here, we study the Mn trilayer on W(001) with a combination of spin-polarized scanning tunneling microscopy (SP-STM) and density functional theory (DFT) calculations. Experimentally, it is shown that the Mn films grow pseudomorphically and exhibit a c(4 × 2) magnetic superstructure consistent with a conical spin spiral ground state. Based on our DFT calculations we compare the total energies of different collinear and non-collinear spin structures including the effect of spin-orbit coupling. We find a complex interplay of magnetic interactions and structural relaxations of the Mn trilayer.

MA 14.7   Tue 11:30   HSZ 04
Structural transitions of magnetic thin films induced by two-dimension materials — •Hangyu Zhou[1,2], Manuel dos Santos Dias[1,3,4], Weisheng Zhao[2], and Samir Lounis[1,3] — [1]Peter Grünberg Institut and Institute for Advanced Simulations, Forschungszentrum Jülich & JARA, 52425 Jülich, Germany — [2]School of Integrated Circuit Science and Engineering, MIIT Key Laboratory of Spintronics, Beihang University, Beijing 100191, China — [3]Faculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany — [4]Scientific Computing Department, STFC Daresbury Laboratory, Warrington WA4 4AD, United Kingdom

Interfaces of magnetic thin films play a key role in determining magnetic behaviors and implementations of spintronic devices. In the last decade, the increased availability of high-quality two-dimensional (2D) materials has helped to broaden the scope of interfaces, leading to the discovery of novel electronic and magnetic properties. Here, we explore with density functional theory calculations the impact of hexagonal boron nitride (h-BN) on the magnetism and structural properties of magnetic monolayers placed on heavy metal surfaces. We found that h-BN induces various structural transitions, and we investigate how magnetic interactions, such as the Heisenberg exchange interaction and the Dzyaloshinskii-Moriya interaction (DMI), are influenced by these reconstructions. These results contribute to new avenues for stabilizing complex spin-textures.

Work funded by DFG (SPP 2244; LO 1659/7-1) and China Scholarship Council program.

MA 15: INNOMAG e.V. Prizes 2023 (Diplom-/Master and Ph.D. Thesis)

Die Arbeitsgemeinschaft Magnetismus der DPG hat einen Dissertationspreis und einen Diplom-/Masterpreis ausgeschrieben, welche auf der Tagung der DPG 2023 in Dresden vergeben werden. Ziel der Preise ist die Anerkennung herausragender Forschung im Rahmen einer Diplom-/Masterarbeit beziehungsweise einer Promotion und deren exzellente Vermittlung in Wort und Schrift. Im Rahmen dieser Sitzung tragen die besten der für ihre an einer deutschen Hochschule durchgeführten Diplom-/Masterarbeit beziehungsweise Dissertation Nominierten vor. Im direkten Anschluss entscheidet das Preiskommittee über den Gewinner des INNOMAG e.V. Diplom/Master-Preises und des Dissertationspreises 2023. Talks will be given in English!

Time: Tuesday 9:30–11:50   Location: HSZ 401

MA 15.1   Tue 9:30   HSZ 401

Cubic magneto-optic Kerr effect in Ni(111) thin films — •Maik Gaerner[1], Robin Silber[2], Tobias Peters[1], Jaroslav Hamrle[3], and Timo Kuschel[1] — [1]Bielefeld University, Germany — [2]IT4Innovations, VŠB - Technical University of Ostrava — [3]Charles University, Prague, Czech Republic

In most studies utilizing the magneto-optic Kerr effect (MOKE), the detected change of polarized light upon reflection from a magnetized sample is supposed to be proportional to the magnetization M. However, MOKE signatures quadratic in M have also been identified and utilized, e.g., to sense the structural order in Heusler compounds, to detect spin-orbit torque or to image antiferromagnetic domains.

In our study, we observe a strong anisotropic MOKE contribution of third order in M in Ni(111) thin films, attributed to a cubic magneto-optic tensor $\propto M^3$ [1]. This cubic MOKE (CMOKE) is responsible for a threefold in-plane angular dependence of the magnetically saturated longitudinal MOKE response. We further show that this angular dependence is affected by the amount of structural domain twinning in the sample. The degree of twinning is determined by off-specular X-ray diffraction. Finally, the dependence of the anisotropic CMOKE on the external magnetic field strength is investigated up to nearly 2 T. Our detailed study on CMOKE for two selected photon energies will open up new opportunities for CMOKE applications with sensitivity to twinning properties of thin films, e.g. CMOKE spectroscopy and microscopy or time-resolved CMOKE.

Switching of Sublattice Magnetization in Quantum Antiferromagnets Described by Schwinger Bosons — •Katrin Bolsmann — Technische Universität Dortmund

Harvesting magnetic excitations in antiferromagnets for information processing is a promising and fast-growing field in the research of magnetism. One of the main foci is the readout and manipulation of the Néel vector of antiferromagnetic (AFM) materials. We study a theoretical approach to describe the non-equilibrium switching of a two-dimensional AFM magnetization on a square lattice. We recall the use of Schwinger bosons in equilibrium to describe the elementary excitations, of the isotropic and anisotropic AFM square lattice, in mean-field approximation. The Bose-Einstein condensation of Schwinger bosons describes the long-range magnetic order. Then, the Schwinger boson mean-field theory is applied to investigate the switching of the sublattice magnetization on the AFM square lattice via an external magnetic field. In the anisotropic system, there is an increase in energy after switching, which depends on the degree of anisotropy. Furthermore, we find a threshold field, below which switching is no longer possible, and investigate its dependence on the anisotropy. Even for low anisotropy, the threshold for the magnetic field turns out to be too large for standard technical applications. Finally, we discuss possible modifications of the protocol to enable switching of the sublattice magnetization with smaller fields.

MA 15.3   Tue 10:10   HSZ 401

Magnetooptical Investigation of nonreciprocal Phonon- Magnon Interaction — •Yannik Kunz[1], Michael Schneider[1], Moritz Geilen[1], Matthias Küss[2], Manfred Albrecht[2], Philipp Pirro[1], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Institut für Physik, Universität Augsburg

The coupling of surface acoustic waves (SAWs) with spin waves (SWs) intrinsically breaks the time-inversion symmetry. The resulting nonreciprocity can be exploited for applications such as miniaturized microwave isolators. SAWs can be efficiently excited and detected by interdigital transducers. Therefore, in experiments the magnetic field dependent transmission induced by the coupling with SWs is commonly detected via electrical methods [1]. However, for the investigation of magnetoelastic interactions with spatial resolution, magnetooptical measurement methods are needed. We employed microfocused Brillouin light scattering spectroscopy and frequency-resolved magneto-optical Kerr effect spectroscopy [2] to map the spatial dependence of the phonon-magnon-coupling on a LiNbO$_3$/Co$_{40}$Fe$_{40}$B$_{20}$(10 nm)/SiN(5 nm)-structure. Our experiments provide direct evidence for coherent and nonreciprocal conversion of phonons to magnons along the SAW propagation path.

We acknowledge the funding by DFG via project No. 492421737.

The Turn of the Screw and the Slide of the Skyrmion — •Nina del Ser — Institute for Theoretical Physics, University of Cologne

We explore the non-equilibirum dynamics of chiral magnets driven by oscillating magnetic fields in the GHz regime. Universal activation of the magnets' translational and rotational Goldstone modes invites many exciting applications. Magnetic screws will turn, skyrmions will swim and skyrmion lattices will rotate. The magnetic Archimedean screw opens the door to new transport applications on the nano-scale, and is shown to be a very efficient electron pump even in the presence of disorder. At stronger driving, Floquet spin wave instabilities provoke the formation of a time quasicrystal, where the magnetisation oscillates at new incommensurate spatial and temporal frequencies. We also investigate the role of fractional charge topological charge in magnets. We show that such charges turn up for example in cubic magnets and in the fragments of exploding skyrmions or trapped between symmetry-broken domain walls. We show how their remarkable scattering properties can be used to build a magnon-powered fractional defect engine.

MA 15.5   Tue 10:55   HSZ 401

Imaging vortex pinning and gyration by time-resolved and in-situ Lorentz microscopy — •Marcel Möller — Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — 4th Physical Institute - University of Göttingen, Göttingen, Germany

Nanoscopic magnetic textures, including vortices, merons and skyrmions promise future applications three-dimensional memory, logic gates or neuromorphic computing. Studying the control of such textures employing electric, magnetic or optical fields, demands instruments with sufficient spatial and temporal resolution. Ultrafast transmission electron microscopy allows for the study of optically-driven dynamics in materials. Yet, its potential to probe current- or field-driven dynamics of magnetic textures has remained unexplored.

In this work, ultrafast Lorentz imaging is developed to map the time-resolved gyration of vortices in a magnetic nanostructure driven by radio-frequency currents. The tracking of the vortex core with a localization precision of ± 2 nm and a temporal resolution below 3 ps is demonstrated [1]. Moreover, we find a transient change in the frequency and damping of the core orbit, attributed to structural disorder in the sample. Combining time-resolved Lorentz microscopy with bright-field imaging is used to identify the origin of this disorder, indicating grain boundaries in the polycrystalline film to be a major source of pinning [2].

MA 16.1   Tue 9:30   HSZ 403

Resonances in periodically driven magnon systems — •Jan Mathis Giesen, Christoph Dauer, Imke Schneider, Sebastian Eggert, Alexandre Abbass Hamadeh, and Philipp Pirro — Department of Physics and Research Center Optimas, Technical University of Kaiserslautern, 67663 Kaiserslautern, Germany

Parametric resonances in ferro- and ferri-magnetic systems under a periodic drive are known for quite some while. So called parallel pumping, which is for example used to realize Magnon BECs in materials like YIG, is normally achieved by driving the system with twice the frequency of a certain magnon mode. Much less research has been dedicated to lower lying resonances, which in theory should also be possible and give rise to some interesting behaviours.

We establish a method based on Floquet theory to efficiently determine and examine instabilities of the microscopic magnon system. As a central consequence parametric resonances occur if the driving frequency is an integer multiple of two times the energy of the elementary excitation. In particular we examine regions of resonances for frequencies below the energy spectrum and predict different effects depending on the driving amplitude and frequency, like the vanishing of instabilities at high driving fields. We compare our results with phenomenological approaches to investigate the role damping plays in such systems and perform micromagnetic simulations in order to confirm our results.

MA 16.2   Tue 9:45   HSZ 403

Topological Hybrids of Magnons and Magnon Bound Pairs — Alexander Mook[1], •Rhea Hoyer[1], Jelena Klinovaja[2], and Daniel Loss[2] — [1]Johannes Gutenberg-University, Mainz, Germany — [2]University of Basel, Basel, Switzerland

We employ anisotropic and spin-nonconserving Heisenberg models on Bravais lattices to predict the existence of topological quantum spin excitations in ferromagnets. We show that a hybridization of a single magnon and a two-magnon bound state can lead to topological spectral gaps that support quantum-Hall-like edge excitations. Such topological chiral hybrids of magnons and magnon pairs are a quantum phenomenon that vanishes in the classical limit and goes beyond the established theory of magnon topology.

MA 16.3   Tue 10:00   HSZ 403

Finite-element micromagnetic modeling of spin-wave propagation with the open-source package TetraX — •Lukas Körber[1,2], Gwendolyn Quasebarth[1,2], Alexander Hempel[1,2], Andreas Otto[2], Jürgen Fassbender[1,2], and Attila Kákay[1] — [1]Helmholtz-Zentrum Dresden - Rossendorf, Bautzner Landstraße 400, Dresden Germany — [2]Fakultät Physik, Technische Universität Dresden

We present a finite-element-method (FEM) dynamic-matrix approach to efficiently calculate the dispersion and spatial mode profiles of spin waves propagating in waveguides with arbitrary cross-section, where the equilibrium magnetization is invariant along the propagation direction. This is achieved by solving a linearized version of the equation of motion of the magnetization numerically only in a single cross-section of the waveguide at hand. To compute the dipolar field, we present an extension of the well-known Fredkin-Koehler method to plane waves. The presented dynamic-matrix approach is implemented within our recently published open-source micromagnetic modeling package TetraX [1], which aims to provide user-friendly and versatile FEM workflows for the magnonics community (not only for the magnonics community but FEM simulations in general), covering several classes of sample geometries and, soon, also antiferromagnets. As a brief introduction, this talk will include a short live demo of TetraX.

Confinement of Bose-Einstein magnon condensates in adjustable complex magnetization landscapes — •Matthias R. Schweizer, Alexander J.E. Kreil, Georg von Freymann, Alexander A. Serga, and Burkard Hillebrands — Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, Germany

We demonstrate the capability to control a room-temperature magnon Bose–Einstein condensate (BEC) by spatial modulation of the saturation magnetization. We use laser heating in combination with a phase-based wavefront modulation technique to create adjustable temperature patterns in an yttrium-iron-garnet film. The increase in temperature leads to a decrease of the local saturation magnetization and in turn to the modification of the corresponding BEC frequency. Over time, a phase accumulation between different BEC-areas arises, leading to phase-driven magnon supercurrents.

The BEC is created by microwave parametric pumping and probed by Brillouin light scattering spectroscopy. We observe a strong magnon accumulation effect caused by magnon supercurrents for several distances between heated

regions. This accumulation effect manifests itself in the confinement of the magnon BEC, which exhibits an enhanced lifetime due to the continuous influx of magnons.

MA 16.5   Tue 10:45   HSZ 403

Time-correlated nonlinear spiking spin waves in Ga:YIG — •David Breitbach[1], Moritz Bechberger[1], Björn Heinz[1], Jan Maskill[1], Bert Lägel[1], Carsten Dubs[2], Burkard Hillebrands[1], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, Germany — [2]INNOVENT e.V. Technologieentwicklung, Jena, Germany

Nonlinear spin-wave phenomena are key for magnon-based information processing and have led to the realization of numerous building blocks for spin-wave based computing. For coherent spin waves, the nonlinear frequency shift is one of the most robust nonlinear effects. In this study, we utilize this effect to build a spin-wave reservoir with temporal signal correlation. We apply time-resolved BLS microscopy to investigate the coherent excitation of spin waves by a microantenna in an in-plane magnetized, gallium-substituted yttrium iron garnet film. This system exhibits an exchange-dominated dispersion relation and PMA, resulting in a positive nonlinear frequency shift. We observe a strongly power-dependent nonlinear excitation and show that the nonlinear frequency shift creates an effective interaction between successive spin-wave excitations. This effectively serves as a fading memory in the system which can be used to temporally correlate input signals. Our work provides a foundation for future implementations of reservoir and neuromorphic computing in magnonic systems. This research is funded by the DFG - Project No. 271741898 and TRR 173-268565370 (B01) and by the ERC Grant No. 101042439 'CoSpiN'.

MA 16.6   Tue 11:00   HSZ 403

Simultaneous multitone microwave emission by DC-driven spintronic nano-element — •A. Hamadeh[1], D. Slobodianiuk[2,3], R. Moukhader[4], G. Melkov[2], V. Borynskyi[3], M. Mohseni[1], G. Finocchio[4], V. Lomakin[5], R. Verba[3], G. de Loubens[6], P. Pirro[1], and O. Klein[7] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany — [2]Taras Shevchenko National University of Kyiv, Kyiv 01601, Ukraine — [3]Institute of Magnetism, Kyiv 03142, Ukraine — [4]Dept. Mathematical and Computer Sciences, Physical Sciences and Earth Sciences, University of Messina, 98166 Messina, Italy — [5]Center for Magnetic Recording Research, University of California San Diego, La Jolla, California 92093-0401, USA — [6]SPEC, CEA, CNRS, Université Paris-Saclay, 91191 Gif-sur-Yvette, France — [7]Univ. Grenoble Alpes, CEA, CNRS, Grenoble INP, INAC-Spintec, 38054 Grenoble, France

The generation of microwave radiation by DC-driven spintronic elements is generally considered a process that generates only one frequency at a time. In our study however, we can show by means of experimental data, micromagnetic simulations, and an analytical model that several frequencies can be generated simultaneously due to non-linear magnon coupling. This discovery opens the way for entirely new multiplexing techniques and synchronization mechanisms that can be used for communication and neuromorphic computing.

MA 16.7   Tue 11:15   HSZ 403

Sensing magnetic excitations in two-dimensional materials with single NV-centers — •Hossein Mohammadzadeh, Dominik Maile, and Joachim Ankerhold — Institute for Complex Quantum Systems Albert-Einstein-Allee 11 D-89069 Ulm

Magnetism in two-dimensional (2D) van der Waals (vdW) materials has recently emerged as one of the most promising areas in condensed matter research, with a significant potential for applications ranging from topological magnonics to low-power spintronics, quantum computing, and optical communications [1]. In this talk, we theoretically investigate the possibility of sensing magnetic excitations in such materials with nitrogen-vacancy (NV) center in diamond. The NV center in diamond is an excellent platform for noninvasively detecting nanoscale signatures and magnetic domain walls [2]. We present a description of the low-energy magnetic excitations within a Kitaev-Heisenberg model for a honeycomb lattice. Coupling these excitations to the single NV-electronic spin paves the way to use magnetic noise spectroscopy to probe magnons in such a system. Utilizing Fermi*s golden rule and quantum linear response theory, we show how the spin relaxation time of the NV alters in the magnetic field induced by magnons in both bulk and topologically protected edge states. The relaxation time of the NV changes by different NV-sample distances and in various strengths of spin-spin interactions inside the material.

MA 16.8   Tue 11:30   HSZ 403

Magnetic excitations in the conductive altermagnet RuO2: ab initio calculations — •Alberto Marmodoro[1], Sergiy Mankovsky[2], Hubert Ebert[2], Ilja Turek[3], Tomas Jungwirth[1], and Ondřej Šipr[1,4] — [1]Institute of Physics (FZU) of the Czech Academy of Sciences, Prague, Czech Republic — [2]Department of Chemistry, Ludwig-Maximilians- University (LMU), Munich, Germany — [3]Institute of Physics of Materials (IPM) of the Czech Academy of Sciences, Brno, Czech Republic — [4]New Technologies Research Centre, University of West Bohemia, Pilsen, Czech Republic

Altermagnets are materials with zero net magnetization, alike traditional antiferromagnets, as well as a characteristic alternation of spin polarization for the electronic structure in reciprocal space, due to the relative orientation for anisotropic crystal field effects on different magnetic sublattices in direct space. This may have significant implications for possible spintronics and nano-electronics applications [1]. We report about the ab initio study of magnetic excitations in the case of the conducting, colinear antiferromagnetic altermagnet material RuO2 [2].

Investigation of magnon-phonon coupling in two dimensional ferromagnetic Fe_3GeTe_2 — •Namrata Bansal[1], Qili Li[1], Paul Nufer[1], Hung-Hsiang Yang[1], Lichaun Zhang[2], Dongwook Go[2], Amir-Abbas Haghighirad[3], Yuriy Mokrousov[2,4], and Wulf Wulfhekel[1,3] — [1]Physikalisches Institut, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany — [2]Peter Gruenberg Institut (PGI-1) and Institute for Advanced Simulation (IAS-1) Forschungszentrum Juelich GmbH, D-52425 Juelich — [3]Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany — [4]Institute of Physics, Johannes Gutenberg-University Mainz, 55099 Mainz, Germany

We use inelastic tunneling spectroscopy (ITS) at 35 mK to investigate phonon-magnon coupling in the ferromagnetic van der Waals crystals Fe3GeTe2 (FGT). ITS is a powerful tool for determining the inelastic scattering of hot carriers with magnons or phonons with the second derivative of the tunneling current with respect to the bias voltage being proportional to the density of states of phonons and/or magnons. We observe excitation peaks at low energy which do not correspond to van Hove singularities of the phonon or magnon density of states but to points in their dispersion, where magnon and phonon bands cross, indicative for phonon-magnon coupling.

MA 17: Thin Films: Magnetic Anisotropy

Time: Tuesday 9:30–11:00   Location: POT 6

Micromagnetic parameters and longitudinal relaxation in ultrathin asymmetrically sandwiched magnetic films — •Oleksii M. Volkov[1], Ivan A. Yastremsky[2], Oleksandr V. Pylypovskyi[1,3], Florian Kronast[4], Claas Abert[5], Eduardo Sergio Oliveros Mata[1], Pavlo Makushko[1], Mohamad-Assaad Mawass[4], Volodymyr P. Kravchuk[6], Denis D. Sheka[2], Boris A. Ivanov[7], Jürgen Fassbender[1], and Denys Makarov[1] — [1]Helmholtz-Zentrum-Dresden-Rossendorf, Dresden, Germany — [2]Taras Shevchenko National University of Kyiv, Kyiv, Ukraine — [3]Kyiv Academic University, Kyiv, Ukraine — [4]Helmholtz-Zentrum Berlin für Materialen und Energie, Berlin, Germany — [5]University of Vienna, Wien, Austria — [6]Karlsruher Institut für Tech, Karlsruhe, Germany — [7]Institute of Magnetism, Nation, Kyiv, Ukraine

Ultrathin asymmetric magnetic films are a prominent material science platform, which combines unique magnetic and electronic properties enabling prospective memory and logic spin-orbitronic devices. Here, we present the quantification mechanism to distinguish all static and dynamic micromagnetic parameters of the layer stack based on magnetometry [1] and quasi-static morphology experiments on domain wall equilibrium tilts [2]. The DW damping is found to be about 0.1 [2] and it is demonstrated to arise from a longitudinal relaxation being dominant among transversal mechanisms for ultrathin films [3].

Control of magnetoelastic coupling in Ni/Fe multilayers using He+ ion irradiation — •Giovanni Masciocchi[1,2], Gyan van der Jagt[3,4], Maria-Andromachi Syskaki[2,5], Alessio Lamperti[6], Niklas Wolff[7], Andriy Lotnyk[8], Jurgen Langer[5], Lorenz Kienle[7], Gerhard Jakob[2], Benjamin Borie[3], Andreas Kehlberger[1], Dafine Ravelosona[3], and Mathias Kläui[2] — [1]Sensitec GmbH, Mainz, Germany — [2]Johannes Gutenberg University Mainz, Mainz, Germany — [3]Spin-Ion Technologies, Palaiseau, France — [4]Universite Paris-Saclay, Gif-sur-Yvette, France — [5]Singulus Technologies AG, Kahl am Main, Germany — [6]CNR-IMM, Agrate Brianza, Italy — [7]Kiel University, Kiel, Germany — [8]Institute of Surface Engineering , Leipzig , Germany

The requirements for the magnetoelastic coefficient in thin films are often demanding. For example, magnetic sensors mostly require strain immunity, while actuators require giant strain effects. One way to obtain the desired value of the saturation magnetostriction, is to use the combination of two or more materials with different magnetic and magnetoelastic properties in a multilayer fashion. However, the material choice alone, does not allow for a local control of the magnetostriction. In this study [1], we investigate the effects of He+ irradiation on the magneto-elastic properties of a Ni/Fe multi-layered stack. The progressive intermixing caused by He+ irradiation at the interfaces of the multilayer, allows us to locally change the magnetoelastic coupling sign with increasing He+ fluences.

Simulating the magnetic structures in twisted double bilayer CrI_3 — •Junichi Okamoto[1], Bowen Yang[2], Tarun Patel[2], and Adam Tsen[2] — [1]University of Freiburg, Freiburg, Germany — [2]University of Waterloo, Waterloo, Canada

After the discovery of superconductivity in twisted bilayer graphene at magic angles, control of material properties by twisting two-dimensional materials has emerged as "twistronics". In this talk, we will discuss the magnetic structures appearing in the Moiré superlattices of twisted double bilayer CrI3. By using classical spin simulations, we will demonstrate that the subtle competition between the exchange anisotropy and the spatially modulated interlayer coupling is the key to understanding the experimentally observed magnetic transitions. We will further explain how the interlayer charge transport depends on the magnetic structures. The effect of various domain walls and skyrmions will also be scrutinized.

MA 17.4   Tue 10:15   POT 6

Characteristics and origin of a $SrRuO_3$ exchange spring — •Martin M. Koch, Antonia Rieche, Diana A. Rata, and Kathrin Dörr — Martin-Luther-Universität Halle-Wittenberg

A particular type of strong interface coupling between magnets is the exchange spring which resembles an interface-parallel domain wall formed in one (or both) magnets. Advances in thin film growth and resulting interface quality of magnetic oxides improve chances to observe such strong exchange coupling across interfaces. Nevertheless, known exchange springs in oxides are yet scarce [1], since the unambiguous identification is not straightforward. An intensely studied model system for strong interface coupling is $SrRuO_3/La_{0.7}Sr_{0.3}MnO_3$ coherently grown on $SrTiO_3(001)$ substrate. We summarize here the characteristics and suggested origin of the Bloch-type exchange spring forming at this interface in bilayers grown by pulsed laser deposition. Strikingly, the spring forms in hard-magnetic $SrRuO_3$ where magnetic anisotropy is suppressed within few unit cells from the interface. We suggest the transfer of oxygen octahedra rotations / tilts to be responsible, a structural coupling mechanism occurring at many other coherent oxide interfaces. Implications of the noncollinear spin configuration for spintronic functionalities will be addressed.

MA 17.5   Tue 10:30   POT 6

Characterization of buffer-free $Sm(Co_{5-x}Cu_x)_5$ thin films grown by molecular beam epitaxy — •Georgia Gkouzia[1], Damian Günzing[2], Teresa Wessels[2,3], Marton Major[1], Alpha T. N Diaye[4], Andras Kovacs[3], Heiko Wende[2], Katharina Ollefs[2], and Lambert Alff[1] — [1]Technical University of Darmstadt, Materials Science, Darmstadt, Germany — [2]University of Duisburg-Essen, Faculty of Physics and Center for Nanointegration, Duisburg, Germany — [3]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons and Peter Gruenberg Institute, Forschungszentrum Juelich, Germany — [4]Lawrence Berkeley National Laboratory, Berkeley, USA

SmCo5 permanent magnets were already known in the 60s due to their enormous uniaxial magnetic anisotropy K1=17.2 MJ/m^3 which has made them key materials for many applications. Sm-Co system, in a certain parameter range, undergoes a phase decomposition into a nanocomposite of SmCo5 and Sm2Co17

phases. Since it is known that Cu stabilizes the $SmCo_5$ phase, in this work, buffer-free $Sm(Co_{5-x}Cu_x)_5$ thin films have been grown by molecular beam epitaxy (MBE). The films have been characterized by x-ray diffraction (XRD), superconducting quantum interference device (SQUID), and transition electron microscopy (TEM). High coercivity, 1.67 T has been achieved, among the largest values for buffer-free $SmCo_5$ films. X-ray magnetic circular dichroism (XMCD) element-specific hysteresis loops show clear evidence of the Sm-Co de-coupled moments due to Cu substitution in the Co-sublattice.

Europium oxide: Growth guide for the first monolayers on oxidic substrates — •Paul Rosenberger[1,2] and Martina Müller[2] — [1]Fakultät Physik, Technische Universität Dortmund, 44221 Dortmund, Germany — [2]Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany

Interfacial oxygen exchange at oxide interfaces bears huge potential in stabilizing metastable or novel phases of functional oxides down to the monolayer limit. Consequently, controlling the underlying interfacial processes opens up the possibility to tailor and tune functionalities of oxide interfaces. By taking advantage of active oxygen supply of the substrate material, waiving any external oxygen dosage, high-quality, crystalline ultrathin films of the Heisenberg ferromagnet europium monoxide (EuO) were stabilized on YSZ (001)[1]. This so-called redox-assisted growth mode was monitored end to end by in situ x-ray photoelectron spectroscopy. The evolution of Eu 3d core levels allows us to disentangle the processes of interfacial oxygen diffusion and vacancy formation in stabilizing the very first monolayers of EuO on YSZ (001). An expedient background correction analysis is presented, which allows us to quantify the critical Eu^{3+}/Eu^{2+} ratio in the ultrathin film regime. We concluded on the key mechanisms of redox-assisted EuO/YSZ (001) thin film synthesis, merging in a universal three-process growth model that may serve as guideline for redox-assisted synthesis of metastable low-dimensional oxides.

Magnetization dynamics in hybrid $Mn_2Au/Ni_{80}Fe_{20}$ system — •Hassan Al-Hamdo[1], Tobias Wagner[2], Yaryna Lytvynenko[2], Gutenberg Kendzo[1], Sonka Reimers[2], Moritz Ruhwedel[1], Misbah Yaqoob[1], Philipp Pirro[1], Olena Gomonay[2], Vitaliy I. Vasyuchka[1], Mathias Kläui[2], Martin Jourdan[2], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Institute of Physics, Johannes Gutenberg-University Mainz, 55099 Mainz, Germany

We study the magnetization dynamics of $Mn_2Au/Ni_{80}Fe_{20}$ thin film bilayers. This system allows us to control the Mn_2Au Néel vector orientation with moderate external magnetic fields [1].Furthermore, Mn_2Au enables current pulse induced switching of the Néel vector via Néel spin-orbit torques [2] making this system intriguing for antiferromagnetic spintronics. By varying the thickness of the ferromagnetic layer, we investigated the effect of strongly exchange coupled $Mn_2Au/Ni_{80}Fe_{20}$ interface on the spin dynamics. Broadband ferromagnetic resonance and Brillion light scattering experiments reveal that interfacial exchange coupling causes an increase in the resonance frequency of $Ni_{80}Fe_{20}$. Our theoretical model based on the modification of the spin-wave wavevector due to interfacial coupling yields good agreement with the experimental observations.

MA 18.2	Tue 15:15	HSZ 02

Magnetization dynamics in hybrid ferromagnetic / antiferromagnetic systems — •Tobias Wagner[1], Hassan Al-Hamdo[2], Mathias Weiler[2], and Olena Gomonay[1] — [1]Institut für Physik, JGU Mainz, Germany — [2]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU in Kaiserslautern, Germany

Strong exchange coupling between Mn_2Au and thin layers of Permalloy ($Ni_{80}Fe_{20}$) has been shown [1]. As a consequence, the coercive field of $Mn_2Au/Ni_{80}Fe_{20}$ was reported to be 0.5 T, which is high compared to 0.02 T in CuMnAs/Fe [2]. Due to strong exchange coupling, the AFM Néel vector and the ferromagnetic (FM) magnetisation rotate coherently, when an external field is applied to the FM. Control of the Néel ordered state in Mn_2Au and the $Ni_{80}Fe_{20}$ spin dynamics has been studied by varying the $Ni_{80}Fe_{20}$ layer thickness [3]. Ferromagnetic resonance spectroscopy revealed two distinct frequencies for the coupled bilayer system, both of which lie above the resonance frequency of Permalloy [3]. We calculate the spectra of the magnons in the coupled FM/AFM system within micromagnetic model. Our model enables us to demonstrate how the interfacial exchange coupling enables tuning of the ferromagnetic resonance frequency by variation of the thickness of the ferromagnetic layer. We estimate the exchange coupling strength to be 5 T [3]. References: [1] Bommanaboyena, S. P. et al., Nat. Comm. 12, 6539 (2021), [2] Wadley, P. et al., Sci. MA 18.3	Tue 15:30	HSZ 02

Optically Triggered Néel Vector Manipulation of a Metallic Antiferromagnet Mn_2Au under Strain — Vladimir Grigorev[1], Mariia Filianina[1], Yaryna Lytvynenko[1], Sergei Sobolev[1], Amrit Raj Pokharel[1], •Amon P. Lanz[1], Alexey Sapozhnik[2], Armin Kleibert[3], Stanislav Bodnar[4], Petr Grigorev[5], Yurii Skourski[6], Mathias Kläui[1], Hans-Joachim Elmers[1], Martin Jourdan[1], and Jure Demsar[1] — [1]JGU, Mainz, Germany — [2]École Polytechnique, Lausanne, Switzerland — [3]PSI, Villingen, Switzerland — [4]TUM, Munich, Germany — [5]Aix-Marseille Université, Marseille, France — [6]HZDR, Dresden, Germany

The absence of stray fields, their insensitivity to external magnetic fields, and ultrafast dynamics make antiferromagnets promising candidates for active elements in spintronic devices. Here, we demonstrate manipulation of the Néel vector in the metallic collinear antiferromagnet Mn_2Au by combining strain and femtosecond laser excitation. Applying tensile strain along either of the two in-plane easy axes and locally exciting the sample by a train of femtosecond pulses, we align the Néel vector along the direction controlled by the applied strain. The dependence on the laser fluence and strain suggests the alignment is a result of optically triggered depinning of 90° domain walls and their motion in the direction of the free energy gradient, governed by the magneto-elastic coupling. The resulting, switchable state is stable at room temperature and insensitive to magnetic fields. Such an approach may provide ways to realize robust high-density memory device with switching time scales in the picosecond range.

MA 18.4	Tue 15:45	HSZ 02

Long-distance magnon spin transport in Orthoferrites. — •E.F. Galindez-Ruales[1], S. Das[1], X. X. Ma[2], G. Jakob[1], S. X. Cao[2], R. Lebrun[3], and M. Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, 55128 Mainz, Germany. — [2]Department of Physics, Materials Genome Institute, International Center for Quantum and Molecular Structures, Shanghai University, Shanghai 200444, China. — [3]Unité Mixte de Physique CNRS, Thales, Université Paris-Saclay, Palaiseau 91767, France.

Antiferromagnets have advantages over ferromagnets, such as terahertz-range magnetization dynamics and stability against external magnetic fields. The efficient transport of spin waves has until now only been observed in the insulating antiferromagnet hematite [1]. In this work [2], we report long-distance spin transport in the antiferromagnetic orthoferrite $YFeO_3$; although the magnetic damping order is in the same range as hematite, the spin transport is different. At zero magnetic field, the magnon modes in $YFeO_3$ are linearly polarized, which cannot transport the spin angular momentum. Nevertheless, under an external magnetic field and the presence of DMI, spin information is carried by elliptically polarized modes. We observe a strong anisotropy in the magnon decay lengths that we attributed to the role of the magnon group velocity in the transport of spin waves in antiferromagnets. This unique mode of transport identified in $YFeO_3$ opens up all the canted antiferromagnets for long-distance spin transport. [1] Lebrun, R., et al. Nat Commun. 11, 6332 (2020). [2] Das, S., et al. Nat. Commun. 13, 6140 (2022).

MA 18.5	Tue 16:15	HSZ 02

Coexistence of antiferromagnetism and ferrimagnetism in adjacent honeycomb layers — •Lilian Prodan[1,2], Viorel Felea[1,2,3], Yurii Skourskii[3], Sergei Zherlitsyn[3], Joachim Wosnitza[3], Alexander Tsirlin[4], Vladimir Tsurkan[1,2], and Istvan Kezsmarki[1] — [1]Experimental Physics V, Institute of Physics, University of Augsburg, D-86159, Augsburg, Germany — [2]Institute of Applied Physics, MD 2028, Chisinau, R. Moldova — [3]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, 01328 Dresden, Germany — [4]Felix Bloch Institute for Solid-State Physics, Leipzig University, 04103 Leipzig, Germany

Recent theoretical and experimental studies of the honeycomb antiferromagnets $A_2Mo_3O_8$ (A = Mn, Fe, Co, Ni, Zn) revealed a plethora of fascinating effects, such as strong linear and non-linear magnetoelectric effects, giant magnetoelectricity, hidden ferromagnetism, and topological magnons, being of interest for both fundamental and applied research. Here, we report a sequence of metamagnetic transitions in the polar antiferromagnet $Co_2Mo_3O_8$ based on magnetization, torque and ultrasound measurements in static and pulsed magnetic fields up to 65 T. Our studies reveal a novel spin state that is composed of an alternating

stacking of antiferromagnetic and ferrimagnetic honeycomb layers. The strong intra-layer and the weak inter-layer exchange couplings together with competing anisotropies at octahedral and tetrahedral Co sites are identified as the key ingredients to stabilize antiferromagnetic and ferrimagnetic layers in such a close proximity [1]. [1]. D. Szaller et al., arXiv:2202.04700 (2022).

MA 18.6   Tue 16:30   HSZ 02

Anisotropic effects in antiferromagnetic curvilinear spin chains — •Oleksandr V. Pylypovskyi[1,2], Yelyzaveta A. Borysenko[3], Denys Y. Kononenko[4], Kostiantyn V. Yershov[4], Ulrich K. Roessler[4], Artem V. Tomilo[1,3], Jeroen van den Brink[4], Jürgen Fassbender[1], Denis D. Sheka[3], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V., Institute of Ion Beam Physics and Materials Research, Dresden — [2]Kyiv Academic University, 03142 Kyiv, Ukraine — [3]Taras Shevchenko National University of Kyiv, 01601 Kyiv, Ukraine — [4]IFW Dresden

Curvilinear spin chains are simplest antiferromagnetic systems revealing direct influence of their shape onto magnetic states via geometry-tracking anisotropies stemming from the dipolar interaction [1] or local surrounding [2]. Here, we show that in addition to the strongest effect onto magnetic state from exchange (biaxial anisotropy and chiral energy term) [1], the local break of the translational symmetry in curvilinear anisotropic antiferromagnets leads to (i) the longitudinal Dzyaloshinskii-Moriya energy term stemming from the single-ion anisotropy and (ii) the local weakly ferromagnetic response [2]. Furthermore, non-zero curvature κ can drive the helimagnetic phase transition in the spin-flop phase and enables the intermediate canted state for rings with large enough κ. [1] O. Pylypovskyi, D. Kononenko et al., Nano Lett. 20, 8157 (2020); [2] O. Pylypovskyi et al., Appl. Phys. Lett. 118, 182405 (2021); [3] Y. Borysenko et al., Phys. Rev. B, 106, 174426 (2022).

MA 18.7   Tue 16:45   HSZ 02

Spin-current driven Dzyaloshinskii-Moriya interaction in the multiferroic BiFeO3 from first-principles — •Sebastian Meyer[1], Bin Xu[2,3], Matthieu J. Verstraete[1], Laurent Bellaiche[3], and Bertrand Dupé[1,4] — [1]Université de Liège, Belgium — [2]Soochow University, China — [3]University of Arkansas, USA — [4]Fonds de la Recherche Scientifique (FRS-FNRS), Belgium

The electrical control of magnons opens up new ways to transport and process information for logic devices. In magnetoelectrical multiferroics, the Dzyaloshinskii-Moriya (DM) interaction directly allow for such a control and, hence, is of major importance [1]. We determine the origin and strength of the (converse) spin current DM interaction [2,3] in the $R3c$ bulk phase of the multiferroic BiFeO$_3$ based on density functional theory. Our data supports only the existence of one DM interaction contribution originating from the spin current model. By exploring the magnon dispersion in the full Brillouin Zone, we show that the exchange is isotropic, but the DM interaction and anisotropy prefer any propagation and magnetization direction within the full (111) plane. Our work emphasizes the significance of the asymmetric potential induced by the spin current over the structural asymmetry induced by the anionic octahedron in multiferroics such as BiFeO$_3$.

MA 18.8   Tue 17:00   HSZ 02

Decoding Antiferromagnetism via Quadrupolar Far Fields — •Michael Paulsen[1], Michael Fechner[2], Julian Lindner[3], Ralf Feyerherm[3], Jörn Beyer[1], Bastian Klemke[3], Yuki Iino[4], Tsuyoshi Kimura[5], Klaus Kiefer[3], and Dennis Meier[6,7] — [1]Physikalisch-Technische Bundesanstalt, Berlin, Germany — [2]Max Planck Institute for the Structure and Dynamics of Matter, CFEL, Hamburg, Germany — [3]Helmholtz-Zentrum Berlin für Materialien und Energie, Germany — [4]Division of Materials Physics, Osaka University, Japan — [5]Department of Advanced Materials Science, University of Tokyo, Japan — [6]Department of Materials Science and Engineering, Norwegian University of Science and Technology (NTNU), Trondheim, Norway — [7]Center for Quantum Spintronics, NTNU, Trondheim, Norway

Antiferromagnets possess zero net dipole magnetization, whereas magnetic higher-order contributions are, in principle, allowed by symmetry. Such higher-order contributions are, however, usually extremely weak and hard to detect experimentally. Here, we present low-temperature magnetometry measurements of the higher-order far fields of the antiferromagnetic model systems Cr$_2$O$_3$ and TbMnO$_3$, using a dedicated SQUID setup. Our results reveal exterior quadrupolar magnetic fields specific to the emergent microscopic spin textures, providing new opportunities for the characterization of antiferromagnets and materials with ultra-small remanent magnetization in general.

MA 19: Molecular Magnetism I

Molecular orientation of Er(III) cyclooctatetraene-based single-molecule magnets on Ag(100) — •Vladyslav Romankov[1], Niéli Daffé[1], Diana Vaclavkova[1], Martin Heinrich[1], Matthias Muntwiler[1], Bernard Delley[1], Katie Harriman[2], Muralee Murugesu[2], Moritz Bernhardt[3], Maciej Korzyński[3], Christophe Copéret[3], and Jan Dreiser[1] — [1]PSI, Switzerland — [2]uOttawa, Canada — [3]ETH Zurich, Switzerland

Recently, organometallic lanthanide-(III)-based single-molecule magnets (SMMs) have shown outstanding magnetic properties up to liquid nitrogen temperature [1]. SMMs with planar ligands, like COT^{2-} (cyclooctatetraene anion) and Cp^{*-} (pentamethylcyclopentadienide), are good candidates to form ordered monolayers, but the packing and the molecule-substrate interaction play a vital role in the properties of such molecules when deposited on metal surfaces [2]. In the present work we show how two similar Er(III) SMMs, K[Er(COT)$_2$] and Cp*ErCOT, order very differently on Ag(100). In particular, X-ray linear and magnetic circular dichroism measurements show that the easy axis of K[Er(COT)$_2$] aligns parallel to the surface, while that of Cp*ErCOT SMMs is consistent with a mixed standing-lying phase. Indeed, low-temperature scanning tunneling microscopy reveals that Cp*ErCOT forms alternating rows of standing-up and lying-down molecules, while X-ray photoemission spectroscopy reveals the integrity of both the SMMs and suggests a weak molecule-surface interaction.

Machine learning based parameterization of magnetic data of single-molecule magnets — •Zayan Ahsan Ali, Julius Mutschler, and Oliver Waldmann — Physikalisches Institut, Universität Freiburg, D-79104 Freiburg, Germany

Single molecule magnets (SMMs) have attracted a rich volume of research in the last two decades due to their potential applications in magnetic memory and quantum computing. Lanthanide-based SMMs in particular demonstrate promising magnetic retention due to large inherent anisotropies. Their magnetic properties can be parameterized by ligand-field theories involving a set of 28 parameters. Experimental data such as magnetization and susceptibility curves, however, are typically featureless for these materials. Multiple distinct parameter sets can describe the data to equal accuracy, making it a formidable task to determine the model parameters for a compound. In this work, the over-parameterization is tackled by Machine Learning (ML) applied to data simulated for a single-ion model. For dimensionality reduction, a variational autoencoder is used to determine hidden system parameters of the data, and an invertible neural network is used to relate hidden parameters with the model parameters from ligand-field theory. The effectiveness of this ML model in producing consistent sets of ligand-field parameters for novel experimental data is investigated and presented.

MA 19.3   Tue 15:30   HSZ 04

Temperature-dependent Raman spectroscopy studies of a Fe(II) spin-crossover complex — •Lea Spieker[1], Stephan Sleziona[1], Gérald Kämmerer[1], André Maas[1], Soma Salamon[1], Senthil Kumar Kuppusamy[2], Mario Ruben[2], Uwe Bovensiepen[1], Peter Kratzer[1], Marika Schleberger[1], and Heiko Wende[1] — [1]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen — [2]Institute of Quantum Materials and Technologies (IQMT), Karlsruhe Institute of Technology

Spin-crossover complexes with a bi-stable spin-state switching in the room temperature regime, influenced by external stimuli such as light, pressure, or temperature, are desirable for future applications, e.g., molecular switches. Combining Raman spectroscopy with optical microscopy, we investigated a Fe(II) complex showing a spin-state switching from a diamagnetic low-spin (S=0) to a paramagnetic high-spin (S=2) state in the room temperature regime ($T_{1/2} = 298$ K) with a broad thermal hysteresis of $\Delta T = 44$ K. Notable molecular bond changes during the temperature-induced spin-state switching are confirmed by Raman spectroscopy measurements combined with density functional theory calculations. In addition, optical microscopy during heating and cooling allowed us to observe the spin-state switching on a macroscopic scale. We gratefully acknowledge the financial support by CRC 1242 Projects A05, B02, and C05 (Project-ID 278162697).

MA 19.4   Tue 15:45   HSZ 04

Spin transition of spin-crossover molecules supported by tridentate ligands deposited on HOPG — •Jorge Torres[1], Jan Grunwald[2], Sascha Ossinger[2], Sangeeta Thakur[1], Clara W. A. Trommer[2], Marcel Walter[1], Ivar Kumberg[1], Rahil Hosseinifar[1], Evangelos Golias[1], Sebastien Hadjaj[1], Jendrik Gördes[1], Pin-Chi Liu[1], Chen Luo[3], Lalminthang Kipgen[1], Tauquir Shinwari[1], Florin Radu[3], Felix Tuczek[2], and Wolfgang Kuch[1] — [1]Freie Universität Berlin, Institut für Experimentalphysik, Berlin, Germany — [2]Christian-Albrechts-Universität zu Kiel, Institut für Anorganische Chemie, Kiel, Germany — [3]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany

In a spin-crossover molecule (SCM) the excitation and relaxation processes can be stimulated by temperature, pressure or light. The latter is known as the light-induced excited spin-state trapping (LIESST) effect. The excitation of the high-spin (HS) and relaxation to low-spin (LS) state can exhibit single- or multi-exponential behavior. Here, we investigate the behavior of different thicknesses of the SCM [Fe{H$_2$B(pz)(pypz)}$_2$] [1] and [Fe{pypypyr}$_2$] deposited on highly oriented pyrolytic graphite (HOPG) by X-ray absorption and differential reflectance spectroscopy. The results show that the amount of molecules in the HS state as a function of temperature at constant illumination presents a sigmoidal behavior. The relaxation rates are discussed in the context of the inverse energy gap law, which is usually invoked to interpret the LIESST behaviour of Fe(II) complexes.

MA 19.5   Tue 16:15   HSZ 04

Observation of exchange interaction in Iron(II) spin crossover molecules in contact with passivated ferromagnetic surface of Co/Au(111) — •Hongyan Chen[1], Hung-Hsiang Yang[1], Timo Frauhammer[1], Haoran You[1], Qing Sun[2], Peter Nagel[3,4], Stefan Schuppler[3,4], Ana Belén Gaspar[5], José Antonio Real[5], and Wulf Wulfhekel[1,3] — [1]Physikalisches Institut, Karlsruhe Institute of Technology (KIT), Germany — [2]Laboratory for Electron Microscopy, KIT — [3]Institute for Quantum Materials and Technologies, KIT — [4]Karlsruhe Nano Micro Facility, KIT — [5]Institut de Ciència Molecular, Universitat de València, Spain

Spin crossover (SCO) complexes sensitively react on changes of the environment by a change in the spin of the central metallic ion making them ideal candidates for molecular spintronics. In particular, the composite of SCO complexes and ferromagnetic (FM) surfaces would allow spin-state switching of the molecules in combination with the magnetic exchange interaction to the magnetic substrate. Unfortunately, when depositing SCO complexes on ferromagnetic surfaces, spin-state switching is blocked by the relatively strong interaction between the adsorbed molecules and the surface. Here, the Fe(II) SCO complex with sub-monolayer (sub-ML) thickness in contact with a passivated FM film of Co on Au(111) is studied. In this case, the molecules preserve thermal spin crossover and at the same time the high-spin species show a sizable exchange interaction of

more than 0.7 T with the FM Co substrate. These observations provide a feasible design strategy in fabricating SCO-FM hybrid devices.

MA 19.6   Tue 16:30   HSZ 04

Magnetic coupling of guest metallocene molecules with SURMOF-2 host matrix — •Alexei Nefedov[1], Chun Li[1], Kai Müller[1], Anemar Bruno Kanj[1], Lars Heinke[1], Chen Luo[2], Kai Chen[2], Florin Radu[2], Evangelos Golias[3], Wolfgang Kuch[3], and Christof Wöll[1] — [1]Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany — [2]Helmholtz-Zentrum Berlin für Materialen und Energie, Berlin, Germany — [3]Freie Universität Berlin, Berlin, Germany

Metal-organic frameworks (MOFs) are crystalline and porous, molecular solids consisting of metal nodes and organic ligands. In the case of surface-anchored MOF-2 (SURMOF-2) systems the Cu^{2+} ions are connected via carboxylate and OH groups in a zipper-like fashion. This unusual coupling of the spin-1/2 ions within the resulting 1-D chains stabilizes a low-temperature ferromagnetic (FM) phase. In this study, the magnetic properties of SURMOF-2 systems (Cu(bdc) and Cu(bpdc)) were investigated using X-ray magnetic circular dichroism both in the absorption and in the scattering geometry. Taking advantage of the element sensitivity of this technique it was established that the magnetic signal originates from Cu^{2+} ions. After loading of SURMOF-2 with metallocene molecules, the magnetic properties of the SURMOF were found to be substantially changed. In the case of nickelocene loading, a polarization effect was found resulting in ferromagnetic ordering of the guest molecules. However, the polarization effect is not observed in the case of manganocene derivatives, these molecules remained in their paramagnetic state.

MA 19.7   Tue 16:45   HSZ 04

Nickelocene molecule as an STM magnetic sensor — •Andres Pinar Sole[1], Oleksandr Stetsovych[1], Pavel Jelínek[1], Jindrich Kolorenc[1], Shaotang Song[2], Jiong Lu[2], Christian Wackerlin[3], and Ales Cahlik[4] — [1]Czech Institute of Physics — [2]University of Singapore — [3]Empa — [4]University of Zurich

Functionalization of the scanning probe of a scanning tunnelling microscopy (STM) with metallocene molecule allows performing spin-sensitive measurements on magnetic systems. Here, as a magnetic sensor, we used a nickelocene molecule (NiCp2) to probe the magnetism on 1D metallorganic chains and graphene nanoribbons (GNR).

In the first part of the work, we examined two derivatives of 1D metallorganic coordination polymers (2,5-diamino-1,4-benzoquinonediimines) on Au(111) [3] with Co or Cr atoms as metal sites respectively. Nickelocene IETS conductance spectrum deformation was observed when approaching the Nc functionalized tip to the Cr sites while no spectra changes were seen on neither Co sites nor ligand sites of the polymers.

In the second part of the work, the Nc functionalized probe was also used to measure the magnetism emerging from the unpaired electron on the edge of a wave-like graphene nanoribbon (GNR) on Au(111).

To understand the IETS from the magnetic sensor, a many-body Hubbard model was proposed. It describes the electron tunnelling through the STM tip, the nickelocene, the magnetic center, and the metallic substrate.

Ab initio studies of chiral crystals for generalized linear response transport and x-ray absorption spectroscopy — •Alberto Marmodoro[1], Hubert Ebert[2], and Ondrej Sipr[1,3] — [1]Institute of Physics (FZU) of the Czech Academy of Sciences, Prague, Czech Republic — [2]Department of Chemistry, Ludwig-Maximilians- University (LMU), Munich, Germany — [3]New Technologies Research Centre, University of West Bohemia, Pilsen, Czech Republic

Materials with a chiral atomic arrangement exhibit specific electronic structure features [1]. The clock-wise or anti-clock-wise winding of sublattices has been associated with a radial spin texture of the Fermi surface in reciprocal space [2]. This provides interesting consequences for the response [3] to e.g. an applied electric field, for instance in terms of Edelstein effect and particularly its dependence on the sign of the perturbation. We report generalized linear response predictions [3] and theoretical x-ray spectroscopy cross-sections [4] for inorganic bulk crystals from first-principles studies performed within the frameworks of a spin-polarized relativistic Korringa, Kohn, Rostoker (SPRKKR) treatment.

MA 20.2   Tue 15:15   HSZ 401

Crystallisation behaviour of Yttrium Iron Garnet thin films — •Sebastian Sailler[1], Michaela Lammel[1], Gregor Skobjin[1], Heike Schlörb[2], Andy Thomas[2,3], and Sebastian T.B. Goennenwein[1] — [1]Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany — [2]Institute for Integrative Nanosciences, Leibniz Institute of Solid State and Materials Science, 01069 Dresden, Germany — [3]Institut für Festkörper- und Materialphysik, Technische Universität Dresden, 01069 Dresden, Germany

Yttrium Iron Garnet (YIG) is a ferrimagnetic insulator commonly used in spin transport and spin dynamics. To obtain highly crystalline thin films we use RF-magnetron sputtering at room temperature to deposit amorphous films and a subsequent annealing step to crystallise them. However, the crystallisation from the amorphous state has not been systematically studied. We therefore analyse the crystallisation behaviour on different substrates utilizing extensive time and temperature series. Structural characterisation using X-ray techniques as well as electron diffraction allow to differentiate between amorphous, polycrystalline and epitaxial films, and to determine the optimal annealing parameters for each substrate. Additionally, we correlate the crystalline state with the resulting magnetic properties inferred from magnetometry and Kerr-microscopy. Our results provide a precise tunability of the structural and magnetic properties of YIG by a rigorous control over the crystallization induced by the subsequent annealing step.

MA 20.3 Tue 15:30 HSZ 401

Excited-state exchange interaction in NiO determined by high-resolution resonant inelastic x-ray scattering at the Ni M$_{2,3}$ edges — •Chun-Yu Liu[1,2], Kari Ruotsalainen[1], Karl Bauer[1], Régis Decker[1], Annette Pietzsch[1], and Alexander Föhlisch[1,2] — [1]Institute for Methods and Instrumentation for Synchrotron Radiation Research (PS-ISRR), Helmholtz-Zentrum Berlin für Materialien und Energie GmbH (HZB), Albert-Einstein-Strasse 15, 12489 Berlin, Germany — [2]Institut für Physik und Astronomie, Universität Potsdam, Karl-Liebknecht-Strasse 24-25, 14476 Potsdam, Germany

The electronic and spin excitations of bulk NiO have been determined using the $^3A_{2g}$ to $^3T_{2g}$ crystal-field transition at the Ni M$_{2,3}$ edges with high resolution resonant inelastic x-ray scattering. We extract an effective exchange field of 89±4 meV in the $^3T_{2g}$ excited final state from empirical two-peak spin-flip model, which is further confirmed with crystal-field model calculations using exchange fields of 60-100 meV. The lower exchange parameter in the excited state is discussed in terms of the modification of the orbital occupancy and of the structural dynamics: (A) With pure electronic effects, the lower exchange energy is attributed to the reduction in effective hopping integral. (B) With no electronic effects, we use the S = 1 Heisenberg model to derive a second-nearest-neighbor exchange constant J$_2$ = 14.8±0.6 meV. Based on the linear correlation between J$_2$ and the lattice parameter from pressure-dependent experiments, an upper limit of 2% local Ni-O bond elongation during the fs scattering duration is derived.

MA 20.4 Tue 15:45 HSZ 401

Strongly coupled magnon-plasmon polaritons in graphene- 2D ferromagnet heterostructures — •António Costa[1], Mikhail Vasilevskiy[1,2], Joaquín Fernández-Rossier[1], and Nuno Peres[1,2] — [1]International Iberian Nanotechnology Laboratory (INL) — [2]Department of Physics, Center of Physics, University of Minho

Magnons and plasmons are two very different types of collective modes, acting on the spin and charge degrees of freedom, respectively. At first sight, the formation of hybrid plasmon-magnon polaritons in heterostructures of plasmonic and magnetic systems would face two challenges, the small mutual interaction, via Zeeman coupling of the electromagnetic field of the plasmon with the spins, and the energy mismatch, as in most systems plasmons have energies in the eV range, orders of magnitude larger than magnons. Here we show that graphene plasmons form polaritons with the magnons of two-dimensional ferrromagnetic insulators, placed up to to half a micron apart, with Rabi couplings in the range of 100 GHz (dramatically larger than cavity QED magnonics). This strong coupling is facilitated both by the small energy of graphene plasmons and the cooperative super-radiant nature of the plasmon-magnon coupling afforded by phase matching. We show that the Rabi coupling can be modulated both electrically and mechanically and we propose an attenuated total internal reflection experiment to implement ferromagnetic resonance experiments on 2D ferromagnets driven by plasmon excitation.

Doping induced ferromagnetism in EuTiO3 and STO/ETO/LAO heterostructures by ab-initio calculations — •Payal Wadhwa and Alessio Filippetti — Department of Physics, University of Cagliari, Sardinia, Italy

The emergence of 2DEG at oxide interfaces such as LaAlO3 (LAO) and SrTiO3 (STO) raised an immense interest in the community of oxide electronics, because of depicting outstanding properties such as field-effect driven superconductivity, high electron mobility, and magnetoresistance. An old dream of the spintronic community, remained eluded so far, has been to spin-polarize the 2DEG by introducing a magnetic layer at the interface of LAO/STO heterostructure, which may enable it to be a paramount material for spintronics and spin-orbitronic technology. A potential candidate as magnetic interlayer is EuTiO3 (ETO), having an identical lattice constant to STO. It is reported that ETO possesses G-type AFM ground state below Tn = 5.3 K, while becomes FM under tensile strain or doping. We have employed an ab-initio approach to study structural, electronic, and magnetic properties of ETO bulk and the STO/ETO/LAO heterostructure. We found, for increasing electron doping, a progressive enhancement of the FM phase in bulk ETO. Since conduction electrons can also be added to the ETO by creating a heterointerface, so we also compared the n-doped bulk ETO results with the STO/ETO/LAO heterostructure. Overall, our results for n-doped ETO and STO/ETO/LAO heterostructure depict them to be potential candidates for electronic transport and magneto-transport applications.

Magnetism and proximity-induced Rashba effect at Mn-3d bands of asymmetric BaMnO$_3$|KTaO$_3$ heterojunction — •Vivek Kumar and Nirmal Ganguli — Indian Institute of Science Education and Research Bhopal, Bhauri, Bhopal 462066, India

Rashba-like spin-orbit interaction (SOI) at oxide heterostructures emerges as a much sought-after feature in the context of oxide spintronics and spin-orbitronics. KTaO$_3$ (KTO) is one of the best substrates available for the purpose,

owing to its strong SOI and alternating +1| − 1 charged layers along the (001) direction. We visualize the Rashba-like interaction in the KTO (001) surface with the help of spin texture plotted directly from DFT calculations along with the isoenergetic contours, providing a confirmatory test of the presence of only linear Rashba interaction [1]. We use *ab initio* DFT to examine the asymmetric BaMnO$_3$|KTaO$_3$ (BMO|KTO) oxide heterostructure where the inequivalent bottom and top interfaces break the inversion symmetry due to their opposite polar discontinuities. We observe Rashba-like splitting for the bands of Mn-$3d$ near the Fermi level of C-type antiferromagnetic (AFM) BMO|KTO owing to the proximity to Ta atoms from the $5d$ series. We comprehensively analyze Rashba-like SOI with the help of three-dimensional band dispersion and projected spin textures for Rashba-like Mn-$3d$ bands. Our results reveal reasonably strong linear Rashba interaction in the heterostructure. The rigorous analysis of spin textures of the AFM heterostructure presented here may be crucial for spintronics. MA 20.7 Tue 16:45 HSZ 401

Spin-mixing states at finite temperature — •Danny Thonig[1,2], Simon Streib[2], Ramon Cardias[3], Sumanta Bhandary[4], Yaroslav Kvashnin[2], and Olle Eriksson[2,1] — [1]Örebro University, Sweden — [2]University Uppsala, Sweden — [3]KTH Royal Institute of Technology, Sweden — [4]Trinity College Dublin, The University of Dublin, Ireland

In spintronics, the electron spins are used as information carriers and, thus, the description of spin relaxation is of fundamental relevance. Spin relaxation characterises how rapidly the non-equilibrium spin population decays due to spin mixing [1], which wise versa depends on the magnetic moment length and on the temperature simulated by disorder acting on the magnetic state. But the latter phenomenons is barely understood.

We quantify the presence of spin-mixed states in spin and lattice disordered magnetic 3d transition metals by calculating the Elliot-Yafet spin-mixing parameter b^2. Here, we are using a self-consistent, relativistic, Slater-Koster parametrized tight-binding electronic structure model.

We, first, compare our results of the collinear order in itinerant magnets with density functional theory calculations and experiment. After, we analyse b^2 at finite temperature, finding a drastic increase by a factor > 10. This can be understood since both spin orbit coupling and disorder have a similar impact on the electronic potential [2].

Spin-caloritronics using spin-polarized scanning tunneling microscopy — •Cody Friesen and Roland Wiesendanger — Department of Physics, University of Hamburg, Hamburg, Germany

The study and control of magneto- and thermoelectric effects have long been of fundamental importance, from the perspectives of both basic condensed matter research and technological development. More recently, driven by the discovery of the spin-Seebeck effect, a growing amount of research is being done at the intersection of these transport channels; a field known as spin-caloritronics [1]. The possible applications of these effects, e.g. the efficient conversion of waste heat into spin or charge currents, or the magnetic control of heat transfer on the atomic scale, have far-reaching implications for future technology.

Using spin-polarized scanning tunneling microscopy (SP-STM) we have investigated magneto-Seebeck tunneling, i.e. the spin-dependent tunneling of electrons across a magnetic tunnel junction driven by a temperature gradient [2]. By scanning a (relatively) heated magnetic probe tip in tunneling contact with a magnetic sample, at cryogenic temperatures the spin-resolved thermopower of the junction can be resolved with atomic-scale lateral resolution [3,4].

In this talk I will present the experimental requirements, challenges, and advantages of using SP-STM for studies of spin-caloritronics. Following this, the expansion of this approach to the measurement of thermal spin-transfer torque, as well as further development of SP-STM as a tool for spin-caloritronic studies, will be discussed.

MA 20.9 Tue 17:15 HSZ 401

Fractional Landau-Lifshitz-Gilbert equation — Robin C. Verstraten[1], •Tim Ludwig[1], Rembert A. Duine[1,2], and Cristiane Morais Smith[1] — [1]Institute for Theoretical Physics, Utrecht University, Princetonplein 5, 3584CC Utrecht, The Netherlands — [2]Department of Applied Physics, Eindhoven University of Technology, P.O. Box 513, 5600 MB Eindhoven, The Netherlands

Gaining a deeper understanding of magnetization or spin dynamics is of great interest to improve modern technological devices. In particular, a deeper understanding of dissipation could help to improve device efficiency. Magnetization dynamics is often described by the Landau-Lifshitz-Gilbert equation with phenomenological Gilbert damping. Using the Caldeira-Leggett approach, we can re-derive Gilbert damping for a specific type of environment (Ohmic) but, in general, we find fractional Gilbert damping. Fractional Gilbert damping is similar to Gilbert damping but the time derivative is replaced by a fractional time derivative. Finally, we discuss experimental consequences of fractional Gilbert damping with a focus on ferromagnetic resonance experiments.

MA 20.10   Tue 17:30   HSZ 401

Driving a magnetic texture by magnon currents — •Michael Vogel[1,2], Bernhard Zimmermann[1], Johannes Wild[1], Felix Schwarzhuber[1], Claudia Mewes[3], Tim Mewes[3], Josef Zweck[1], and Christian H. Back[1,4] — [1]Department of Physics, Regensburg University, Regensburg, Germany — [2]Institute for Materials Science, Kiel University, Kiel, Germany — [3]Department of Physics and Astronomy, The University of Alabama, Tuscaloosa, USA — [4]Department of Physics, Technical University Munic, Munich, Germany

Thermally-induced spin dynamics in solids have sparked broad interest in both fundamental physics and spintronic applications. As theoretically proposed, thermally excited magnons created by temperature gradients can be used to manipulate spin textures such as topological magnetic solitons. However, in practice, the effectiveness of such thermomagnonic torques has remained a problem. Here the dynamics of magnetic vortex cores driven by thermomagnonic torques are explored by high-resolution Lorentz Transmission Electron Microscopy. Large deflections of the magnetic vortex core transverse to the direction of the temperature gradient are observed. The magnitude of the contribution of the associated torques is determined using a generalized Thiele equation model. Our findings pave the path for thermomagnonic currents to manipulate magnetic domains and shed light on the relationship between temperature and spin. The authors gratefully acknowledge financial support from the DFG within SpinCaT (SPP 1538) and the BMBF.

MA 21.1   Tue 15:00   HSZ 403

Material design of topological magnetism in 2D heterostructures — •Nihad AbuAwwad[1,2], Manuel dos Santos Dias[3], and Samir Lounis[1,2] — [1]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich & JARA, 52425 Jülich, Germany — [2]Faculty of Physics, University of Duisburg-Essen, 47053 Duisburg, Germany — [3]Scientific Computing Department, STFC Daresbury Laboratory, Warrington WA4 4AD, United Kingdom

The discovery of two-dimensional (2D) van der Waals magnetic materials and their heterostructures provided an exciting platform for emerging phenomena with intriguing implications in information technology. $CrTe_2$ is a particular example that hosts complex magnetism strongly intertwined with its crystal structures [1,2]. Here, based on a multiscale modelling approach that combines first-principles calculations and a Heisenberg model, we demonstrate that interfacing this 2D layer with various Te-based layers hosting heavy or light elements enables the control of the Dzyaloshinskii-Moriya interaction and magnetic anisotropy energy of the whole heterostructure, and thereby the emergence of new magnetic phases of matter, which are of topological nature such as skyrmions and merons.

–Work funded by the Palestinian-German Science Bridge (BMBF–01DH16027) and Priority Programme SPP 2244 2D Materials Physics of van der Waals Heterostructures of the DFG (project LO 1659/7-1). MA 21.2   Tue 15:15   HSZ 403

Tuning the magnetic interactions in van der Waals Fe_3GeTe_2 heterostructures — Dongzhe Li[1], •Soumyajyoti Haldar[2], Tim Drevelow[2], and Stefan Heinze[2] — [1]CEMES, Université de Toulouse, CNRS, 29 rue Jeanne Marvig, F-31055 Toulouse, France — [2]Institute of Theoretical Physics and Astrophysics, University of Kiel, Leibnizstrasse 15, 24098 Kiel, Germany

We investigate the impact of mechanical strain, stacking order, and external electric fields on the magnetic interactions of a Fe_3GeTe_2 monolayer deposited on Germanene using density functional theory [1]. We find that an electric field of $\mathscr{E} = \pm 0.5$ V/Å applied perpendicular to the Fe_3GeTe_2/germanene heterostructure leads to significant changes of the exchange constants. We show that the Dzyaloshinskii-Moriya interaction (DMI) in Fe_3GeTe_2/Germanene is mainly dominated by the nearest neighbors. Furthermore, we demonstrate that the DMI is highly tunable by strain, stacking, and electric field, leading to a large DMI comparable to that of ferromagnetic/heavy metal interfaces. The geometrical change and hybridization effect explain the origin of the high tunability of the DMI at the interface. The magnetocrystalline anisotropy energy (MAE) can also be drastically changed by the application of compressive or tensile strain. The tunability of DMI and MAE by using strain allows the occurrence of nanoscale skyrmions [2].

MA 21.3   Tue 15:30   HSZ 403

Spin-texture of graphene on Co films on heavy metals — •Donya Mazhjoo[1,2], Gustav Bihlmayer[1], and Stefan Blügel[1] — [1]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, D-52425 Jülich, Germany — [2]Physics Department, RWTH-Aachen University, 52062 Aachen, Germany

Graphene(Gr) covered ferromagnetic films deposited on heavy metals (HM) have been proposed for the exploration of novel spin-orbitronic devices since they possess a perpendicular magnetic anisotropy (MA) as well as a sizable Dzyaloshinskii-Moriya interaction (DMI). By using density functional theory as implemented in the Fleur-code [1], we investigate the spin-orbit (SO) induced spin-texture of Gr covered Co/Ir(111) heterostructures. We consider SOC in first order perturbation theory to study the DMI and self-consistently for the MA energy. Various thicknesses of Co are investigated and compared to experimental data. There, for thin Co films, spin- and angular-resolved photoemission spectroscopy found an in-plane spin-polarization of the Gr π bands, consistent with a HM induced Rashba-type SO coupling at the Gr/Co interface [2]. We compare to Pt(111) as HM substrate looking for signatures of the DMI in the (induced) spin-textures.

Magnetism and THz excitations in quasi-2D systems perturbed by external fields — •Karel Carva and Krishna K. Pokhrel — Charles University, Faculty of Mathematics and Physics, DCMP, Ke Karlovu 5, 121 16 Prague 2, Czech Republic

Systems with a very weak exchange coupling between magnetically ordered layers represent an interesting intermediate stage between the well-known isotropic bulk magnets and the recently intensively studied 2D magnets [1]. We perform a complex investigation of lattice and magnetic excitations induced by external perturbations in such quasi-2D system, trihalide VI_3, employing the synergy of DFT calculations, infrared, THz, and Raman spectroscopies [2]. The transition to the long-range ferromagnetic order is accompanied by the observed variations of phonon frequencies indicating strong magnetoelastic coupling. The acoustic magnon mode acquires here unusually high energy reaching to the THz range, but dramatically softens at temperatures where a second lattice distortion has been reported. First-principles calculations also show the strong connection of magnetic ordering and anisotropy to the lattice and its low temperature distortions [3]. These findings suggest the possibility of controlling magnetic anisotropy in this system by selective occupation of specific lattice modes. In this way magnon spectra would be strongly modified as well. We also show changes induced by strong magnetic fields in VI_3 and similar systems.

Characterisation of the Ising-tye 2D magnet $FePS_3$: A DFT+U study — Mohammad Amirabbasi and •Peter Kratzer — Faculty of Physics, University Duisburg-Essen, 47057 Duisburg, Germany

Among the 2D magnetic system that can be prepared via exfoliation, iron phosphorus trisulfide ($FePS_3$) excels due to its unusual Ising-type magnetic order which makes it interesting for applications in spintronic nano-devices. We carried out a computational study of the structural and magnetic properties of single-layer $FePS_3$ by using Density Functional Theory (DFT+U). Our findings show that the sublattice of the Fe^{2+} ions is not a perfect honeycomb; rather the nearest-neighbor Fe distances vary by 0.14 Å as a result of orbital ordering. These lattice distortions, albeit small, trigger different (ferromagnetic and antiferromagnetic) exchange couplings so that the ground state consists of ferromagnetically aligned zig-zag chains along the long Fe-Fe bonds which couple antiferromagnetically along the shorter Fe-Fe bonds of the distorted honeycomb. Within the DFT+U framework, we parameterize a spin Hamiltonian including Heisenberg, single-ion anisotropy, Dzyaloshinskii-Moriya and biquadratic interactions that allows us to calculate the critical temperature and the magnon spectrum. By comparing to prior results from neutron scattering, we conclude that it is the upper magnon branch in a doubled unit cell that has been observed in these experiments.

MA 21.6   Tue 16:30   HSZ 403

Interaction parameters in magnetic 2D systems from symmetric invariants — •Jonathan Kipp[1,2], Yuriy Mokrousov[2,3], and Fabian R. Lux[3] — [1]Department of Physics, RWTH Aachen University, 52056 Aachen, Germany — [2]Institute for Advanced Simulation, Forschungszentrum Jülich Wilhelm-Johnen-Straße, 52428 Jülich — [3]Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany

The electronic properties of 2D materials hosting complex magnetic order can have crucial implications for information storage and processing applications. At the heart of the complexity in these materials is the interplay of external fields, fluctuations and electronic structure with the magnetic properties. In this work, we are aiming to uncover the direct implications that changes in the magnetic texture have on the electronic characteristics of the system. We develop an expansion in terms of the textures symmetric invariants and compare to data obtained from Heisenberg Hamiltonians, tight-binding (TB) calculations or possibly even density functional theory (DFT) calculations by employing a machine learning (ML) algorithm for the fitting task. Specifically, this enables us to identify the relevant interaction terms from the expansion to the total energy, since there is a diverse palette of ML fitting algorithms aiming at sparse models with the smallest possible number of coefficients, including regularized and sequential approaches.

Locally driven quantum phase transition cascades in a strongly correlated molecular monolayer — Soroush Arabi[1,2,3], Taner Esat[2,5], Aizhan Sabitova[2,5], Yuqi Wang[2,3], Hovan Lee[7], Cedric Weber[7], Klaus Kern[3,4], F. Stefan Tautz[1,2,5], Ruslan Temirov[2,6], and •Markus Ternes[1,2,5] — [1]Institute of Physics IIB, RWTH Aachen University, 52074 Aachen, Germany — [2]Peter-Grünberg-Institute (PGI 3), Research Center Jülich, 52425 Jülich, Germany — [3]Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany — [4]Institut de Physique, École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland — [5]Jülich Aachen Research Alliance, 52425 Jülich, Germany — [6]Institute of Physics II, University of Cologne, 50937 Cologne, Germany —

[7]King's College London, Theory and Simulation of Condensed Matter, London WC2R 2LS, UK

The molecular monolayer of 1,4,5,6-naphthalene tetracarboxylic acid dianhydride on Ag(111) creates a perfectly ordered lattice of π-conjugated organic molecules. Using a movable atomically sharp electrostatic gate we drive this lattice of strongly correlated electrons through a cascade of quantum phase transitions. Performing spectroscopic imaging with sub-Angstrom resolution, we show that as the gate field is increased, the molecular building blocks change from a Kondo-screened to a paramagnetic phase one by one, enabling us to reconstruct their complex interactions in detail. We anticipate that the supramolecular nature of the system will, in future, allow engineering quantum correlations in arbitrary patterned structures.

MA 21.8   Tue 17:00   HSZ 403

Electrically Tunable Curie Temperature in a 2D Ferromagnetic Semiconductor — •Tania Mukherjee[1,2] and Soumya Jyoti Ray[1] — [1]Department of Physics, Indian Institute of Technology Patna, Bihta 801106, India — [2]Institute of Optics and Atomic Physics, Technical University of Berlin, Straße des 17. Juni 135, 10623 Berlin, Germany

Magnetic van der Waal's nanocrystals with intrinsic magnetic anisotropy provide an ideal platform for exploring magnetism in the low-dimensional limit. We investigate the electronic and magnetic properties of a novel 2D material $VClBr_2$ by using spin polarised density functional theory calculations. We observe complex electronic and magnetic phase transitions, tunable bandgap, and extremely large enhancement of the Curie temperature under the application of strain (η) and electric field (Ez). A Monte Carlo approach to the resolution of the Ising model reveals that the Curie temperature (T_c) can reach up to 340K under the application of an E_z = 2.5 V/nm, a colossal enhancement of ∼ 6700% of its base value. The coexistence of high-temperature spin-ordering along with large magnetic anisotropic energy (MAE), high magnetic moment, tunable band gap, and excellent stability make single layer $VClBr_2$ a promising material for applications in an electric field driven spin gating, room temperature spintronics, and 2D spin circuit design.

MA 22: Terahertz Spintronics

MA 22.1   Tue 15:00   POT 6

Optimizing spin-based terahertz emission from magnetic heterostructures — •Francesco Foggetti, Francesco Cosco, and Peter M. Oppeneer — Uppsala University, Uppsala, Sweden

Terahertz radiation pulses can be generated efficiently through femtosecond laser excitation of a magnetic heterostructure, where an ultrafast laser-induced spin current results in an electromagnetic THz pulse due to the inverse spin Hall effect. It is however still poorly known how the THz emission amplitude and its bandwidth in the frequency regime can be optimized. Here, we perform a systematic analysis of the THz emission from various magnetic heterostructures. The dynamics of the spin current is described by the semiclassical, superdiffusive spin-transport model and, in order to identify the optimal setup for the THz emission, the properties of the wave profile are studied by changing the materials of the heterostructures, their thicknesses, and the laser pulses, allowing us to give optimization guidelines. The energy dependence of spin Hall effect of hot electrons is furthermore taken into account, leading to emission profiles comparable to experiment.

MA 22.2   Tue 15:15   POT 6

Terahertz probing of interfacial Curie temperatures in spintronic thin-film stacks — •Oliver Gueckstock[1], Reza Rouzegar[1], Vincent Baltz[2], Gerhard Jakob[3], Mathias Kläui[3], Tom S. Seifert[1], and Tobias Kampfrath[1] — [1]FU Berlin, Germany — [2]SPINTEC, France — [3]JGU Mainz, Germany

Transport of spin angular momentum and spin-charge-current interconversion are fundamental operations for future spin-electronic devices. Femtosecond laser pulses are well suited to trigger ultrafast spin transport from a ferromagnetic metal F into an adjacent paramagnetic layer P [1,2]. The inverse spin Hall effect converts the spin current into an in-plane charge current that gives rise to the emission of an electromagnetic pulse with frequencies extending into the terahertz (THz) range. As the ultrafast currents are confined to only ~1 nm around the F/P interface, the emitted THz pulse is expected to be a highly sensitive probe of interface properties. Here, we investigate the impact of the F/P interface morphology and sample temperature on the THz-emission signal. We find that the temperature-dependence of the THz emission signal depends critically on the roughness of the F/P interface. We conclude that the Curie temperature of F at the F/P interface is strongly reduced relative to the bulk by the higher degree of disorder at the F/P interface.

Switching and excitation of THz spin waves in Mn_2Au due to femtosecond spin-transfer torques — •Markus Weissenhofer[1,2], Francesco Foggetti[1], and Peter Oppeneer[1] — [1]Department of Physics and Astronomy, Uppsala University — [2]Department of Physics, Free University Berlin

In trilayer spin valves consisting of Fe|Cu|Fe, ultrafast laser pulses can generate hot-electron spin currents that exert spin-transfer torques, which excite THz spin waves [1]. Here, we replace the second Fe layer by antiferromagnetic Mn_2Au and demonstrate that spin waves with even higher frequencies can be excited. We compute the temporal evolution of the hot-electron spin currents by means of the superdiffusive transport model and simulate the response of the Mn_2Au layer to the resulting femtosecond spin-transfer torque pulse using atomistic spin dynamics simulations. Our results reveal that - due to the small thickness of the Mn_2Au layer and exchange enhancement - standing spin waves of up to several THz can be excited. Upon increasing the laser fluence, we even find that the excited spin-current pulses are sufficient to induce switching of Mn_2Au layer, faster than the experimentally demonstrated electrically induced switching of Mn_2Au [2].

MA 22.4   Tue 15:45   POT 6

Element-selective and THz study of spin dynamics in Fe/Ru/Ni tri-layer systems — •Christian Greb[1,2], Roman Adam[1], Daniel Bürgler[1], Sarah Heidtfeld[1,2], Markus Büscher[1,3], and Claus M. Schneider[1,2] — [1]Peter Grünberg Institut (PGI-6), Forschungszentrum Jülich,52425 Jülich, Germany — [2]Faculty of Physics, University of Duisburg-Essen, 47048 Duisburg, Germany — [3]Institut für Laser- und Plasmaphysik, Heinrich-Heine-Universität Düsseldorf, 40225 Düsseldorf, Germany

Ultrafast spin dynamics induced by femtosecond optical laser pulses in ferromagnetic thin films are of great interest due to their high potential for future information technology. Relevant materials are often multi-element compounds or multilayer stacks. We present an element-selective study of Ni/Ru/Fe/MgO(capping) multilayers in which Ni and Fe layers are coupled either ferromagnetically or antiferromagnetically, depending on the Ru thickness. The spin dynamics in the multilayers can be explained by super-diffusive spin

transport [1,2]. In addition to element-selective T-MOKE measurements using a high harmonic generation source, we measured and analyzed THz transients [3] to gain further insight into the non-equilibrium interlayer spin transport. We show that spin currents can be triggered at lower laser fluences (<1uJ/cm2) than previously reported [1]. The THz amplitude as a function of the external magnetic field gives insights into the interlayer exchange coupling. [1] D. Rudolf et al., Nature Commun. 3, 1037 (2012). [2] M. Battiato et al., Phys. Rev. Lett. 105, 027203 (2010). [3] R. Adam et al., Appl. Phys. Lett. 114, 212405 (2019).

Impact of the magnetic layer crystal growth optimization on the THz emission from spintronic Fe/Pt emitters — •LAURA SCHEUER[1], AGNE CIUCIULKAITE[2], ANNA L. RAVENSBURG[2], MERLIN POHLIT[2], TOBIAS WARNATZ[2], GARIK TOROSYAN[3], RENÉ BEIGANG[1], GEORG SCHMIDT[4], EVANGELOS TH. PAPAIOANNOU[4], and VASSILIOS KAPAKLIS[2] — [1]Fachbereich Physik and Landes-

forschungszentrum OPTIMAS, Technische Universität Kaiserslautern, Erwin-Schrödinger-Str. 56, 67663, Kaiserslautern, Germany — [2]Department of Physics and Astronomy, Uppsala University, Box 516, SE-75120 Uppsala, Sweden — [3]Photonic Center Kaiserslautern, 67663, Kaiserslautern, Germany — [4]Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, Von-Danckelmann-Platz 2, 06120 Halle, Germany

We investigate the THz emission characteristics of ferromagnetic/non-magnetic metallic heterostructures, focusing on thin Fe/Pt bilayers. In particular, we report on the impact of optimized crystal growth of the epitaxial Fe layers on the THz emission amplitude and spectral bandwidth. We demonstrate a 5% enhancement of the emitted intensity related to structural quality of the Fe layer. Our work provides a pathway for optimal spintronic THz emitters devices based on epitaxial Fe. It also highlights how THz emission measurements can be utilized to characterize the changes in out-of-equilibrium spin current dynamics in metallic heterostructures, driven by subtle structural refinement.

MA 23: Poster Magnetism I

Time: Tuesday 17:00–19:00 Location: P1

MA 23.1 Tue 17:00 P1

Lattice effects of the skyrmion compound $SrFeO_3$ in high magnetic fields — •MATHIAS DOERR[1], NIKITA ANDRYUSHIN[1], CLARA EBERSBACH[1], SERGEY GRANOVSKY[1], DARREN PEETS[1], YURI SKOURSKI[2], and DMITRO INOSOV[1] — [1]Institut für Festkörper- und Materialphysik, TU Dresden, Germany — [2]Dresden High Magnetic Field Laboratory, Helmholtz-Zentrum Dresden-Rossendorf, Germany

The magnetic properties of the cubic perovskites ABO_3 (A = alkalis, B = transition metal, *e.g.* Mn, Fe, Co) strongly depend on lattice variations. In particular, the magnetoelastic properties of $SrFeO_3$, which is characterised by a variation of topological helical spin structures with the formation of skymions, were investigated in steady and pulsed magnetic fields up to 50 T. Magnetostriction measurements in longitudinal and transversal geometry confirmed lattice distortions in the order of 10^{-5} only occur in the domain-selection processes, in these cases with an irreversible character. Other magnetic phase transitions are not triggered by lattice effects. Based on the new data, the (H, T) phase diagram could be refined and supplemented. At the same time, the results show fundamental differences to other perovskites containing Mn or Co on the B-site.

MA 23.2 Tue 17:00 P1

Asymmetric skyrmion flow in a periodically modulated channel — •KLAUS RAAB[1], MAARTEN A. BREMS[1], MAURICE SCHMIDT[1], JAN ROTHÖRL[1], FABIAN KAMMERBAUER[1], PETER VIRNAU[1], and MATHIAS KLÄUI[1,2] — [1]Institut für Physik, Johannes Gutenberg-Universität Mainz, Staudingerweg 7, 55128 Mainz, Germany — [2]Graduate School of Excellence Materials Science in Mainz, Staudingerweg 9, 55128 Mainz, Germany

We investigate the non-equilibrium flow behavior of skyrmions driven by spin-torques in complex channel geometries and construct functional building blocks for targeted manipulation of skyrmion flow. Poiseuille-like velocity flow-profiles usually occur due to no-slip boundary conditions, meaning moving particles do interfere with the boundary e.g. the wall of a geometry, reducing the velocity of particles closer to a wall. Skyrmions on the other hand should experience slip at the boundaries du to the repulsive nature of the skyrmion-edge and skyrmion-skyrmion interaction. Adding structured obstacles along the boundary may lead to partial or even no-slip behavior and thus to Poiseuille-like flow profiles while skyrmions are forced through a wire due to spin-torques. Selected edge shapes (sawtooth, triangles, ...) and the periodicity and amplitude of the modulation of the wire width influencing the flow were optimized and tested using simulations. Understanding flow dynamics and velocity profiles of skyrmions, their interaction with each other and their harboring geometry is essential for skyrmionic applications like the racetrack memory.

MA 23.3 Tue 17:00 P1

Time-Multiplexed Reservoir Computing with Skyrmions — •GRISCHA BENEKE[1], THOMAS WINKLER[1], MAARTEN A. BREMS[1], KLAUS RAAB[1], FABIAN KAMMERBAUER[1], JOHAN H. MENTINK[2], and MATHIAS KLÄUI[1] — [1]Institut für Physik, Johannes Gutenberg-Universität Mainz, Germany — [2]Institute for Molecules and Materials, Radboud University, The Netherlands

Reservoir computing (RC) is a key method for significantly reducing the computational effort of complex tasks like pattern recognition [1]. Magnetic skyrmions, topological particle-like spin textures, are very promising candidates for RC systems given their non-linear interactions and a multitude of established mechanisms for skyrmion manipulation. By exploiting the thermally activated diffusive motion of skyrmions [2] and an automatic reset mechanism enabled by the repulsion of skyrmions form the boundaries of the magnetic materials, we have previously realized spatially multiplexed RC using a single skyrmion [3]. Here, we employ time-resolved inputs, exploiting the electrically gated skyrmion motion and use the time-dependent state of our device as an output mechanism [4]. We experimentally demonstrate that already a minimalistic device suffices to perform linearly non-separable logic operations. Increasing the complexity of the device using multiple skyrmions or an interplay of multiple devices, may pave the way for low-power and low-training classification of real-life data. [1] D. Gauthier et al., Nat. Comms. 12, 5564 (2021). [2] J. Zázvorka et al., Nat. Nanotechnol. 14, 658 (2019). [3] K. Raab et al., Nat. Comms. 13, 6982 (2022). [4] G. Beneke et al., in preparation (2022).

MA 23.4 Tue 17:00 P1

Skyrmionic spin structures in layered Fe5GeTe2 up to room temperature — •MAURICE SCHMITT[1], THIBAUD DENNEULIN[2], ANDRÁS KOVÁCS[2], TOM SAUNDERSON[1,3], PHILIPP RÜSSMANN[3,4], AGA SHAHEE[1], TANJA SCHOLZ[5], AMIR TAVABI[2], MARTIN GRADHAND[1,6], PHIVOS MAVROPOULOS[7], BETTINA LOTSCH[5,8], RAFAL DUNIN-BORKOWSKI[2], YURIY MOKROUSOV[1,3], STEFAN BLÜGEL[3], and MATHIAS KLÄUI[1,9] — [1]JGU Mainz — [2]Ernst Ruska-Centre, Jülich — [3]Peter Grünberg Institut and Institute for Advanced Simulation, Jülich — [4]University of Würzburg — [5]Max Planck Institute for Solid State Research, Stuttgart — [6]University of Bristol — [7]University of Athens — [8]LMU, München — [9]NTNU, Trondheim

The role of the crystal lattice, temperature and magnetic field for the spin structure formation in the 2D van der Waals magnet Fe5GeTe2 with magnetic ordering up to room temperature is a key open question. Using Lorentz transmission electron microscopy, we experimentally observe topological spin structures up to room temperature in the metastable pre-cooling and stable post-cooling phase of Fe5GeTe2. Over wide temperature and field ranges, skyrmionic magnetic bubbles form without preferred chirality, which is indicative of centrosymmetry. These skyrmions can be observed even in the absence of external fields. To understand the complex magnetic order in Fe5GeTe2, we compare macroscopic magnetometry characterization results with microscopic density functional theory and spin-model calculations. Our results show that even up to room temperature, topological spin structures can be stabilized in centrosymmetric van der Waals magnets.

MA 23.5 Tue 17:00 P1

Enhanced diffusion of antiferromagnetically coupled skyrmions — TAKAAKI DOHI[1], MARKUS WEISSENHOFER[2], NICO KERBER[1], FABIAN KAMMERBAUER[1], •MARIA-ANDROMACHI SYSKAKI[1], GERHARD JAKOB[1], ULRICH NOWAK[2], and MATHIAS KLÄUI[1] — [1]Institut für Physik, Johannes Gutenberg-Universität

Mainz, Staudingerweg 7, 55128 Mainz, Germany — [2]Fachbereich Physik, Universität Konstanz, DE-78457 Konstanz, Germany

Magnetic skyrmions are attractive for the intriguing responses governed by their topology [1]. However, some of the topology-dependent features of magnetic skyrmions are recognized as an obstacle to device applications, e.g. the skyrmion Hall effect [2], which however does not occur in antiferromagnetic skyrmions. Here we demonstrate that a synthetic antiferromagnetic (SyAFM) system [3] with low pinning enables thermally-activated diffusive motion of antiferromagnetically-coupled skyrmions. The systematic investigation varying the compensation ratio of magnetic moments in the magnetic sub-lattices with our analysis accounting for pinning effects allows for disentangling the influence of the topology on the diffusive motion. Our analysis reveals an at least 10 times larger diffusion coefficient for highly compensated antiferromagnetically-coupled skyrmions that is a direct consequence of the reduction of the effective topological charge, which enables energy-efficient unconventional computing.

MA 23.6   Tue 17:00   P1

Thermal skyrmion diffusion with alternating current excitations — •Tobias Sparmann, Raphael Gruber, Jan Rothörl, Maarten A. Brems, Fabian Kammerbauer, and Mathias Kläui — Department of Physics, Johannes-Gutenberg University Mainz

Magnetic skyrmions are considered promising candidates for implementing probabilistic computing devices since they respond strongly nonlinearly to external stimuli and feature multiscale dynamics [1].

The implementation of such probabilistic computing relies on thermal excitation and diffusive movement of the magnetic skyrmions within thin films, which exhibit pinning due to sample defects [2]. Especially the combination of skyrmion diffusion and current-induced motion has been shown to be useful in Brownian reservoir computing devices [3]. As thermal skyrmion diffusion is often slow due to the impact of pinning, a depinning procedure using the already present electric excitation of the skyrmions can be key for applications.

To reach such a regime of very high diffusion, we propose and experimentally demonstrate depinning by applying alternating currents to the sample [4]. In particular, we show that the energy landscape is effectively flattened and diffusion drastically enhanced for sufficient current densities. This can therefore be useful to reduce pinning effects and accelerate non-conventional computing devices.

MA 23.7   Tue 17:00   P1

Current driven skyrmion movement and their electrical detection in Ta/CoFeB/MgO — •Hauke Lars Heyen[1], Malte Römer-Stumm[2], Jakob Walowski[1], Christian Denker[1], Kornel Richter[2], Jeffey McCord[2], and Markus Münzenberg[1] — [1]Institute of Physics, University of Greifswald, Felix-Hausdorff-Straße 6, 17489 Greifswald, Germany — [2]Christian-Albrechts-University in Kiel, Institute for Materials Science, Nanoscale Magnetic Materials and Magnetic Domains, 24143 Kiel, Germany

Magnetic skyrmions, the two-dimensional topological protected round spin structures, have a strong potential for implementation into future storage devices as information bits e.g., in the conceptual racetrack memory. For this purpose, the dynamics of skyrmion motion and their detection is an essential tool. Skyrmions can be generated in Ta/CoFeB/MgO layer stacks at room temperature. Using current pulses in the nanosecond range, it is possible to move the skyrmions with current densities of 10^12 - 10^13 A/m^2. The dynamic trajectories hint to the skyrmion-Hall-effect and superdiffusion, requiring special racetrack design. The skyrmion-Hall-effect results from the skyrmion topology and the superdiffusion occurs due to defects on the motion path. Magnetic tunnel junctions (MTJ) are a promising tool to detect small magnetization changes. The selected Ta/CoFeB/MgO material system allows to build MTJs into skyrmion samples. But this integration of MTJs remains challenging, even though they work fine independently.

MA 23.8   Tue 17:00   P1

Design of an rf antenna for fast skyrmion lattice relaxation — •Ephraim Spindler[1], Philipp Schwenke[1], Abbass Hamadeh[1], Raphael Gruber[2], Vitaliy Vasyuchka[1], Mathias Kläui[2], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Institut für Physik, Johannes Gutenberg-Universität Mainz, Mainz, Germany
Understanding skyrmion dynamics is a key requirement for their potential applications in data storage and processing. We designed an omega-type microwave antenna to study the lattice formation dynamics of micrometer-scale skyrmions in thin film materials under rf excitation. We evaluated the antenna performance by measuring its electrical transmission and the magnetic field generated by dc

current flow through the antenna. To quantify the rf performance of the antenna further, we used it for ferromagnetic resonance (FMR) measurements on reference thin-film $Y_3Fe_5O_{12}$ samples. From our power-dependent FMR measurements we determined the microwave power of the transition to the nonlinear regime. The microwave power threshholds are compared to expectations from micromagnetic simulations considering the inhomogeneous rf field profile of the antenna. These power-dependent measurements and simulations allowed us to quantify the rf fields generated by the antenna. The rf fields generated by the omega antenna can potentially accelerate the skyrmion lattice relaxation through its direct influence on skyrmion size oscillations.

MA 23.9   Tue 17:00   P1

Influence of lattice strain on possible skyrmions in $SrRuO_3$-based oxide heterostructures — •Robert Gruhl, Ludwig Scheuchenpflug, and Philipp Gegenwart — Experimentalphysik VI, Universität Augsburg, 86159 Augsburg, Germany

Dzyaloshinskii-Moriya interaction can lead to the formation of skyrmions in crystal lattices with a broken inversion symmetry, as it is the case at interfaces of artificial heterostructures. Néel-type skyrmions were proposed to form in bilayers of ferromagnetic $SrRuO_3$ and paramagnetic $SrIrO_3$ with strong spin-orbit coupling as indicated by the observation of a topological hall effect [1].
Heterostructures of $SrRuO_3$ and $SrIrO_3$ on $SrTiO_3$ substrates show a rather bad structural compatibility due to the large lattice mismatch of about 1.1 % between $SrIrO_3$ and the substrate. To address this, we reduced the lattice constant of the iridate by doping it with calcium. Superlattices composed of $[SrRuO_3]_5/[Ca_xSr_{1-x}IrO_3]_2$ with various levels of doping were grown on STO (001) substrates by the means of metal-organic aerosol deposition. The structural properties of the samples were studied by x-ray diffraction, reciprocal space mapping and TEM imaging. Hall measurements were carried out to search for topological contributions as an indication for the formation of skyrmions and compared with the results of [1,2].

MA 23.10   Tue 17:00   P1

Magnon propagation across Quantum Hall Skyrmion crystals — •Nilotpal Chakraborty[1], Roderich Moessner[1], and Benoit Doucot[1,2] — [1]Max Planck Institute for Physics of Complex Systems, Dresden — [2]LPTHE, CNRS and Sorbonne Universite,
Skyrmion crystals have a rich collective mode spectrum and are hypothesized to appear in quantum Hall ferromagnets in the lowest Landau level at small dopings away from one filled level. We develop a model of a ferromagnet-skyrmion crystal-ferromagnet junction, relevant to recent experiments in monolayer graphene, to study the influence of collective modes of skyrmion crystals on the propagation of a ferromagnetic magnon. We show, using an appropriate set of generalized theta functions, how to smoothly interpolate between regions of zero (the ferromagnetic ends) and spatially modulating finite topological charge density (the sandwiched skyrmion crystal). The collective mode equations for such a configuration, from a suitably defined energy functional, map onto the Bogoliubov-De Gennes equation. Using this mapping, along with a slice-wise recursive transfer matrix approach, we calculate the transmission amplitudes of an incoming ferromagnetic magnon. We also show how changing the collective mode spectrum of the skyrmion crystal, by varying the strength of the topological charge density terms in the functional, affects magnon transmission. Our results present unique signatures of Skyrmion crystals due to their characteristic collective mode spectrum, and can be used as evidence for their presence in graphene and possibly in twisted bilayer graphene.

MA 23.11   Tue 17:00   P1

Magnetization dynamics of skyrmions in thin film and bulk materials — •Philipp Schwenke[1], Ephraim Spindler[1], Raphael Gruber[2], Vitaliy Vasyuchka[1], Aisha Aqeel[3], Mathias Kläui[2], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Institut für Physik, Johannes Gutenberg-Universität Mainz, 55122 Mainz, Germany — [3]Physik-Department, Technische Universität München, 85748 Garching, Germany

Magnetic skyrmions are topologically protected chiral spin textures which hold a rich variety of phenomena and that can be stabilized in both bulk materials and thin films. In order to establish efficient means to control skyrmions it is important to understand the magnetization dynamics of these magnetic textures. Therefore, we study the magnetization dynamics of a CoFeB thin film exhibiting μm sized quasi 2D skyrmions [1] and compare these to the dynamics observed in a bulk Cu_2OSeO_3 crystal exhibiting a skyrmion lattice phase [2] by means of broadband ferromagnetic resonance measurements at varying temperatures. Additionally, we investigate the dynamics of μm sized quasi 2D skyrmions in CoFeB-based thin film heterostructures in a Kerr-microscope while applying out-of plane rf fields. We observe a perturbation of the skyrmion lattice due to finite size oscillations which might provide a pathway for the manipulation of skyrmion lattices.

MA 23.12   Tue 17:00   P1

Static and dynamical properties of magnetic (bi-)skyrmions in the absence of Dzyaloshinskii-Moriya interaction — •David Eilmsteiner[1], Levan Chotorlishvili[2], Xi-guang Wang[3], Paweł Buczek[4], and Arthur Ernst[1] — [1]Johannes Kepler University Linz, Linz, Austria — [2]Rzeszów University of Technology, Rzeszów, Poland — [3]Central South University, Changsha , China — [4]Hamburg University of Applied Sciences, Hamburg, Germany

The interest in topologically non-trivial states in magnetic materials, for instance magnetic skyrmions, arises not only from the fascinating connection between the mathematical concept of topology and phenomena observable in the lab, but also from possible future applications of those configurations in technology. The main obstacle towards a future technological applicability is the limited range of materials in which skyrmions intrinsically occur – for instance, Dzyaloshinskii-Moriya interaction is usually required. However, a sophisticated design of multilayer systems can help to circumvent this constraint. My poster will discuss two such set-ups. The one demonstrates how a circular nanodot in combination with a switching magnetic field can help to nucleate a magnetic skyrmion. The other studies the motion of a bi-skyrmion bound to a vortex-domain wall. In the latter case, we not only found the, for technological application highly favorable, disappearance of the skyrmion Hall effect, we also observed a chirality dependence of the propagation velocity.

MA 23.13   Tue 17:00   P1

muSR on single crystals of GaV4S8 — •Elaheh Sadrollahi[1,2], Andre Borchers[2], Jochen Litterst[2,3], Isván Kézsmárki[4], Sandor Bordacs[5], Vladimir Tsurkan[4], and Alois Loidl[4] — [1]Institut für Festkörper- und Materialphysik, Technische Universität Dresden, 01062 Dresden, Germany — [2]Institut für Physik der kondensierten Materie, Technische Universität Braunschweig, 38110 Braunschweig, Germany — [3]Centro Brasileiro de Pesquisas Físicas, 22290-180, Rio de Janeiro, RJ, Brazil — [4]Institut für Physik, Universität Augsburg, 86135 Augsburg, Germany — [5]Department of Physics, Budapest University of Technology and Economics, 1111 Budapest, Hungary

The lacunar thio-spinel GaV4S8 possesses a complex magnetic phase diagram with several magnetic phases in zero and applied field, in part with supposed cycloidal, ferromagnetic, and/or short-range cycloidal spin structures, eventually even including skyrmion structures in the ferromagnetic phase [1,2]. We have performed muon spin rotation and relaxation (muSR) experiments on oriented single crystals. In a zero magnetic field, the spontaneous rotation signals allow us to distinguish between the cycloidal (ca. 8-13 K) and the low temperature 'ferromagnetic' phase, yet with a smooth continuous transition extending over several degrees, which is interpreted with a spin-reorientation. The observed changes at low temperatures and in the applied field indicate that this phase has no simple ferromagnetic character. We will discuss the observed field distribution patterns under various applied fields.[1] I. Kezsmarki et al., Nature Mater. 14, 1116 (2015).[2] S.Widmann et al., unpubl., arXiv 1606.04511 (2016).

MA 23.14   Tue 17:00   P1

Bloch points in helimagnetic nanostrips — •Martin Lang[1,2], Marijan Beg[1,3], Ondrej Hovorka[1], and Hans Fangohr[1,2,4] — [1]University of Southampton, Southampton, United Kingdom — [2]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [3]Imperial College London, London, United Kingdom — [4]Center for Free-Electron Laser Science, Hamburg, Germany

Complex magnetic materials hosting topologically non-trivial particle-like objects such as skyrmions are intensely researched. One important class of materials are helimagnetic materials with Dzyaloshinskii-Moriya interaction. Recently, it was demonstrated that nanodisks consisting of two layers with opposite chirality can host a single stable Bloch point (BP) of two different types [1]. The BP represents an interesting topological excitation in a helimagnetic system, which expands the set of well-known magnetic states such as domain walls, vortices, and skyrmions.

In this work [2], we use micromagnetic simulations [3] to show that FeGe nanostrips consisting of two layers with opposite chirality can host multiple coexisting BPs. We demonstrate that the two different BP types can be geometrically arranged in any arbitrary order and these magnetization configurations are meta-stable. We can determine an optimal spacing between BPs within a line of BPs allowing us to predict strip geometries suitable for an arbitrary number of BPs.

MA 23.15   Tue 17:00   P1

Magnetic hopfions in frustrated magnets — •Sandra Chulliparambil Shaju[1], Ross Knapman[1], Riccardo Hertel[2], and Karin Everschor-Sitte[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, 47057 Duis-

burg, Germany — [2]Université de Stras- bourg, CNRS, Institut de Physique et Chimie des Matériaux de Stras- bourg, F-67000 Strasbourg, France

Research in 3D nanomagnetism, driven by advanced nanofabrication methods [1] and novel experimental 3D magnetization visualization methods [2], has revealed new nanostructures and physics beyond those in 1D and 2D. Magnetic Hopfions are topological magnetic textures that can be considered as closed loops of twisted Skyrmion strings [3]. The number of twists and knots of the Hopfion is characterized by the Hopf index. Both Skyrmions and Hopfions require the interplay of competing interactions to stabilize them. In contrast to Skyrmions, which can be stabilized, for example, by the competition of inversion symmetry-breaking Dzyaloshinskii-Moriya interactions and standard exchange interactions, Hopfions require competing exchange interac- tions beyond second-order derivatives [3,4]. We consider frustrated magnets that obey the interplay of such competing exchange interac- tions and want to investigate the physics of three-dimensional topo- logical structures.

MA 23.16   Tue 17:00   P1

Suppression of magnetic fluctuations lead to a better reversibility in low-field entropy changes near triple point — •Tapas Samanta[1], Chris Taake[1], and Luana Caron[1,2] — [1]Faculty of Physics, Bielefeld University, PO Box 100131, D-33501 Bielefeld, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin 12489, Germany

We report the detailed study of the phase transitions in $MnNi_{1-x}Co_xGe_{0.97}Al_{0.03}$ (x=0.20, 0.25 0.30, 0.35, 0.37, 0.40 and 0.45) compounds. In the parent Al-free compound, the structural and magnetic phase transitions are decoupled. Small amounts of Al substitution for Ge can lower the structural phase transition temperature, resulting in a coupled first-order magnetostructural transition (MST) near room temperature for all reported compositions. An antiferromagnetic-type (AFM) to paramagnetic (PM) MST has been observed for lower Co concentrations. At x=0.37 the phase transition transforms to a ferromagnetic-type (FM) to PM MST after exhibiting a triple point (where AFM, FM and PM phase transitions coincide) in the close vicinity of x=0.36. Interestingly, a relatively large reversible low-field entropy change (ΔS=-6.9 J/kg K for ΔH=2 T) has been observed near the triple point for x=0.37, which is rather rare in this class of materials due to the large associated thermal hysteresis. The observed reversible ΔS reaches values of -17.2 and -24.5 J/kg K for ΔH=5 and 7 T, respectively, for x=0.30. Our observations further reveal that a sudden decrease of magnetic fluctuation results in larger reversible entropy change near triple point.

MA 23.17   Tue 17:00   P1

Probing the nature of first-order magnetostructural transitions as responsible for magnetocaloric effects: A case study for In-based Heusler alloys — •Chris Taake[1], Tapas Samanta[1], and Luana Caron[1,2] — [1]Faculty of Physics, Bielefeld University, PO Box 100131, D-33501 Bielefeld, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin 12489, Germany

The subtle nature of magnetostructural transitions (MST) and associated magnetocaloric effects (MCE) in B-substituted In-based Heusler alloys $Ni_{50}Mn_{34.8}In_{15.2-x}B_x$ (x=1, 2 and 3) have been studied. Boron substitution acts as a positive chemical pressure and shifts the martensitic phase transition temperature (T_M) towards higher temperature with increasing B concentration. Magnetic field sensitivity of T_M as well as thermal hysteresis decrease with increasing B substitution. Because of the compensation effect between the loss of field sensitivity and decreased thermal hysteresis, a similar reversible MCE can be expected for all studied compositions. However, a much better reversible isothermal entropy change (ΔS) has been observed for x=1, which reaches a value of +20.8 J/kg K for ΔH=5 T. The observed behavior clearly indicates that the nature of the MST responsible for the MCE is changing with composition. To understand the nature of the MST in depth, the behavior of the local magnetic field exponent, n ($\Delta S \propto H^n$), has been examined for all the compositions. Interestingly, a much larger n^{max} (=10.35, where n >2 is the indication of a first-order phase transition) has been detected for x=1 when compared to other compositions which are less field sensitive (n^{max}=3.66, x=3).

MA 23.18   Tue 17:00   P1

Magnetocaloric materials for the liquefaction of hydrogen — •Tino Gottschall[1], Eduard Bykov[1,2], Marc Strassheim[1,2], Timo Niehoff[1,2], Catalina Salazar-Mejia[1], and J. Wosnitza[1,2] — [1]Dresden High Magnetic Field Laboratory (HLD-EMFL), HZDR, Dresden, Germany — [2]Institut für Festkörper- und Materialphysik, TU Dresden, Germany

Magnetic cooling is a refrigeration technique that is based on the so-called magnetocaloric effect, the change of temperature caused by a magnetic field. It can be utilized to construct environmentally friendly cooling devices, air conditioners, and heat pumps. Originally, magnetic cooling was used to achieve ultra-low temperatures by adiabatic demagnetization of magnetic salts. Recently, low tem-

peratures have once again become the focus of attention as an area of application for magnetocaloric cooling namely for hydrogen liquefaction. In this work, we would like to discuss our current progress for the creation of a materials library for cryogenic applications. The basis for this is our characterization infrastructure for materials research at the Dresden High Magnetic Field Laboratory in static and pulsed fields. With this, we aim to understand these materials better to further optimize their magnetic cooling performance near the boiling temperature of hydrogen.

MA 23.19   Tue 17:00   P1

Direct measurements of the adiabatic temperature change in heavy rare-earth RCo$_2$ compounds in high magnetic fields — •E. Bykov[1,2], T. Gottschall[1], K. Skokov[3], A. Karpenkov[3], W. Liu[3], F. Scheibel[3], O. Gutfleisch[3], and J. Wosnitza[1,2] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — [2]Technische Universität Dresden, Dresden, Germany — [3]Technische Universität Darmstadt, Darmstadt, Germany

Rare-earth elements and their intermetallic compounds are interesting candidate materials for magnetic cooling at and below room temperature. Although the group of heavy rare-earth Laves phases RM_2 (R is a rare earth, M a transition metal) is one of the most intensively investigated classes of magnetocaloric materials, data on directly determined adiabatic temperature changes are scarce. Continuing our work with ferromagnetic RNi$_2$ and RAl$_2$ compounds, we are now focussed on ferrimagnetic RCo$_2$. Some of them show complex magnetic behavior, such as metamagnetism at T_C, or an additional spin-reorientation transition and reduction of the Co magnetic moment below this temperature. In this work, we present a comprehensive analysis of the magnetocaloric effect in polycrystalline RCo$_2$ with R = Er, Ho, Dy, and Tb in high magnetic fields up to 20 T.

Single Molecule Magnets based on dimetallofullerenes — •Matheus Barbosa, Wei Yang, Fupin Liu, and Alexey Popov — Leibniz Institute for Solid State and Materials Research - Dresden, Germany

Dimetallofullerenes are compounds with metal-metal bonds encapsulated in fullerene cages, recognized as good Single Molecule Magnets (SMMs). In the last years, molecules based on Terbium (Tb) and Dysprosium (Dy) have been demonstrating high potential applicability owing to the strong ferromagnetic coupling of 4f-electrons and trapped valence electron of the bond between them. Their static and dynamic properties are under investigation and have showed high blocking temperatures of magnetization, giant coercive fields and complexes relaxation processes. Dy-Dy dimer inside the fullerene cage C_{80} ($Dy_2@C_{80}$) shows different magnetic behavior depending on the chosen stabilizing chemical groups. In comparation, for $Dy_2@C_{80}(CF_3)$ the susceptibility χ_m per temperature (ZFC-FC curves) is observed to be double-peak below 21 K, with the shape dependent of the temperature and field sweep rates, in contrast to $Dy_2@C_{80}(CH_2C_6H_5)$. The estimated energy barrier (613 K for $\{Dy_2\} - CF_3$ and 615 K for $\{Dy_2\} - CH_2C_6H_5$) and the ferromagnetic coupling constant have the similar values. However, at low temperature in zero magnetic field (QTM regime) the relaxation rate is c.a. 10 times faster for $\{Dy_2\} - CF_3$ than for the $\{Dy_2\} - CH_2C_6H_5$. Dilution studies demonstrated that this difference does not depend on the intermolecular interactions and should be ascribed to a different influence of the exohedral group.

Study of magneto-electric (M-E) coupling effect in spin triangle based metal (III) carboxylate [M3O(O2CPh)6(py)3] ClO4.py (M= Fe, Ga) molecular magnet. — •Balwant Singh Chauhan[1], Ratnamala Chatterjee[1], AK Boudalis[2], and P Turek[2] — [1]Department of Physics, IIT Delhi, Hauz Khas, New Delhi 110016, India — [2]Institut de Chimie de Strasbourg (UMR 7177, CNRS-Unistra), Université de Strasbourg, 4 rue Blaise Pascal, CS 90032, Strasbourg, 67081, France

Materials with magneto-electric coupling effect having coupled magnetic and electric properties have potential applications in energy efficient data storage and other multifunctional device technology. In recent literature organic molecules like molecular magnets/molecular ferroelectric materials are being explored for their possible novel magneto-electric characteristics. In this context, a work by French group [1] on Fe spin triangle based metal carboxylates [F3O(O2CPh)6(py)3]ClO4.py have attracted a lot of attraction. In this work, we would clearly demonstrate a correlation between dielectric and magnetic properties of the [F3O(O2CPh)6(py)3]ClO4.py complex. The highlight of the work is the observation of direct ME coupling coefficient in this molecular magnet complex. A comparison of the same with nonmagnetic Ga(III) complex will be discussed too. Chiral induced spin selectivity effect at hybrid molecule metal interfaces. — •Ashish Moharana[1], Shuanglong Wang[2], Hao Wu[2], Fabian Kammerbauer[1], Maria-Andromachi Syskaki[1], Tomasz Marszalek[2], Qiu Zijie[2,3], and Angela Wittmann[1] — [1]Institut für Physik, Johannes-Gutenberg-Universität Mainz, 55128 Mainz, Germany — [2]Max Planck Institute for Polymer Research, Ackermannweg 10, 55128, Mainz, Germany — [3]Shenzhen Institute of Aggregate Science and Technology, School of Science and Engineering, The Chinese University of Hong Kong, 2001 Longxiang Boulevard, Longgang District, Shenzhen City, Guangdong, 518172, China

The observation of spin-dependent transmission of electrons through chiral molecules has led to the discovery of chiral-induced spin selectivity. The high efficiency of the spin filtering effect in chiral molecules has recently gained significant interest due to the high potential for novel hybrid molecule magnetic spintronics applications. In our work, we explore spintronic phenomena at hybrid chiral molecule magnetic interfaces to elucidate the underlying mechanisms of the chiral-induced spin selectivity effect. For this, we investigate the spin-to-charge conversion efficiency in chiral molecule/ metallic thin film heterostructures. Quantifying the impact of the adsorption as a function of the structure of the chiral molecules will reveal the role of the structural design in the spin filtering effect paving the path towards three dimensional engineering of hybrid interfaces.

MA 23.23   Tue 17:00   P1

Chiral induced spin selectivity effect at hybrid molecule metal interfaces. — •Ashish Moharana[1], Shuanglong Wang[2], Hao Wu[2], Fabian Kammerbauer[1], Maria-Andromachi Syskaki[1], Tomasz Marszalek[2], Qiu Zijie[2,3], and Angela Wittmann[1] — [1]Institut für Physik, Johannes-Gutenberg-Universität Mainz, 55128 Mainz, Germany — [2]Max Planck Institute for Polymer Research, Ackermannweg 10, 55128, Mainz, Germany — [3]Shenzhen Institute of Aggregate Science and Technology, School of Science and Engineering, The Chinese University of Hong Kong, 2001 Longxiang Boulevard, Longgang District, Shenzhen City, Guangdong, 518172, China

Density-functional studies of Cu-based metallacrowns on metal surfaces — •Abolfazl Tavakoli[1], Benjamin Stadtmüller[1], and Hans Christian Schneider[1,2] — [1]Department of Physics and OPTIMAS Research Center, TU Kaiserslautern — [2]Institute of Physics, Johannes Gutenberg University Mainz

Metallacrowns are a promising material system for single-molecule magnets as they exhibit favorable chemical and structural features. Here, we present a first-principles study of the electronic and magnetic properties of Cu4-Cu metallacrown complexes adsorbed on an Au (111) surface. We benchmark our calculations on the drosophila system CuPc and discuss the changes of the ligand structure and DOS around the metal centers. As an outlook, preliminary results on the Fe4-Cu metallacrown will also be presented.

MA 23.25   Tue 17:00   P1

Origin of Ferromagnetism in the Copper(II) Triangle NMe$_4$[Cu$_3$(μ_3-F)(TFA)$_6$(Py)$_3$] — •Kevin Ackermann[1,2], Changhyun Koo[1], Ahmed Elghandour[1], Rüdiger Klingeler[1], and Maurits W. Haverkort[2] — [1]1Kirchhoff Institute for Physics, Heidelberg, Germany — [2]for Theoretical Physics, Heidelberg, Germany

The new copper(II) triangle NMe$_4$[Cu$_3$(μ_3-F)(TFA)$_6$(Py)$_3$] [1] was studied using magnetic susceptibility and high-field electron paramagnetic resonance (HF-EPR) experiments, as well as numerically by ab-initio methods. The magnetization and susceptibility data reveal dominant ferromagnetic spin-spin exchange as well as the importance of anisotropy in the system. An Anderson Impurity Model based on LDA-DFT calculations elucidates that the ferromagnetic interactions originate from super-exchange via the central fluorine. For the super-exchange interaction, not only the fluorine's $2p$ shell but also the $2s$ shell needs to be considered. In the HF-EPR date a substantial curvature of the resonance branches is observed and explained within the model by mixing between exited $S_z \approx 1/2$ and $S_z \approx -1/2$ states. The model also suggests that the spins are not parallel to each other in the ferromagnetic ground state but rather arranged in a chiral manner which is given by the molecular structure.

Magnetization of magnetotactic bacteria: influence of additional nitrate during incubation — •Nicole Sander, Imke Wellesen, and Mathias Getzlaff — Institute of Applied Physics, Heinrich-Heine-Universität Düsseldorf

Magnetotactic bacteria (MTB) have the ability to orient and migrate along a magnetic field. The orientation of those bacteria is based on intracellular magnetic structures called magnetosomes, which are formed from magnetite surrounded by a lipid-biolayer. These magnetic properties of MTB are currently of interest for magnetic hyperthermia as an application for cancer therapy.

Here we report on new findings how additional nitrate during incubation of MTB can prolong cell formation and increase magnetization. With additional nitrate we found, that the storage in an incubator can be extended and magnetosome concentration per bacteria was increased due to higher cell mass. A feeding of MTB after five days of incubation maximized the messured optical density being a measure for the number of bacteria respectivly a feeding on the seventh day of incubation maximized magnetization. The data was obtained twenty-four hours after adding nitrate and further incubation. Considering a longer incubation period the data shows, that incubating up to fourty-eight hours after feeding bacteria with nitrate apopotsis can be delayed. These findings display an advantage for magnetic hyperthermia because of higher cell mass and magnetosome concentration per cell the specific absorption rate (SAR) will be enlarged. Otherwise for same SAR a smaller concentration of bacteria is needed.

MA 23.27   Tue 17:00   P1

The influence of storage on magnetotactic bacteria — •Imke Wellesen, Nicole Sander, and Mathias Getzlaff — Heinrich-Heine-Universität, Düsseldorf

Magnetic nanoparticles offer many new possibilities in medical applications e.g. in hyperthermia for cancer therapy. However, their production is largely challenging since it is often very complicated and costly. Therefore, the focus of research has been drawn to special organisms: Magnetotactic bacteria (MTB) naturally synthesize magnetic nanoparticles to orient themselves along the earth's magnetic field. In the future they could be used as nanoparticle producers. A problem is the resulting dependence of the applications on the life cycles of the bacteria. Therefore, optimal storage conditions must be evaluated so that the nanoparticles may still be used effectively at all times.

In this work we investigated the influence of storage at room and low temperatures on the bacteria and nanoparticles. The bacterial growth was examined via the optical density. The progression of the optical density and magnetisation of the organisms was observed over a period of 19 days. The results showed the positive effect of low temperatures on the bacteria. Storage at room temperature resulted in exponentially decreasing optical density and the destruction of the chain structure of the nanoparticles. Optical density and magnetisation of the bacteria at low temperatures on the other hand remained constant. Thus, the experiments showed that storage of magnetotactic bacteria should be realised at lower temperatures.

MA 23.28   Tue 17:00   P1

Biomarker detection using Frequency Mixing Magnetic Detection Technique — •Faranak Eivazi and Hans-Joachim Krause — Institute of Biological Information Processing (IBI-3), Forschungszentrum Jülich

Superparamagnetic nanoparticles (SPNs) with non-hysteretic magnetization curves have significant potential for biomarker detection. The aim of our study is to probe the binding states of targets to SPNs using the frequency mixing magnetic detection technique (FMMD) [1]. As the SPNs bind to the target, the change in the hydrodynamic radius of the system leads to a longer Brownian relaxation time. The FMMD exposes SPNs bound to their targets to 2 alternating magnetic fields. The low-frequency field f_2 with high amplitude drives the SPNs to saturation, and a high-frequency field f_1 with low amplitude is used to probe the nonlinear magnetization. The response of the particles induces a voltage in the detection coil. The demodulated frequency mixing harmonics $f_1 + nf_2$ are characteristic of particle properties. The hydrodynamic radius of SPNs can be determined by observing a phase shift toward lower frequencies caused by the longer Brownian relaxation of the particles. This method can be used to determine the quantity and size of the target in the sample. [1] S. Achtsnicht, et al., PLoS ONE, 14(7), 2019.

MA 23.29   Tue 17:00   P1

Methods of electron transport in the theory of spin stiffness — •Ilja Turek[1], Josef Kudrnovsky[2], and Vaclav Drchal[2] — [1]Institute of Physics of Materials, Czech Acad. Sci., Brno, Czech Rep. — [2]Institute of Physics, Czech Acad. Sci., Prague, Czech Rep.

We present an ab initio theory of the spin-wave stiffness for itinerant ferromagnets [1] with pair exchange interactions derived from the magnetic force theorem [2]. The resulting formula involves one-particle propagators and effective velocity operators appearing in a recent theory of electron transport [3]. Application of this approach to clean crystals allows one to overcome the problem of ill-converging lattice summations, as documented by results for pure metals Fe, Co, and Ni. Application to random alloys within the coherent potential approxi-

mation, illustrated by results for fcc Ni-Fe and bcc Fe-Al systems, enables one to include the disorder-induced vertex corrections, often neglected in evaluation of the exchange interactions.

MA 23.30   Tue 17:00   P1

Abelian spin-Berry curvature of the Haldane model and non-Abelian generalisation — •Nicolas Lenzing, Simon Michel, and Michael Potthoff — I. Institute of Theoretical Physics, Department of Physics, University of Hamburg

The feedback of the geometrical Berry phase, accumulated in an electron system, on the slow dynamics of classical degrees of freedom is governed by the Berry curvature. Here, we study local magnetic moments, modelled as classical spins, which are locally exchange coupled to the (spinful) Haldane model. In the emergent equations of motion for the slow classical-spin dynamics there is a an additional anomalous geometrical spin torque, which originates from the corresponding spin-Berry curvature. Due to the explicitly broken time-reversal symmetry, this is nonzero but usually small in a condensed-matter system. We develop the general theory and compute the spin-Berry curvature, mainly in the limit of weak exchange coupling, in various parameter regimes, particularly close to a topological phase transition. The spatial structure of the spin-Berry curvature tensor, its symmetry properties and the distance dependence of its nonlocal elements are discussed. The investigation has been done in the strict adiabatic limit, where one considers the groundstate only, resulting in an Abelian spin-Berry curvature. It is possible to generalise the formalism for a relaxed adiabatic constraint that takes into account a low-energy subspace. This type of subspace arises, for example, in the case of a degenerate groundstate. The spin-Berry curvature corresponding to the subspace is non-Abelian and does not necessarily vanish for time-reversal symmetric systems.

MA 23.31   Tue 17:00   P1

Nonlocal correlation effects due to virtual spin-flip processes in itinerant electron ferromagnets — •Sebastian Paischer[1], Mikhail Katsnelson[2], Giovanni Vignale[3], Arthur Ernst[1], and Pawel Buczek[4] — [1]Johannes Kepler University, Linz, Austria — [2]Radboud University, Nijmegen, Netherlands — [3]National University of Singapore, Singapore — [4]Hamburg University of Applied Sciences, Hamburg, Germany

An important type of the many-body effects in itinerant-electron magnets originates from the interaction of electrons with bosonic spin-flip excitations, both coherent (magnons) and incoherent (Stoner particle-hole excitations). While there has been a steady progress in understanding the properties of spin-flip excitations at a model level only little is known about microscopic details of their interactions with the electronic degrees of freedom in specific materials. Over the last few years we developed a first-principles method to account for the electron-magnon interaction in complex solids. While the method is based upon many body perturbation theory, we approximate the complex quantities from perturbation theory with quantities from time dependent density functional theory. This drastically reduces the numerical burden of the calculations and allows to consider complex materials like half-metallic ferromagnets. In this poster session some details of the theory and selected results will be presented.

MA 23.32   Tue 17:00   P1

Exploration of 2D magnetic matierials using parallelized HSE functionals in FLEUR — •Sabastian Granberg Cauchi[1,2], Daniel Wortmann[1], Gregor Michalicek[1], and Stefan Blügel[1,2] — [1]Peter Grünberg Institute and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, Germany — [2]RWTH Aachen University, Germany

Density functional theory has become a standard of electronic structure calculations, often implemented in the LDA/GGA approximations. Increased accuracy can be achieved in many systems using computationally expensive hybrid functionals, e.g. PBE0 and HSE, which factor in the exact exchange energy. An implementation of hybrid functionals in the all-electron full-potential linearized augmented-plane-wave code FLEUR [1,2,3] has been realized and applied to many materials, e.g. perovskites and rare-earth compounds, in the past. Recently, high-performance techniques have been employed to achieve extreme parallelization scaling of the PBE0 implementation for optimized supercomputer use [4]. In this study, these techniques are extended to the HSE06 functional and applied to 2D magnetic materials.

Magnon excitations in two-dimensional doped Antiferromagnets — •Pit Bermes — Department of Physics and Arnold Sommerfeld Center for Theoretical Physics (ASC), Ludwig-Maximilians-Universität München, Theresienstr. 37, München D-80333, Germany — Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, D-80799 München, Germany

When a mobile hole is doped into an antiferromagnet, its movement will distort the surrounding magnetic order and yield a magnetic polaron. The resulting complex interplay of spin and charge degrees of freedom gives rise to very rich physics and is widely believed to be at the heart of high-temperature superconductivity in cuprates. Although the parton theory has been successful in describing many properties of these magnetic polarons, it is still unclear how these couple to the collective magnon excitations. In this paper, we derive this effective coupling between the polaron and magnons and their influences on the polaron's properties. We therefore start from a single hole doped into an AFM described in the aforementioned polaron model by a 'geometric string' and will then introduce magnon excitations through a generalized 1/S expansion to arrive at an effective Hamiltonian. After making a Born-Oppenheimer-type approximation, this system will be solved using the self-consistent Born approximation to extract the renormalized polaron properties, like its dispersion relation and the single-particle spectrum.

MA 23.34   Tue 17:00   P1

Self-assembly as a tool to study microscale curvature and strain-dependent magnetic properties — •Balram Singh[1], Jorge. A. Otálora[2], Tong H. Kang[1], Ivan Soldatov[1], Dmitriy D. Karnaushenko[3], Christian Becker[3], Rudolf Schäfer[1], Daniil Karnaushenko[3], Volker Neu[1], and Oliver G. Schmidt[3] — [1]Institute for Integrative Nanosciences, Leibniz IFW Dresden, 01069 Dresden, Germany. — [2]Departamento de Física, Universidad Católica del Norte, Avenida Angamos 0610, Casilla 1280 Antofagasta, Chile — [3]Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, 09126 Chemnitz, Germany

The extension of 2D ferromagnetic structures into 3D curved geometry enables tuning its magnetic properties such as magnetic anisotropy. Tuning the anisotropy with strain and curvature has become a promising ingredient in modern magnetoelectronic devices, however, has been limited to extended thin films and to only moderate bending. By applying a self-assembly rolling technique using a polymeric platform, we provide a template that allows homogeneous and controlled bending of a functional layer adhered to it, irrespective of its shape and size. This is an intriguing possibility to tailor the sign and magnitude of the surface strain of integrated, micron-sized devices. In this article, the impact of strain and curvature on the magnetic ground state and anisotropy is quantified for thin-film Permalloy micro-scale structures, fabricated on the surface of the tubular architectures, using solely electrical measurements.

MA 23.35   Tue 17:00   P1

Switchable magnetic probe for scanning probe microscopy — •Rachappa Ravishankar, Aniruddha Sathyadharma Prasad, Stefan Baunack, Thomas Mühl, Volker Neu, Rudolf Schäfer, and Bernd Büchner — Leibniz Institute for Solid State and Materials Research (IFW) Dresden

Magnetic force microscopy (MFM) has been demonstrated as a valuable technique for the characterization of magnetic nanomaterials. Conventional MFM is a two-pass method, in which the topography of the surface is first obtained by probing the strong Van der Waals and other short-range interactions between probe and sample. During the second scan, the probe is lifted away from the sample, and it experiences long-range magnetic and electrostatic interactions.

A typical approach to disentangle magnetic from non-magnetic signals is by switching the magnetization of the tip in a global external field by means of physically removing the tip from the MFM setup. In the course of our work, we aim at developing an on-chip solution for switching the magnetization of a magnetic probe. We accomplish this by a local Oersted field from a current carrying planar coil, lithographically patterned on either the tip or sample.

This poster highlights switching tip magnetization by a homogeneous field source from a macroscale electromagnetic coil versus an inhomogeneous field from lithographically patterned micro coils on the sample. We showcase this for: (i) commercial MFM probes, and (ii) commercial MFM probes tailored by focused ion beam milling.

MA 23.36   Tue 17:00   P1

Imaging magnetization dynamics of non-bubble domains in ferromagnetic multilayer systems for quantification of Dzyaloshinskii-Moriya interaction (DMI) — •Arne Vereijken[1], Sapida Akhundzada[1], Florian Ott[1], Maxwell Li[2], Tim Mewes[3], Michael Vogel[1], Vincent Sokalski[2], and Arno Ehresmann[1] — [1]Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Kassel, Germany — [2]Department of Materials Science and Engineering, Carnegie Mellon University, Pittsburgh, USA — [3]Department of Physics and Astronomy, University of Alabama, Tuscaloosa, USA

DMI promotes chiral coupling between spins [1], giving rise to robust, chiral spin textures, e.g., skyrmions with excellent properties for information storage

and processing [2]. Recently it has been demonstrated that the DMI is measurable via imaging of magnetization dynamics of bubble domains, which possesses great potential in becoming an experimental standard method [3]. By enhancing this method with a self-segmentation for growth identification, more complex domain shapes may be accessible. We systematically studied the DMI in a perpendicularly magnetized ferromagnet/heavy metal system with different dendrimeric domain textures. [1] T. Moriya, New Mechanism of Anisotropic Superexchange Interaction, Phys. Rev. Lett. 4 (1960) [2] C. Back et al., The 2020 Skyrmionics Roadmap, J. Phys. D 53.36 (2020) [3] A. Magni et al., Key Points in the Determination of the Interfacial DMI from Asymmetric Bubble Domain Expansion, (2022)

MA 23.37   Tue 17:00   P1

Kerr microscopy for all-optical helicity-dependent magnetization switching (AOHDS) — •Lucas Vollroth[1], Marcel Kohlmann[1], Kristýna Hovořáková[2], Eva Schmoranzerová[2], Markus Münzenberg[1], and Jakob Walowski[1] — [1]Greifswald University, Greifswald, Germany — [2]Charles University, Prague, Czech Republic

The demand of data storage capabilities is growing rapidly since the invention of the computer. The development of big data in science and economy intensifies this evolution. To fulfill the demand of storage capabilities there is need of new data storage techniques. One of these new techniques is heat assisted magneto recording (HAMR) where the bit size is drastically decreased by high coercive fields of granular FePt.

Besides the heat assisted writing with a magnet, we are investigating the writing on HAMR media with all-optical helicity-dependent switching (AOHDS) as a novel data storage technology [1]. Wide field Kerr-microscopy is a well-suited method to explore and analyze the outcome of our AOHDS experiments.

We present a build from scratch and cost-efficient Kerr microscope for the observation of magnetic domains and writing with AOHDS on HAMR media simultaneously. It can also be used for the investigation of skyrmions and can be refined to investigate magnetization changed in a pump-probe experiment after the deposition of ultrashort laser pulses on magnetic thin films.

MA 23.38   Tue 17:00   P1

Nitrogen Vacancy Center in Diamond - Study of Correlated Electron Systems — •Sreehari Jayaram and Malik Lenger — 3rd Physics Institute, University of Stuttgart, Allmandring 13, Stuttgart, Germany

Investigation of emergent nanoscale magnetic properties of materials is a challenging field, which requires both, high sensitivity and spatial resolution. The scanning probe magnetometry based on the nitrogen-vacancy (NV) center in diamond is capable to fulfill these requirements and delivers complete vectorial magnetic field reconstructions. Due to optically detected magnetic resonance (ODMR), the NV center can operate as a quantum sensor from cryogenic temperatures up to room temperature with a frequency range from DC to GHz under high bias field conditions and UHV. In combination with atomic force microscopy, a sensor-sample distance of a few nanometers can be achieved with an NV-containing diamond AFM tip.

This has enabled investigations into the imaging of magnetic domains in single-layer CrBr3, the coexistence of AFM and FM domains in Moire twisted CrI3 trilayer, antiskyrmions in Heusler compounds, etc.

Thus, NV magnetometry opens the path to observe static and dynamic magnetic phenomena with nanoscale spatial resolution at a wide temperature range.

MA 23.39   Tue 17:00   P1

Improvement of Magnetic Force Microscopy measurements using magnetics tips grown by Focused Electron Beam Induced Deposition — •A.T. Escalante-Quiceno[1], V.V Fernández[2], A. Hierro-Rodríguez[2,3], J.I. Martín[2,3], C. Magén[1,4], and J.M De Teresa[1,4] — [1]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, 50009 Zaragoza, Spain — [2]Depto. Física, Universidad de Oviedo, 33007 Oviedo, Spain — [3]CINN (CSIC-Universidad de Oviedo), 33940 El Entrego, Spain — [4]Laboratorio de Microscopías Avanzadas (LMA), Universidad de Zaragoza, 50009 Zaragoza, Spain

We report the fabrication of magnetic tips for Magnetic Force Microscopy (MFM) using Focused Electron Beam Induced Deposition (FEBID). Due to their high aspect ratio and metallic content, these magnetic tips present a good magnetic behaviour, providing a number of advantages as lower non-magnetic tip-sample interaction, higher lateral resolution and higher coercivity than commercial magnetic tips when used for simultaneous topographical and magnetic measurements. A sharp tip apex with a diameter of 10 nm enables a high lateral resolution. Depending on the particular needs of the samples, the shape, length and diameter of the tip can be adjusted in a reproducible way. Because of its versatility, FEBID can produce magnetically hard tips customized with specific requirements. Ni80Fe20/NdCo5 bilayers with perpendicular magnetic anisotropy will be measured with FEBID-grown magnetic tips, where the resolution limit in MFM measurements will be tested.

MA 23.40   Tue 17:00   P1

Spatio-temporal Characterization of 3D Perovskites with Faraday Holography — •Julia Anthea Gessner, Jonathan Zerhoch, Shangpu Liu, and Felix Deschler — Physikalisch-Chemisches Institut, Im Neuenheimer Feld 229, Heidelberg, Germany

Hybrid metal halide perovskites have shown to be a promising class of semiconducting materials for a variety of applications ranging from LEDs, solar cells to spintronic devices. Compared to conventional materials, perovskites exhibit some advantageous features as a high quantum efficiency and tunability in the visible range, as well as a strong spin-orbit coupling for an efficient optical spin manipulation.

A preliminary step towards the integration of perovskites in spintronic devices is the time- and space-resolved optical study of their magnetic properties. In the present work, we study the spatio-temporal spin dynamics of Methylammonium Lead Tribromide (MAPbBr3) by the unique combination of two spectroscopic methods: time-resolved Faraday rotation spectroscopy and off-axis holographic imaging. The Faraday angle, which is a measure for the materials' magnetic moment, is imaged by an Ultrafast Transient Holographic Microscope (UTHC). The UTHC works as an all-optical lock-in amplifier with no upper limitations in the signal repetition rate.

By performing Faraday Holography at different temperatures and fluences, we are hence able to investigate the spatial evolution of optically spin-polarized excitons and identify the dominating spin relaxation mechanisms. This is essential for the optimization of the materials' properties and the future realization of spintronic systems.

MA 23.41   Tue 17:00   P1

Planar scanning probes - A new platform for nanoscale magnetometry with NV centers and nearfield microscopy — •Paul Weinbrenner[1], Stefan Ernst[2], Patricia Quellmalz[3], Christian Giese[3], and Friedemann Reinhard[1] — [1]Universität Rostock, Rostock, Germany — [2]ETH Zürich, Zürich, Switzerland — [3]Fraunhofer Institut für Angewandte Festkörper Forschung, Freiburg, Germany

We present the application of a new scanning probe technique to magnetometry with nitrogen-vacancy (NV) centers in diamond. Instead of using sharp tips we use flat mesas (shallow pillars) with a lateral size of 50 micrometers and height of up to 5 micrometers. Due to their geometry these so-called planar scanning probes offer a unique advantage for nanoscale magnetometry and novel optical near-field sensors.

Despite their large lateral size, they can still be scanned at a standoff distance of several nanometers. To achieve this alignment, we use tilt and distance control with optical far- and near-field measurements.

We fabricate planar diamond probes and use NV center quantum sensors for magnetic field measurements. The lateral size of the planar probes enables highly parallel scanning probe magnetometry. Additionally, the fabrication is less complex compared to conventional diamond tips.

With this new approach to scanning probe measurements, we propose the emergence of new material systems as sensors for nanoscale imaging. These next generation sensors include plasmonic nanostructures, defects in 2D materials, and encapsulated, single molecules.

MA 23.42   Tue 17:00   P1

Analysing the Domain Structure of a Thin Film and a GMR Stack with Magnetic Transmission Electron Microscopy — •Judith Bünte, Björn Büker, Daniela Ramermann, Inga Ennen, and Andreas Hütten — Universität Bielefeld, Dünne Schichten und Physik der Nanostrukturen, Universitätsstr. 25, 33615 Bielefeld, Germany

The Transmission Electron Microscope (TEM) can be used to image magnetic domains in magnetic samples. Two prominent techniques for magnetic imaging are Differential Phase Contrast (DPC) and Lorentz Microscopy (LTEM). Both techniques base on the Lorentz force inside the magnetic domain of a specimen which deflects the transmitted electron beam depending on the orientation of the corresponding magnetic field. This deflected beam results in a different intensity distribution in the recorded image which can be analysed.

In this contribution both the DPC and the LTEM technique are used to image the magnetic landscape of two different model systems: One sample consists of pure cobalt, while the other sample is a nanostructured multilayer CoFe/Co/Ru sample. While the domains of the pure cobalt sample are unbound, the nanostructure inside the multilayer sample yields an interesting domain structure, which is constrained to the structure of the sample. Both samples are analysed quantitatively to draw conclusions regarding the characteristics of the samples through the measurements.

Application of high magnetic fields to micron-scale NMR spectroscopy with quantum sensors in diamond — •Rouven Maier, Jonas Meinel, Vadim Vorobyov, and Jörg Wrachtrup — [3]rd Institute of Physics, University of Stuttgart, Germany

Nuclear magnetic resonance (NMR) spectroscopy is widely used in fields ranging from chemical structure analysis to tissue imaging in clinical applications. The requirement of large sample volumes poses one of the major drawbacks of classical NMR measurements. Micron- and nano-scale NMR spectroscopy using quantum sensors, such as nitrogen-vacancy (NV) centers in diamond, has been a constant field of research over the past years. Recent developments of innovative detection schemes, such as the quantum-heterodyne (qdyne) protocol showed promising results by enabling resolutions independent of the lifetime of the sensor spin. We present the experimental layout for the extension of quantum NMR sensing towards high magnetic fields, to enable chemical resolution at the micron-scale. This approach combines the frequency resolution necessary for chemical characterization with accurate spatial information. Signal sources could include ^{2}H, ^{13}C and ^{19}F from biomolecules and materials attached to the diamond surface.

MA 23.44   Tue 17:00   P1

Modulated spin-wave system for neuromorphic machine learning — •Jan Maskill, David Breitbach, Milan Ender, Burkard Hillebrands, and Philipp Pirro — Landesforschungszentrum OPTIMAS und Rheinland Pfälzische Technische Universität

In this work, a prototype physical reservoir based on spin-wave dynamics is developed and investigated numerically by micromagnetic simulations. The system under study is a nanometer-sized magnonic waveguide, on top of which a coplanar waveguide (CPW) antenna is placed for spin-wave excitation, as well as a localized region for spin current injection. The inputs of the reservoir are spin current pulses injected via the spin Hall effect, which modulates the amplitude of a carrier spin-wave created by the CPW. The carrier spin wave is reflected at the end of the waveguide, which allows for an interaction of the subsequent input signals. The resulting spin dynamics are shown to become highly nonlinear under the influence of the spin current. The output of the reservoir is its magnetic state as a function of time, which is calculated as part of numerical simulations. Based on an analysis using the kernel and generalization rank, it is shown that the reservoir exhibits a non linear input-output relation. In the kernel rank analysis, the nonlinearity of the reservoir is extracted with spatial resolution, uncovering regions of interest for possible output definitions. This work contributes to the realization of neuromorphic applications based on spin waves and helps to improve benchmarks for physical reservoirs.

MA 23.45   Tue 17:00   P1

Calculation of the temperature-dependent exchange stiffness from Domain Wall modelling — •Felix Schug[1,2], Nils Neugebauer[2,3], Michael Czerner[1,2], and Christian Heiliger[1,2] — [1]Institute for Theoretical Physics, Justus Liebig University Giessen — [2]Center for Materials Research (LaMa), Justus Liebig University Giessen — [3]Institute of Experimental Physics I, Justus Liebig University Giessen

Understanding the different influences on the macroscopic magnetic properties of a material at finite temperatures is of great interest from a theoretical point of view. As macroscopic magnetic properties, such as anisotropies or the exchange stiffness, are related to the quantum nature of electrons and thus to the most fundamental level of solids, the atomic level, atomistic modelling of magnetic material may promote a more profound understanding of the microscopic processes. Performing the corresponding numerical simulations at various temperatures from 0 K to the Curie-temperature T_C, the temperature dependence of the associated macroscopic properties may be modelled. These modelled material parameters can be used to simulate magnetic properties in large-scale temperature-dependent micromagnetic simulations, leading to the so-called multiscale modelling approach. Here the approach of simulating Bloch walls of a finite cobalt stripe at different temperatures is demonstrated to extract the macroscopic crystalline anisotropy constant K_C and the exchange stiffness parameter A_{exc}.

MA 23.46   Tue 17:00   P1

Calculation of magnetic fields, forces and velocities by means of conductor trace segmentation using the example of the magnetic on-off ratchet. — •Torben Tappe, Inga Ennen, and Andreas Hütten — Bielefeld University, Bielefeld, Germany

For the evaluation of an optimal combination of ratchet geometry and particles, the calculation of the magnetic fields is essential, since in this way the acting forces on the particles and the resulting velocity of these can be determined prior to manufacturing. While the finite element method (FEM) is a standard tool for the calculation of magnetic fields of systems, in this work the trace segmentation is used for the modeling of the magnetic field occurring in the ratchet and is compared to the results of the FEM. Trace segmentation is based on the superposition principle, in which the magnetic field of a trace is approximated by many individual straight conductors whose magnetic fields are known. To evaluate the results of this method, various examples, ranging from just one trace to modeling an entire ratchet, were used and compared to Finite Element Method Magnetics (FEMM) calculations. These comparisons showed that the two methods, with a mean squared error of $2 \cdot 10^{-17}$ T to $3 \cdot 10^{-16}$ T, give the same results. This demonstrated that the trace segmentation is capable of reproducing the results of the standard tool FEM and therefore it is suitable for modeling a magnetic on-off ratchet.

MA 23.47   Tue 17:00   P1

Finite-size scaling for 5D Ising model with free boundary conditions —
•Yulian Honchar[1,2,3], Bertrand Berche[1,4], Yurij Holovatch[1,3], and
Ralph Kenna[1,2] — [1]$\mathbb{L}^4$ Collaboration & Doctoral College for the Statistical Physics of Complex Systems, Leipzig-Lorraine-Lviv-Coventry, Europe — [2]Centre for Fluid and Complex Systems, Coventry University, United Kingdom — [3]Institute for Condensed Matter Physics, National Acad. Sci. of Ukraine, Lviv, Ukraine — [4]Laboratoire de Physique et Chimie Théoriques, Université de Lorraine - CNRS, Nancy, Vandœuvre les Nancy, France

It is widely known that in systems with dimensionality higher than the upper critical, the scaling exponents assume their mean field values. However, in this case, the hyperscaling relation, which contains the dimensionality of space, is violated. In addition, mean-field exponents do not agree with the finite-size scaling. One of the theories that aimed to theoretically describe the behaviour of a finite-sized system is the Gaussian fixed point (so-called G-scaling) at which the interactions in the Landau-Ginsburg action are put to zero. Monte Carlo simulations of hypercubic lattices in the Ising model, where $d_{uc} = 4$, show that for periodic boundary conditions the exponents of the GFP do not correspond to the FSS. Another theory emerges with the introduction of a new exponent q into hyperscaling, which is equal to 1 for the dimensions $d \leq d_{uc}$, and $q = d/d_{uc}$ for higher dimensions. Q-scaling is confirmed for lattices with PBC. In this work, we investigated FSS on $d = 5$ lattices with free boundary conditions and showed that, unlike in systems with PBC, it is closer to G-scaling.

MA 23.48   Tue 17:00   P1

Equivalent Circuit for the Consideration of Frequency-Dependent Effects in Electronics Simulations of Induction Hobs — •Lennart Schwan[1,2], Michael Feige[1], Andreas Hütten[2], and Sonja Schöning[1] — [1]Bielefeld Institute for Applied Materials Research (BIfAM), Bielefeld University of Applied Sciences, Department of Engineering Sciences and Mathematics — [2]Thin Films & Physics of Nanostructures, Bielefeld University, Department of Physics

Inductive power transfer is a well-established technology, e.g. for inductive heating in industrial applications and household appliances like inductions hobs. An inductive heating system usually consists of a coil (transmitter) which is powered by an alternating current and a ferromagnetic material (receiver), for example a cooking vessel. FEM simulations are a powerful tool for simulating the electromagnetic processes in coil and vessel. For electronics development, FEM simulations of the coil cooking vessel system are too computationally intensive.

In electronics, the coil is an RL element and thus is also represented as such in electronics simulations. This equivalent circuit is sufficient for simple considerations, but neglects that R and L are frequency dependent. Frequency dependent variables can be used in the frequency domain only but not in the important time domain simulations with non-sinusoidal signals. In order to consider the frequency dependence of R and L in time domain simulations for non-sinusoidal signals, we use an improved equivalent circuit based on passive components that includes the frequency dependence.

MA 23.49   Tue 17:00   P1

Demistifying exchange mechanisms in the 2D FenGeTe2 family through Wannierization — •Soheil Ershadrad, Sukanya Ghosh, and Biplab Sanyal — Uppsala Univeristy, Uppsala, Sweden

The FenGeTe2 (n=3,4,5) family of 2D ferromagnets features near-room temperature ferromagnetism, making them promising for use in spintronic devices. In these crystals, a metallic film of FenGe is sandwiched between two layers of Te, separated by a van der Waals (vdW) gap. Due to their complex structures, the physics behind their exotic magnetic behavior is not well understood. Using density functional theory, we investigated the magnetic properties of the FenGeTe2 family. Through the projection of Bloch states into Wannier functions, the orbital resolved Heisenberg exchange parameters based on the tight-binding hopping parameters were determined. Based on the extracted hopping parameters, we investigate exchange mechanisms and explain the differences in exchange interactions. Our calculations indicate that the relative position of Ge with respect to Fe atoms has a significant impact on the strength of the exchange, resulting in a strong short-range indirect exchange in the FenGeTe2 structures along with a long-ranged RKKY type of interaction.

MA 23.50   Tue 17:00   P1

Magnon transport in magnetically ordered insulator/platinum nanostructures — •Maria Sigl[1,2], Janine Gückelhorn[1,2], Monika Scheufele[1,2], Franz Weidenhiller[1,2], Matthias Opel[1], Stephan Geprägs[1], Hans Huebl[1,2,3], Matthias Althammer[1,2], and Rudolf Gross[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, Garching, Germany — [3]Munich Center for Quantum Science and Technology, München, Germany

For energy-efficient information processing, the transport and manipulation of spin waves (magnons) in magnetically ordered insulators (MOIs) offers a promising route. To this end, we investigate the magnon transport in MOI/Pt bilayers by all-electrical means utilizing the spin Hall effect. Here, we focus on the transport in the ferrimagnet yttrium iron garnet ($Y_3Fe_5O_{12}$, YIG) and the antiferromagnet hematite (α-Fe_2O_3) using two- and three-terminal devices. Two electrically isolated Pt strips on top of the MOI, act as spin current injector and detector. An applied charge current to a third strip, the modulator, in between injector and detector allows for electrical control of the diffusive magnon spin transport. We systematically study the distance and magnetic field dependence of the magnon transport in YIG and hematite and compare our results to simultaneous spin Hall magnetoresistance measurements.

MA 23.51   Tue 17:00   P1

Super-Nyquist-sampling MOKE elucidates the role of interfacial exchange coupling when measuring spin Hall effect in the noncollinear antiferromagnet Mn_3Ir — Piet Urban[1], Rouven Dreyer[1], James M Taylor[1], •Srishti Dongare[1], Binoy K Hazra[2], Stuart S P Parkin[2], and Georg Woltersdorf[1] — [1]Institute of Physics, Martin Luther University Halle-Wittenberg, 06120 Halle, Germany — [2]Max Planck Institute for Microstructure Physics, 06120 Halle, Germany

Non-collinear antiferromagnets (AFs) have been found to serve as an efficient source of intrinsic spin Hall effect (SHE). However, the role of their chiral domain structure in this process, and the transmission of the resulting spin current across interfaces with ferromagnets (FMs), remain open questions. Using a combination of electrically-detected spin-torque ferromagnetic resonance (ST-FMR) and optically-detected super-Nyquist-sampling magneto-optical Kerr effect (SNS-MOKE) measurements, we investigate the SHE generated by the noncollinear spin texture of Mn_3Ir in heterostructures with $Ni_{80}Fe_{20}$. The enhanced damping due to interfacial exchange coupling between the AF and FM complicates extraction of the spin Hall angle (SHA) using ST-FMR. In contrast, spatially-resolved SNS-MOKE studies allow for a local detection of the SHA, and reveal modifications of the coupling-induced anisotropy upon exposure to a combination of DC current and RF power. These findings offer us a path to quantify the SHE generated by an AF more accurately, as well as to control their domain structure in a local manner.

MA 23.52   Tue 17:00   P1

Magneto-optical probing of orbital accumulation in a light metal — •Sanaz Alikhah[1], Marco Berritta[2], Peter M. Oppeneer[1], Igor Lyalin[3], and Roland K. Kawakami[3] — [1]Uppsala University, Uppsala, Sweden — [2]University of Exeter, Exeter, United Kingdom — [3]Ohio State University, Ohio, USA

Orbital currents and orbital accumulation are attractive alternatives to the commonly employed spin counterparts, generated typically by the spin Hall effect in heavy metals. However, the detection of orbital currents and accumulation is a challenging task. Here we investigate theoretically the possibility of magneto-optical (MO) detection of current-induced orbital accumulation in the light metal chromium. Using linear-response theory, we compute, first, the spin and orbital accumulation and then predict the expected MO spectrum for pure spin accumulation or pure orbital accumulation. We find that the orbital Hall effect is much larger than the spin Hall effect, and that the orbital MO response is much larger than that due to the spin polarization. This result opens the door for MO detection of current-induced orbital accumulation. Finally, we compare the computed MO responses with recent MO Kerr effect measurements on chromium.

MA 23.53   Tue 17:00   P1

Spin Hall Magnetoresistance in Hybrid Chiral Molecule / Metal / Magnet Systems — •Simon Sochiera[1], Ashish Moharana[1], Shuanglong Wang[2], Hao Wu[2], Fabian Kammerbauer[1], Maria-Andromachi Syskaki[1], Zijie Qiu[2,3], Tomasz Marszalek[2], and Angela Wittmann[1] — [1]Institut für Physik, Johannes-Gutenberg-Universität Mainz, 55099 Mainz, Germany — [2]Max Planck Institute for Polymer Research, Ackermannweg 10, 55128, Mainz, Germany — [3]Shenzhen Institute of Aggregate Science and Technology, School of Science and Engineering, The Chinese University of Hong Kong, 2001 Longxiang Boulevard, Longgang District, Shenzhen City, Guangdong, 518172, China

The high efficiency of spin filtering has propelled chiral molecules to the center of attention in molecular spintronics. In conventional ferromagnet/ heavy-metal heterostructures, the spin Hall magnetoresistance has been established as a highly sensitive probe of the interplay between a charge current and magnetization mediated via spin currents. Here, we investigate the chiral-induced spin selectivity effect by probing the impact of the adsorption of chiral molecules on the spin Hall magnetoresistance of a well-characterized device. The change in the magnetoresistive behavior of the device will give insight into the underlying mechanisms at in hybrid chiral molecule/ metal/ ferromagnet multilayer structures.

MA 23.54   Tue 17:00   P1

2D nearfield imaging of cells with high broadband spintronic THz emitters — •Tristan Winkel, Finn-Frederik Stiewe, Doreen Biedenweg, Oliver Otto, and Markus Münzenberg — Universität Greifswald, Greifswald, Deutschland

Gaining information about cells is very important in many fields of science such as biology and medicine. 2D nearfield imaging of cells with high broadband

spintronic THz emitters provides effective means to gain information about the cells. Since measurements are made with broadband teraherz pulses, the absorption spectrum can also be determined for each spatial measurement point. The spatial resolution can reach 5μm with our setup[1]. Among other things, this allows conclusions to be drawn about the water content of the cell. Our technical approach offers great potential for medical applications due to the high gain of information.

[1] Spintronic emitters for super-resolution in THz-spectral imaging Appl. Phys. Lett. 120, 032406 (2022); https://doi.org/10.1063/5.0076880

MA 23.55   **Tue 17:00**   **P1**

THz emission from Ni/NiO/Pt and Co/CoO/Pt multilayers — •Nikos Kanistras[1], Laura Scheuer[2], Dimitrios Anyfantis[3], Panagiotis Poulopoulos[3], and Evangelos Th. Papaioannou[1] — [1]Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, 06120 Halle, Germany — [2]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Technische Universität Kaiserslautern, 67663, Kaiserslautern, Germany — [3]Department of Materials Science, School of Natural Sciences University of Patras, Rio, 26504 Patras, Greece

Ultrafast spin-to-charge conversion in heterostructures composed of ferromagnetic (FM)/non-magnetic(NM) thin films can give rise to the emission of THz electromagnetic waves[1]. In this work we investigate the role of an antiferromagnetic oxide interlayer like NiO and CoO in the THz emission. The trilayers are grown with the sputtering technique. The samples exhibit in plane magnetic easy axis as revealed by magneto-optical and Squid magnetometry. The presence of very thin NiO and CoO allows the spin transport from the ferromagnetic to the Pt layer and lead to the THz emission. However, there is a reduction on the signal which is discussed in conjunction of the structural and magnetic properties of the antiferromagnetic layers. [1]E. Papaioannou, R. Beigang Nanophotonics10, 1243*1257 (2021).

MA 23.56   **Tue 17:00**   **P1**

Investigating spin dynamics in MoS$_2$/permalloy bilayers — •Rieke von Seggern, Lina Hansen, Jonathan Weber, Christopher Rathje, and Sascha Schäfer — Insitute of Physics, University of Oldenburg, Germany

For the successful integration of spin degrees of freedom in information processing devices, spin-injection into semiconductors plays a crucial role. It was recently demonstrated that an optically generated out-of-equilibrium spin population in a ferromagnetic metal can be efficiently transferred into an adjacent MoS$_2$ layer across its bandgap [1]. Due to the deflection of the spin current the bilayer then emits electromagnetic pulses in the terahertz (THz) domain analogous to the already established metallic spintronic THz emitters (STE) [2].

In this work, we explore the microscale THz emission properties of single-flake MoS$_2$/permalloy bilayer systems driven by ultrashort optical pulses (780-nm central wavelength, 70-fs pulse duration). We apply electro-optic sampling to measure the emitted THz electric field in the time domain. An optical excitation spot size in the micrometer range allows for a high spatial resolution of the sample's emission features. With this approach a more detailed understanding of the underlying processes in these TMDC-based samples can be achieved.

MA 23.57   **Tue 17:00**   **P1**

Modulation of exchange bias in Fe3GeTe2/CrPS4 van der Waals heterostructures — Aravind P. Balan[1], •Aditya Kumar[1], Ulrich Nowak[2], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg-University Mainz, Staudingerweg 7, Mainz 55128, Germany — [2]Department of Physics, University of Konstanz, Universitätsstraße 10, Konstanz 78464, Germany

Exchange bias (EB) is a well-explored phenomenon in thin film systems. The mechanism of exchange bias in such systems is often associated with defects at the interface. Due to the intrinsic layered structure of the 2D materials, they can be mechanically stacked to form heterostructures with extremely clean and flat interfaces. CrPS4 is an A-type anti-ferromagnet that is stable in an ambient atmosphere. Its out-of-plane anisotropy and layered spin structure make it an ideal anti-ferromagnet for inducing exchange bias in a ferromagnet (FM)/antiferromagnet (AFM) van-der Waal (vdW) heterostructures.[1] In this work exchange bias in Fe3GeTe2 (FGT)/ CrPS4 (CPS) heterostructure has been studied using anomalous hall effect measurements. For a clean FGT/CPS interface, an EB of magnitude 50 mT was observed at 5 K with a blocking temperature of 20 K. Interestingly, the introduction of oxidized FGT at the interface modulates the EB considerably. EB in this system could be induced even without the conventional field-cooling, but by just applying a small pre-set field. References : [1] R. Wu et al., Phys. Rev. Applied 17, 064038 (2022) [2] T. Zhang et al., Advanced Science 9.11, 2105483 (2022)

Quantum transport through 2D metallic magnets: Effects of defects and stacking sequence — Masoumeh Davoudiniya and •Biplab Sanyal — Department of Physics and Astronomy, Uppsala University, Box 516, 751,20 Uppsala, Sweden

In recent times, two-dimensional van der Waals (vdW) bonded magnetic materials with high Curie temperatures have attracted a lot of attraction due to their high potential in future spintronic nanodevices. In this regard, it is important to understand the properties of these magnetic systems even in the presence of several types of defects and stacking of layers, often controlling the properties. Based on density functional theory calculations, this work aims to theoretically address the quantum transport properties of Fe4GeTe2 (FGT) as new 2D vdW layered metallic magnetic materials applicable for the next-generation electronic and magnetic industry. In particular, we investigate the spin-dependent electronic transport through vdW bonded FGT layers connected to Cu electrodes by nonequilibrium Green*s function approach. The influence of the inclusion of Fe atoms in the vdW gap and stacking sequence of layers will be discussed too. Moreover, we will present the studies on the magnetoresistance of the system for different magnetic configurations of FGT layers separated by semimetallic and insulating 2D layers.

MA 23.59   **Tue 17:00**   **P1**

Dependence of resistance area product and tunnel magnetoresistance on MgO crystalline quality in CoFeB/ MgO/ CoFeB Magnetic Tunnel Junctions — •Tobias Peters und Günter Reiss — Center for Spinelectronic Materials and Devices, University of Bielefeld, Germany

We investigated the tunnel magnetoresistance (TMR) and resistance area product (RA) in CoFeB/MgO/CoFeB magnetic tunnel junctions (MTJs) grown via sputtering deposition and investigated the influence of MgO crystalline quality. Therefore, the Ar-pressure was varied from 0.004 mbar to 0.14 mbar during the MgO deposition. X-ray diffraction (XRD) measurements performed on pseudo spin valves with 10nm thick MgO reveal the highest (001) oriented crystallographic texture of MgO for an Ar-pressure of 0.08 mbar. This MgO sputtering conditions transfered to exchange biased MTJs provides the best barrier quality, which resulted in the lowest RA (17 $\Omega\mu m^2$) with high TMR ratio (198%) for a MgO thickness of 0.8nm. Additionally we found higher Ar partial pressure (above 0.14 mbar) resulting in amorphous MgO with even lower RA (5 $\Omega\mu m^2$), but with significantly reduced TMR ratio (74%).

MA 23.60   **Tue 17:00**   **P1**

Atomic Layer Deposition of Yttrium Iron Garnet (YIG) for 3D Spintronics — •Michaela Lammel[1,2,3], Daniel Scheffler[4], Darius Pohl[5], Peter Swekis[4,6], Sven Reitzig[2], Helena Reichlova[3,4], Richard Schlitz[4], Kevin Geishendorf[1,2], Luise Siegl[2,4], Bernd Rellinghaus[5], Lukas M. Eng[2,7], Kornelius Nielsch[1,2,7,8], Sebastian T. B. Goennenwein[3,4,7], and Andy Thomas[1,4] — [1]IFW Dresden — [2]Institute of Applied Physics, TU Dresden — [3]FB Physik, Universität Konstanz — [4]Institut für Festkörper- und Materialphysik, TU Dresden — [5]DCN, cfaed, TU Dresden — [6]MPI CPfS, Dresden — [7]ct.qmat, TU Dresden — [8]Institute of Materials Science, TU Dresden

Three-dimensional (3D) magnetic structures have recently gained increasing interest in the field of spintronics, since going beyond planar films is expected to lead to a variety of new phenomena. Routes for the fabrication of 3D magnetic insulators are of key importance in order to separately study the magnetic and the electronic response of a given 3D structure. Here, we demonstrate the fabrication of thin films of the magnetic insulator yttrium iron garnet (Y$_3$Fe$_5$O$_{12}$, YIG) via atomic layer deposition. To that end we utilize a supercycle approach based on sub-nanometer thin layers of the binary systems Fe$_2$O$_3$ and Y$_2$O$_3$ with the corresponding atomic ratios. We deposit Y$_2$O$_3$/Fe$_2$O$_3$ multilayer stacks on Y$_3$Al$_5$O$_{12}$ substrates and use a subsequent annealing step to obtain YIG films with a high crystalline quality and magnetic properties comparable to the ones realized via other deposition techniques.

MA 23.61   **Tue 17:00**   **P1**

Coupling Strength Controlling Vortex Trajectories' Oscillations in Coupled Vortices Spintronic Oscillator — •Abbass Hamadeh[1], Abbas Koujok[1], Salvatore Perna[2], Steffen Wittrock[3], Vitaliy Lomakin[4], Gregoire de Loubens[5], Olivier Klein[6], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany — [2]University of Naples Federico II, Naples, Italy — [3]Max-Born-Institute for Nonlinear Optics & Short Pulse Spectroscopy, Berlin, Germany — [4]Center for Magnetic Recording Research, Uni. of California San Diego, La Jolla, California 92093-0401, USA — [5]SPEC, CEA, CNRS, Université Paris-Saclay, 91191 Gif-sur-Yvette, France — [6]Univ. Grenoble Alpes, CEA, CNRS, Grenoble INP, INAC-Spintec, 38054 Grenoble, France

The magnetic vortex state in nano-magnetic structures is a subject of intensive research since it can be brought into auto-oscillation by spin transfer torque. The coupling of vortices via spin-transfer torque and dipolar fields allows to realize complex non-linear dynamics potentially useful for unconventional computing and data processing. For this purpose, we have studied the auto-oscillating modes of an oscillator based on two coupled vortices in a NiFe/Cu/NiFe nanopatterned stack. The respective system was investigated both experimentally and micro-magnetically for different applied magnetic fields and currents. Experimentally, we observed four qualitatively different configurations of GMR spectra. Our simulations show that these different states can be related to the complex, non-circular motion of the coupled vortices.

MA 23.62   Tue 17:00   P1

Experimental detectability of spin current shot noise — •Luise Siegl[1], Michaela Lammel[1], Akashdeep Kamra[2], Hans Huebl[3,4,5], Wolfgang Belzig[1], and Sebastian T. B. Goennenwein[1] — [1]Department of Physics, University of Konstanz — [2]Condensed Matter Physics Center (IFIMAC) and Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, Spain — [3]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching — [4]TUM School of Natural Sciences, Technische Universität München, Garching — [5]Munich Center for Quantum Science and Technology (MCQST), München

A spin current crossing a ferromagnet-metal interface is accompanied by spin current shot noise. This shot noise is well understood in spin space. However, its experimental detection requires a conversion to an observable quantity. Consideration of the established conversion from a spin current to a charge current enables a quantitative analysis of the entire process. Here, we analyze the challenges of detecting spin current shot noise from an experimental perspective. In detail, we show that in a typical electrically detected spin pumping experiment, the voltage noise originating from the spin current shot noise is orders of magnitude smaller compared to the contribution of the Johnson-Nyquist noise. We quantify the ratio between spin current shot noise and Johnson-Nyquist noise and find that this ratio does not scale favorably with geometry and only depends on intrinsic material parameters. Our results suggest that the detection of spin current shot noise using the spin Hall effect is experimentally at best very challenging.

MA 23.63   Tue 17:00   P1

Strain engineering M, L and P in antiferromagnetic AFeO$_3$ films (A = La, Bi) — •Antonia Rieche, Aurora Diana Rata, Wolfgang Hoppe, and Kathrin Dörr — Martin-Luther-Universität Halle-Wittenberg

Magnetization (M), antiferromagnetic order (L) and ferroelectric polarization (P) are ferroic properties which can be probed and potentially also manipulated with light. A major requirement for this is a successful control over the ferroic domain structures in samples, such that a large averaged value of M (L, P) can be reached. Antiferromagnetic ferrites AFeO$_3$ with weak canted ferromagnetism have revealed fascinating optical properties in bulk (crystal) form, whereas film work is quite limited due to nanoscopic multidomain coexistence in such films. Here, early results of our attempt to optimize such ferrite films for optical experiments are presented. Epitaxial strain controlled by the choice of substrate is employed to direct the structural domain formation in AFeO$_3$ (A = La or Bi) films in a desirable way regarding the magnitude and orientation of ferroic order parameters. The films are grown using pulsed laser deposition (KrF 248 nm) and characterized by x-ray diffraction, magnetization measurements, magnetooptical Kerr effect (MOKE) and scanning probe microscopies.

MA 23.64   Tue 17:00   P1

Optimizing the growth of Mn$_3$Sn thin films in order to investigate magneto-optical Kerr effect, anomalous Nernst effect, and spin-orbit torque switching — •Anagha Mathew[1,2], Srishti Dongare[1], Atul Pandey[1,2], James M Taylor[1], Binoy K Hazra[2], Stuart SP Parkin[2], and Georg Woltersdorf[1,2] — [1]Institute of Physics, Martin Luther University Halle-Wittenberg, 06120 Halle, Germany — [2]Max Planck Institute for Microstructure Physics, 06120 Halle, Germany

Mn$_3$Sn is a promising candidate material for antiferromagnetic spintronic devices, because of its large magneto-transport responses, such as the anomalous Hall effect (AHE), arising from topological band structure features. For future applications, it is important to be able to efficiently reverse the sense of rotation of its noncollinear spin texture on short timescales via spin torques. Achieving this requires a more detailed understanding of such switching mechanisms, in particular the role of chiral domains. To this end, we have optimized the growth of Mn$_3$Sn films, to show low coercive field and a large fractional change of AHE during spin-orbit torque switching. In addition, these thin films demonstrate significant magneto-optical Kerr effect and anomalous Nernst effect arising from Berry curvature generated by their noncollinear spin texture. We exploit these measurement techniques to map the chiral domain structure of the Mn$_3$Sn films in an optical and electro-optical manner, respectively.

MA 23.65   Tue 17:00   P1

Dilution of polar antiferromagnet Co$_2$Mo$_3$O$_8$ — •Lilian Prodan[1,2], Irina Filippova[2], Alexander Tsirlin[3], Vladimir Tsurkan[1,2], and Istvan Kezsmarki[1] — [1]Experimental Physics V, Institute of Physics, University of Augsburg, D-86159, Augsburg, Germany — [2]Institute of Applied Physics, MD 2028, Chisinau, R. Moldova — [3]Felix Bloch Institute for Solid-State Physics, Leipzig University, 04103 Leipzig, Germany

Antiferromagnetic materials hold great promise for design of ultra-fast and energy-efficient spintronic devices. To this end, understanding the robustness of crystal and magnetic structures and their manipulation are of high importance. Here, we report the effects of site-selective substitution of Zn^{2+} for Co^{2+} ions on the crystal structure, magnetic and thermodynamic properties of the hexagonal polar antiferromagnet Co$_2$Mo$_3$O$_8$. In contrast to the transformation from the antiferromagnetic to a ferrimagnetic state in the isostructural Fe$_2$Mo$_3$O$_8$ upon even a small Zn-doping [1], a robust antiferromagnetic behavior is preserved in Co$_{2-x}$Zn$_x$Mo$_3$O$_8$ up to x = 0.55. We found that in the low doping regime (x < 0.2) the Zn^{2+} ions primarily occupy the octahedrally coordinated sites, although at higher doping levels they show a clear preference for occupying the tetrahedral sites [2]. Due to the multiple inter-layer exchange paths, dependent on the different coordination of the Co^{2+} ions, the site-selective substitution is reflected in the non-monotonic variation of the magnetic parameters.

Epitaxial Growth of Magnetic Oxides and their magnetic Coupling — •Akashdeep Akashdeep[1], Sven Becker[1], Mathias Kläui[1,2], and Gerhard Jakob[1,2] — [1]Institute of Physics, Johannes Gutenberg-University Mainz, Staudingerweg 7, Mainz 55128, Germany — [2]Graduate School of Excellence *Materials Science in Mainz* (MAINZ), Staudingerweg 9, Mainz 55128, Germany

Due to its exceptionally low damping, ferrimagnetic Y3Fe5O12 Y3Fe5O12 (YIG) is the prototypical material for studying magnonic properties. By substituting the non-magnetic yttrium with the temperature-dependent magnetic moment of gadolinium, we can introduce an additional spin degree of freedom in the form of a magnetic compensation point. Here, we grow epitaxial RuO2 films and Y3Fe5O12/Gd3Fe5O12 (YIG/GIG) by pulsed laser deposition and study the magnetic coupling in the heterostructures. The XRD patterns show Laue oscillations and a narrow rocking curve, indicating a smooth surface and interface. From bulk-sensitive magnetometry and surface-sensitive spin Hall magnetoresistance measurements, we can control the heterostructures' magnetic properties by tuning the thickness of the individual layers. These bilayer devices could potentially control the magnon transport analogously to electron transport in giant magnetoresistive devices [1]. The RuO2 is tested for the novel altermagnetism effects[2].

MA 23.67   Tue 17:00   P1

AI-based Recognition of Numerically Generated Multimode Dispersions — •Paul Schreier[1], Milan Ender[1,2], Pascal Frey[1,2], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, Germany — [2]Aithericon, Kaiserslautern, Germany

The collective excitation of a magnetic system can lead to the excitation of spin waves. The relation between their wave vector and frequency is described by their dispersion relation. This can be determined by means of micromagnetic simulations. The resulting numerical data give an intensity distribution of all frequency-wave vector combinations. To extract the dispersion relations from these data, peak detection algorithms must be used. Compared to, for example, optical dispersion relations, spin wave dispersion relations are much more complex and non-linear, which makes their extraction from the raw data difficult. For this reason, a Convolutional Neural Network is trained with synthetic data to obtain a robust analysis tool. The network is specialized to classify segments in images. The training data consists of intensity distributions and dispersion relations calculated from micromagnetic simulations. Conventional peak detection algorithms were first applied to simple dispersion relations to generate a base set of training data. Recombination of this data produces a more complex and larger data set that requires very few resources. Compared to conventional peak detection algorithms, the robustness and fault tolerance can be increased by appropriate training. Evaluations based on dispersion relations can thus be automated to a large extent.

MA 23.68   Tue 17:00   P1

Imaging and phase-locking of non-linear spin waves — •Rouven Dreyer[1], Alexander F. Schäffer[1], Hans G. Bauer[2], Niklas Liebing[1], Jamal Berakdar[1], and Georg Woltersdorf[1,3] — [1]Institute of Physics, Martin Luther University Halle-Wittenberg, Von-Danckelmann-Platz 3, 06120 Halle, Germany — [2]Jahnstrasse 23, 96050 Bamberg, Germany — [3]Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle, Germany

Non-linear processes are a key feature in the emerging field of spin-wave based information processing and allow to convert uniform spin-wave excitations into propagating modes at different frequencies. Recently, the existence of non-linear magnons at half-integer multiples of the driving frequency has been predicted for Ni$_{80}$Fe$_{20}$ at low bias fields. However, it is an open question under which conditions such non-linear spin waves emerge coherently and how they may be used in device structures. Usually non-linear processes are explored in the small modulation regime and result in the well known three and four magnon scattering processes. Here we demonstrate and image a class of spin waves oscillating at half-integer harmonics that have only recently been proposed for the strong modulation regime. The direct imaging of these parametrically generated magnons in Ni$_{80}$Fe$_{20}$ elements allows to visualize their wave vectors. In addition, we demonstrate the presence of two degenerate phase states that may be selected

by external phase-locking. These results open new possibilities for applications such as spin-wave sources, amplifiers and phase-encoded information processing with magnons.

MA 23.69   Tue 17:00   P1

Magnetoacoustic excitation of spinwaves in yttrium iron garnet / zinc oxide heterostructures — •Kevin Künstle[1], Finlay Ryburn[2], Michael Schneider[1], Yannik Kunz[1], Vitaliy Vasyuchka[1], Carsten Dubs[3], John Gregg[2], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU in Kaiserslautern — [2]University of Oxford — [3]INNOVENT e.V. Technologieentwicklung, Jena, Germany

Surface Acoustic Waves (SAWs) that operate in the Gigahertz regime with wavelengths on the micrometer scale enable the miniaturization of telecommunication microwave devices. In recent years, the coupling of SAWs with spin waves (SWs) in ferromagnetic metals has proven to be a viable option for the realization of applications like acoustic diodes, as the interaction is intrinsically nonreciprocal [1]. However, the coupling of SAWs with SWs in ferrimagnetic insulators is much less explored. We investigated SAWs excited by interdigital transducers made of Ti/Au, which were deposited on a GGG/YIG structure and covered by a piezoelectric ZnO layer. The ferrimagnetic YIG layer serves as a source for SWs to which the SAWs can couple. We used a vector network analyzer and microfocused Brillouin light scattering spectroscopy to identify the SAW characteristics in the YIG-based heterostructure. The observed magnetoelastic coupling of SAWs with SWs is highly nonreciprocal.

MA 23.70   Tue 17:00   P1

Ultrafast magnetization precession in metallic heterostructures driven by different excitation mechanisms — •Jasmin Jarecki[1], Maximilian Mattern[1], Jan-Etienne Pudell[1,2,3], Michel Hehn[4], Fried Weber[1], Alexander von Reppert[1], and Matias Bargheer[1,2] — [1]Institut für Physik und Astronomie, Universität Potsdam, Potsdam, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany — [3]European X-Ray Free-Electron Laser Facility, Schenefeld, Germany — [4]Institut Jean Lamour (UMR CNRS 7198), Universite Lorraine, Nancy, France

We study the magnetization precession induced by different excitation mechanisms, i.e. ultrafast demagnetization, temperature dependent anisotropy change and magneto-elastic coupling, in 20 nm Ni films within PtCuNi-heterostructures. The samples are excited by an ultrashort laser pulse from the Pt side and designed such that light does not excite Ni directly. The indirect excitation of the Ni is tailored in different ways: strain waves, heat waves and/or hot electrons. We combine time-resolved x-ray diffraction (UXRD) and magneto-optical Kerr effect measurements (MOKE) under variation of the external field angle to access the strain dynamics and therefore also the energy transfer within the sample and the out-of-plane component of the Ni magnetization. We observe a distinct angle-dependence of the precession amplitude depending on the predominant excitation mechanism. While temperature related effects cause high amplitudes for nearly out-of-plane external fields, recurring strain pulses amplify the amplitudes resonantly around 50°.

MA 23.71   Tue 17:00   P1

Dynamics of magnon condensates in microscopic temperature landscapes — •Franziska Kühn[1], Matthias R. Schweizer[1], Georg von Freymann[1,2], Alexander A. Serga[1], and Burkard Hillebrands[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, Germany — [2]Fraunhofer Institute for Industrial Mathematics ITWM, Fraunhofer-Platz 1, 67663 Kaiserslautern, Germany

This contribution focuses on the behavior of a magnon-Bose–Einstein condensate (BEC) in artificial magnetization landscapes on the scale of wavelengths of condensed magnons. In our work, the magnon condensate is created by over-populating a magnon gas using parametric microwave pumping. A heating laser combined with a phase-based wave front modulation technique imprints a complex microscopic temperature pattern onto the yttrium-iron-garnet film sample that can be varied in magnitude and intensity. In this way, the spatial saturation magnetization profile is adjusted and acts as an artificial potential for the BEC, affects its dynamics and drives magnon supercurrents and Bogoliubov waves. Since these micro-sized patterns are small compared to the area of BEC formation, it is possible to investigate the BEC in two-dimensional potential landscapes. In the experiment, we use micro-focused Brillouin light scattering spectroscopy to investigate the anisotropy of the two-dimensional density distribution of a magnon BEC and the possibility of interference effects between Bogoliubov waves. Funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) -TRR 173-268565370 (project B04)

MA 23.72   Tue 17:00   P1

Nonreciprocal microwave transmission enabled by magnon-phonon conversion — •Florian Kraft[1], Yannik Kunz[1], Michael Schneider[1], Matthias Küss[2], Manfred Albrecht[2], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische

Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Institut für Physik, Universität Augsburg

The magnetoelastic coupling between surface acoustic waves (SAWs) and spin waves (SWs) may enable applications such as miniaturized microwave isolators. The required nonreciprocity can be induced by symmetry breaking coupling mechanisms between phonons and magnons [1]. Here, we investigate nonreciprocal microwave transmission in a device based on the conversion of SAWs, excited by interdigital transducers (IDTs), to SWs, which are detected by a microwave antenna and vice versa. To this end, we use a sample structure made of $LiNbO_3$/Ta(3 nm)/$Co_{40}Fe_{40}B_{20}$(10 nm). We use a setup for combined microwave and optical spectroscopy based on microfocused Brillouin light scattering spectroscopy and vector network analysis. This allows for simultaneous electrical and optical detection of phonon-magnon-interactions. We analyze the nonreciprocal microwave transmission while simultaneously investigating the phonon-magnon-coupling with spatial resolution.

We acknowledge funding by DFG via project No. 492421737.

MA 23.73   Tue 17:00   P1

Frequency multiplication by collective nanoscale spin-wave dynamics — •Chris Koerner[1], Rouven Dreyer[1], Martin Wagener[1], Niklas Liebing[1], Hans G. Bauer[2], and Georg Woltersdorf[1,3] — [1]Institute of Physics, Martin Luther University Halle-Wittenberg, Von-Danckelmann-Platz 3, 06120 Halle, Germany — [2]Jahnstrasse 23, 96050 Bamberg, Germany. — [3]Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle, Germany

Frequency multiplication is a process in modern electronics in which harmonics of the input frequency are generated in nonlinear electronic circuits. Devices based on the propagation and interaction of spin waves are a promising alternative to conventional electronics. The characteristic frequency of these excitations is in the gigahertz (GHz) range and devices are not readily interfaced with conventional electronics. Here, we locally probe the magnetic excitations in a soft magnetic material by optical methods and show that megahertz-range excitation frequencies cause switching effects on the micrometer scale, leading to phase-locked spin-wave emission in the GHz range. Indeed, the frequency multiplication process inside the magnetic medium covers six octaves and opens exciting perspectives for spintronic applications, such as all-magnetic mixers or on-chip GHz sources.

MA 23.74   Tue 17:00   P1

Excitation of propagating spin waves in Ga:YIG thin films — •Moritz Bechberger[1], David Breitbach[1], Björn Heinz[1], Bert Lägel[1], Carsten Dubs[2], Burkard Hillebrands[1], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, Germany — [2]INNOVENT e.V. Technologieentwicklung, Jena, Germany

The material parameters of yttrium-iron-garnet (YIG), a well-known material in the research field of magnonics, can be modified by a partial substitution with gallium atoms leading to a lower saturation magnetization. In this study the propagation properties of spin waves in a YIG thin film doped with gallium (Ga:YIG) were investigated and characterized. Direct excitation of coherent spin waves was performed by patterned microantennas and they were detected using TR-BLS microscopy. Our experiments confirm the presence of fast, exchange dominated spin waves, as well as an isotropic spin-wave dispersion relation. In addition, the influence of nonlinear effects on the spin wave excitation was determined. In agreement with the negative effective magnetization of the Ga:YIG film, using high amplitude excitation, we find a positive nonlinear frequency shift for an in-plane magnetization. This results in a significant power-dependent foldover effect, which provides nonlinear power dependencies for the excitation. This study is of high interest for magnonic data processing and reveals novel possibilities for magnonic devices with a tunable nonlinearity. This research is funded by the DFG - Project No. 271741898 and TRR 173-268565370 (B01) and the ERC Grant No. 101042439 'CoSpiN'.

MA 23.75   Tue 17:00   P1

In Stitu Inverse Design for Magnonic Logic Devices — •Malte Koster[1], Philipp Pirro[1], and Georg von Freymann[1,2] — [1]Physics Departement and Research Center OPTIMAS - Technical University of Kaiserslautern, 67663 Kaiserslautern, Germany — [2]Fraunhofer Institute for Industrial Mathematics ITWM, 67663 Kaiserslautern, Germany

The need for fast and energy-efficient computing devices is currently a topic of great interest. Magnonic logic devices could offer a promising solution to this need. Due to the intrinsic nonlinearity of spin waves, novel approaches to computation arise in a single logic gate. At the same time, the nonlinear nature makes the design of such devices particularly challenging. We propose a method for inverse design of magnetic logic gates in structured or unstructured yttrium-iron-garnet film samples by using thermal landscapes.

In this design approach, the desired function is specified and the design is modified until it is achieved. The thermal landscapes are created using a laser whose intensity distribution on the sample is arbitrarily modified via a spatial

light modulator. The resulting local heating modifies the magnetization landscape. The function of the device is determined using a vector network analyzer. Compared to inverse design via micromagnetic simulations [1], our approach promises significantly higher speed as well as direct proof of functionality in real applications.

MA 23.76   Tue 17:00   P1

Microwave Control of Magnon Transport and Spin Pumping in Nanostructures — •Franz Weidenhiller[1,2], Janine Gückelhorn[1,2], Manuel Müller[1,2], Korbinian Rubenbauer[1,2,3], Hans Huebl[1,2,3], Matthias Althammer[1,2], and Rudolf Gross[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, Garching, Germany — [3]Munich Center for Quantum Science and Technology, München, Germany

Magnon transport in magnetically ordered insulators is of great interest for the implementation of magnonic devices. Here we report our results on the diffusive magnon transport in yttrium iron garnet (YIG) and its control by the simultaneous excitation of magnons with electromagnetic microwaves. Using e-beam lithography, we pattern two platinum (Pt) strips on top of the YIG for the injection and detection of magnons. The Pt strips are electrically insulated from an aluminum microwave antenna, which covers both strips and the gap in between. Via the antenna, microwave-driven generation of magnons in the active device area by parallel and perpendicular pumping is possible. Our proposed device geometry allows us to distinguish these two pumping contributions in the acquired signal. We investigate how these microwave injected magnons affect the magnon transport between the two Pt strips. Moreover we study the spin pumping signal at different magnetic fields, microwave frequencies and powers. Finally, we discuss relevant magnon relaxation mechanisms in our experiments.

MA 23.77   Tue 17:00   P1

Elementary magnetic excitations in epitaxial strained Sr_2IrO_4 thin films probed by resonant inelastic X-ray scattering — •Herman Muzychko[1,2], Monika Scheufele[1,2], Dan Mannix[3,4], Stephan Geprägs[1], and Rudolf Gross[1,2,5] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, Garching, Germany — [3]European Spallation Source, Lund, Sweden — [4]Institut Néel, CNRS, Grenoble, France — [5]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

The Ruddlesden-Popper series $Sr_{n+1}Ir_nO_{3n+1}$ has attracted considerable scientific attention due to the possibility of generating new physics properties within a strong spin-orbit coupling regime. In the first member of the series, the layered Sr_2IrO_4 (SIO) compound, the large spin-orbit coupling combined with a moderate Coulomb repulsion results in a Mott insulating $J_{eff} = 1/2$-ground state, which is similar to the $S = 1/2$-ground state of high-T_c superconducting Cu oxides. By performing resonant inelastic X-ray scattering (RIXS) experiments, we have investigated the elementary magnetic excitations in epitaxial strained-SIO thin films. The thus obtained spin wave dispersions have been simulated within the linear-spin wave theory by using the program package SpinW. With this, we are able to resolve the effect of epitaxial strain [1] on the elementary magnetic excitations in SIO by comparing our results to bulk SIO spin wave properties.

MA 23.78   Tue 17:00   P1

Spontaneous emergence of spin-wave frequency combs mediated by vortex gyration — •Christopher Heins[1,2], Katrin Schultheiss[1], Lukas Körber[1,2], Attila Kákay[1], Tobias Hula[1,3], Mauricio Bejarano[1,2], Jür-

gen Lindner[1], Jürgen Fassbender[1,2], and Helmut Schultheiss[1,2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Fakultät Physik, Technische Universität Dresden, Dresden, Germany — [3]Institut für Physik, Technische Universität Chemnitz, Chemnitz, Germany

We present experimental investigations of spin-wave frequency combs forming in a confined system, a magnetic vortex. The magnetic vortex shows rich spin-wave dynamics with frequencies in the GHz range, which can be harnessed for pattern recognition [1]. Additionally, there is the low frequency gyration of the vortex core itself. The combination of these dynamics on two different time scales inside magnetic vortices, results in the generation of spin-wave frequency combs with their spacing given by the vortex gyration frequency. Using time-resolved Brillouin light scattering microscopy, we show that large amplitude excitations of spin waves purely in the GHz range can induce a gyration of the vortex core and vice versa, which leads to the formation of frequency combs.

The authors acknowledge financial support from the Deutsche Forschungsgemeinschaft within program SCHU 2922/1-1.

MA 23.79   Tue 17:00   P1

Manipulation of spin-waves dynamics in two-sublattice antiferromagnet by an electric field — •Olha Boliasova[1,2] and Vladimir Krivoruchko[2] — [1]Leibniz Institute for Solid State and Materials Research Dresden, Dresden, Germany — [2]Donetsk Institute for Physics and Engineering named after O.O. Galkin, Kyiv, Ukraine

Spin waves are one of the promising candidates for information carriers in future electronic devices. They are applicable in the wide frequency region and reduce energy losses. Now the main challenge is to uncover mechanisms of proper propagation, manipulation, and detection of spin waves. Recent research shows that a magnetic and electric field could manipulate spin dynamics. The last variant opens the possibility to realize different propagation spin-waves in opposite directions, not limited to the magnets with inversion symmetry breaking. It is possible as an external electric field could induce the Dzyaloshinskii-Moriya interaction that changes the spatial distribution of spin waves in the nonchiral magnets. Confirmation of this is already available for ferromagnets, and we provide more in-depth studies of this effect for a two-sublattice antiferromagnet. We use a phenomenological approach based on the Landau-Lifshitz-Gilbert equations to detect spin dynamics. The dependence of spin dynamics on the magnitude of the applied electric field was found.

MA 23.80   Tue 17:00   P1

Undirectional spin wave propagation mediated by $Co_{25}Fe_{75}$- and $Ni_{80}Fe_{20}$-nanogratings — •Monika Scheufele[1,2], Christian Mang[1,2], Manuel Müller[1,2], Johannes Weber[1,2], Vincent Haueise[1,2], Hans Huebl[1,2,3], Matthias Althammer[1,2], Stephan Geprägs[1], and Rudolf Gross[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

The unidirectional propagation of spin waves provides novel functionalities for magnonic logic devices. Here, we report the fabrication of $Co_{25}Fe_{75}$ (CoFe)- and $Ni_{80}Fe_{20}$ (Py)-nanogratings via electron beam lithography and DC magnetron sputtering on yttrium iron garnet (YIG) and CoFe thin films, respectively. The dipolar magnetic coupling between the nanogratings and the continuous thin films induces a finite nonreciprocity of the spin wave propagation if the magnetization within the gratings and the thin films is collinear [1]. By performing broadband ferromagnetic resonance as well as spin wave spectroscopy, we study the coupled spin wave modes in these magnonic devices. Moreover, we compare the properties of the CoFe/YIG and Py/CoFe platforms and also compare them with micromagnetic simulations.

Studies of decoherence in strongly anisotropic spin triangles with toroidal or general non-collinear easy axes — Kilian Irländer and •Jürgen Schnack — Universität Bielefeld, Bielefeld, Deutschand

Magnetic molecules are investigated with respect to their usability as units in future quantum devices. In view of quantum computing, a necessary prerequisite is a long coherence time of superpositions of low-lying levels. In this article, we investigate by means of numerical simulations whether a toroidal structure of single-ion easy anisotropy axes is advantageous as often conjectured. Our results demonstrate that there is no general advantage of toroidal magnetic molecules, but that arrangements of tilted anisotropy axes perform best in many cases.

MA 24.2   Wed 9:45   HSZ 02

Electrically driven singlet-triplet transition in triangulene spin-1 chains — Gabriel Martínez-Carracedo[1,2], •László Oroszlany[3,4], Amador García-Fuente[1,2], László Szunyogh[5,6], and Jaime Ferrer[1,2] — [1]Universidad de Oviedo, Oviedo, Spain — [2]CINN, Universidad de Oviedo-CSIC, El Entrego, Spain — [3]Eotvos Lorand University, Budapest, Hungary — [4]MTA-BME Lendulet Topology and Correlation Research Group, Budapest University of Technology and Economics, Budapest, Hungary — [5]Budapest University of Technology and Economics, Budapest, Hungary — [6]ELKH-BME Condensed Matter Research Group, Budapest University of Technology and Economics, Budapest, Hungary

Recently, graphene triangulene chains have been synthesized and their magnetic response has been analyzed by STM methods by Mishra and coworkers (Nature 598, 287 (2021)). Motivated by this study, we determine the exchange bilinear and biquadratic constants of the triangulene chains by calculating two-spin rotations in the spirit of the magnetic force theorem. We then analyze open-ended, odd-numbered chains, whose edge states pair up forming a triplet ground state. We propose three experimental approaches that enable us to trigger and control a singlet-triplet spin transition. Two of these methods are based on applying a mechanical distortion to the chain. We finally show that the transition can be controlled efficiently by the application of an electric field.

Linear magnets: a structure-property-relation for finding unquenched orbital moments — •ANTON JESCHE — EP VI, Center for Electronic Correlations and Magnetism, Augsburg University, 86135 Augsburg, Germany

The presence of orbital magnetic moments in rare-earth-elements is one of the major differences to transition metal compounds and is at the heart of magnetic anisotropy, stability, and functionality. A large crystal electric field effect acting on an unquenched orbital moment can lead to extremely large anisotropy and coercivity as experimentally verified for iron-doped lithium nitride [1]. In the dilute limit, those iron atoms can be considered as single-atom magnets and are ideal candidates to study the quantum dynamics of anisotropic spins [2,3]. This, together with the strong field dependence of the spin reversal, allows the creation of stable but switchable states that could act as a 'quantum bit' at elevated temperatures of 10 K. A recent Mössbauer study revealed dominant magnetic quantum tunneling at even higher temperatures [4]. The presence of orbital moments in iron-doped lithium nitride is not a coincidence and not a solitary case: based on the proposed structural motif of the 'linear chain', we have identified several other 'linear magnets' with similar physical properties: iron-doped Li4SrN2, LiSr2(CoN2), and (Sr6N)[FeN2][CN2]2. Implications and limitations of linear coordination are discussed in relation to the electronic structure. [1] M. Fix et al. PRB 97, 064419 (2018) [2] M. Fix et al. PRL 120, 147202 (2018) [3] M. Modelling of saw-tooth chain molecules composed of 3d and 4f ions — •DENNIS WESTERBECK and JÜRGEN SCHNACK — Universität Bielefeld, D-33501 Bielefeld, Deutschland

Metal- and lanthanide-ion containing systems are of great interest for the investigation of the magnetic properties of molecular systems. Especially the gadolinium containing systems are promising in view of magnetocaloric applications. In addition, saw-tooth like systems are considered as favorable for low-temperature cooling due to their massively degenerate ground-state. Although Fe^{III} and Gd^{III} are mostly considered as isotropic in multi-ion systems, we show that zero-field splittings are inevitable for the proper description of some of these molecules.

Furthermore, these anisotropic saw-tooth systems show a significant isothermal entropy change, which is surprisingly well described by our simulations.

MA 24.5   Wed 10:30   HSZ 02

High-field/high-frequency EPR studies on heterometallic $3d$-$4f$-complexes — •JAN ARNETH[1], CHANGYUN KOO[1], XIANGFENG LI[2], ANNIE K. POWELL[2], and RÜDIGER KLINGELER[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Institute of Inorganic Chemistry, Karlsruhe Institute of Technology, Germany

On the road to the construction of novel efficient single molecular magnets and molecular magnetic refrigerants experimental investigation of the exchange coupling mechanism between $4f$ and $3d$ moments is an important, yet still challenging, task. The difficulty in understanding the rich physics underlying this coupling arises from the strong participation of orbital angular momentum leading to large anisotropy and a complex energy spectrum in $4f$ metal compounds. Here, we present high-field/high-frequency electron paramagnetic resonance (HF-EPR) studies on heterometallic $3d$-$4f$ complexes with so-called butterfly motif Fe$_2$Ln$_2$ (Ln = Y, Gd, Dy), V$_2$Ln$_2$ (Ln = Er, Ho) and in the sawtooth coordination V$_4$Ln$_4$ (Ln = La, Gd), which allow us to directly determine not only the exchange coupling constants but also other spin-hamiltonian parameters, such as g-values and anisotropy. Our spectroscopic measurements are further complemented by high-field magnetisation studies.

MA 24.6   Wed 10:45   HSZ 02

AOM-guided Linked Fits for Analysing Inelastic Neutron Scattering and Magnetic Data of $3d$-$4f$ Heterometallic M$_2$Ln$_2$ Single-Molecule Magnets — •JULIUS MUTSCHLER[1], THOMAS RUPPERT[2], YAN PENG[2], JACQUES OLLIVIER[3], QUENTIN BERROD[3], JEAN-MARC ZANOTTI[3], CHRISTOPHER E. ANSON[2], ANNIE K. POWELL[2], and OLIVER WALDMANN[1] — [1]Physikalisches Institut, Universität Freiburg, D-79104 Freiburg, Germany — [2]Institut of Inorganic Chemistry, Karlsruhe Institute of Technology (KIT), D-76131 Karlsruhe, Germany — [3]Institut Laue-Langevin, F-38042 Grenoble Cedex 9, France

The discovery two decades ago of slow relaxation and quantum tunnelling of the magnetization in the single molecule magnets (SMMs) has inspired a flurry of research into their magnetic properties. This class of molecules has been extended to heterometallic clusters containing ions of transition metals and rare earths. The $4f$ ions are of interest because of their large angular momentum and magnetic anisotropies, but also present challenges in the analysis of inelastic neutron scattering (INS) and magnetic data. As presented in the previous meeting, excellent INS data were recorded on the time-of-flight disk-chopper spectrometers IN5 and IN6 at ILL on the Mn$_2$Ln$_2$-squares with

Ln = Y, Tb, Ho, Dy, and the M$_2$Ln$_2$-butterflies with M = Fe, Al and Ln = Dy, Er. In this talk, the analysis of the complete set of magnetic data using an AOM-guided linked fit is presented. The resulting ligand field and coupling parameters give crucial hints for the analysis of the rich INS spectra.

MA 25: Focus Session: Startups in Magnetism

This session offers academic researchers an insight into a possible third career path, besides staying in science or going to industry. Building your own company can be very rewarding and fun, big decisions to make decide over success or failure. 5 young entrepreneurs describe their business cases developed out of our magnetism community and will explain challenges, pitfalls, university support and constraints, IP, legal and business issues. After the talks there is a Panel Discussion with all speakers and Q and A with the audience.

Organizers: Manfred Fiebig (ETH Zürich) and Oliver Gutfleisch (TU Darmstadt).

Time: Wednesday 9:30–12:30   Location: HSZ 04

Invited Talk   MA 25.1   Wed 9:30   HSZ 04

MAGNOTHERM – One way to start a deep tech spin-off from research — •MAX FRIES — MagnoTherm Solutions GmbH, Pfungstädter Straße 102, 64297 Darmstadt

Founded as a spin-off from Prof. Oliver Gutfleisch's Functional Materials group at Technische Universität Darmstadt in 2019, MAGNOTHERM holds world-leading expertise in permanent magnets and magnetic cooling.

Our technology, based on solid state materials and water, is capable of revolutionizing the way we provide temperatures: By updating the standard gas compression cycle by our magnetic refrigeration cycle, we can build the next-generation cooling or heating solutions.

What does it mean for scientists to become entrepreneurs? What does it need to transform innovative research into market-ready, valuable products? From initial idea, raising first (venture) capital and sales over to recruiting talents and building a diverse team, I will take you along my professional journey so far. Doing so, I will highlight my personal key learnings along the way, while still providing time for a vivid discussion.

My aim is to motivate and inspire potential founders as well as up and coming Startup-entrepreneurs with a scientific background to implement their ideas by themselves, developing a beneficial impact on the world of today and the future.

Invited Talk   MA 25.2   Wed 10:00   HSZ 04

Spin-Ion Technologies : taking the research from a lab to a start-up company — •DAFINÉ RAVELOSONA — Spin-Ion Technologies, 10 Bd Thomas Gobert, 91120 Palaiseau, FRANCE

At Spin-Ion technologies, we have developed a new manufacturing process based on He ion irradiation to tailor the structural properties of ultra-thin magnetic films and spintronic devices at atomic level and improve their performance. The key feature of the technology is the post-growth control at the atomic scale of structural properties, which enables a precise control of magnetic properties. When realized through a mask this technology enables lateral modulation of magnetic properties without any physical etching. In this talk, I will describe the development of our idea from a research lab to a start-up company and how we envision our development toward the commercialization of our solution.

Invited Talk   MA 25.3   Wed 10:30   HSZ 04

MagREEsource : the green Rare Earth Magnet company — •Sophie Rivoirard[1,2] and Erick Petit[2] — [1]CNRS-UGA/Institut Neel, Grenoble, France — [2]MagREEsource SAS, Grenoble, France

Nd-Fe-B is the most widely used hard magnetic material in applications including the electronic and automotive sectors, electromobility and wind powder (e.g. motors, turbines, magnetic valves, sensors). Current standard Nd-Fe-B magnets contain up to 30% of rare earth elements, such as Neodymium or Dysprosium, which are on the EU list of critical elements and which are, for more than 95%, mined in the People*s Republic of China. This sourcing raises both environmental and geopolitical issues while the present demand for rare earth magnets is increasing by a rate of nearly 9%/year due to an increasing production of green technologies items (electric vehicles, wind turbines*). Therefore, one incentive in the European Union is to develop recycling processes for Nd-Fe-B magnets. MagREEsource is a spin off company from CNRS founded in 2020, which benefits from more than 25 years of expertise within CNRS laboratories in Grenoble. MagREEsource has licensed the know-how and Intellectual Property developped in Neel Institute at CNRS Grenoble on the recycling of Rare Earth based magnets. MagREEsource is currently working on an industrial plant in the Rhone-Alpes region to start high scale production. As a player in the Circular Economy, MagREEsource's objective is therefore to promote magnets at the end of their life, by producing new magnets for European manufacturers of motors promoting a loop as short as possible between supply and customer.

Invited Talk   MA 25.4   Wed 11:00   HSZ 04

THATec Innovation – we automate your lab — •Thomas Sebastian — THATec Innovation GmbH, Ludwigshafen, Deutschland

The idea behind THATec Innovation was born in the lab with the major goal to develop hardware and software solutions to overcome the challenges many scientists face in their daily work. Based on our long-standing experience as experimentalists, our services encompass the following areas: the automation of laboratory devices, optical scanning microscopy, and Brillouin light scattering.

THATec Innovation GmbH was founded in 2016 as a spin-off of the Helmholtz Center Dresden-Rossendorf and supported by the Helmholtz association in the framework of the Helmholtz Enterprise program. Since then, THATec Innovation offers the software framework thaTEC:OS for laboratory automation as well as software and hardware for Brillouin light scattering spectroscopy and microscopy.

In this talk, I am going present the experiences I gathered from the foundation of THATec Innovation as well as from my day-to-day business.

Invited Talk   MA 25.5   Wed 11:30   HSZ 04

Kiutra: Magnetic refrigeration for science and technology — •Alexander Regnat[1], Jan Spallek[1], Tomek Schulz[1], and Christian Pfleiderer[1,2] — [1]kiutra GmbH, D-81369 Munich, Germany — [2]Physik-Department, Technische Universität München, D-85748 Garching, Germany

Kiutra was founded in 2018 as a spin-off of the Technical University of Munich. With an interdisciplinary team of more than 30 employees, we innovate cryogenics to provide the best, most scalable and sustainable cooling solutions for basic research, material science and applied quantum technologies. Our products and services are successfully used by academic and industrial customers in Germany, Europe and the USA. Here we report on the scientific roots of our company, as well as the main challenges and successes we experienced developing our business. In addition, we highlight the various financing tools that have helped kiutra grow as a deep-tech hardware manufacturer.

30 min. Panel discussion with all speakers/industry representatives; then Q and A with the audience

MA 26: Non-Skyrmionic Magnetic Textures II

Time: Wednesday 9:30–11:30   Location: HSZ 401

Invited Talk   MA 26.1   Wed 9:30   HSZ 401

The self-induced spin glass: the perplexing magnetism of elemental neodymium — •Alexander Khajetoorians — Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands

Spin glasses are a class of disordered magnetic materials characterized by a flat multi-well energy landscape that exhibits aging dynamics. Spin glass behavior is often described by two key ingredients: (a) competing spin interactions, and (b) external disorder. It was recently proposed that a special type of spin glass can be realized, solely by competing interactions (1). In 2020 (2), we discovered that the controversial and perplexing magnetic state of elemental Nd(0001) is a self-induced spin glass. Using spin-polarized scanning tunneling microscopy/spectroscopy (SP-STM/STS), we found that the zero-field state shows a multiplicity of favorable short-range ordered Q-states, but in the absence of long-range order. The magnetic state shows aging dynamics, and it stems from frustrated indirect exchange. More recently (3), we showed that with increasing temperature, frustration is broken leading to a long-range ordered multi-Q state. In this talk, I will review the concept of the self-induced spin glass in Nd. Moreover, I will discuss new results concerning the aging dynamics and magnetic phase diagram of the material, as well as perspectives to use such multi-well systems for new memory and computing applications. Low-temperature properties of single-crystal ErB$_2$ — •Christoph Resch, Georg Benka, Daria Nuzhina, Anh Tong, Andreas Bauer, and Christian Pfleiderer — Physik Department E51, Technische Universität München, 85748 Garching, Germany

We present a comprehensive study of single crystals of the hexagonal rare-earth diboride ErB$_2$ prepared by means of the optical floating-zone approach. Measurements of the specific heat, the ac susceptibility, the magnetisation, and the electrical transport at low temperatures and fields up to 18 T consistently establish magnetic order of the Er^{3+} moments below a second-order phase transition at $T_c = 14$ K with competing ferromagnetic and antiferromagnetic interactions. The magnetocrystalline anisotropies exhibit strong easy-plane characteristics with ⟨001⟩ being the magnetic hard axis.

                  MA 26.3   Wed 10:15   HSZ 401

Helitronics for unconventional computing — •Nicolai Timon Bechler[1] and Jan Masell[1,2] — [1]Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany — [2]RIKEN CEMS, Wako, Japan

Non-trivial magnetic structures have been proposed to be a promising route to unconventional computing. The interplay between magnetic stiffness and Dzyaloshinskii-Moriya interaction can stabilize a helical order of the magnetisation which is often discarded as trivial. However, recent studies have shown that the orientation of these helical magnetisation structures can be manipulated by strong enough magnetic fields [1] and spin currents [2] which revealed their unexpectedly complex dynamics. Using micromagnetic simulations, we investigate novel magnetic memory devices such as MRAM-cells and memristors which use the orientation of the helical phase as an order parameter, dubbed helitronics. We propose a way to read-out said devices using the anisotropic magneto resistance and point out their use for unconventional computing purposes.

                  MA 26.4   Wed 10:45   HSZ 401

Investigating a stable Bloch point in a magnetic disk comprising layers with two different chiralities — •Thomas Brian Winkler[1], Marijan Beg[2], Martin Lang[3,4], Mathias Kläui[1], and Hans Fangohr[3,4] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Germany — [2]Department of Earth Science and Engineering, Imperial College London, United Kingdom — [3]Faculty of Engineering and Physical Sciences, University of Southampton, United Kingdom — [4]Max Planck Institute for the Structure and Dynamics of Matter Hamburg, Germany

Bloch points (BPs) are highly confined spin structures, that often occur in transient processes [1]. However, they can also be stabilized in specific systems. Beg et al. showed the existence of a stable Bloch point by stacking two cylindrical nanodisks of FeGe on top of each other, with opposite sign of the DMI vector [2]. In both layers a magnetic vortex is formed, with the same circularity, but opposite polarity, leading to a Bloch point at the interface. In this study we investigate the energetics of the system within the micromagnetic (MM) framework and validate results with atomistic simulations. Further, an in-plane field is applied to shift the BP out of the center of the disk. The dynamics of the system are analysed after the field switch-off. The BP does not show any precessional motion, which is different to a classical magnetic vortex [3]. We also find, that qualitatively, the MM framework produces the same results as atomistic simulation.

MA 26.5   Wed 11:00   HSZ 401

Stability of Hopfions in Bulk Magnets with Competing Exchange Interactions — •Moritz Sallermann[1,2,3], Hannes Jónsson[3], and Stefan Blügel[1] — [1]PGI-1 and IAS-1, Forschungszentrum Jülich and JARA, Jülich, Germany — [2]Department of Physics, RWTH Aachen, Aachen, Germany — [3]Science Institute and Faculty of Physical Sciences, University of Iceland, Reykjavík, Iceland

Magnetic hopfions are three-dimensional topological solitons, characterised by the Hopf number. Based on a micromagnetic model, the existence of free moving hopfions has been predicted in certain magnets with competing exchange interactions [1]. However, physical realisations of free moving hopfions in bulk magnets have so far been elusive. Here, we consider an effective spin lattice Heisenberg model with competing exchange interactions and computationally study the stability of small toroidal hopfions with unity Hopf number by finding first-order saddle points representing the transition state for the decay of hopfions to the ferromagnetic ground state, via the formation of two coupled Bloch points. We show that the energy barriers can reach substantial heights and are largely determined by the size of the hopfions. The saddle point methods are discussed.

MA 26.6   Wed 11:15   HSZ 401

Blowing magnetic smoke rings (hopfions) — •Philipp Gessler[1] and Jan Masell[1,2] — [1]Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany — [2]RIKEN CEMS, Wako, Japan

Hopfions are three-dimensional topological defects in magnetization, consisting of a closed skyrmion-string loop. Embedded in the field polarized phase, they are reminiscent of smoke rings in the air. In contrast to their two-dimensional counterparts, i.e. skyrmions, hopfions appear anything but ubiquitously in experiments. One reason is the lack of proposals for efficient ways to create these complex magnetic textures. Recently, ideas emerged for the creation of skyrmion-antiskyrmion pairs in two dimensions [1]. We generalize this idea to three dimensions. Using micromagnetic simulations, we show that spin-polarized currents can create hopfions at defects, similar to blowing smoke rings.

MA 27: Electron Theory of Magnetism and Correlations

Time: Wednesday 9:30–11:30 Location: HSZ 403

MA 27.1   Wed 9:30   HSZ 403

Electronic structure of the non-centrosymmetric antiferromagnetic AgCrSe$_2$ — •Seo-Jin Kim[1], Haijing Zhang[1], Marcus Schmidt[1], Michael Baenitz[1], Gesa Siemann[2], Chiara Bigi[2], Phil D. C. King[2], Vincent Polewczyk[3], Giovanni Vinai[3], and Helge Rosner[1] — [1]MPI CPfS, D-01187 Dresden, Germany — [2]IOM-CNR, Laboratorio TASC, Area Science Park, S.S. 14 km 163.5, Trieste I-34149, Italy — [3]School of Physics and Astronomy, University of St. Andrews, St. Andrews KY16 9SS, United Kingdom

We present the theoretical studies of the electronic structure and the anomalous Hall effect in AgCrSe$_2$ based on density functional theory together with experimental results. AgCrSe$_2$ is a layered triangular lattice system that lacks inversion symmetry. It exhibits a cycloidal coupling in the CrSe$_2$ layer with a small angle and an antiferromagnetic coupling between adjacent layers with a small canting along c-axis. The comparison of the Cr partial DOS determined from the photoemission measurements and the magnetic LDA+U calculations with a value of U = 0.75 eV shows a good agreement. This reveals that this compound is rather weakly correlated due to a strong hybridization with the ligands. The Se 4p states are dominating near the Fermi energy, resulting in a sizable band split of the order of 300 meV induced by the SOC. This system shows an unconventional anomalous Hall effect. The anomalous Hall conductivity is calculated based on the Berry curvature using an effective model constructed by the Wannierisation. The calculated σ_{xy} shows a good agreement to the experiments.

MA 27.2   Wed 9:45   HSZ 403

Geometrical dynamics of magnetic moments coupled to a correlated antiferromagnet — •David Alan Krüger, Nicolas Lenzing, and Michael Potthoff — Department of Physics, University of Hamburg, Hamburg, Germany

The geometrical spin torque represents an indirect interaction of magnetic moments, which are weakly exchange coupled to a system of itinerant electrons. It originates from a finite spin-Berry curvature, it modifies and adds to the conventional indirect RKKY exchange, and it leads to an anomalous, non-Hamiltonian dynamics of the magnetic moments. We demonstrate that there is an unprecedentedly strong geometrical spin torque in case of an electron system, where correlations cause antiferromagnetic long-range order. The key observation is that the anomalous torque is strongly boosted by low-energy magnon modes emerging in the two-electron spin-excitation spectrum as a necessary consequence of spontaneous spin-rotation symmetry breaking. As long as single- electron excitations are gapped out, the effect is largely universal, i.e., essentially independent of the details of the electronic structure, but decisively dependent on the lattice dimension. Analogous to the reasoning that leads to the Mermin-Wagner theorem, there is a lower critical dimension at and below which the spin-Berry curvature diverges. Our proposal is supported by numerical results obtained by the random-phase approximation and by Holstein-Primakov spin-wave theory for the Hubbard model in the weak- and in the strong-coupling limit, respectively.

MA 27.3   Wed 10:00   HSZ 403

Exploring electron correlation effects in the electronic structure and spin transport properties of transition metal multilayers — •Andrea Droghetti[1], Miloš Radonjić[2], Declan Nell[1], Liviu Chioncel[3], and Ivan Rungger[4] — [1]Trinity College Dublin (Ireland) — [2]University of Belgrade (Serbia) — [3]University of Augsburg (Germany) — [4]National Physical Laboratory (UK)

Magnetic thin film heterostructures, which are the material platforms for spintronic devices, are quite correlated systems. However, to date, most theoretical studies dedicated to their electronic and spin transport properties, rely on effective single-particle pictures. To go beyond these limitations, we present a computational approach, which combines Density Functional and Dynamical Mean Field Theory, for layered systems, using a multi-orbital perturbative solver for the many-body problem [1]. Calculations accurately describe the spin splitting of 3d states and the appearance of satellite features at transition metal surfaces and interfaces, where electron correlations can get drastically enhanced [2]. Furthermore, when combined with quantum transport schemes [3], our method allows for the simulation of spintronic devices thus addressing how electron correlations affect the giant and tunnel magnetoresistance [4].

MA 27.4   Wed 10:15   HSZ 403

The role of non-local Coulomb interaction on spin models in the Hubbard limit — •Wejdan Beida, Markus Hoffmann, Juba Bouaziz, and Stefan Blügel — Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA,52425 Jülich Germany

We extend the derivation of model spin Hamiltonians by including the non-local Coulomb interaction in the multi-band Hubbard model. We use Löwdin partitioning as the downfolding method of the dynamical electronic degrees of freedom described in the extended Hubbard model at half filling into low energy spin corner. The ground state of spin systems has been perturbatively corrected up to fourth order in the hopping parameter of the Hubbard model. The role which the non-local Coulomb interaction plays is strengthening the magnetism of the ground state. More importantly, it increases the importance of higher-order spin interactions beyond Heisenberg; Biquadratic, Four-spin, and Three-spin interactions. Generally speaking, this is confirmed by spin lattices with a site total spin in the range 1/2 * S * 3/2. For S = 1/2, we characteristically investigate the effect of next nearest neighbour hopping and inter-site Coulomb interaction on spin models for square and hexagonal lattice geometries.

MA 27.5   Wed 10:45   HSZ 403

Influence of the temperature on the relation between the magnetic hyperfine field and the magnetic moment — •Ondrej Sipr[1,2] and Hubert Ebert[3] — [1]Institute of Physics, Czech Academy of Sciences, Praha — [2]New Technologies Research Centre, University of West Bohemia, Plzeň — [3]Ludwig-Maximilians-Universität München

The magnetic hyperfine field B_{hf} is often used to probe magnetism in alloys, compounds and doped systems in an element-specific way. Accompanying this is the question about the relationship between B_{hf} and the magnetic moment. It was shown before both experimentally and theoretically that the ratio between B_{hf} and the magnetic moment depends on the alloy system and the composition. Here, we apply ab initio calculations to investigate how B_{hf} and its relation to the magnetic moment depend on the temperature.

We find that the contribution of the core electrons to B_{hf} is indeed proportional to the magnetic moment over the whole temperature range, from zero up to the Curie temperature. However, the temperature-dependence of the contribution of the valence electrons is more complicated and as a result of this, the ratio between the total B_{hf} and the magnetic moment significantly varies with the temperature. Based on our theoretical results, we show that probing element-specific magnetism by means of measuring the magnetic hyperfine field and by measuring the x-ray magnetic circular dichroism will lead in general to different pictures.

MA 27.6   Wed 11:00   HSZ 403

Nonlocal correlation effects due to virtual spin-flip processes in itinerant electron ferromagnets — •Sebastian Paischer[1], Mikhail Katsnelson[2], Giovanni Vignale[3], Arthur Ernst[1], and Pawel Buczek[4] — [1]Johannes Kepler University, Linz, Austria — [2]Radboud University, Nijmegen, Netherlands — [3]National University of Singapore, Singapore — [4]Hamburg University of Applied Sciences, Hamburg, Germany

An important type of the many-body effects in itinerant-electron magnets originates from the interaction of electrons with bosonic spin-flip excitations, both coherent (magnons) and incoherent (Stoner particle-hole excitations). While there has been a steady progress in understanding the properties of spin-flip excitations at a model level only little is known about microscopic details of their interactions with the electronic degrees of freedom in specific materials. Over the last few years we developed a first-principles method to account for the electron-magnon interaction in complex solids. While the method is based upon many body perturbation theory, we approximate the complex quantities from perturbation theory with quantities from time dependent density functional theory. This drastically reduces the numerical burden of the calculations and allows to consider complex materials like half-metallic ferromagnets. In this talk some of the main results and insights from this method will be presented.

MA 27.7   Wed 11:15   HSZ 403

Data-driven estimation of spin models in undoped cuprates — •Denys Y. Kononenko[1], Ulrich K. Rössler[1], Jeroen van den Brink[1,2], and Oleg Janson[1] — [1]Institute for Theoretical Solid State Physics, IFW Dresden, Dresden, Germany — [2]Institute for Theoretical Physics, TU Dresden, Dresden, Germany

Undoped cuprates host a wide variety of low-dimensional and frustrated spin models. The typically leading antiferromagnetic contribution to a magnetic exchange can be accurately estimated if the respective transfer integral is known. To date, the computational estimation of the transfer integral involves a well-established but cumbersome computational procedure. We demonstrate how the Gaussian Process Regression (GPR) model, trained on the results of the density functional theory calculations, can be employed to predict the transfer integrals using crystal structure as the only input. The GPR model receives descriptors of the local crystal environment of two copper sites as an input. The descriptors are based on the truncated expansion of the site position functions on the basis of the three-dimensional Zernike functions [1]. In this way, information on the spatial configuration and the chemical composition of the local crystal environment is incorporated into the descriptor. The approach facilitates rapid screening of spin models with desirable features among a broad range of known and unknown cuprates.

MA 28: Bulk Materials: Soft and Hard Permanent Magnets

Time: Wednesday 9:30–10:45   Location: POT 6

MA 28.1   Wed 9:30   POT 6

Local stiffness tailoring of magneto-active composites produced by laser powder bed fusion — •Kilian Schäfer[1], Matthias Lutzi[1], Muhammad Bilal Khan[1], Sebastian Bruns[2], Claas Hartmann[3], and Oliver Gutfleisch[1] — [1]Functional Materials, Institute of Materials Science, TU Darmstadt, — [2]Physical Metallurgy, Institute of Materials Science, TU Darmstadt, — [3]Measurement and Sensor Technology Group, TU Darmstadt,

Magnetic actuation of mechanically soft actuators allows fast response, wireless operation and safe interaction with the human body. With additive manufacturing, the production of magneto-active composites in complex and bioinspired shapes is possible. To mimic the properties of biological systems, the fabrication of composites with locally different mechanical properties is needed. Here, we present a method to locally tailor the stiffness of a magneto-active compound, consisting of hard magnetic Nd2Fe14B particles in a thermoplastic polyurethane (TPU) matrix with laser powder bed fusion. By utilizing different laser parameters at different locations during the process, the mechanical properties of the composite are modified locally. The range in which the mechanical properties can be tailored is investigated with compression and tensile tests of the composite produced with different laser parameters. The stiffness can be increased tenfold when the laser power is increased from low to high values. The stiffness gradient within one sample is verified by line scans of Vickers indentations with a nanoindentation system. Then the actuation performance is evaluated for samples with and without stiffness gradients.

MA 28.2   Wed 9:45   POT 6

Magnetic properties of rare-earth-lean ThMn$_{12}$-type (Nd,X)Fe$_{11}$Ti (X: Y and Ce) compounds: A DFT study — •Stephan Erdmann, Thorsten Klüner, and Halil Ibrahim Sözen — Institute of Chemistry, Carl-von-Ossietzky University of Oldenburg, D-26129 Oldenburg, Germany

Due to the resource criticality of rare-earths (RE), an alternative to the well-known Nd$_2$Fe$_{14}$B magnets with a lower amount of critical elements is required. In this work, we performed density functional theory (DFT) calculations to investigate the influence of partial Nd substitution with more abundant elements (X: Y and Ce) in ThMn$_{12}$-type (Nd,X)Fe$_{11}$Ti compounds. In order to have a systematic understanding, the intrinsic magnetic properties such as saturation magnetization M_S, Curie temperature T_C and magnetocrystalline anisotropy energy, are screened starting from binaries RFe$_{12}$ (R: Y, Ce and Nd). Ti is considered for the thermodynamic stabilization and different concentrations of Ti are taken into account for ternaries RFe$_{12-y}$Ti$_y$, and quaternaries (Nd,X)Fe$_{12-y}$Ti$_y$ (0.5≤y≤1). In addition, the effect of nitrogenation is examined for each considered compound. In case of (Nd,Y)Fe$_{11}$Ti, |BH|$_{max}$ is found to be 384 kJ/m^3 and T_C is calculated to be 595 K. Similarly, |BH|$_{max}$ and T_C are calculated to be 365 kJ/m^3 and 593 K for (Nd,Ce)Fe$_{11}$Ti magnet, respectively. Both 50 % Nd-lean magnets exhibit higher |BH|$_{max}$ compared to Sm$_2$Co$_{17}$ and T_C than Nd$_2$Fe$_{14}$B. For both cases, our theoretical magnetic hardness factor κ is calculated to be 1.20, which qualifies them as good candidates for RE-lean permanent magnets.

MA 28.3   Wed 10:00   POT 6

Ab initio thermodynamic modelling for Ce-based alternative hard magnetic materials — •Halil Ibrahim Sözen[1], Tilmann Hickel[2], and Thorsten Klüner[1] — [1]Institute of Chemistry, Carl-von-Ossietzky University of Oldenburg, D-26129 Oldenburg, Germany — [2]BAM Federal Institute for Materials Research and Testing, 12489 Berlin, Germany

The utilization of the RE-lean ThMn$_{12}$ materials system in combination with the abundant RE element Ce is a promising strategy for modern hard magnet applications. One of the main challenges for the Ce-based hard-magnetic materials is the formation of detrimental Laves phases next to the ThMn$_{12}$-type compound CeFe$_{11}$Ti. In this contribution, we present an ab initio-based approach to modify the stability of these phases in the Ce-Fe-Ti system by additions of 3d and 4d-elements. The results are used to provide two fundamental methodological insights. One of them is our recently developed modeling concept of partial decomposition, which considers the enrichment of the added solutes in phases that would at the considered temperature not be stable in a conventionally used full decomposition model. The second conclusion is the dominant impact of 0 K formation enthalpies on the solute-enhances phase stability compared to finite temperature entropy terms. Based on this, a screening approach is developed, considering the substitution of all 3d and 4d-elements. We show that substituted elements with more than a half-filled 3d-shell or with less than a half-filled 4d-shell mainly reduce the formation temperature of the 1:12 phase.

MA 28.4   Wed 10:15   POT 6

Rare earth lean permanent magnets from computational design and the challenge of the 4f electrons — •H. C. Herper[1], K. P. Skokov[2], S. Ener[2], P. Thunström[1], L. V. B. Diop[3], O. Gutfleisch[2], and O. Eriksson[1,4] — [1]Department of Physics and Astronomy, Uppsala University, Sweden — [2]Functional Materials, Department of Material Science, TU Darmstadt, Germany — [3]Université de Lorraine, CNRS, IJL, Nancy, France — [4]School of Science and Technology, Örebro University, Örebro, Sweden

Computational design has been proven to be a powerful tool to tailor properties of functional materials but it becomes challenging in presence of 4f electrons. Here, NdFe$_{11}$Ti and YFe$_{11}$Ti serve as prototypes for rare-earth (RE) lean or RE-free magnets with the ThMn$_{12}$ structure. Though, for Sm (Ce) counterparts a core (valence) treatment was sufficient to describe the magnetic properties, the complex low temperature magnetism of NdFe$_{11}$Ti could only be reproduced with an intermediate sized LDA+U or a DMFT approach (full potential LMTO). We compare our calculations to experimental values obtained from single crystals. The investigations clearly demonstrate the crucial dependence of the calculated magnetic properties of NdFe$_{11}$Ti on the treatment of the 4f electrons.[1]

Using Nd$_{1-x}$Y$_x$Fe$_{12-y}$Ti1 + y as a test case we investigated how far the strong dependence of the magnetic properties on the description of the Nd 4f states influences the prediction of new phases.

MAELAS: MAgneto-ELAStic properties calculation via computational high-throughput approach — Pablo Nieves[1], Sergiu Arapan[1], Shihao Zhang[2], Andrzej Kadzielawa[1], Ruifeng Zhang[2], and •Dominik Legut[1] — [1]IT4Innovations, VSB-TU Ostrava, Ostrava, Czech Republic — [2]School of Mat. Sci. and Eng., Beihang University, Beijing, China

Magnetostriction is a physical phenomenon in which the process of magnetization induces a change in the shape or dimension of a magnetic material. Nowadays, materials with large magnetostriction are used in many electromagnetic microdevices as actuators and sensors. By contrast, magnetic materials with extremely low magnetostriction are required in applications such as electric transformers. In this work, we present results based on the in-house developed code MAELAS to determine anisotropic magnetostriction coefficients and magnetoelastic constants in an automated way by quantum-mechanical calculations. The behavior of the magnetocrystalline anisotropy energy and magnetostrictive coefficients under a general external magnetic field could be visualized as a relative length change using our MAELASviewer tool. To verify accuracy and our approach in general we present a number of examples of each crystal symmetry class with calculated magnetostriction and magnetoelastic constants and compare them with recorded data. One of our highlights with this novel approach is an ability to separate exchange-striction (ω_s) from the magnetic part and to avoid the calculation of the paramagnetic state that is still a challenge.

Brownian Computing Realized Using Skyrmions — •Maarten A. Brems[1], Klaus Raab[1], Grischa Beneke[1], Jan Rothörl[1], Peter Virnau[1], Johan H. Mentik[2], and Mathias Kläui[1] — [1]Institut für Physik, Johannes Gutenberg-Universität Mainz, Staudingerweg 7, 55128 Mainz, Germany — [2]Radboud University, Institute for Molecules and Materials, Heyendaalseweg 135, 6525 AJ Nijmegen, The Netherlands

Reservoir computing (RC) has been considered as one of the key computational principles beyond von-Neumann computing. Magnetic skyrmions, topological particle-like spin textures in magnetic films, are particularly promising for implementing RC since they respond strongly nonlinear to external stimuli and feature inherent multiscale dynamics. We propose and experimentally demonstrate a conceptually new approach to skyrmion computing that combines the RC and Brownian computing [1] concepts. By confining the thermal skyrmion motion [2] that can be electrically gated, we find that already a single skyrmion in a confined geometry suffices to realize non-linearly separable functions, which we demonstrate for the XOR gate along with all other Boolean logic gate operations [3]. Our proposed concept ensures low training costs as well as ultra-low power operation and can be readily extended by including more skyrmions in the reservoir, suggesting high potential for scalable and low-energy reservoir computing. Superparamagnetic tunnel junctions for neuromorphic computing — •Leo Schnitzspan[1,2], Gerhard Jakob[1,2], and Mathias Kläui[1,2] — [1]Institut für Physik, Johannes Gutenberg Universität Mainz — [2]Max Planck Graduate Center, Mainz

Superparamagnetic tunnel junctions (SMTJ) are promising building blocks in the field of neuromorphic computing. In a SMTJ, the magnetic free layer can switch its magnetic orientation induced by thermal activation, leading to a random two-level resistance fluctuations[1]. We show nanosecond fluctuations with dwell times below 10 ns for our in-plane magnetized SMTJs. Their intrinsic stochastic behaviour and additional tunability by external magnetic fields, Spin Transfer Torques (STT) or Spin Orbit Torques (SOT) are prerequisites for low-energy artificial neurons in neural networks. True random number generation is demonstrated and evaluated by the statistical test suite from NIST. The probability of a P- (=0) or AP- (=1) state depends on the energy landscape and can be affected by STT. However, the average fluctuation speed is strongly dependend on the temperature. We demonstrate that Joule heating, induced by a large applied current, leads to significantly shorter dwell times. From dwell time measurements, the contributions of STT and Joule heating are extracted.

Impact of DMI on magnonic antiferromagnetic leaky integrate-and-fire neuronal networks — •Verena Brehm and Alireza Qaiumzadeh — QuSpin, NTNU Trondheim, Norway

Two shifts of paradigms promise to revolutionize modern day computation: First, neuromorphic computing aims to mimic the human brain, which is a fundamentally different approach compared to the state-of-the-art von Neuman computing architecture. Second, antiferromagnetic magnonics promises to be faster and more energy-efficient compared to conventional electronics through avoidance of Joule heating and high-frequency eigenexcitations. We combine both fields and study a proof-of-principle antiferromagnetic spiking neural network, more specifically a leaky integrate-and-fire model both analytically and numerically [1,2].

Light-controlled nanomagnetic logic circuits — •Naëmi Leo[1,2], Matteo Menniti[2], Pieter Gypens[3], Jonathan Leliaert[3], and Paolo Vavassori[2] — [1]CSIC - INMA, Zaragoza, Spain — [2]CIC nanoGUNE BRTA, Spain — [3]Ghent University, Belgium

Magnetic metamaterials with magnetostatically-coupled elements offer an interesting platform to implement low-power and neuromorphic-inspired data processing, in particular when combined with thermally-driven switching processes. By combining nanomagnetic elements with light-controlled plasmonic heaters, here we demonstrate how to design nanomagnetic Boolean OR or AND gates with nanosecond operation. The reconfigurability logic is achieved either by modifying the field protocol setting the initial state or optically, by changing the polarisation and order of the laser pulses exciting the system. Thermoplasmonic-nanomagnetic metamaterials thus lend themselves for the implementation of future fast (up to GHz), energy-efficient (picojoule), and optically-reconfigurable platform for in-memory computation schemes.

MA 29.5   Wed 12:30   HSZ 02

Antiferromagnet-based neuromorphics using dynamics of topological charges — •Shu Zhang — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

We propose a spintronics-based hardware implementation of neuromorphic computing, specifically, the spiking neural network, using topological winding textures in one-dimensional antiferromagnets. The consistency of such a network is emphasized in light of the conservation of topological charges, and the natural spatiotemporal interconversions of magnetic winding. We discuss the realization of the leaky integrate-and-fire behavior of neurons and the spike-timing-dependent plasticity of synapses. Our proposal opens the possibility for an all-spin neuromorphic platform based on antiferromagnetic insulators.

MA 30: PhD Focus Session: Non-equilibrium dynamics in theory and experiment

Non-equilibrium phenomena often occur at the edge of phase transitions, for example, in maintaining the organism and cells, photosynthesis, or other exciting reactions. Nevertheless, many of these phenomena are poorly understood or require various disciplines to come together to understand these phenomena in a significant context. Here, however, there is still a need for communication between theory and experiment. Since today's experiments and ideas often have a large gap, we want to use this focus session to create an environment where young researchers can get an overall picture. In doing so, this Ph.D. focus session should emphasize highlights and show the current front of research, in addition to the character of tutorial lectures, and give a chance to conclude in a lively discussion. This PhD Focus Session is organized by Lea Spieker and Gérald Kämmerer (Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Germany).

Femto- phono- magnetism — •SANGEETA SHARMA — Max Born Institute for Nonlinear Optics and Short Pulse Spectroscopy, Max-Born-Str. 2A, 12489 Berlin, Germany

From the outset of research into femtomagnetism, the field in which spins are manipulated by light on femtosecond or faster time scales, several questions have arisen and remain highly debated: How does the light interact with spin moments? How is the angular momentum conserved between the nuclei, spin, and angular momentum during this interaction? What causes the ultrafast optical switching of magnetic structures? What is the ultimate time limit on the speed of spin manipulation? What is the impact of nuclear dynamics on the light-spin interaction?

In my talk I will advocate a parameter free ab-initio approach to treating ultrafast light-matter interactions, and discuss how this approach has led both to new answers to these old questions but also to the uncovering of novel and hitherto unsuspected early time spin dynamics phenomena. In particular I will show that selective excitation of phonon modes exert a strong influence on femtosecond demagnetisation. Our finding demonstrates that the nuclear system, typically assumed to play a role of an energy sink aiding remagnetization of the spin system, plays a profound role in controlling femtosecond demagnetization of magnetic materials.

Invited Talk MA 30.2 Wed 15:30 HSZ 02

Spin-switchable molecules in interaction with their environment. — •CYRILLE BARRETEAU — University Paris-Saclay, CEA, CNRS,SPEC, 91191, Gif-sur-Yvette, France

Molecules that can switch spin-state form a very important class of molecules that offers a formidable test bed for fundamental studies and applied research due to the multiple possible channels to tune their properties. Spin-crossover (SCO) molecules are the most common spin-switchable molecules where the spin-state of the metal complex changes under the application of an external stimulus such as light, temperature, pressure etc.. SCO crystals have been the subject of intense studies however; it is much more recent that these molecules have been deposited on surfaces. In practice, the number of SCO that are robust enough to remain intact on surface and retain their switchability is rather limited. In addition, from the modelling point, these systems are also delicate to describe accurately. In this talk, I will present coupled experimental and theoretical results of various spin-switchable molecules that have successfully been deposited on inorganic surfaces. It will be shown how their properties are affected by their environment, in particular we will investigate the role of molecule-molecule and molecule-substrate interaction or the application of an electric field. This will provide us with the tools to manipulate the properties of such systems and give hint for possible strategies to optimize the magneto-transport properties of materials/devices.

Yep, real photodoping. — LUKAS GIERSTER[1,2] and •JULIA STÄHLER[1,2] — [1]Humboldt-Universität zu Berlin, Inst. f. Chemie, Berlin, Germany — [2]Fritz-Haber-Institut der MPG, Abt. PChem, Berlin, Germany

The advent of photoinduced phase transitions and the investigation of their non-equilibrium dynamics on ultrafast timescales coined various fashionable terms like *hidden phases*, *new phases of matter*, or *photodoping*. They were not always used rigorously and partially developed a life on their own. For instance, a photoexcited solid is not necessarily in a different phase just because it shows different properties than in its ground state - and the pure redistribution of charges after photoexcitation is not equivalent with chemical doping even if the photoexcitation drives a phase transition.

I will discuss these subtle, but important differences using the example of ZnO that undergoes a semiconductor-to-metal transition upon real photodoping at very low excitation densities [1]. Notably, the hidden, metallic phase has no equivalent in the equilibrium phase diagram and shows decay dynamics on ultrafast timescales, but can also be retained and become metastable [2].

Probing ultrafast magnetization thanks to ultrashort soft X-ray pulses — •EMMANUELLE JAL — Sorbonne Université, CNRS, Laboratoire de Chimie Physique - Matière et Rayonnement, LCPMR, Paris 75005, France

Even after more than 25 years of studies and debates, the mechanisms of ultrafast demagnetization remain disputed. In order to bring new experimental information into this field, and with the advent of femtosecond X-rays sources, new time-resolved XUV and soft X-ray-based pump/probe techniques are performed on magnetic thin films. During this talk, I will give an overview of what can be done with XUV and soft x-ray short pulses to probe electronic, magnetic, and structural dynamics. A special emphasis will be given to (i) simultaneous electronic and magnetism dynamics [1,2] and (ii) simultaneous structural and magnetism dynamics [3, 4,5].

Role of substrate clamping on anisotropy and domain structure in the canted antiferromagnet α-Fe2O3 — •ANGELA WITTMANN[1,2], O GOMONAY[1], K LITZIUS[2,3], A KACZMAREK[2], A KOSSAK[2], D WOLF[4], A LUBK[4], T N JOHNSON[5], E TREMSINA[2], A CHURIKOVA[2], F BÜTTNER[6], S WINTZ[6], M A MAWASS[6], M WEIGAND[6], F KRONAST[6], L SCIPIONI[7], A SHEPARD[7], T NEWHOUSE-ILLIGE[7], J A GREER[7], G SCHÜTZ[3], N O BIRGE[2,5], and G S D BEACH[2] — [1]Johannes Gutenberg Universität Mainz, Germany — [2]Massachusetts Institute of Technology, USA — [3]Max Planck Institute for Intelligent Systems, Germany — [4]Leibniz IFW

Dresden, Germany — [5]Michigan State University, USA — [6]Helmholtz-Zentrum Berlin, Germany — [7]PVD Products, USA

Antiferromagnets are at the forefront of research in spintronics. However, many of the underlying phenomena remain to be explored. This work investigates the domain structure in a thin-film canted antiferromagnet α-Fe2O3 in an external magnetic field. Using x-ray magnetic linear dichroism (XMLD) and spin Hall magnetoresistance (SMR) measurements, we find that the internal long-range destressing fields driving the formation of domains do not follow the crystal symmetry of α-Fe2O3 but fluctuate due to substrate clamping [1]. This leads

to locally varying effective anisotropy in thin films allowing for the stabilization of long-range complex domain structures. The insights gained from our work serve as a foundation for further studies of electrical and optical manipulation of the domain structure of antiferromagnetic thin films. [1] arXiv:2210.16141

MA 31.2   Wed 15:15   HSZ 04

Two-directional electrical switching of insulating antiferromagnetic thin films — •Christin Schmitt[1], Adithya Rajan[1], Grischa Beneke[1], Aditya Kumar[1], Tobias Sparmann[1], Hendrik Meer[1], Rafael Ramos[2], Miguel Angel Niño[3], Michael Förster[3], Eiji Saitoh[2,4], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg-University Mainz, Germany — [2]WPI-AIMR, Tohoku University, Japan — [3]ALBA Synchrotron Light Facility, Spain — [4]Department of Applied Physics, The University of Tokyo, Japan

Antiferromagnets (AFMs) have gained increasing interest as active elements in spintronic devices due to intrinsic dynamics in the THz range and the absence of stray fields. However, efficient electrical writing and reading is necessary for applications. For insulating antiferromagnets different switching mechanisms based on spin-orbit torques or thermomagnetoelastic effects have been put forward [1,2]. Here, we focus on CoO/Pt thin films where we observe that electrical pulses along the same trajectory can lead to an increase or decrease of the electrical signal, depending on the current density of the pulse. By photoemission electron microscopy (PEEM) employing the x-ray magnetic linear dichroism (XMLD) effect we shed light on this observation and determine whether this is a sign for two competing switching mechanisms or rather some result of the sensitivity distribution of how the electrical measurement is conducted [3]. MA 31.3   Wed 15:30   HSZ 04

Control and manipulation of antiferromagnetic domains in NiO — •Hendrik Meer[1], Christin Schmitt[1], Olena Gomonay[1], Stephan Wust[2], Paul Herrgen[2], Baerbel Rethfeld[2], Benjamin Stadtmüller[1,2], Martin Aeschlimann[2], Jairo Sinova[1], Rafael Ramos[3,4], Lorenzo Baldrati[1], Eiji Saitoh[4,5], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg-University Mainz, Mainz, Germany — [2]Department of Physics and Research Center OPTIMAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany — [3]CIQUS, Departamento de Quimica-Fisica, Universidade de Santiago de Compostela, Santiago de Compostela, Spain — [4]WPI-Advanced Institute for Materials Research, Tohoku University, Sendai, Japan — [5]Department of Applied Physics, The University of Tokyo, Tokyo, Japan

Control of the spin structure is key for the development of future antiferromagnetic spintronic devices. We show how the antiferromagnetic domains of NiO/Pt bilayers can be modified by applying electric currents [1], patterning geometric elements [2], and irradiating with laser light [3]. We image the induced changes in the antiferromagnetic order with synchrotron and lab-based magnetic microscopy. We are able to reveal writing mechanisms for the antiferromagnetic order, laying the foundation for an active role of antiferromagnets in future devices.

MA 31.4   Wed 15:45   HSZ 04

Gate-tunable anomalous Hall effect in an antiferromagnet — Seo-jin Kim[1], Jihang Zhu[2], Mario Piva[1], Marcus Schmidt[1], Dorsa Fartab[1], Andrew Mackenzie[1,3], Michael Baenitz[1], Michael Nicklas[1], Helge Rosner[1], Ashley Cook[1,2], and •Haijing Zhang[1] — [1]Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany — [2]Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany — [3]Scottish Universities Physics Alliance, School of Physics and Astronomy, University of St Andrews, St Andrews KY16 9SS, UK

Probing and engineering the magnetic states is a key goal in contemporary condensed matter physics because it can facilitate the understanding of underlying mechanisms of many fundamental physical phenomena, such as the anomalous Hall effect. Here, we report the observation of an anomalous Hall effect in $AgCrSe_2$, a layered triangular lattice metal that lacks inversion symmetry, and has a sizeable antiferromagnetic coupling between Cr spin 3/2 moments in adjacent layers. The anomalous Hall resistivity 3 $\mu\Omega$ cm is comparable to the largest magnitude observed in any antiferromagnetic system to date. We further demonstrate that the anomalous Hall response in thin layer devices can be switched on and off by an ionic gate. We also present the results of an illustrative model that suggests the anomalous Hall effect is driven by Berry curvature that correlates closely with the Rashba spin-orbit coupling. The capability of electrically switching the anomalous Hall effect opens up new avenues for potential voltage controlled spintronic devices.

15 min. break

MA 31.5   Wed 16:15   HSZ 04

In plane magnetic field dependence of anomalous Hall effect in a non-collinear antiferromagnet — •Adithya Rajan[1], Tom Saunderson[1,2], Fabian Lux[1], Dongwook Go[1], Hasan Abdullah[3], Tetsuya Hajiri[4], Hidefumi Asano[4], Udo Schwingenschloegl[3], Yuriy Mokrousov[1,2], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University, Staudingerweg 7, 55128 Mainz, Germany — [2]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, 52424 Jülich, Germany — [3]King Abdullah University of Science and Technology (KAUST), Thuwal 23955-6900, Saudi Arabia — [4]Department of Materials Physics, Nagoya University, Nagoya 464-8603, Japan

Non-collinear antiferromagnets (NC-AFM) have attracted much attention recently due to the observation of the anomalous Hall effect (AHE) in these materials [1]. Here we study the AHE as a function of magnetic field direction in the Kagome plane of the antiperovskite nitride Mn3Ni0.35Cu0.65N. We explain the results in the context of irreducible representations of the three-spin unit cell, showing a strong interplay between field dependence of AHE and the octupole moment by fitting to density functional theory calculations. Further, we present non-trivial features in the field dependent AHE loops signifying additional stable spin configurations, and potentially novel transport phenomena. These results open the possibility of a lever through which the spin structure in NC-AFMs can be controlled.

MA 31.6   Wed 16:30   HSZ 04

Anomalous Hall Effect in Antiperovskite Nitride Thin Films Driven by Structural Disorder — •Berthold H. Rimmler, Binoy K. Hazra, Holger L. Meyerheim, and Stuart S. P. Parkin — Max Planck Institute of Microstructure Physics, Halle

Antiperovskites display unusual properties such as complex magnetism, superconductivity, negative thermal expansion and distinct magneto-transport effects, which render them interesting for various applications. For instance, Mn-based antiperovskite nitrides, Mn3ZN (Z = Ni, Ga, Sn), have attracted attention in spintronics, as they can host non-collinear antiferromagnetism and other complex magnetic phases. These give rise to unusual intrinsic magneto-transport effects, such as the anomalous Hall effect in absence of magnetization or the spin Hall effect where spin currents display arbitrary spin polarization directions. Control of the antiferromagnetic domain structure in these materials is essential for using these effects in spintronic devices. Therefore, an imbalance of the otherwise fully compensated non-collinear antiferromagnetic textures is required. Previously, strain-driven tetragonal distortion was assumed to be the mechanism allowing for domain control. In this work we show, by comparison of different Mn-based antiperovskite nitrides and using advanced X-ray diffraction measurements, that domain structure control is, instead, enabled by displacements of Mn atoms out of high symmetry positions that locally break the global crystal and magnetic symmetry. We demonstrate that this effect is a general feature of a number of Mn3ZN compounds and might, therefore, also have implications for other antiperovskites.

MA 31.7   Wed 16:45   HSZ 04

Flexomagnetism and vertically graded Néel temperature of antiferromagnetic Cr_2O_3 thin films — •Pavlo Makushko[1], Tobias Kosub[1], Oleksandr Pylypovskyi[1], Natascha Hedrich[2], Jiang Li[1], Alexej Pashkin[1], Stanislav Avdoshenko[3], René Hübner[1], Fabian Ganss[1], Daniel Wolf[3], Axel Lubk[3,4], Maciej Oskar Liedke[1], Maik Butterling[1], Andreas Wagner[1], Kai Wagner[2], Brendan Shields[2], Paul Lehmann[2], Igor Veremchuk[1], Jürgen Fassbender[1], Patrick Maletinsky[2], and Denys Makarov[1] — [1]HZDR, Dresden, Germany — [2]University of Basel, Basel, Switzerland. — [3]IFW Dresden, Dresden, Germany — [4]TU Dresden, Dresden, Germany.

Thin films of antiferromagnetic insulators are a prospective material platform for magnonics, spin superfluidity, THz spintronics, and non-volatile data storage. Here, we explore the presence of flexomagnetic effects in epitaxial Cr_2O_3 [1]. We demonstrate that a gradient of mechanical strain affects the order-disorder magnetic phase transition, resulting in the distribution of the Néel temperature along the thickness of a Cr_2O_3 film. The inhomogeneous reduction of the antiferromagnetic order parameter induces a flexomagnetic coefficient of about $15\mu B$ nm^{-2}. The antiferromagnetic ordering in the strained films can persist up to $100°C$, rendering Cr_2O_3 as a prospective material for industrial electronics applications.

MA 31.8   Wed 17:00   HSZ 04

Ferromagnetism and Ferroelectricity in a Superlattice of Antiferromagnetic Perovskite Oxides Without Ferroelectric Polarization — •Avijeet Ray, Paresh C. Rout, and Udo Schwingenschlögl — Physical Sciences and Engineering Division (PSE), King Abdullah University of Science and Technology (KAUST), Thuwal 23955-6900, Saudi Arabia

Using density functional theory with onsite Coulomb interaction, we study the structural, electronic, and magnetic properties of the $SrCrO_3$/$YCrO_3$ superlat-

tice and their dependence on epitaxial strain. We discover that the superlattice adopts an A-type antiferromagnetic (A-AFM) ordering in contrast to its constituents (SrCrO₃: C-AFM; YCrO₃: G-AFM) and retains it under compressive strain while becoming ferromagnetic (5 μ_B per formula unit) at +1% strain. The obtained ferroelectric polarization is significantly higher than that of the R_2NiMnO_6/La_2NiMnO_6 (R = Ce to Er) series of superlattices [Nat. Commun. 5, 4021 (2014)] due to a large difference between the antipolar displacements of the Sr and Y cations. The superlattice is a hybrid-improper multiferroic ma-

terial with a spontaneous ferroelectric polarization (13.5 $\mu C/cm^2$) approaching that of bulk $BaTiO_3$ (19 $\mu C/cm^2$). In addition, the charge-order-driven p-type semiconducting state of the ferromagnetic phase (despite the metallic nature of $SrCrO_3$) is a rare property and interesting for spintronics. Monte Carlo simulations demonstrate a magnetic critical temperature of 90 K for the A-AFM phase without strain and of 115 K for the ferromagnetic phase at +5% strain, for example.

MA 32: Magnetic Imaging Techniques I

Time: Wednesday 15:00–16:30   Location: HSZ 401

MA 32.1 Wed 15:00 HSZ 401

Correlating Magnetic Force Microscopy imaging with bulk Magnetometry for ferroelastic Fe7S8 inspection — •Samuel Seddon[1], Peter Milde[1], Marin Alexe[2], Charles Haines[3], Michael Carpenter[3], and Lukas Eng[1,4] — [1]TU Dresden, Institute of Applied Physics, Noethnitzer Straße 61, 01187 Dresden, Germany — [2]University of Warwick, Coventry, CV4 7AL, England — [3]Universtiy of Cambridge, Cambridge, CB3 0WA, England — [4]ct.qmat: Dresden-Wuerzburg Cluster of Excellence-EXC 2147, TU Dresden, 01062 Dresden

Pyrrhotite, Fe7S8, is a natural mineral exhibiting a strong magnetoelastic coupling - which is to say that the material's ferroelastic domains directly determine the allowed directions of its magnetic moments. This system provides an interesting environment to explore the role that a material's crystal structure has on its magnetic properties, on a unit-cellular level. Here, magnetic force microcopy (MFM) is used to directly correlate local magnetic switching behaviors with various features observed from the bulk magnetic hysteresis; a magnetic hysteresis as acquired from MFM field dependent measurements is visualized. Local magnetic domains thus can be directly correlated to the expected ferroelastic domain wall pinning, as well as to domains that are responsible for the differences observed in saturation magnetization. Preliminary results pertaining to the application of mechanical strain will also be presented.

MA 32.2 Wed 15:15 HSZ 401

Simultaneous Magnetic Field and Field Gradient Mapping of Hexagonal MnNiGa by Quantitative Magnetic Force Microscopy — Norbert H. Freitag[1], Christopher F. Reiche[2], Volker Neu[1], Parul Devi[3], Ulrich Burkhardt[3], Claudia Felser[3], Daniel Wolf[1], Axel Lubk[1], Bernd Büchner[1], and •Thomas Mühl[1] — [1]Leibniz Institute for Solid State and Materials Research IFW Dresden, 01069 Dresden, Germany — [2]Department of Electrical and Computer Engineering, University of Utah, Salt Lake City, UT-84112, USA — [3]Max Planck Institute for Chemical Physics of Solids Dresden, 01187 Dresden, Germany

A quantitative, single-pass magnetic force microscopy (MFM) technique is presented that maps one magnetic stray-field component and its spatial derivative at the same time. This technique uses a special cantilever design and a special high-aspect-ratio magnetic interaction tip that approximates a monopole-like moment. Experimental details, such as the control scheme, the sensor design, which enables simultaneous force and force gradient measurements, as well as the potential and limits of the monopole description of the tip moment are discussed. To demonstrate the merit of this technique for studying complex magnetic samples it is applied to the examination of polycrystalline MnNiGa bulk samples. In these experiments, the focus lies on mapping and analyzing the stray-field distribution of individual bubble-like magnetization patterns in a centrosymmetric [001] MnNiGa phase. The results indicate that the magnetic bubbles have a significant spatial extent in depth and a buried bubble top base.

MA 32.3 Wed 15:30 HSZ 401

Quantum calibration of Magnetic Force Microscopy — •Baha Sakar[1], Yan Liu[2], Sibylle Sievers[1], Fedor Jelezko[2], and Hans W. Schumacher[1] — [1]Physikalisch Technische Bundesanstalt — [2]University of Ulm

Magnetic Force Microscopy (MFM) is a magnetic imaging technique that allows to image magnetic structures with nanometer resolution. However, per se it only delivers qualitative information since the magnetic properties of the tip are not known. The only method of obtaining quantitative information from these qualitative data is through a calibration. In this study we report the quantum calibration of a magnetic force microscope (MFM) by measuring the two-dimensional magnetic stray-field distribution of the MFM tip using a single nitrogen vacancy (NV) center in diamond. From the measured stray-field distribution and the mechanical properties of the cantilever a calibration function is derived allowing to convert MFM images to quantum calibrated stray-field maps. This approach overcomes limitations of prior MFM calibration schemes and allows quantum calibrated nanoscale stray-field measurements in a field range inaccessible to scanning NV magnetometry. Quantum calibrated measurements of a stray-field reference sample allow its use as a transfer standard, opening the road towards fast and easily accessible quantum traceable calibrations of virtually any MFM.

MA 32.4 Wed 15:45 HSZ 401

Controlled surface-modification to revive shallow NV⁻-centers — •Toni Hache[1,5], Jeffrey N. Neethirajan[1,2,5], Domenico Paone[1,2,5], Dinesh Pinto[1,3], Andrej Denisenko[2], Rainer Stöhr[2], Péter Udvarhelyi[4], Anton Pershin[4], Ádám Gali[4], Jörg Wrachtrup[1,2], Klaus Kern[1,3], and Aparajita Singha[1] — [1]Max Planck Institute for Solid State Research — [2]3rd Institute of Physics and Research Center SCoPE, University of Stuttgart — [3]Institute de Physique, École Polytechnique Fédérale de Lausanne — [4]Wigner Research Centre for Physics, Institute for Solid State Physics and Optics, Hungarian Academy of Sciences — [5]Equal contribution.

Nitrogen-vacancy (NV) centers in diamond have attracted an immense interest for non-invasive magnetic imaging and quantum sensing. All NV based magnetic sensing protocols rely on the negative charge state of this quantum sensor (NV⁻). In this work we demonstrate dramatic charge state conversions within individual NV centers at cryogenic (4.7 K) and $2 \cdot 10^{-10}$ mbar ultra-high-vacuum (UHV) conditions. The NV centers are characterized based on autocorrelation measurements, ODMR contrast and emission spectra. Under these extreme conditions, each of these measurements indicate a significant decrease of the relative occupancy of the NV⁻ charge state. Furthermore, we note a slight recovery of the NV⁻ charge state by dosing water (H_2O) on top of the diamond surface under UHV conditions. These results indicate that controlled surface treatments are essential for implementing NV center based quantum sensing protocols at cryogenic-UHV conditions.

MA 32.5 Wed 16:00 HSZ 401

Deep learning assisted reconstruction of the magnetization from the 2D antiferromagnetic van der Waals material CrSBr — •Riccardo Silvioli, Michele Bissolo, Kartikay Tehlan, Martin Schalk, Ferdinand Menzel, Nathan P. Wilson, Andreas V. Stier, and Jonathan J. Finley — Walter Schottky Institute and TUM School of Natural Sciences, Technische Universität München

We investigate the layered antiferromagnet (AFM) CrSBr, a material with three phase transitions. Order within the layers ($T_{intra} \sim 160K$), order between the layers ($T_N \sim 135K$) and a low T phase close to 40K that is speculated to originate from the ordering of Br vacancies. We use widefield nitrogen vacancy (NV) vector magnetometry to investigate the magnetic phases of this material. We image the 3D magnetic stray field in the plane of the NV centers, located 100nm from the surface of the diamond. Retrieving information on the magnetization (M) from an NV measurement requires reconstruction of M. For out-of-plane M, this is an analytically solvable problem, whereas for in-plane M this problem is ill-posed. We employ a deep learning (DL) approach based on a convolutional neural network (CNN), in order to solve the inverse problem, and determine M from the data. We apply additional constrains to the CNN to follow Maxwells equations by incorporating micro magnetic simulations in the computation of loss during the training phase. We discuss the advantages of this physics informed CNN training approach and compare it to conventional CNN methods as well as reconstruction efforts.

MA 32.6 Wed 16:15 HSZ 401

Magnetic imaging with spin defects in hexagonal boron nitride — Pawan Kumar[1], Florentin Fabre[1], Alrik Durand[1], Tristan Clua-Provost[1], Jiahan Li[2], James H. Edgar[2], Nicolas Rougemaille[3], Johann Coraux[3], Xavier Marie[4], Pierre Renucci[4], Cédric Robert[4], Isabelle Robert-Philip[1], Bernard Gil[1], Guillaume Cassabois[1], •Aurore Finco[1], and Vincent Jacques[1] — [1]Laboratoire Charles Coulomb, Université de Montpellier, CNRS, Montpellier, France — [2]Tim Taylor Department of Chemical Engineering, Kansas State University, Manhattan, Kansas, USA — [3]Université Grenoble Alpes, CNRS, Grenoble INP, Institut Néel, Grenoble, France — [4]Université de Toulouse, INSA-CNRS-UPS, LPCNO, Toulouse, France

Optically-active spin defects hosted in hexagonal boron nitride (hBN) are promising candidates for the development of a two-dimensional quantum sensing unit. Here, we demonstrate quantitative magnetic imaging with hBN flakes doped with negatively-charged boron-vacancy (V_B^-) centers through neutron irradiation [1]. As a proof-of-concept, we image the magnetic field produced by

CrTe$_2$, a van der Waals ferromagnet with a Curie temperature slightly above 300 K. The advantages of the hBN-based magnetic sensor described in this work are its ease of use, high flexibility and, more importantly, its ability to be placed in close proximity to a target sample and included in van der Waals heterostructures.

MA 33: Frustrated Magnets I

Time: Wednesday 15:00–17:15   Location: HSZ 403

MA 33.1   Wed 15:00   HSZ 403

Frequency-resolved functional renormalization group for quantum magnetic systems — •Janik Potten, Tobias Müller, and Ronny Thomale — Julius-Maximilians-Universität, Würzburg, Deutschland

Strongly correlated materials are one of the most prolific topics of contemporary condensed matter physics. Within this field, the functional renormalization group (FRG) approach for spin models relying on a pseudo-fermionic description has proven to be a very powerful technique in simulating ground state properties of strongly frustrated magnetic lattices. However, the FRG as well as many other theoretical models, suffer from the fact that they are formulated in the imaginary-time Matsubara formalism and thus are only able to predict static correlations directly. Nevertheless, describing the dynamical properties, especially of magnetic systems is one of the fundamental theoretical challenges, as they are the key to bridging the gap to experimental data from neutron scattering experiments. For the pseudo-fermion FRG, we remedy this shortcoming by establishing a methodical approach based on the Keldysh formalism, originally developed to handle non-equilibrium physics. This novel approach allows for calculating the dynamic properties of spin systems on arbitrary lattices. We can identify the correct low-energy behavior of the dynamic spin structure factors for examplary nearest neighbor Heisenberg systems. These first results are promising and extensions of this work might allow for an easy calculation of dynamic properties even for non-equilibrium magnetic systems in the future.

MA 33.2   Wed 15:15   HSZ 403

Spin functional renormalization group for the $J_1 J_2 J_3$ quantum Heisenberg model — Dmytro Tarasevych, •Andreas Rückriegel, Savio Keupert, Vasilios Mitsiioannou, and Peter Kopietz — Institut für theoretische Physik, Universität Frankfurt

We use our recently developed functional renormalization group (FRG) approach for quantum spin systems to investigate the phase diagram of the frustrated $J_1 J_2 J_3$ quantum Heisenberg model on a cubic lattice. From a simple truncation of the hierarchy of FRG flow equations for the irreducible spin-vertices which retains only static spin fluctuations and neglects the flow of the four-spin interaction, we can estimate the critical temperature with a similar accuracy as the numerically more expensive pseudofermion FRG. In the regime where the ground state exhibits either ferromagnetic or antiferromagnetic order, a more sophisticated truncation including the renormalization of the four-spin interaction as well as dynamic spin fluctuations reveals the underlying renormalization group fixed point and yields critical temperatures which deviate from the accepted values by at most 4%.

MA 33.3   Wed 15:30   HSZ 403

Thermal Hall conductivity near field suppressed magnetic order in a Kitaev Heisenberg model — •Aman Kumar and Vikram Tripathi — Tata Institute Of Fundamental Research, Mumbai, India

We investigate thermal Hall conductivity κ_{xy} of a J-K Kitaev-Heisenberg model with a Zeeman field in the (111) direction in the light of the recent debate surrounding the possible re-emergence of Ising topological order (ITO) and half-quantized κ_{xy}/T upon field-suppression of long-range magnetic order in Kitaev materials. We use the purification-based finite temperature Tensor Network approach making no prior assumptions about the nature of the excitations: Majorana, visons or spin waves. For purely Kitaev interactions and fields $h/K \gtrsim 0.02$ sufficient to degrade ITO, the peak κ_{xy}/T monotonously decreases from half-quantization associated with lower fields - a behavior reminiscent of vison fluctuation corrections. In our J-K model (with ferro-K and antiferro-J), in the vicinity of field-suppressed magnetic order, we found κ_{xy}/T to be significant, with peak magnitudes exceeding half-quantization followed by a monotonous decrease with increasing h. We thus conclude that half-quantized thermal Hall effect, if found in our model in the vicinity of field suppressed magnetic order, is a fine-tuning effect and is not associated with a Majorana Hall state with ITO.

MA 33.4   Wed 15:45   HSZ 403

Thermal spin dynamics of Kitaev magnets — •Oliver Franke — Institut für Theoretische Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Deutschland

The honeycomb magnet α-RuCl$_3$ is a prime candidate material for realizing the Kitaev quantum spin liquid (QSL), but it shows long-range magnetic order at low temperature. Nevertheless, its broad inelastic neutron scattering (INS) response at finite frequency has been interpreted as that of a 'proximate QSL'. A moder-

ate magnetic field indeed melts the residual zigzag order, giving rise to peculiar intermediate field phases before the high-field polarized state.

Are the scattering continua observed in experiments signatures of quantum fractionalized excitations in a QSL phase? Or are they caused by thermal fluctuations that break the large unit cell intermediate field phases predicted by theory? In this talk, I will present our recent study on the subject, which helps to answer these topical questions and highlights the importance of distinguishing finite temperature fluctuations from genuine quantum fractionalization signatures in frustrated magnets.

MA 33.5   Wed 16:15   HSZ 403

Disorder effects in the Kitaev-Heisenberg model — •Ayushi Singhania[1], Jeroen van den Brink[1,2], and Satoshi Nishimoto[1,2] — [1]Institute for Theoretical Solid State Physics, IFW Dresden, 01069 Dresden, Germany — [2]Department of Physics, Technical University Dresden, 01069 Dresden, Germany

We study the interplay of disorder and Heisenberg interactions in Kitaev model on honeycomb lattice. The effect of disorder on the transition between Kitaev spin liquid and magnetic ordered states as well as the stability of magnetic ordering is investigated. Using Lanczos exact diagonalization we discuss the consequences of two types of disorder: random-coupling disorder & singular-coupling disorder. They exhibit qualitatively similar effects in the pure Kitaev-Heisenberg model without long-range interactions. The range of spin liquid phases is reduced and the transition to magnetic ordered phases becomes more crossover-like. Furthermore, the long-range zigzag and stripy orderings in the clean system are replaced by their three domains with different ordering direction. Especially in the crossover range the coexistence of magnetically ordered and Kitaev spin-liquid domains is possible. Surprisingly, in presence of long range interactions, the stability of magnetic ordered state is diminished by singular-coupling disorder, and accordingly, the range of spin-liquid regime is extended. This mechanism may be relevant to materials like α-RuCl3 and H3LiIr2O6 where the zigzag ground state is stabilized by weak long-range interactions. We also find that the flux gap closes at a critical disorder strength and vortices appears in the flux arrangement.

MA 33.6   Wed 16:30   HSZ 403

ZnCr$_2$Se$_4$ as a spiral-spin-liquid approximant — •D. S. Inosov[1], Y. V. Tymoshenko[1], A. Akopyan[2], D. Shukla[2], N. Prasai[2], M. Doerr[1], D. Gorbunov[3], S. Zherlitsyn[3], D. J. Voneshen[4,5], M. Boehm[6], V. Tsurkan[7,8], V. Felea[8], A. Loidl[7], Y. O. Onykiienko[1], J. Ollivier[6], and J. L. Cohn[2] — [1]IFMP, TU Dresden — [2]University of Miami, Florida, USA — [3]Hochfeld-Magnetlabor Dresden-Rossendorf — [4]ISIS Facility, RAL, Didcot, UK — [5]Royal Holloway University of London, UK — [6]Institut Laue-Langevin, Grenoble, France — [7]Institute of Physics, University of Augsburg — [8]Institute of Applied Physics, Chisinau, Moldova

We investigated the cubic spinel helimagnet ZnCr$_2$Se$_4$ in its single-domain spin-spiral state by a combination of neutron scattering, thermal conductivity, ultrasound velocity, and dilatometry measurements. In zero magnetic field, the magnon spectrum consists of conventional gapless Goldstone modes and soft pseudo-Goldstone modes with a small energy gap of ~0.17 meV. In an applied magnetic field, this gap closes nonmonotonically, so that upon reaching a critical field of 6 T, the gap vanishes over a whole 2D manifold in the reciprocal space. This was recently identified as a prerequisite for a putative spiral-spin-liquid ground state [see S. Gao *et al.*, Phys. Rev. Lett. **129**, 237202]. This highly unusual behavior of the spin gap causes large anomalies in thermal conductivity at subkelvin temperatures — nearly two orders of magnitude below the Néel temperature. Our results apply to a broad class of centrosymmetric Heisenberg helimagnets where discrete lattice symmetry is spontaneously broken by the magnetic order.

MA 33.7   Wed 16:45   HSZ 403

Magneto-elastic coupling and new phases in the Shastry-Sutherland compound NdB$_4$ discovered by high-resolution dilatometry — •Rahel Ohlendorf[1], Sven Spachmann[1], Lukas Fischer[1], Daniel Brunt[2], Jasper Linnartz[3], Steffen Wiedmann[3], Geetha Balakrishnan[2], Oleg Petrenko[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg, Germany — [2]Department of Physics, University of Warwick, Coventry, UK — [3]HFML Nijmegen, Netherlands

We report high-resolution dilatometry studies on single crystals of the Shastry-Sutherland-lattice magnet NdB4 supported by specific heat and magnetometry data. The evolution of magnetically ordered phases below T_N = 17.2 K (commensurate antiferromagnetic phase), T_{IT} = 6.8 K (intermediate incommensurate phase), and T_{LT} = 4.8 K (low-temperature phase) is associated with pronounced anomalies in the thermal expansion coefficients. The data imply significant magneto-elastic coupling and evidence of a structural phase transition at T_{LT}. Grüneisen analysis of the ratio of thermal expansion coefficient and specific heat enables the derivation of uniaxial as well as hydrostatic pressure dependencies. From the observed anomalies the magnetic phase diagrams for B∥c up to 15 T and for B∥[110] up to 35 T are constructed. New in-field phases are discovered for both field directions and already known phases are confirmed. In particular, phase boundaries are unambiguously shown by sign changes of observed anomalies and corresponding changes in uniaxial pressure effects.

MA 33.8   Wed 17:00   HSZ 403

Emergent U(1) symmetry due to off-diagonal symmetric exchange interactions — •Sagar Ramchandani, Ciarán Hickey, and Simon Trebst — Institute for Theoretical Physics, University of Cologne, Germany

Frustrated magnetic systems are a result of competing interactions. These systems are of interest as they can exhibit a large ground state degeneracy, sometimes in the form of an emergent symmetry for the ground state.

Here, we study the effects of off-diagonal symmetric exchange interactions on classical O(3) spins on the Kagome lattice. We find an emergent U(1) symmetry in the ground state. We study the critical properties and the influence of thermal order-by-disorder on this symmetry using a combination of analytical and Monte Carlo methods.

The symmetry can be understood on the level of a single triangle. Using this understanding, we also propose a set of rules to generate a lattice model with these off-diagonal interactions that will exhibit the same emergent U(1) symmetry. The rules combine N triangles exhibiting N*U(1) symmetries into a single U(1) symmetry. These lattices can be generated in 1D, 2D & 3D.

MA 34: Focus Session: Spin-Phonon Coupling

Recent work on ultrafast demagnetization in ferromagnets has demonstrated that angular momentum can be transferred from the spin system to the lattice on ultrashort time scales. These findings demonstrate that a detailed understanding of the mechanisms that transfer angular momentum between the spin system and the lattice are of key importance in spintronics. The goal of this focus session is to give an overview over spin-phonon coupling effects in solids, ranging from the Einstein-de Haas effect on ultrafast time scales to magnon-phonon coupling and acoustic spin pumping at GHz frequencies. Coordinators: Tobias Kampfrath, Freie Universität Berlin and Uli Nowak, Universität Konstanz.

Invited Talk   MA 34.1   Thu 9:30   HSZ 02

Polarized phonons carry angular momentum in ultrafast demagnetization — •Peter Baum — Universität Konstanz, Germany

Many laser-excited magnetic materials lose their magnetic order almost completely within femtosecond timescales, but where is the missing angular momentum in such a short time? Here we use ultrafast electron diffraction with THz-compressed electron pulses to reveal in nickel an almost instantaneous, long-lasting, non-equilibrium population of anisotropic high-frequency phonons with an anisotropy plane that is perpendicular to the direction of the initial magnetization. We explain these observations by means of circularly polarized phonons that quickly absorb the angular momentum of the spin system before macroscopic sample rotation. The time that is needed for demagnetization is related to the time it takes to accelerate the atoms. These results provide an atomistic picture of the Einstein-de Haas effect and signify the general importance of polarized phonons for non-equilibrium dynamics and phase transitions.

Invited Talk   MA 34.2   Thu 10:00   HSZ 02

Spin-phonon coupling in ordered magnets: origin and consequences — •Akashdeep Kamra — Universidad Autónoma de Madrid, Madrid, Spain

Interaction between the spin and lattice degrees of freedom in magnets underlies a broad range of phenomena from magnetic damping to the Einstein-de Haas effect. Despite its long history and high importance, an adequate understanding of spin-phonon coupling's origin and potential consequences has eluded us. In this talk, we will discuss the microscopic mechanisms and related symmetry-breaking that underlie the spin-phonon coupling thereby achieving guidance on how to engineer it. In this discussion, we will pay special attention to the rotational invariance or total angular momentum conservation and how to account for it in the simulation of coupled spin and lattice dynamics. Then, we will examine some of the direct consequences of this coupling, focusing on magnon-polaron formation in ferro and antiferromagnets as well as the Einstein-de Haas effect in magnetic nanoparticles. If time permits, we will briefly discuss future directions and challenges.

Invited Talk   MA 34.3   Thu 10:30   HSZ 02

Magnon-mechanics in high overtone acoustic resonators — •Hans Huebl — Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — School of Natural Sciences, Technische Universität München, Garching, Germany — 3Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

Magnetoelastic coupling between excitation modes of the spin system (spin waves) and the lattice (phonons) is of interest from a fundamental perspective and can enable mode hybridization. For quantum sensing and transduction protocols, excitation exchange between the magnetic and elastic systems is of importance, however typically this requires strong coupling between the modes. In this presentation, I will present our current results on coupling the magnetization dynamics of a Kittel mode to a high-overtone bulk acoustic resonator and discuss this hybrid system in the context of sensing and transduction.

Cavity Magnomechanics: Harnessing the Magnomechanical Coupling for Applications in the Microwave and Optical Regimes — •Silvia Viola Kusminskiy — Institute for Theoretical Condensed Matter, RWTH Aachen University, 52074 Aachen, Germany — Max Planck Institute for the Science of Light, Staudtstr. 2 91058 Erlangen, Germany

Cavity magnonic systems are ideally suited to explore the range of possibilities opened by tailoring the interactions between photons, phonons, and magnons. In this talk I will discuss the different coupling mechanisms and propose applications ranging from quantum thermometry to wavelength conversion.

Invited Talk   MA 34.5   Thu 11:45   HSZ 02

Coherent spin-wave transport in an antiferromagnet — •Andrea Caviglia — Department of Quantum Matter Physics, University of Geneva, 24 Quai Ernest Ansermet, CH-1211 Geneva, Switzerland

Magnonics is a research field complementary to spintronics, in which the quanta of spin waves replace electrons as information carriers, promising lower dissipation. The development of ultrafast, nanoscale magnonic logic circuits calls for new tools and materials to generate coherent spin waves with frequencies as high and wavelengths as short as possible. Antiferromagnets can host spin waves at terahertz frequencies and are therefore seen as a future platform for the fastest and least dissipative transfer of information. However, the generation of short-wavelength coherent propagating magnons in antiferromagnets has so far remained elusive. Here we report the efficient emission and detection of a nanometre-scale wavepacket of coherent propagating magnons in the antiferromagnetic oxide dysprosium orthoferrite using ultrashort pulses of light. The subwavelength confinement of the laser field due to large absorption creates a strongly non-uniform spin excitation profile, enabling the propagation of a broadband continuum of coherent terahertz spin waves. The wavepacket contains magnons with a shortest detected wavelength of 125nm that propagate into the material with supersonic velocities of more than 13kms-1. This source of coherent short-wavelength spin carriers opens up new prospects for terahertz antiferromagnetic magnonics and coherence-mediated logic devices at terahertz frequencies.

MA 34.6 Thu 12:15 HSZ 02

Magnon-phonon coupling in polycrystalline metallic thin films — •Manuel Müller[1,2], Johannes Weber[1,2], Fabian Engelhardt[3,4,5], Victor A. S. V. Bittencourt[3,6], Thomas Luschmann[1,2,7], Silvia Viola Kusminskiy[5,3], Stephan Geprägs[1], Rudolf Gross[1,2,7], Matthias Althammer[1,2], and Hans Huebl[1,2,7] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]TUM School of Natural Sciences, Technische Universität München, Garching, Germany — [3]Max Planck Institute for the Science of Light, Erlangen, Germany — [4]Department of Physics, University Erlangen-Nuremberg, Erlangen, Germany — [5]Institute for Theoretical Solid State Physics, RWTH Aachen University, Aachen, Germany — [6]ISIS (UMR 7006), Université de Strasbourg, 67000 Strasbourg, France — [7]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

Magnetoelastic coupling between wave-like excitations of the spin system (spin waves) and the lattice (elastic waves) can result in a hybridization of both modes. This is of interest for future applications, such as microwave-to-optics transducers and phononic spin valve devices. As a finite magnetoelastic coupling affects the magnetization dynamics of the magnetic layer, it can be characterized with high sensitivity using ferromagnetic resonance spectroscopy. By using broadband ferromagnetic resonance spectroscopy, we have studied study the magnetoelastic coupling between silicon and sapphire substrates and ferromagnetic thin films deposited on them via DC sputtering.

MA 34.7 Thu 12:30 HSZ 02

Parametric excitation and instabilities of spin waves driven by surface acoustic waves — •Moritz Geilen[1], Roman Verba[2], Alexandra Nicoliou[3], Daniele Narducci[1], Adrian Dinescu[2], Milan Ender[1], Morteza Mohseni[1], Florin Ciubotaru[4], Mathias Weiler[1], Alexandru Müller[3], Burkard Hillebrands[1], Christoph Adelmann[4], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern Landau, Germany — [2]Institute of Magnetism, Kyiv, Ukraine — [3]National Institute for Research and Development in Microtechnologies, Bucharest, Romania — [4]imec, Leuven, Belgium

We present our experimental results on the parametric excitation of spin waves by coherent surface acoustic waves in metallic magnetic thin film structures.

The involved magnon modes are analyzed with micro-focused Brillouin light scattering spectroscopy and complementary micromagnetic simulations combined with analytical modelling to determine the origin of the spin-wave instabilities. Depending on the experimental conditions, we observe spin-wave instabilities originating from different phonon-magnon and magnon-magnon scattering processes. Our results demonstrate that an efficient excitation of high amplitude, strongly nonlinear magnons in metallic ferromagnets is possible by surface acoustic waves, which opens novel ways to create micro-scaled nonlinear magnonic systems for logic and data processing.

MA 34.8 Thu 12:45 HSZ 02

Magnetic ordering and spin-lattice interactions in MCrO$_2$ and MCrS$_2$ (with M = Li, Na, K, Cu, Ag, Au) — •S. Mankovsky, H. Lange, S. Polesya, and H. Ebert — Department Chemie, Ludwig Maximilian University, Munich, Germany

The triangular lattice antiferromagnets (TLA) are discussed in the literature as materials exhibiting a variety of magneto-elastic and magneto-electric properties determined by a complex magnetic structure driven by magnetic frustrations. In the present work we have investigated two groups of TLA compounds, MCrO$_2$ and MCrS$_2$, with M = Li, Na, K, Cu, Ag, Au. Their properties are discussed on the basis of first-principles calculations of their electronic structure as well as exchange coupling and spin-lattice coupling (SLC) parameters. The properties of these two groups are expected to be quite different, among others, because of a different distance dependency of the Cr-Cr exchange interactions. In particular one finds that the Cr layers in MCrS$_2$ cannot be treated as independent, in contrast to MCrSO$_2$ with quasi-2D frustrated AFM Cr layers. We discuss different contributions to the magnon-phonon interaction responsible for a modification of the phonon spectra in these materials, as well as a transition to the AFM state in some of them, accompanied by a lattice distortion as observed by experiment. In addition, a contribution of the inverse Dzyaloshinskii-Moriya (DM) interaction mechanism [PRL **95**, 057205 (2005)] to the ferroelectric properties driven by the magnetic ordering is discussed on the basis of the calculated DM-SLC parameters.

MA 35: Skyrmions III

Time: Thursday 9:30–12:00 Location: HSZ 04

MA 35.1 Thu 9:30 HSZ 04

Skyrmion dynamics and applications — •Ismael Ribeiro de Assis, Ingrid Mertig, and Börge Göbel — Martin-Luther-Universität Halle-Wittenberg, Halle, Germany

Skyrmionics and neuromorphics are among the most promising fields of physics with the perspective of creating future devices and technologies. Magnetic skyrmions are nanoscale magnetic whirls that are topologically protected and can be moved by currents, leading to the prediction of several applications. Its topological charge leads to high stability; however, it also leads to the skyrmion Hall effect. From memory storage devices, like the racetrack memory [1], to computing devices, like artificial neurons[2,3], this shortcoming is one of the primary reasons why skyrmion-based spintronic devices have yet to be achieved. Here, we study the motion of skyrmions with different topological charges and helicities. Using an effective center-of-mass description of these magnetic quasiparticles, namely, the Thiele equation, we analyze their dynamics under different gradient landscapes and interactions aiming to suppress or take advantage of the skyrmion Hall effect. Additionally, we discuss possible applications in neuromorphic computing. [1] A. Fert et al., Nature Nanotechnology 8, 152-156(2013) [2] S. Li et al., Nanotechnology 28, 31LT01 (2017) [3] I.R. de Assis et al., arXiv preprint arXiv:2209.11017 (2022).

MA 35.2 Thu 9:45 HSZ 04

Moving Antiferromagnetic Skyrmions with Spin Waves — •Michael Lau[1,2], Wolfgang Häusler[3], and Michael Thorwart[1,2] — [1]I. Institut für Theoretische Physik, Universität Hamburg — [2]The Hamburg Centre for Ultrafast Imaging, Universität Hamburg — [3]Institute of Physics, University of Augsburg

The possibility to move magnetic Skyrmions opens the pathway of technical applications in the form of nanoscale information carriers. While it is well-studied for ferromagnetic materials that spin waves are able to move Skyrmions, driving antiferromagnetic Skyrmions with spin waves is a relatively new topic. We present simulations on a two-dimensional lattice, with classical magnetic moments on each site, which reveal that antiferromagnetic Skyrmions can be accelerated by spin waves injected at one edge of the lattice. We consider in detail various forms of spin waves and draw connections between Skyrmion behavior and the spin wave attributes. To this end we analytically and numerically investigate classical antiferromagnetic spin waves at first. We derive a consistent analytical description of circularly- and linearly polarized spin waves and the two

modes of each polarization. Using this knowledge we investigate their impact on the Skyrmion and show that the symmetries of the spin wave modes is reflected in the resulting Skyrmion motion. One example is the non-vanishing Skyrmion Hall effect for circularly polarized spin waves. It turns out that also frequency and amplitude of the spin waves significantly influence the Skyrmion motion.

MA 35.3 Thu 10:00 HSZ 04

Geometry-induced motion of magnetic skyrmions in curved ferro- and antiferromagnetic films — •Kostiantyn V. Yershov[1,2], Attila Kákay[3], and Volodymyr P. Kravchuk[2,4] — [1]Leibniz Institute for Solid State and Materials Research, Dresden, Germany — [2]Bogolyubov Institute for Theoretical Physics, Kyiv, Ukraine — [3]Helmholtz-Zentrum Dresden-Rossendorf e.V., Institute of Ion Beam Physics and Materials Research, Germany — [4]Institut für Theoretische Festkörperphysik, Karlsruher Institut für Technologie, Germany

Here, we present the effect of the spontaneous drift of a magnetic skyrmion in curved films under the action of the curvature gradients without any external stimuli [1]. The strength of the curvature-induced driving is determined by the type of the intrinsic Dzyaloshinskii–Moriya interaction, while the trajectory is determined by the type of magnetic ordering: ferro- or antiferromagnetic. Using rigid particle approximation, we show that for the case of Néel skyrmion the driving force is linear with respect to the gradient of the curvature, while for Bloch skyrmion the driving is proportional to the product of mean curvature and its gradient. During the motion along the surface, skyrmion experiences deformation which depends on the skyrmion type. Equations of motion for Néel and Bloch magnetic skyrmions in curved ferromagnetic and antiferromagnetic materials are obtained in terms of collective variables. [1] K. Yershov et al, PRB **105** (2022), 054425.

MA 35.4 Thu 10:15 HSZ 04

Non-equilibrium dynamics of quantum skyrmion upon projective measurements — •Fabio Salvati, Andrey Bagrov, Tom Westerthout, and Mikhail I. Katsnelson — Institute for Molecules and Materials, Radboud University, Heijendaalseweg 135, 6525 AJ Nijmegen, The Netherlands

Magnetic skyrmions are particle-like spin structures characterized by nanometer size and long lifetime. These remarkable properties make them a promising candidate for the role of information carriers in magnetic information storage and processing devices.

Although considerable progress has been made in studying skyrmions in classical systems, little is known about skyrmions in quantum systems, since the quantum skyrmion state cannot be directly observed probing the local magnetization of the system. A characterization is possible using the scalar chirality - a particular local three-spin correlation function defined on neighboring lattice sites - as a quantum analog of the skyrmionic topological index.

In our work, we use the scalar chirality to investigate the local dynamics of a quantum skyrmion on a triangular lattice, following a projective measurement. Findings reveal the robustness of the quantum skyrmion state supported by spin waves. Besides we identify a feature to detect experimentally quantum skyrmions, performing the analysis of the Fourier transform of the spin-spin correlation function.

MA 35.5   Thu 10:30   HSZ 04

Nonlinear dynamics of skyrmion strings — •Volodymyr Kravchuk[1,2] and Markus Garst[1] — [1]Institut für Theoretische Festkörperphysik, Karlsruher Institut für Technologie, 76131 Karlsruhe, Germany — [2]Bogolyubov Institute for Theoretical Physics of the National Academy of Sciences of Ukraine, 03143 Kyiv, Ukraine

A skyrmion core, percolating the magnet volume, forms a skyrmion string – the topological Dirac string-like object. Here we analyze the nonlinear dynamics of a skyrmion string in a low-energy regime by means of the collective variables approach generalized for the case of strings. Using the perturbative method of multiple scales (both in space and time), we show that the weakly nonlinear dynamics of the translational mode propagating along the string is captured by the Nonlinear Schrödinger equation of the focusing type. As a result, the fundamental helix-shaped "planar-wave" solution experiences modulational instability, which leads to the formation of cnoidal waves. Both types of cnoidal waves, dn- and cn-waves, as well as the separatrix soliton solution [1], are confirmed by the micromagnetic simulations. Beyond the class of the traveling-wave solutions, we found Ma-breather propagating along the string. Finally, we proposed a generalized approach, which enables one to describe nonlinear dynamics of the modes of different symmetries, radially symmetrical, elliptical, etc.

Manipulation of Skyrmion Helicity in Frustrated Magnets — •Ross Knapman[1,2], Timon Tausendpfund[1], Sebastián A. Díaz[2], and Karin Everschor-Sitte[2,3] — [1]Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany — [2]Faculty of Physics, University of Duisburg-Essen, 47057 Duisburg, Germany — [3]Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47057 Duisburg, Germany

Aside from the well-studied mechanisms of the stabilisation of magnetic skyrmions via the Dzyaloshinskii-Moriya interaction, skyrmions can be stabilised with magnetic frustration. [1] In such a system, the helicity becomes a degree of freedom which can be manipulated using externally-applied electric and magnetic fields. [2,3] In our work, we use a Ginzburg-Landau description of the system [4] to model the dynamics of the skyrmion using analytical and numerical approaches. In tuning in the time dependences of the electric and magnetic fields, we can manipulate the energy landscape to induce interesting phenomena, including helicity rotations.

Non-synthetic antiferromagnetic multi-meronic Néel spin-textures in thin films — •Amal Aldarawsheh[1,2], Moritz Sallermann[1,3,4], Muayad Abusaa[5], and Samir Lounis[1,2] — [1]Peter Grünberg Institute and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, D-52425 Jülich,

Germany — [2]Faculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany — [3]RWTH Aachen University, 52056 Aachen, Germany — [4]Science Institute and Faculty of Physical Sciences, University of Iceland, VR-III, 107 Reykjavík, Iceland — [5]Arab American University, Jenin, Palestine

The realization of topological antiferromagnetic (AFM) solitons in real materials is a major goal towards their use in information technology. In contrast to their ferromagnetic version, they are expected to be insensitive to the Hall effect and dipolar interactions. Here, based on density functional theory in conjunction with atomistic spin dynamics, we predict the emergence in a triangular lattice of complex Néel AFM vortex-antivortex structures in transition metallic thin films interfaced with Ir and Pd layers. These topological structures are intrinsic, i.e. they form in a single AFM material, but are different from the recently predicted intrinsic AFM skyrmions [1]. They can carry various topological charges and can combine in hexameronic or dodecameronic textures, which can show enhanced stability with respect to external magnetic field depending on the electronic nature of the interfaces. [1] A. Aldarawsheh et al., ArXiv:2202.12090 (2022). Work funded by the PGSB (BMBF-01DH16027) and DFG (SPP 2137; LO 1659/8-1).

MA 35.8   Thu 11:30   HSZ 04

Investigation of the stability of exchange-stabilized skyrmions — •Sarina Lebs[1], Markus Hoffmann[1], Moritz Sallermann[1,2], and Stefan Blügel[1] — [1]Peter Grünberg Institut & Institute for Advanced Simulation, Forschungszentrum Jülich & JARA, Jülich, Germany — [2]Science Institute of the University of Iceland, VR-III, Reykjavík, Iceland

To utilize magnetic skyrmions, localized topologically nontrivial textures, in technological applications, a long lifetime at room temperature is required. Therefore, a major focus of magnetism research is the analysis of the stability of such skyrmions. The main focus in the past was on DMI-stabilized skyrmions, little is known about exchange stabilized ones.

In this presentation, we discuss the significance of the different stabilization mechanisms for the skyrmion lifetimes. Using the Spirit code [1], we perform LLG, GNEB, as well as HTST simulations to calculate skyrmion profiles, transition paths, and lifetimes for both DMI- as well as exchange-stabilized skyrmions. We discuss similarities as well as differences between the stabilization mechanisms for the lifetime.

We acknowledge funding by the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (Grant No. 856538, project 3D MAGiC).

MA 35.9   Thu 11:45   HSZ 04

Lifetime of coexisting sub-10 nm zero-field skyrmions and antiskyrmions — •Moritz A. Goerzen[1], Stephan von Malottki[1,2,3], Sebastian Meyer[1,4], Pavel F. Bessarab[2,5], and Stefan Heinze[1] — [1]ITAP, University of Kiel, Germany — [2]Science Institute of the University of Iceland, Iceland — [3]Thayer School of Engineering, Dartmouth College, USA — [4]Nanomat/Q-mat/CESAM Université de Liège, Belgium — [5]Department of Physics and Electrical Engineering, Linnaeus University, Sweden

Localized spin structures such as magnetic skyrmions have raised high hopes for future spintronic devices. For many applications it can be of great advantage to have more than one particle-like texture available. The coexistence of skyrmions and antiskyrmions has been proposed in inversion symmetric magnets with exchange frustration. However, so far only model systems have been discussed and the interplay with the Dzyaloshinskii-Moriya interaction (DMI) has not been studied. Here, we predict that skyrmions and antiskyrmions with diameters below 10 nm can coexist at zero magnetic field in a Rh/Co bilayer on the Ir(111) surface. Based on an atomistic spin model parameterized from density functional theory, we show that the lifetimes of metastable skyrmions and antiskyrmions in the ferromagnetic ground state are above one hour for temperatures up to 75 K and 48 K, respectively. The entropic contribution to nucleation and annihilation rates is different for skyrmions and antiskyrmions. This opens the route to thermal control of coexisting skyrmions and antiskyrmions in frustrated magnets with DMI.

MA 36: Magnetic Particles / Clusters

Time: Thursday 9:30–11:00   Location: HSZ 401

MA 36.1   Thu 9:30   HSZ 401

Magnetic properties of metastable single-crystalline cobalt iron oxide nanoflakes investigated by Mössbauer spectroscopy — Soma Salamon[1], Joachim Landers[1], •Anna Rabe[1,2], Franz-Philipp Schmidt[3], Thomas Lunkenbein[3], Malte Behrens[2], and Heiko Wende[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen — [2]Institute of Inorganic Chemistry, Kiel University — [3]Department of Inorganic Chemistry, Fritz Haber Institute of the Max Planck Society

Spinel-type transition metal oxides are of high interest for a variety of applications, including heterogeneous catalysis, energy conversion and magnetic materials with fine-tuned properties. The compound Co_2FeO_4 is of particular interest, but its phase diagram contains a large immiscibility. Using Mössbauer spectra recorded at low temperatures (4.3 K) and high magnetic fields (10 T), we were able to precisely determine the distribution of Fe ions across tetrahedral and octahedral sites. This enabled us to characterize the influence of different calcination temperatures from 400 °C up to 900 °C on the phase composition and

miscibility, while also providing valuable insights on the temperature dependent evolution of the spectral hyperfine structure. These findings were successfully correlated with results from magnetometry, showing clear signs of a change in magnetic properties based on different degrees of intermixing, interface area, and phase separation, as also supported by TEM and EDX measurements. Financial support by the German Research Foundation (DFG) via the CRC/TRR 247 (Project-ID 388390466, sub-project B02) is gratefully acknowledged.

MA 36.2   Thu 9:45   HSZ 401

Mössbauer spectroscopy study of anisotropic barium ferrite hybrid systems — •Juri Kopp[1], Joachim Landers[1], Soma Salamon[1], Benoît Rhein[3], Hajnalka Nádasi[2], Darja Lisjak[4], Patricija Hribar Boštjančič[4], Alenka Mertelj[4], Alexey Eremin[2], Annette Schmidt[3], and Heiko Wende[1] — [1]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen — [2]Department of Nonlinear Phenomena, Institute for Experimental Physics, Otto von Güricke University Magdeburg — [3]Department of Chemistry, Physical Chemistry, University of Cologne — [4]Department of Complex Matter, Jožef Stefan Institute

Using anisotropic barium ferrite nanoplatelets in liquid or liquid crystalline (LC) environments, we obtain ferrofluids with anisotropic properties such as nematic formation of the platelets or a magneto-responsive LC system. The aim of this work is to study magnetic hybrid systems with temperature- and field-dependent Mössbauer spectroscopy, which gives us access to the diffusion processes of the particles via line broadening, and to the magnetic orientation behavior based on relative line intensity ratios. As barium ferrite exhibits a rather complex crystal structure, we use reference data of powder samples in order to investigate each individual iron sublattice position of this system. In an approach to analyze anisotropic diffusion and alignment processes more efficiently, spectra are recorded with gamma incidence direction perpendicular and parallel relative to the applied magnetic field. This work is supported by the DFG (LA5175/1-1.).

MA 36.3   Thu 10:00   HSZ 401

High throughput analysis of surface-functionalized superparamagnetic particles in dynamic magnetic field landscapes — •Yahya Shubbak[1,2], Rico Huhnstock[1,2], Kristina Dingel[2,3], Bernhard Sick[2,3], and Arno Ehresmann[1,2] — [1]Institute of Physics & Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, D-34132 Kassel — [2]AIM-ED - Joint Lab Helmholtzzentrum für Materialien & Energie, D-14109 Berlin — [3]Intelligent Embedded Systems, University of Kassel, D-34121 Kassel

The precise manipulation of magnetic micro- and nano-particles in microfluidic environments opens new avenues for investigations of biomolecular analyte detection and interactions.[1] Motion control schemes based on a combination of static magnetic field landscapes superposed with external magnetic field pulses enable translatory motion control of magnetic particles at the nanoscale over macroscopic distances.[3] Here we demonstrate a novel method harnessing AI-enhanced fully-automated optical recognition algorithms [4] to analyze changes in the motion behaviour of such particles due to liquid mediated surface to surface (particle to substrate) interaction.

MA 36.4   Thu 10:15   HSZ 401

Reversible on-chip focusing and clustering of superparamagnetic beads using engineered magnetic domain patterns — •Rico Huhnstock[1], Lukas Paetzold[1], Maximilian Merkel[1], Piotr Kuświk[2], and Arno Ehresmann[1] — [1]Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Str. 40, D-34132 Kassel — [2]Institute of Molecular Physics, Polish Academy of Sciences, M. Smoluchowskiego 17, Poznań 60-179, Poland

To realize fast and reliable point-of-care medical diagnostics, incorporating magnetic particles into a Lab-on-a-chip technology platform is considered promising. For sensitive detection, binding of the analyte species to surface-functionalized particles and subsequent formation of particle aggregates with the analyte acting as molecular bridges is a possible route [1]. As close proximity between particles is required for this scheme, we demonstrate in this work a locally defined focusing of superparamagnetic microparticles within an aqueous medium above a magnetically patterned flat substrate. Combining the magnetic stray field landscape that originates from periodic magnetic stripe domains of gradually decreasing/increasing length with external magnetic field pulses, converging and diverging motion trajectories were induced for the particles. Ultimately, this led to a controlled formation and decomposition of closely packed particle clusters. We will discuss how the observed behavior is determined by the acting forces and how it is influenced by the duration of the external field pulses.

MA 36.5   Thu 10:30   HSZ 401

Distance- and size-dependence of the interactions within highly ordered magnetic nanoparticle mesocrystals — •Nils Neugebauer[1,2], Yi Wang[3], Matthias Elm[1,2], Xingchen Ye[3], Christian Heiliger[1,4], and Peter Klar[1,2] — [1]) Institute of Experimental Physics I, Justus Liebig University Giessen, Heinrich-Buff-Ring 16, 35392 Giessen, Germany — [2]Center for Materials Research (LaMa), Justus Liebig University Giessen, Heinrich-Buff-Ring 16, 35392 Giessen, Germany — [3]Department of Chemistry, Indiana University, Bloomington, Indiana 47405, United States — [4]) Institute for Theoretical Physics, Justus Liebig University Giessen, Heinrich-Buff-Ring 16, 35392 Giessen, Germany

Ferromagnetic resonance (FMR) experiments in combination with micromagnetic simulations are employed to investigate and characterize dipolar interactions between magnetic nanoparticles (MNPs) within such mesocrystals. The MNPs investigated in this work consist of iron oxide (magnetite - Fe3O4) and are coated with non-magnetic polymers, forming highly ordered hexagonal monolayer crystals. The magnetic response of the regularly arranged hexagonal mesocrystals can be tuned in a controlled way by varying the thickness of the non-magnetic polymer coating of the MNPs and thus the lattice constant of the mesocrystal.

The spectral features show distinct dipolar coupling phenomena within the mesocrystal and reveal that the material parameters of the MNPs such as the magnetization and the magnetocrystalline anisotropy are reduced with respect to their bulk counterpart.

MA 36.6   Thu 10:45   HSZ 401

Monte Carlo simulation of the aggregation of confined superparamagnetic colloids — •Javier Valenzuela[1,2], Francisco Gámez[2], and Perla Viveros-Méndez[3] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Complutense University of Madrid, Madrid, Spain — [3]Autonomous University of Zacatecas, Zacatecas, Mexico

The properties of colloidal suspensions of superparamagnetic nanoparticles confined within inorganic and organic cavities have led to a number of interesting applications in areas such as nanomedicine, microfluidics, and nanorobotics. Therefore, predicting the morphology of the structures formed during the aggregation process of these particles under different scenarios is of key scientific interest.

In this work, the Monte Carlo and cluster-moving Monte Carlo methods have been employed to study the aggregated structures formed by magnetic particles confined in spherical (3D) and circular (2D) cavities. The impact of the number of particles, their initial configuration and the pair-potential model between the particles and between the particles and the cavity surface on the aggregated structure is assessed. Moreover, we present an improvement of the cluster-moving Monte Carlo method to increase the computational performance under curved confinement situations. This work provides insights that might prove useful for the development of more efficient simulation strategies that could play a crucial role in the design and prediction of new applications of this relevant type of colloidal systems.

MA 37: Magnetic Heuslers

Time: Thursday 9:30–11:00   Location: HSZ 403

MA 37.1   Thu 9:30   HSZ 403

Enhanced magnetism of antiphase boundaries in Fe$_2$CoAl compound — Martin Friák[1], Josef Gracias[2], Jana Pavlů[2], and •Mojmír Šob[2,1] — [1]Inst. Phys. Mat., Czech Acad. Sci., Brno, Czech Rep. — [2]Dept. Chem., Fac. Sci., Masaryk Univ., Brno, Czech Rep.

We performed a quantum mechanical examination of thermodynamic, structural, elastic, and magnetic properties of single-phase ferromagnetic Fe$_2$CoAl with a chemically disordered B2-type lattice with and without antiphase bound-

aries (APBs) with (001) crystallographic orientation. Fe$_2$CoAl was modeled using two different 54-atom supercells with atoms on the two B2 sublattices distributed according to the special quasi-random structure (SQS) concept. Both computational models used exhibited very similar formation energies (−0.243 and −0.244 eV/atom), B2-structure lattice parameters (2.849 and 2.850 Å), magnetic moments (1.266 and 1.274 μ_B/atom), practically identical single-crystal elastic constants (C$_{11}$ = 245 GPa, C$_{12}$ = 141 GPa, and C$_{44}$ = 132 GPa) and auxetic properties (the lowest Poisson ratio close to -0.1). In contrast to these similari-

ties, the averaged APB interface energies were observed to be 199 and 310 mJ/m^2 for the two models. The studied APBs increased the total magnetic moment by 6 and 8 % due to a volumetric increase as well as local changes in the coordination of Fe atoms (their magnetic moments are reduced for increasing number of Al neighbors but increased by the presence of Co). The APBs also enhanced the auxetic properties.

MA 37.2   Thu 9:45   HSZ 403

VTaNbAl: A new class of spin gapless semiconductor with topological non-trivial features — •Deepika Rani[1], P. C. Sreeparvathy[2], K. Gopi Suresh[2], Ratnamala Chatterjee[1], and Aftab Alam[2] — [1]Department of Physics, Indian Institute of Technology Delhi, Hauz Khas, New Delhi 110016, India — [2]Department of Physics, Indian Institute of Technology Bombay, Mumbai 400076, Maharashtra, India

We report the theoretical prediction of a new class of spin gapless semiconductor (SGS) hosting topological non-trivial features along with a fully compensated ferrimagnetic state in VTaNbAl, a quaternary Heusler alloy. Unlike conventional SGS, this new class of compound acquires a unique band structure with opposite spin characters in the valance and conduction band edges making them potential candidates for spin valves and large anomalous Nernst effect. Interestingly, despite of a compensated ferrimagnetic (CF) behavior, VTaNbAl shows a reasonably large anomalous Hall effect possibly arising from the intrinsic non-vanishing Berry curvature. The CF state breaks the time-reversal symmetry and hence opens the possibility of Weyl nodes. We found four pairs of Weyl nodes located near the Fermi level leading to the non-zero Berry curvature, and hence a large anomalous Hall conductivity (~ 100 S/cm). Our experimental synthesis confirms NbVTaAl to crystallize in a cubic Heusler structure with an A2-type disorder. Magnetization measurement shows a very small saturation moment, which agrees fairly well with our theoretical findings of fully compensated ferrimagnetism in the alloy.

MA 37.3   Thu 10:00   HSZ 403

Long range ordering in NiCoMnAl magnetic shape memory thin films with martensitic intercalations — •Inga Ennen, Dario Stierl, Laila Bondzio, and Andreas Hütten — Thin Films and Physics of Nanostructures, Physics Department, Bielefeld University, 33615 Bielefeld, Germany

Magnetic shape memory Heusler alloys, like NiMnX (X=Al,Ga,Sn,In), are considered as promising materials for magnetocaloric cooling applications due to their magnetoelastic coupling near room temperature. In order to reduce the thermal hysteresis in NiCoMnAl thin films, the usage of alternating active transforming austenitic and martensitic intercalation layers are beneficial. Therefore, the stoichiometry of these two layers is chosen in such a way that their thermal hysteresis does not overlap. If the austenite active layers have a similar thickness compared to the martensite intercalations a 3D check board pattern becomes visible in HRTEM cross section images. The contrast is due to alternating martensite/austenite domains.

In this contribution we aim for an improved understanding of the 3D check board pattern formation. Therefore, the number of the alternating layers as well as the ratio between the thicknesses of the two different layers have been varied. The phase transition has been characterized by temperature dependent XRD and TEM analysis. Furthermore, freestanding Heusler films have been prepared and analyzed in comparison to the substrate-bounded systems.

MA 37.4   Thu 10:15   HSZ 403

Anomalous Hall effect in epitaxial thin films of the hexagonal Heusler MnPtGa noncollinear hard magnet — •Edouard Lesne[1], Rebeca Ibarra[1,2], Bushra Sabir[3], Bachir Ouladdiaf[4], Ketty Beauvois[4], Alexandr Sukhanov[2], Rafal Wawrzynczak[1], Walter Schnelle[1], Anton Devishvili[4], Dmytro Inosov[2], Jacob Gayles[3], Claudia Felser[1], and Anastasios Markou[1] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]Technische Universität Dresden, Dresden, Germany — [3]University of South Florida, Tampa, United States of America — [4]Institut Laue-Langevin, Grenoble, France

Centrosymmetric MnPtGa Heusler films grown by magnetron sputtering on (0001)−Al$_2$O$_3$ crystallize with an out-of-plane c-axis crystal orientation, along which they exhibit perpendicular magnetic anisotropy below their Curie temperature (T_C = 263 K). Further, below a thermally induced spin reorientation transition at 160 K, the magnetic groundstate, determined by single-crystal neutron diffraction, is found to be a noncollinear spin-canted state where the Mn moments tilt 20° away from the c-axis [*Appl. Phys. Lett.* 120, 172403 (2022)].

Furthermore, the anomalous Hall conductivity (AHC) of 20−60 nm thick MnPtGa epitaxial films is found to exhibit a strongly nonmonotonic behaviour as a function of longitudinal conductivity and temperature, whereby the AHC changes sign at T^* = 110 K. Our findings, supported by first-principle calculations, hint at an anomalous Hall effect of intrinsic origin driven by a momentum-space Berry curvature mechanism [*Adv. Mater. Interfaces* 9, 2201562 (2022)].

MA 37.5   Thu 10:30   HSZ 403

Effect of increasing Mn content on twin mobility in Mn-excess Ni-Mn-Ga alloys — •Martin Heczko[1], Petr Šesták[2], and Martin Zelený[1] — [1]Institute of Materials Science and Engineering, Faculty of Mechanical Engineering, Brno University of Technology, Brno, Czech Republic — [2]Institute of Physical Engineering, Faculty of Mechanical Engineering, Brno University of Technology, Brno, Czech Republic

Martensitic phases of Ni-Mn-Ga ferromagnetic shape memory alloy are considered to be useful in various advanced engineering applications due to reported giant magnetic field induced strain (MFIS). The MFIS originates in the high mobility of twin boundaries combined with large magneto-crystalline anisotropy. We calculated the generalized planar fault energy (GPFE) curves using the spin-polarized DFT method implemented in the Vienna Ab Initio Simulation Package (VASP) to reveal the effect of increasing concentration of excess Mn and its magnetic ordering on formation and propagation of twin boundaries. Effects of local arrangement of excess Mn atoms in Ga sublattice has been considered as well.

Our results show that the barriers for nucleation and grow of a twin rise with increasing content of Mn. It results in more difficult twin formation and propagation in compositions far from stoichiometry. This effect is even more enhanced if excess Mn atom in Ga sublattice is located exactly in the planar fault, and when they are ordered antiferromagnetically.

MA 37.6   Thu 10:45   HSZ 403

The impact of disorder on the 4O-martensite of Ni-Mn-Sn Heusler alloy — •Martin Friák[1], Martin Zelený[2,3], Jiří Kaštil[4], Jiří Kamarád[4], Martin Míšek[4], Zdeněk Arnold[4], Ilja Turek[1], Oldřich Schneeweiss[1], and Mojmír Šob[5,1] — [1]Institute of Physics of Materials, Czech Academy of Science, Brno, CZ — [2]Institute of Materials Science and Engineering, Faculty of Mechanical Engineering, Brno University of Technology, Brno, CZ — [3]Faculty of Mathematics and Physics, Charles University, Prague, CZ — [4]Institute of Physics, Czech Academy of Sciences, Prague, CZ — [5]Department of Chemistry, Faculty of Science, Masaryk University, Brno, CZ

We have performed a quantum-mechanical study of thermodynamic, elastic, magnetic and structural properties of four different ferrimagnetic states in Ni$_{1.9375}$Mn$_{1.5625}$Sn$_{0.5}$ martensite. They are modeled by the four-layer modulated 4O structures with Mn-excess atoms randomly distributed in Ni and Sn sublattices. The Mn atoms at the Ni sublattice turn out to play a key role in the system. A reversal of the orientation of their local magnetic moments has a huge impact on the properties of the whole system. The lowest-energy configuration exhibits anti-parallel local magnetic moments of these Mn atoms with respect to the orientation of the total magnetic moment. By testing both elasticity and phonons we conclude that the lowest-energy state is mechanically stable. Vibrational properties of individual atoms are found to be very sensitive to the chemical disorder. For details see Intermetallics 151 (2022) 107708, DOI:10.1016/j.intermet.2022.107708.

MA 38: Micro- and Nanostructured Magnetic Materials

Time: Thursday 11:30–12:45   Location: HSZ 401

MA 38.1   Thu 11:30   HSZ 401

Chemically modulated Fe-Ni cylindrical nanowires with asymmetric magnetic response — •Claudia Fernandez[1,2], Alba Berja[2,3], Lucia Aballe[4], Laura Alvaro[1], Carolina Martin[5], Michael Foerster[4], Ruy Sanz[5], Arantzazu Mascaraque[2], Lucas Perez[1,2], and Sandra Ruiz[6] — [1]IMDEA Nanoscience, 28049, Spain — [2]Materials Physics Department, UCM, 28040, Spain — [3]Institute of Ceramics and Glass (CSIC), 28040, Spain — [4]ALBA Synchrotron, 08290, Spain — [5]National Institute of Aerospace Technology, 28850, Spain — [6]MPI for Chemical Physics of Solids, 01187, Germany

The control of the magnetic domain walls (DWs) movement along cylindrical nanowires (NWs) by means of magnetic fields or electric currents is a key aspect in the design of novel spintronic devices. In recent studies, we have demonstrated that local changes in composition along the axis of Fe20Ni80 nanowires can pin the DWs and that the DWs can be moved under the application of magnetic field. Expanding this concept, in this work we propose a gradual change in Fe/Ni ratio along the axial direction of the nanowires in order to create an asymmetric energy landscape with the aim to induce asymmetric domain wall motion. Combining X-ray imaging techniques (XAS and XMCD) we have cor-

related the chemical structure of single nanowires with their magnetic configuration. In First Order Reversal Curves (FORC) diagrams we have observed that an asymmetry arises evidencing the emerging of asymmetrical magnetization processes in the array.

MA 38.2   Thu 11:45   HSZ 401

Chirality coupling in curvilinear nanoarchitectures — •Oleksii M. Volkov[1], Daniel Wolf[2], Oleksandr V. Pylypovskyi[1,3], Attila Kákay[1], Denis D. Sheka[4], Bernd Büchner[2,5], Jürgen Fassbender[1], Axel Lubk[2,5], and Denys Makarov[1] — [1]Helmholtz-Zentrum-Dresden-Rossendorf, Dresden, Germany — [2]Institute for Solid State Research, IFW Dresdenm Dresden, Germany — [3]Kyiv Academic University, Kyiv, Ukraine — [4]Taras Shevchenko National University of Kyiv, Kyiv, Ukraine — [5]Institute of Solid State and Materials Physics, TU Dresden, Dresden, Germany

Symmetry effects are key building blocks of condensed matter physics as they define not only interactions but also resulting responses for the intrinsic order parameter. Namely, in magnetism geometric curvature governs the appearance of chiral and anisotropic responses [1], that introduce a new toolbox to create artificial chiral nanostructures from achiral magnetic materials [2,3]. Here, we demonstrate both theoretically and experimentally the existence of non-local chiral effects in geometrically curved asymmetric permalloy caps with the vortex texture. We find that the equilibrium vortex core obtain bend and curling deformation, that are dependent on the geometric symmetries and magnetic texture parameters.

MA 38.3   Thu 12:00   HSZ 401

Towards magnetic MXenes via thermal activation of $Ti_3C_2T_x$ and Fe intercalation — •Tim Salzmann[1], Hanna Pazniak[2], Ivan Tarasov[1], Michael Farle[1], and Ulf Wiedwald[1] — [1]University of Duisburg-Essen and Center for Nanointegration Duisburg-Essen, Germany — [2]Université Grenoble Alpes, CNRS, Grenoble INP, LMGP, France

MXenes are 2D materials obtained from a MAX phase precursor. The $Ti_3C_2T_x$ MXene surface is stabilized by a T_x termination in the form of $-F, -Cl, = -O, -OH$ [1]. $Ti_3C_2T_x$ MXenes deposited on $Si(100)/SiO_2$ are annealed at T=1023 K in ultrahigh vacuum removing $-F, -Cl$ and $-OH$ confirmed by in situ mass spectroscopy, and Auger electron spectroscopy (AES). Additionally, we find a reduction of interplanar spacing between MXene sheets $(d_{ini} - d_{ann} = 0.30 \pm 0.04$ nm) by X-ray diffraction (XRD). Subsequently, a 6 nm thick Fe film is deposited and annealed between 550 K and 1000 K. AES displays a linear decrease of the Fe concentration at the surface from 85% to 15% as a function of annealing temperature. The intercalation of Fe is confirmed by XRD measurements showing an increase of the interplanar spacing between MXene sheets $(d_{int} - d_{ann} = 0.16 \pm 0.02$ nm). In plane vibrating sample magnetometry reveals a saturation magnetization of 1728 ± 150 kA/m for the 6 nm Fe film on top of MXenes confirming bulk metallic Fe. After annealing up to 800 K, the magnetization decreases to 660 ± 80 kA/m and the Curie temperature to 485 K. Funded by DFG-Project-ID 405553726-TRR 270.

MA 38.4   Thu 12:15   HSZ 401

Magneto-optical investigation of 3D-curved toroidal ferromagnetic thin films — •Christian Janzen[1], Sapida Akhundzada[1], Bhavadip Bharatbhai Rakholiya[1], Arne Vereijken[1], Claudio Beck[1], Piotr Kuświk[2], Michał Matczak[2,3], Michael Vogel[1,4], and Arno Ehresmann[1] — [1]Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Germany — [2]Institute of Molecular Physics, Polish Academy of Science, Poznań, Poland — [3]Faculty of Physics, University of Białystok, Poland — [4]Department of Materials Science, University of Kiel, Germany

Magnetic thin films, typically examined as flat two-dimensional systems, may be extended to the third dimension by deposition of the magnetic material on curved substrates. To experimentally investigate physical effects induced by the geometry and curvature of a thin film magnet, micron-sized curved structures with minimal surface roughness were prepared by optimized two-photon polymerization lithography processes. These structures are deliberately placed with well-defined lateral as well as axial spacing, leading to periodic arrays where, e.g., the influence of varying magnetostatic interactions between the individual objects can be investigated. In this work, the magnetization reversal of periodic arrays of hemispherical tori with varying lattice geometry of the periodic array will be investigated by magneto-optical Kerr magnetometry/microscopy. The experimental results are further compared with micromagnetic simulations.

MA 38.5   Thu 12:30   HSZ 401

Sprayed Nanometer-Thick Hard Magnetic Coatings with Strong Perpendicular Anisotropy for Data-Storage Applications — •Andrei Chumakov[1], Calvin J. Brett[1,2], Korneliya Gordeyeva[2], Dirk Menzel[3], Lewis O. O. Akinsinde[4], Marc Gensch[1], Matthias Schwartzkopf[1], Wei Cao[5], Shanshan Yin[5], Manuel A. Reus[5], Michael A. Rübhausen[4], Peter Müller-Buschbaum[5,6], Daniel Söderberg[2], and Stephan V. Roth[1,2] — [1]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]DE 118714904 — [3]Notkestraße 85, DESY — [4]Universität Hamburg, Hamburg, Germany — [5]Technische Universität München, Garching, Germany — [6]Heinz Maier-Leibnitz Zentrum, Garching, Germany

We present a study of a facile technology for establishing mono- and multi-layer surfaces from various single-domain flat magnetic nanoparticles that exhibit a strong perpendicular-oriented magnetic moment on solid and flexible substrates. Surfactant-free, hard ferromagnetic and single-domain anisotropic strontium hexaferrite nanoparticles with perpendicular magnetic moment orientation and two different aspect ratios are self-ordered into magnetic thin nanofilms exploiting the templating effect of cellulose nanofibrils and magnetic fields. Uniform magnetic coatings obtained by scalable layer-by-layer spray deposition from a monolayer coverage up to thicknesses of a few tens of nanometers show preferred in-plane orientation of the hard-magnetic nanoparticles.

Topological spin textures stabilised by Weyl fermions — •Juba Bouaziz[1], Gustav Bihlmayer[1], Julie B. Staunton[2], and Stefan Blügel[1] — [1]Peter Grünberg Institut Forschungszentrum Jülich — [2]The university of Warwick

Rare-earth intermetallic (REI) constitute a playground for the realization of topological spin textures relying on Ruderman-Kittel-Kasuya-Yosida (RKKY) interactions between the localized 4f-moments [1]. In non-centrosymmetric REI, namely REAlGe (Si), the breaking of inversion symmetry generates Weyl nodes which display interesting topological properties. The Weyl fermions mediate highly anisotropic RKKY interactions leading to the emergence of Kitaev (KT) and Dzyloshinksii-Moriya (DM) interactions. The incommensurate magnetic order present in these systems can be tied to the nesting of topological Fermi pockets [2]. We perform a systematic first-principles analysis in the framework of the DFT+U for REAlGe (RE=Ce-Gd) and investigate the contributions of the different exchange interactions (isotropic, DM, and KT) to incommensurate order. The local crystal field coefficients are computed from first-principles as well and are used to evaluate the magneto-crystalline anisotropy. Finally, we employ atomistic spin-dynamic simulations and identify the magnetic phases that are stabilized in presence of an external magnetic field. Our analysis aims at drawing a direct connection between the topology of the electronic band structure and the topology of the spin structures in real space. [1] J. Bouaziz et al. PRL 128, 157206 (2022) [2] J. Gaudet et al. Nat Mat 20, 1650 (2021)

MA 39.2   Thu 11:45   HSZ 403

Pressure induced ferromagnetic collapse and valence instability in EuB_6 — •Leonardo Kutelak[1], Raimunda Sereika[2], Gilberto Fabbris[3], Gustavo Lombardi[1], Daniel Haskel[3], Narcizo Souza Neto[1], Priscila Rosa[4], Wenli Bi[2], and Ricardo Reis[1] — [1]Brazilian Synchrotron Light Laboratory (LNLS), Brazilian Center for Research in Energy and Materials (CNPEM),Campinas, Sao Paulo, Brazil — [2]University of Alabama at Birmingham - Birmingham, AL 87545, USA — [3]Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA — [4]Los Alamos National Laboratory - Los Alamos, NM 87545, USA

The only ferromagnetic rare earth hexaboride, EuB_6, presents previously reported interesting behavior such as a two-step magnetic transition below 15 K[1] and magnetic polarons up to 40 K[1]. Most recently, it was proposed that EuB_6 may host non-trivial electronic behavior near Fermi surface presenting either Weyl Points or nodal lines depending upon magnetization ordering and direction. We show evidences for EuB_6 ferromagnetic collapse above 20 GPa with mean valency increase by X-ray spectroscopy techniques. No signs for structural phase transitions were observed in high pressure X-ray diffraction. This opens up new possibilities for fine tuning topological properties utilizing pressure in rare earth hexaborides.

MA 39.3 Thu 12:00 HSZ 403

High pressure studies of the topological Hall effect on CeAlGe — •Mario M. Piva[1], Jean C. Souza[2], Gustavo A. Lombardi[3,1], Kevin R. Pakuszewski[4], Cris Adriano[4], Pascoal G. Pagliuso[4,5], and Michael Nicklas[1] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]The Weizmann Institute of Science, Rehovot, Israel — [3]Brazilian Synchrotron Light Laboratory (LNLS), Campinas, Brazil — [4]"Gleb Wataghin" Institute of Physics, Campinas, Brazil — [5]Los Alamos National Laboratory, Los Alamos, USA

The Weyl semimetal CeAlGe is an excellent playground to investigate non-trivial topologies in real and momentum space due to the presence of a topological magnetic phase [1]. Our findings show that, the THE in CeAlGe is sensitive to slight stoichiometric variations, similar to its magnetism [2]. The observed change of a single THE region to two distinct regions upon application of external pressure is in agreement with previous reports [3]. Remarkably, we find that application of high pressures leads to the appearance of a THE even in samples where it was absent at ambient pressures.

This project has received funding from the European Unions Horizon 2020 research and innovation programme under the Marie Skłodwska-Curie grant agreement No 101019024.

MA 39.4 Thu 12:15 HSZ 403

Magnetic and Electronic Structure of Eu(Cd,Zn)$_2$P$_2$ — •Sarah Krebber[1], Kristin Kliemt[1], Marvin Kopp[1], Charu Garg[1], Jens Müller[1], Kurt Kummer[2], Denis Vyalikh[3], and Cornelius Krellner[1] — [1]Institute of Physics, Goethe-University, Frankfurt (Main), Germany — [2]ESRF, Grenoble, France — [3]DIPC, Donostia-San Sebastián, Spain

The interplay of topology and magnetism has been of great interest in the last few years. The coexistence of both phenomena can be realized in europium based compounds with the 122 stoichiometry and a trigonal crystal structure (P3̄m1). Recently, a spin fluctuation induced Weyl semimetal state in the paramagnetic phase of EuCd$_2$As$_2$ [1,2] and its tunability by pressure [3] was discovered. Fur-

thermore, EuCd$_2$P$_2$ has been explored due to its colossal magnetoresistance [4], where the origin of the effect was explained by the formation of ferromagnetic clusters [5].

With the aim of studying the magnetic and electronic properties of EuCd$_2$P$_2$ compound in detail and finding similar effects in EuZn$_2$P$_2$ both systems were studied. Here, we present the successful crystal growth and characterization via magnetization, electrical transport, heat capacity and spectroscopy.

MA 39.5 Thu 12:30 HSZ 403

Novel thermo-electric transport channel in the conformal limit of tilted Weyl semimetals — Thorvald Ballestad[1], Alberto Cortijo[2], María Vozmediano[3], and •Alireza Qaiumzadeh[1] — [1]Center for Quantum Spintronics, Norwegian University of Science and Technology, Trondheim, Norway — [2]Universidad Autonoma de Madrid, Madrid, Spain — [3]Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain

Recently, a new contribution to the Nernst current was proposed in 3D Dirac and Weyl semimetals, originated from quantum conformal anomaly [1,2]. In the present study, we analyze the effect of the tilt on the transverse thermo-electric coefficient of Weyl semimetals in the conformal limit, i.e., zero temperature and zero chemical potential. Using the Kubo formalism, we find a non-monotonic behavior of the thermoelectric conductivity as a function of the tilt perpendicular to the magnetic field, and a linear behavior when the tilt is aligned to the magnetic field. An "axial Nernst" current is generated in inversion symmetric materials when the tilt vector has a projection in the direction of the magnetic field. This analysis will help in the design and interpretation of thermo-electric transport experiments in recently discovered topological quantum materials [3].

The spectrum of localized excitations of spin nanoclusters and their stability in a magnetic field — •Oksana Charkina[1,2], Mikhail Bogdan[2], and Igor Poltavsky[1] — [1]University of Luxembourg, L-1511 Luxembourg City, Luxembourg — [2]B. Verkin ILTPE of NASU, Kharkiv, 61103, Ukraine

Engineering novel materials with predefined spectral and dynamical properties from recently synthesized giant magnetic molecules, permitting well-controlled exchange interaction, is essential for creating memory elements in modern computer technologies. To provide the necessary theoretical basis, we studied the structure and internal dynamics of spin nanoclusters limited by discrete domain walls in ferromagnetic chains placed in a magnetic field. The spin nanoclusters and their spectra of localized excitations are described analytically within the framework of the discrete Takeno-Homma equation [1], which fully accounts for the exchange interaction between spins. Explicit expressions for the internal mode oscillations were found, and the frequency dependences on the parameters of the exchange and the magnetic field were calculated. In addition, a stripe-like stability diagram and the Peierls energy barrier for the noncollinear discrete domain walls were established. We found that the magnetic field can effectively control the localization of information and energy on spin clusters. Our results can be used in developing spin-cluster resonance methods for investigating magneto-optical properties of a new class of low-dimensional metamaterials.

MA 40.2 Thu 14:00 P2/EG

Curvature-induced effects in dynamics of domain walls in chiral biaxail nanotubes — •Kostiantyn V. Yershov[1,2] and Denis D. Sheka[3] — [1]Leibniz Institute for Solid State and Materials Research, Dresden, Germany — [2]Bogolyubov Institute for Theoretical Physics, Kyiv, Ukraine — [3]Taras Shevchenko National University of Kyiv, Ukraine

Tubular geometry is paradigmatic example for studying numerous chiral effect. The competition between intrinsic Dzyaloshinskii–Moriya interactions (DMI) and geometry-governed DMI become the source of emergent magnetochiral effects leading to essential modification of critical DMI strength, appearance of new type of domain walls (DWs) [1]. Here, we present a detailed study of static and dynamic properties of DWs in chiral biaxial nanotubes. The easy and hard axes are oriented in azimuthal and radial directions, respectively. (i) First, we considered the static properties of magnetic DWs in nanotubes with different symmetries of DMI. We found that the presence the chiral interaction results in the deformation of the DW profile: for interfacial type of DMI the DW phase has an asymmetrical slope; for bulk type of DMI the DW phase has a linear shift. In both cases deformation is proportional to the strength of DMI (ii) Dynamics of DWs with interfacial DMI results in the linear shift of the Walker field. While, for the case of the a bulk type of DMI we show that the presence of chiral interation results in the emergent magnetochiral effect, i.e. the polarity-helicity coupling. [1] K. Yershov et al, SciPost Phys. **9** (2020), 043.

MA 40.3 Thu 14:00 P2/EG

Dynamics of bound domain walls in the 3D magnetic double helix — •Imelda Pamela Morales Fernandez[1], Sandra Ruiz-Gómez[1], Aurelio Hierro-Rodríguez[2], Simone Finizio[3], Sebastian Wintz[4], Näemi Leo[5], Markus König[1], Claas Abert[6], Dieter Süss[6], Amalio Fernandez-Pacheco[5], and Claire Donnelly[1] — [1]Max Planck Institute for Chemical Physics of Solids — [2]University of Oviedo — [3]Paul Scherrer Institute — [4]Helmholtz Center Berlin — [5]Institute of Nanoscience and Materials of Aragon — [6]University of Vienna

Magnetic domain walls are stable magnetic textures that promise exciting opportunities for advances in technological applications in a wide range of fields. In contrast with their 2D counterparts, DWs in 3D nanosystems can exhibit more complex configurations, with prospects for exotic dynamic behavior. In this framework, double helix nanostructures combine geometrical effects of curvature and chirality with intrinsic exchange and magnetostatic coupling giving rise to a new state consisting of a highly coupled pair of domain walls (head-to-head and tail-to-tail) within the neighboring helices. The cobalt double helix fabricated by the FEBID technique is an ideal platform to experimentally investigate the static and dynamic properties of the coupled domain walls: it is a trustworthy platform to induce the vortex and antivortex textures in the magnetic field of the coupled domain wall state and on the other hand it is a promising system to achieve robust DW motion and synchronous dynamics with ultra-high DW mobilities overcoming the Walker breakdown.

MA 40.4 Thu 14:00 P2/EG

Current-induced creation of domain walls in synthetic antiferromagnets — Robin Msiska[1], •Omer Fetai[1], Raphael Kromin[2], Davi Rodrigues[3], and Karin Everschor-Sitte[1,4] — [1]TWIST group, University of Duisburg-Essen, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, Germany — [3]Politecnico di Bari, Italy — [4]Center for Nanointegration Duisburg - Essen (CENIDE)

Improvements in the storage capacity of modern-day memory devices are slowing down and new concepts for storing data are required. A suggestion for a three-dimensional data storage is the racetrack memory which stores information in terms of magnetic domains. The use of synthetic antiferromagnets (SAF), i.e., antiferromagnetically coupled ferromagnetic bilayer systems, accelerates the information access time because the domain walls can be moved up to ten times faster [1]. To obtain a market-ready device, many challenges must be overcome, one of which is integrating a controlled domain wall write process into SAFs. We study the controlled creation of domain walls in SAFs by electrical means. In the case of spin-transfer torques, we find a critical current strength above which antiferromagnetic domain walls are created from an inhomogeneity. In contrast to the ferromagnetic case [2] we show that the critical current density is an order of magnitude higher.

MA 40.5 Thu 14:00 P2/EG

Imaging the antiferromagnetic domain structure of α-Fe2O3 and its magnetic field dependence — •Julian Skolaut[1], Kai Litzius[2,3], Markus Weigand[4], Olena Gomonay[1], Elizaveta Tremsina[5], Sebastian Wintz[3,4], Norman Birge[6], Geoffrey Beach[5], and Angela Wittmann[1] — [1]Johannes Gutenberg University, Mainz — [2]University Augsburg — [3]MPI Intelligent Systems, Stuttgart — [4]HZB, Berlin — [5]MIT, Cambridge, USA — [6]Michigan State University, East Lansing, USA

In recent years, antiferromagnets have gained increasing attention for spintronics applications due to their favorable properties such as vanishing stray fields. Moreover, the domain structure formation mechanism is different from ferromagnets. Here, we study the canted antiferromagnet hematite α-Fe2O3. The canting of the spins yields a small in-plane magnetization, lifting the degeneracy of the Néel vector orientation w.r.t. an external magnetic field. Our measurements investigate the magnetic domain structure of hematite, specifically the movement of domain walls by application of an external magnetic field. For this, we have imaged the domain structure of α-Fe2O3 by taking x-ray magnetic linear dichroism (XMLD) contrast images of the domain structure of α-Fe2O3 by total electron yield using a scanning x-ray microscope. This method allows imaging the domain structure within an applied magnetic field and studying the domain structure, as well as the displacement of domain walls as a function of the magnetic field. A thorough analysis of the changes in domain structure will elucidate the underlying mechanisms for the formation of magnetic domains.

MA 40.6 Thu 14:00 P2/EG

Tuning all-optical magnetization switching efficiency by laser pulse wavelength variation — •Marcel Kohlmann[1], Lucas Vollroth[1], Kristýna Hovořáková[2], Eva Schmoranzerová[2], Robin John[4], Denise Hinzke[4], Peter Oppeneer[3], Ulrich Nowak[4], Markus Münzenberg[1], and Jakob Walowski[1] — [1]Greifswald University, Greifswald, Germany — [2]Charles University, Prague, Czech Republic — [3]Uppsala University, Uppsala, Sweden — [4]Konstanz University, Konstanz, Germany

The relevance of heat-assisted magnetic recording (HAMR) motivates ongoing research and development in magnetization manipulation. We study all-optical helicity-dependent switching (AOHDS) of FePt granular media as a viable alternative method for magnetic writing of HAMR media. The interplay of magnetic dichroism and inverse Faraday effect is currently understood as driving process behind the magnetization reversal. Ab-initio calculations of magnetic dichroism and inverse Faraday effect for the switching rates of single FePt nano particles provided us with a stochastic model for the switching process. We now present data for the wavelength dependent efficiency of the writing process from 800 nm - 1550 nm. We greatly acknowledge the DFG funding within the project "Fundamental aspects of all-optical single pulse switching in nanometer-sized magnetic storage media.

MA 40.7 Thu 14:00 P2/EG

Coherent excitation of spin waves in thin nickel films during ultrafast remagnetization — •Akira Lentfert[1], Anulekha De[1], Laura Scheuer[1], Benjamin Stadtmüller[1,2], Burkard Hillebrands[1], Georg von Freymann[1,3], Martin Aeschlimann[1], and Philipp Pirro[1] — [1]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, Germany — [3]Fraunhofer Institute for Industrial Mathematics ITWM, Germany

The remagnetization process after ultrafast demagnetization can be described by relaxation mechanisms between the spin, electron, and lattice reservoirs. The angular momentum transfer between them is the subject of current research, especially the role of collective spin excitations remains comparably unexplored. In our work, we study the pump fluence-dependent excitation of coherent spin waves in thin nickel films. Using the all-optical, time-resolved magneto-optical Kerr-effect (tr-MOKE) technique, we investigate the role of coherent spin waves after the laser-induced demagnetization. We show that the largest spin-wave amplitude is observed close to the fully demagnetized state. Furthermore, the coherence of the system appears to be conserved during de- and remagnetization, even when the magnetization is quenched by up to 90%. Interestingly, the phase of the coherent oscillations relative to the initial laser pulse is strongly dependent on the laser fluence which indicates that the coherent precession is influenced by the demagnetization itself. This research was supported by the DFG through No. TRR 173-268565370 (project B11).

MA 40.8 Thu 14:00 P2/EG

Laser-induced ultrafast magnetization dynamics in Ni|Au heterostructures — •Stephanie Roden[1], Christopher Seibel[1], Marius Weber[1], Martin Stiehl[1], Sebastian T. Weber[1], Martin Aeschlimann[1], Benjamin Stadtmüller[1,2], Hans Christian Schneider[1], and Bärbel Rethfeld[1] — [1]Department of Physics and Research Center OPTIMAS, RPTU, Kaiserslautern, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, Germany

Studying the optically induced magnetization dynamics of heterostructures has provided clear insights into the particle and energy transport effects on ultrafast timescales. This understanding leads to new concepts to control the magnetization dynamics by tuning the wavelength of optical excitation [1, 2, 3].

In this contribution we demonstrate how the magnetization dynamics of Ni|Au heterostructures can also be controlled by the thickness of the non-magnetic gold layer. Our conclusions are based on an extended temperature-based μT-model which includes the thickness-dependent absorption profile. We find that thin gold films slow down the demagnetization process of nickel while the demagnetization times decrease again for larger gold film thicknesses. Furthermore we consider transport effects within the gold layer and demonstrate the dependence of the induced spin polarization into the substrate on the considered depth in the substrate.

MA 40.9 Thu 14:00 P2/EG

Optical manipulation of magnetic order parameter in magentic insulators by ultrashort laser pulses — •Paul Herrgen[1], Benjamin Stadtmüller[1,2], and Martin Aeschlimann[1] — [1]Department of Physics and Research Center OPTIMAS, Technische Universität Kaiserslautern, 67663 Kaiserslautern, Germany — [2]Institute of Physics, Johannes Gutenberg-Universität Mainz, 55128 Mainz, Germany

Magnetic insulators are highly intriging materials for high performance and sustainable magnetic storage technology. However, the existance of a band gap of several eV makes it rather challenging to optically manipulate these materials on an ultrafast, fs timescale.

Here, we used strong fs laser pulses with high photon energies to optically overcome this bandgap. Using a second ultrashort laser pulse, we were able to measure the dynamics of the magnetic order parameter of this insulator in a time-resolved manner. We find that the optical excitation leads to a fast reduction of the magnetic order on a subpicosecond time scale. In addition, the remagnetization process takes more than 100ps to fully return to the initial magnetic ground state.

MA 40.10 Thu 14:00 P2/EG

Laser-induced metamagnetic phase transition of FeRh studied by combined UXRD and MOKE experiments — •Maximilian Mattern[1], Jasmin Jarecki[1], Vojtech Uhlir[2], Jon Ander Arregi[2], and Matias Bargheer[1,3] — [1]Institut für Physik und Astronomie, Universität Potsdam, Germany — [2]CEITEC BUT, Brno University of Technology, Czech Republic — [3]Helmholtz-Zentrum Berlin, Germany

We use time-resolved x-ray diffraction (UXRD) and the time-resolved polar magneto-optical Kerr effect (MOKE) to study the laser-induced metamagnetic phase transition in FeRh. The first-order phase transition from an antiferromagnetic (AFM) to a ferromagnetic (FM) phase is accompanied by a gigantic expansion ($\approx 0.6\%$) of the unit cell. While UXRD access the transient FM volume fraction independent of the orientation of the magnetic moment probing the enhanced lattice constant, MOKE is sensitive on the orientation of the magnetization probing the net out-of-plane magnetization.

Our combined UXRD and MOKE experiments access the nucleation, growth and coalescence of the arising FM domains and disentangle their in- and out-of-plane expansion by comparing two samples, with a thickness below and above the optical penetration depth. The thin FeRh film displays a fluence-independent rise time of the FM phase of 8 ps and a much slower rise of the net magnetization within 150 ps starting 10 ps after excitation. For the inhomogeneously excited film, we observe a strong fluence dependence of these rise times originating from an out-of-plane growth of the FM domains by heat transport.

MA 40.11 Thu 14:00 P2/EG

Consequences of Orbital Angular Momentum of Light for Electronic Dynamics — •Marvin Goronczy and Hans Christian Schneider — Physics Department, RPTU Kaiserslautern, 67653 Kaiserslautern

Recent experiments show that the orbital angular momentum (OAM) of laser pulses affects the demagnetization dynamics in ferromagnets by slowing it down or speeding it up depending on the direction of the orbital angular momentum. [1] Motivated by these experiments, we consider here the basic problem of the interaction of OAM-light with electrons in a generic band structure in order to study the effect of OAM-light on the electronic system, without attempting to include demagnetization dynamics yet. We derive the dynamical equations for the reduced electronic density matrix and its Wigner transform. We discuss the role played by different contributions, such as multipole transitions and the inhomogeneities introduced by the beam profile. Finally, we compare our results with earlier approaches to this problem.[2]

MA 40.12 Thu 14:00 P2/EG

Magnetization dynamics in magnetic trilayers with a wedged antiferromagnetic spacer layer at ultrafast timescales — •Jendrik Gördes[1], Ivar Kumberg[1], Chowdhury Awsaf[1], Rahil Hosseinifar[1], Marcel Walter[1], Tauqir Shinwari[1], Sangeeta Thakur[1], Christian Schüssler-Langeheine[2], Niko Pontius[2], and Wolfgang Kuch[1] — [1]Institut für Experimentalphysik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Albert-Einstein-Straße 15, 12489 Berlin

We studied the time-resolved magnetization dynamics of an epitaxially grown heterostructure comprised of an antiferromagnetic (AFM) Mn wedge sandwiched between two ferromagnetic (FM) Co layers on Cu(001). The two FM layers were coupled indirectly by the Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction and directly exchange coupled through the AFM spin structure, leading to parallel or antiparallel alignment of the FM layers, depending on the Mn thickness [1]. Deposition of Mn in a wedge allowed for access to different coupling regimes on the same sample. Magnetization dynamics were observed after excitation with 800 nm laser pulses by X-ray magnetic circular dichroism (XMCD) in resonant soft X-ray reflectivity. We point out the effect an antiferromagnetic spacer layer has on the magnetization dynamics of the FM layers.

MA 40.13 Thu 14:00 P2/EG

Anomalous relaxation dynamics of different types of impurity models — •Michael Elbracht and Michael Potthoff — I. Institute of Theoretical Physics, University of Hamburg, Germany

The real-time relaxation dynamics of different types of one-dimensional lattice models with two additional impurities is investigated numerically. We study purely classical, purely quantum mechanical as well as semiclassical systems: (i) a model with two classical spins exchanged coupled to the classical Heisenberg model, (ii) two classical spins exchanged coupled to a tight-binding model of independent electrons, and (iii) a model with the spins replaced by two additional orbitals locally hybridizing with the tight-binding chain.

After an initial local excitation of the impurities, we trace the real-time dynamics by solving the respective fundamental equations of motion. Depending on the exact position of the impurities, the system does or does not fully relax to its local ground state. In all cases, one observes for an even distance between

the impurities and after a prerelaxation to a low-energy state, that the system is trapped in a stationary oscillatory mode. Various mechanisms for this incomplete relaxation are considered, including the dynamical emergence of conserved local quantities.

MA 40.14 Thu 14:00 P2/EG

Spin reduction in the covalent chain antiferromagnets $RbFeSe_2$ and $KFeS_2$ — •Z. Seidov[1], H.-A. Krug von Nidda[1], A. Kiiamov[2], M. Kuznetsov[2], V. Tsurkan[2,3], I. Filippova[3], D. Croitori[3], F. Mayr[1], S. Widmann[1], F. Vagizov[2], D. Tayurskii[2], and L. Tagirov[2] — [1]EPV, EKM, Institute of Physics, University of Augsburg, D-86135 Augsburg, Germany — [2]Kazan, Russia — [3]Institute of Applied Physics, MD-20208 Chisinau, Moldova

SQUID susceptibility, Mössbauer and specific-heat measurements show that $RbFeSe_2$ and $KFeS_2$ exhibit antiferromagnetic order below T_N = 248 K and T_N = 251 K, respectively. The magnetic specific heat and the spin state of the Fe^{3+} ions in the compounds have been analyzed. Phonon dispersion and phonon density of states (PDOS), were evaluated from first-principles calculations. Analysis of our Mössbauer data, utilizing the calculated Fe PDOS, as well as our optical absorption measurements have shown full agreement with the location of the high-frequency optical-type lattice vibrations within the FeX_4 (X = S, Se) tetrahedra. The phonon contribution to the heat capacity has been calculated from the PDOS and subtracted from the experimental data to extract the magnetic specific heat of the quasi 1D antiferromagnetically correlated Fe^{3+} ion chains. The corresponding magnetic entropy suggests a reduced spin value for the Fe^{3+} ions in both compounds, which seems to be close to an intermediate spin state $S = 3/2$ in $RbFeSe_2$ and to a low-spin state $S = 1/2$ in $KFeS_2$.

MA 40.15 Thu 14:00 P2/EG

Growth optimization and magnetotransport properties of ferromagnetic gadolinium nitride (GdN) thin films — •Raphael Hoepfl[1,2], Manuel Müller[1,2], Johannes Weber[1,2], Matthias Opel[1], Stephan Geprägs[1], Hans Huebl[1,2,3], Rudolf Gross[1,2,3], and Matthias Althammer[1,2] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), München, Germany

Ferromagnetic (FM) semiconductors are of great interest for spintronic devices. Gadolinium nitride (GdN) is one candidate for a FM semiconductor with a Curie temperature T_C=65-70 K [1]. By performing SQUID magnetometry and magnetotransport experiments in a cryogenic environment, we investigate the static magnetic and magnetoresistive properties of GdN thin film heterostructures. Tantalum nitride (TaN)/GdN/TaN trilayers are grown on the thermal oxide of Si substrates using DC magnetron sputtering, where the TaN is used as a electrically conductive seed and top layer. We study the impact of the various deposition parameters, such as deposition pressure, substrate temperature, growth rate and reactive N_2 gas flow on the static magnetic properties of GdN such as T_C and saturation magnetization M_s. For GdN layer stacks grown with our optimized recipe, we perform magnetotransport experiments and identify the origin of magnetoresistance in our heterostructures.

MA 40.16 Thu 14:00 P2/EG

Tuning the physical properties of La0.7Sr0.3MnO3-δ via oxygen off-stoichiometry using thermal annealing — •Chenyang Yin[1], Lei Cao[1], Suqin He[2], Tomas Duchon[3], Yunxia Zhou[4], Oleg Petracic[1], and Thomas Brückel[1] — [1]Jülich Centre for Neutron Science (JCNS-2) and Peter Grünberg Institut (PGI-4), JARA-FIT, Forschungszentrum Jülich GmbH, Jülich, Germany — [2]Peter Grünberg Institut (PGI-7), JARA-FIT, Forschungszentrum Jülich GmbH, Jülich, Germany — [3]Peter Grünberg Institut (PGI-6), JARA-FIT, Forschungszentrum Jülich GmbH, Jülich, Germany — [4]Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Dresden, Germany

The oxygen off-stoichiometry in La0.7Sr0.3MnO3-δ (LSMO) thin films on SrTiO3 (STO) substrates has been investigated employing Al-assisted vacuum annealing. The gradual deoxygenation during annealing induces a topotactic phase transition from the as-prepared Perovskite (PV, ABO3) phase to a layered oxygen-vacancy-ordered Brownmillerite (BM, ABO2.5) phase. The structural change is monitored by XRD. A metal-to-insulator and simultaneously a ferromagnetic (FM)-to-antiferromagnetic (AF) transition is found. The variation of the manganese oxidation state is characterized using XAS. The BM phase shows in magnetization vs. temperature curves a peculiar peak above room temperature which cannot be explained within the usual AF ordering at low temperatures. Moreover, to elucidate the role of the strain to the substrate, bulk-like LSMO powder samples were prepared and annealed at similar conditions as the film samples. Also here the PV-BM phase transition is achieved.

MA 40.17 Thu 14:00 P2/EG

Growth and characterization of $Ca_xSr_{1-x}RuO_3$ ($x = 0, 0.3, 0.5, 0.7$) and $Sr_4Ru_3O_{10}$ single crystals — •Zahrasadat Ghazinezhad[1], Akshay Tewari[1], Agustinus Agung Nugroho[2], Kevin Jenni[1], and Markus Braden[1] — [1]II. Physikalisches Institut, Universität zu Köln, Zülpicher Straße 77, D-50937 Köln, Germany — [2]Faculty of Mathematics and Natural Sciences, Institut Teknologi Bandung, Jl. Ganesha 10, Bandung 40132, Indonesia

The Ruddlesden-Popper (RP) series of strontium ruthenates $Sr_{n+1}Ru_nO_{3n+1}$ manifests an interesting variety of phenomena. Here we focus on the crystal growth and on the detailed characterization of the ferromagnetic $SrRuO_3$ (n=∞, 1-1-3) and $Sr_4Ru_3O_{10}$ (n=3, 4-3-10) systems. A peculiar property of the mixed 1-1-3 materials $Ca_xSr_{1-x}RuO_3$ with $x = 0, 0.3, 0.5, 0.7$ concerns the tuning of electronic and magnetic features by substitution of smaller Ca^{2+} ions into the Sr^{2+} sites while not changing the electronic configuration [1].The triple-layer ruthenate compound $Sr_4Ru_3O_{10}$ exhibits a ferromagnetic transition at $T_C = 105K$ followed by an additional magnetic transition at $T_M = 50K$ which remains matter of controversy. This layered material also shows strong anisotropy concerning the application of magnetic fields [2]. Large single-crystals of $Sr_4Ru_3O_{10}$ could be grown by the floating-zone technique and were characterized by structural and magnetization measurements.

MA 40.18 Thu 14:00 P2/EG

Analysis of Exchange Bias training effect in Exchange coupled LaFeO3 /NiO nanocomposite — •Priyanka Sharma[1] and Ratnamala Chatterjee[2] — [1]Indian Institute of Technology Delhi, New Delhi 110016, India — [2]Indian Institute of Technology Delhi, New Delhi 110016, India

Existence of exchange bias (EB) resulting from antiferromagnetic/ferromagnetic interface is well known in the literature. EB phenomenon is characterized by the horizontal shift of the magnetic hysteresis loop as the system is cooled through Neel's temperature in presence of an external magnetic field. EB is the backbone of designing magnetic storage devices and is among the modern approaches to spintronics. One of the interesting characteristics of EB is the training effect [1]. In this work, we investigate the EB training effect (TE) in LaFeO3/NiO nanocomposite synthesized by a chemical route. The consecutive measurement of field cooled (60 kOe) magnetic hysteresis loops at 5 K show that the exchange bias field (HE) decreases with the increasing number of cycles of M-H loops (n) confirming the presence of the TE effect in our sample. The experimentally observed trend between HE and n was fitted using the power law and Binek's recursive relation. From the Binek's recursive relation, the obtained value of HE infinity (EB field in the limit of infinite loops) and γ (sample dependent constant) is 1118 Oe & 6.9X10^(-7) (Oe)-2, respectively. Both, the power law and Binek's recursive relation points coincide well with the experimental observations.

Impact of Currents on SDW Order in Sr_2RuO_4 — •Felix Wirth, Thomas Lorenz, and Markus Braden — II. Physikalisches Institut, Köln, Germany

Unconventional superconductivity and magnetic correlations are expected to be closely coupled in Sr_2RuO_4. Ca- and Ti-doped Sr_2RuO_4 exhibit incommensurate (IC) spin density wave (SDW) order below about 20 K appearing at the same wave vector where IC antiferromagnetic spin fluctuations exist in the pure compound. A recent attempt to explain the magnetic order induced by Ti-doping, proposed a potential enhancement of the SDW order by applying an external charge current[1]. To prove this idea Sr_2RuO_4 single crystals doped with 25 % Ca or with 9 % Ti were grown by the optical floating zone technique. The crystal quality was greatly improved during the iterative process of crystal growth. For the investigations of the impact of currents on the SDW order, the MPMS SQUID magnetometer was adapted. No influence of currents on the SDW state was observed that could not be attributed to sample heating issues. Recorded I-U characteristics did not reveal correlations between the SDW and the electronic properties of the system. Thermal expansion shows significant differences for both cases. The thermal expansion of the Ca-doped crystal qualitatively agrees with results for higher Ca concentrations but does not indicate connections to the SDW state. A negative thermal expansion at low temperatures in the Ti-doped crystal may point to a weak correlation to the SDW state but it also resembles the behaviour in pure Sr_2RuO_4.

Magnetic phases in the perovskite vanadate ErVO3 — •Elaheh Sadrollahi[1], Jochen Litterst[2], Tobias Ritschel[1], and Jochen Geck[1] — [1]Institut für Festkörper- und Materialphysik, Technische Universität Dresden, 01069 Dresden, Germany — [2]Institut für Physik der Kondensierten Materie, Technische Universität Braunschweig, 38106 Braunschweig, Germany

The perovskite-type vanadium oxide, ErVO3, with Jahn-Teller active t2g electrons at the V site, is a prototypical correlated electron system with orbital degrees of freedom [1-3]. It features an intimate interplay between spin, orbital, and lattice interactions leading to several magnetic transitions. We have performed muSR on the perovskite vanadate ErVO3. Magnetic susceptibility, specific heat, and neutron diffraction measurements on single crystals reveal orbital ordering and orbital-flipping transitions, as well as spin ordering/spin reorientation transitions. Our muSR survey picks up these magnetic transitions and spin freezing of about 20% of the sample volume below 3 K. [1] P. Telang et al, Journal of Crystal Growth 507, 406-412 (2019) [2] P. MA 40.21 Thu 14:00 P2/EG

Theoretical investigation of magnetic order in crystals with space group $I4_1md$ — •Maurice Colling[1] and Jan Masell[1,2] — [1]Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany — [2]RIKEN CEMS, Wako, Japan

Non-collinear magnetic textures with short ranged modulation in the magnetization exhibit novel transport behavior. Such textures have been proposed to be useful in next generation magnetic memory devices. [1] Materials in the space group $I4_1md$ (#109), such as the Weyl semimetal GdAlSi, are interesting candidates for investigations in this direction because of the many potentially competing interactions. Long-ranged RKKY interaction might stabilize atomic scale spin spirals. Broken inversion symmetry generates an interfacial Dzyaloshinskii-Moriya interaction which favors Néel type spirals. Dipolar interactions, in turn, favor Bloch type helices. We derive a phenomenological Hamiltonian based on symmetry analysis and present the rich phase diagram.

MA 40.22 Thu 14:00 P2/EG

Crystal structural investigations of frustrated 3D spin-$\frac{1}{2}$ system $CuSn(OH)_6$ — •Kaushick Parui[1], Anton Kulbakov[1], Ellen Häussler[2], Thomas Doert[2], Vladimir Pomjakushin[3], Dmytro Inosov[1], and Darren Peets[1] — [1]IFMP, TU Dresden, Germany — [2]Professur f. Anorganische Chemie II, TU Dresden, Germany — [3]LNS, Paul Scherrer Institut, Switzerland

Copper tin hydroxide, $CuSn(OH)_6$ is an A-site-vacant double perovskite with the general stoichiometry $\square_2(BB')(OH)_6$, where B and B' are transition metals. Here, the magnetic Cu^{2+} ions sit on a face-centred sublattice, which makes the system frustrated and is expected to exhibit exotic quantum magnetism. Room-temperature x-ray diffraction performed on polycrystalline samples reveals tetragonal $P4_2/n$ symmetry, possibly with a minor monoclinic distortion. The structure is characterized by the presence of alternating corner-sharing $[Cu^{2+}(OH)_6]$ and $[Sn^{4+}(OH)_6]$ at 4d and 4c sites, respectively. Low-temperature neutron diffraction performed on deuterated powder samples accurately determined hydrogen positions. The positions of other atoms differ significantly from the previously published structure. Our proposed crystal structure of $CuSn(OH)_6$ is consistent with the tilt system $a^+a^+c^-$, as compared to the earlier proposed $a^0b^+b^+$. Magnetization measurements reveal a weak anomaly at 4.1 K suggesting a possible magnetic transition. Surprisingly, magnetic neutron diffraction revealed no long-range order down to 1.6 K. The Curie-Weiss temperature of −7.1(3) K, indicating antiferromagnetic interactions, and a paramagnetic moment of ≈ $2.2\mu_B$ were also determined.

MA 40.23 Thu 14:00 P2/EG

Magnetoelastic Coupling, Grüneisen Scaling and Magnetic Phase Diagram of the Kitaev Material $Na_2Co_2TeO_6$ — •Marius Säubert[1], Jan Arneth[1], Kwang-Yong Choi[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Department of Physics, Sungkyunkwan University, Republic of Korea

We report high-resolution thermal expansion and magnetostriction measurements on the Kitaev candidate material $Na_2Co_2TeO_6$ down to low temperatures and up to high magnetic fields. Our data enable us to quantify magnetoelastic coupling and identify dominant energy scales by means of Grüneisen analysis. Combined magnetisation and magnetostriction studies reveal a hitherto unreported, field-induced crossover for $B||c$ accompanied by a sign change of $\partial T_N/\partial B$. For magnetic fields applied parallel to the honeycomb planes, magnetostriction shows that the anomaly in magnetisation at $B_C \simeq 6$ T, which has recently been speculated to mark the onset of magnetic disorder, is connected to discontinuous lattice changes. Finally, our dilatometric studies allow us to construct the magnetic phase diagram of $Na_2Co_2TeO_6$ which displays strong hysteresis at low temperatures.

MA 40.24 Thu 14:00 P2/EG

Non-Coplanar Magnetic Orders in Classical Square-Kagome Antiferromagnets — •Martin Gembé[1], Heinz-Jürgen Schmidt[2], Ciarán Hickey[1], Johannes Richter[3,4], Yasir Iqbal[5], and Simon Trebst[1] — [1]Institute for Theoretical Physics, University of Cologne, Germany — [2]Fachbereich Physik, Universität Osnabrück, Germany — [3]Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Germany — [4]Max-Planck-Institut für Physik Komplexer Systeme, Dresden, Germany — [5]Department of Physics and Quantum Centers in Diamond and Emerging Materials (QuCenDiEM) group, Indian Institute of Technology Madras, India

Motivated by the recent synthesis of $KCu_6AlBiO_4(SO_4)_5Cl$, we study the classical Heisenberg model on the square-kagome lattice – also called the squagome or shuriken lattice. This cousin of the kagome lattice exhibits, already on the classical level, a rich phenomenology of frustrated magnetism including residual entropy, order-by-disorder, and non-coplanar ordering tendencies. Having in mind that upon introducing quantum fluctuations, non-coplanar order melts into chiral spin liquids, we explore the multitude of non-coplanar orders including some which break rotational symmetry (possibly leading to nematic quantum orders), for an elementary, classical Heisenberg model on the squagome lattice supplemented by cross-plaquette interations.

MA 40.25   Thu 14:00   P2/EG

Frustrated Low-dimensional Copper Compounds Bluebellite and Rouaite.
— •Aswathi Mannathanath Chakkingal[1], Falk Pabst[2], Vladimir Pomjakushin[3], Maxim Avdeev[4], Roman Gumeniuk[5], Darren Peets[1], and Dmytro Inosov[1] — [1]IFMP, TU Dresden, Germany — [2]Professur f. Anorganische Chemie II, TU Dresden, Germany — [3]PSI, Switzerland — [4]ANSTO, Australia — [5]Institut für Experimentelle Physik, TU Bergakademie Freiberg, Germany

The hydrothermal technique is an efficient strategy to synthesize mineralogically inspired structures, including natural and synthetic cuprate minerals with a variety of exciting frustrated magnetic lattices. We report the hydrothermal synthesis of bluebellite ($Cu_6[(IO_3)(OH)_3](OH)_7Cl$) and rouaite ($Cu_2(NO_3)(OH)_3$). Neutron diffraction studies were performed to determine both compound's crystal structure and magnetic structure. $Cu_2(NO_3)(OH)_3$ crystallizes in a monoclinic structure consisting of a ferromagnetic chain and an antiferromagnetic chain of Cu^{2+}. This is similar to the botallackite ($Cu(OH)_3Br$) in which spinon-magnon mixing was recently reported. $Cu_6[(IO_3)(OH)_3](OH)_7Cl$ crystallizes in a trigonal structure, and the magnetic Cu^{2+} forms a distorted maple-leaf lattice. Frustration effects and quantum fluctuations in spin-1/2 maple-leaf lattice antiferromagnets may give rise to interesting phenomena. We report details of the crystal structure, magnetic structure, and the low-temperature magnetic and thermal properties.

MA 40.26   Thu 14:00   P2/EG

Variational iPEPS —
•Erik Weerda[1], Jan Naumann[2], Matteo Rizzi[3], Jens Eisert[1], and Philipp Schmoll[1] — [1]Institute for Theoretical Physics, University of Cologne, D-50937 Köln, Germany — [2]Dahlem Center for Complex Quantum Systems and Institute for Theoretical Physics, Freie Universität Berlin, 14195 Berlin, Germany

Tensor networks capture large classes of ground states of phases of quantum matter faithfully and efficiently. Their manipulation and contraction has remained a challenge over the years, however. For most of the history of projected entangled pair states, ground state simulations of two-dimensional quantum lattice systems using (infinite) projected entangled pair states have relied on what is called a time-evolving block decimation. In recent years, multiple proposals for the variational optimization of the quantum state have been put forward, overcoming accuracy and convergence problems of previously known methods. The incorporation of automatic differentiation in tensor networks algorithms has ultimately enabled a new, flexible way for variational simu- lation of ground states and excited states. In this work, we present and explain the functioning of an efficient, comprehensive and general tensor network library for the simulation of infinite two-dimensional systems using iPEPS, with support of different lattice geometries, flexible unit cells, the use of symmetries and GPU calculations.

MA 40.27   Thu 14:00   P2/EG

Charge dynamics in doped frustrated magnets and quantum spin liquids —
•Luke Staszewski and Alexander Wietek — Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany

The advent of recent developments in algorithms, namely finite temperature tensor network related algorithms, has opened the doors to a serious numerical testbed for investigating the plethora of interesting phenomenology in strongly interacting electron systems. This testbed is taking us a step closer to understanding an array of systems displaying unconventional superconductivity as well as helping answer questions about the delicate interplay between magnetic correlations and the onset of superconductivity in such materials. This work looks at how the mobility of holes is affected by various magnetic environments and vice versa in the hope to shed some more light on the nature of the mechanisms at play in the resulting phases that have recently been demonstrated both numerically and experimentally. We focus on the role geometric magnetic frustration plays in leading to both unconventional superconductivity, and exotic magnetic order, such as quantum spin liquids.

MA 40.28   Thu 14:00   P2/EG

Micromagnetic simulation of magnetic reversal processes in exchange biased thin film geometries —
•Lukas Paetzold, Sapida Akhundzada, Christian Janzen, and Arno Ehresmann — Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Strasse 40, 34132 Kassel, Germany

As first observed by Meiklejohn and Bean [1] and described as a unidirectional anisotropy, the exchange bias is a well-known interface effect between antiferromagnetic and ferromagnetic thin films. Initiated by field cooling [1], sputter deposition [2], or light-ion bombardment [3] the effect appears as a shift of the hysteresis loop and increased coercive fields [4]. Micromagnetic simulations [5,6] are presented for investigating the magnetic reversal processes in exchange biased thin film systems with a polycrystalline uncompensated antiferromagnetic layer. Different geometries like stripes, squares and discs in the micrometer range are simulated and the influence of modified magnetic parameters in the edges is investigated.

MA 40.29   Thu 14:00   P2/EG

Magneto-ionic control of magnetic properties in perpendicular magnetized synthetic antiferromagnet stacks —
•Maria-Andromachi Syskaki[1], Takaaki Dohi[2,3], Mona Bhukta[2], Jürgen Langer[1], Mathias Kläui[2], and Gerhard Jakob[2] — [1]Singulus Technologies AG, 63796 Kahl am Main, Germany — [2]Institut für Physik, Johannes Gutenberg-Universität Mainz, Staudingerweg 7, 55128 Mainz, Germany — [3]Laboratory for Nanoelectronics and Spintronics, Research Institute of Electrical Communication, Tohoku University, Sendai, Japan

Voltage-controlled spintronic devices are the key to a more energy-efficient way for future storage applications [1]. Electric field effect experiments in this direction reported that the application of a low-power ionic liquid gating technique [2] to nearly compensated synthetic antiferromagnet (SAF) stacks gives rise to high domain wall velocities [3]. In our work, we have grown a SAF stack by magnetron sputtering consisting of two ferromagnetic layers coupled by a non-magnetic spacer layer. The coupling strength is modified by tuning the thickness of the spacer layer to investigate the electric field modulation. With room temperature voltage-controlled magneto-ionic effects, we focus on the modulation of the magnetic properties in this system, i.e., the control of the compensation ratio, the perpendicular magnetic anisotropy, and the antiferromagnetic RKKY coupling strength. MA 40.30   Thu 14:00   P2/EG

Exchange bias in PtMn/Co: New insights into its origin and possibilities for manipulation —
•Beatrice Bednarz[1], Maria-Andromachi Syskaki[2], Rohit Pachat[3], Liza Herrera-Diez[3], Armin Kleibert[4], Mathias Kläui[1], and Gerhard Jakob[1] — [1]Johannes Gutenberg-University, Mainz, Germany — [2]Singulus Technology AG, Kahl, Germany — [3]Université Paris-Saclay, Palaiseau, France — [4]Paul Scherrer Institute, Villigen PSI, Switzerland

Exchange bias is fundamental for many spintronic devices as a means of pinning the direction of the ferromagnetic layer [1,2] and for exerting an intrinsic magnetic field for field-free switching [3]. One of the most commonly used antiferromagnets for this purpose is PtMn [4]. It has a CuAu-I type structure with a high bulk Néel temperature of 975 K and high thermal stability [4]. In this study, we report on new insights into its magnetic structure and the effect on the exchange bias. The magnetic domains were imaged for crystalline as well as polycristalline PtMn by x-ray magnetic linear dichroism (XMLD) photo-emission electron microscopy (PEEM). We found that the drastic difference in the exchange bias is not caused by a difference in the domain size but only by differences in the domain orientations. Furthermore, we show that the magnetic properties of the exchange biased system can be reversibly controlled by ionic liquid gating.

MA 40.31   Thu 14:00   P2/EG

Relaxation behavior of antiferromagnetic grains in polycrystalline exchange-biased bilayers —
•Maximilian Merkel, Rico Huhnstock, Meike Reginka, and Arno Ehresmann — Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Str. 40, D-34132 Kassel

Measuring first-order reversal curves, a prototypical polycrystalline exchange-biased bilayer was found to exhibit a viscous decrease of the ferromagnetic in-plane magnetization upon increasing the external magnetic field. [1] The observed phenomenon is mediated by a rotatable magnetic anisotropy arising from thermally unstable antiferromagnetic grains coupled to the probed ferromagnet. The investigations, performed with the help of angular-resolved vectorial Kerr magnetometry and Kerr microscopy, are further in agreement with a generalized description of polycrystalline exchange-bias systems. The study emphasizes

the relevance of understanding minor loop behavior addressing non-saturated magnetic states for systems susceptible to dynamic changes on the hysteresis loop timescale.

MA 40.32 Thu 14:00 P2/EG

Tailoring the electronic and magnetic properties of the layered antiferromagnet CrCl$_2$ — •DIANA VACLAVKOVA, VLADYSLAV ROMANKOV, NIÉLI DAFFÉ, and JAN DREISER — Swiss Light Source (SLS), Paul Scherrer Institut (PSI), CH-5232 Villigen PSI, Switzerland

The electronic and magnetic properties of two-dimensional van der Waals (vdW) materials differ greatly when comparing mono- and few-layered flakes to their bulk counterparts. In the case of atomically thin single layers the substrate has a profound influence on their properties. CrCl$_2$, belonging to the family of vdW materials, is expected to show a geometrical frustration in the monolayer limit given antiferromagnetic interactions are present [1]. Our preliminary studies involve X-ray magnetic circular dichroism measurements of mono- and few-layered CrCl$_2$ deposited on different materials. Based on the initial interpretation of the experimental data, methods for tailoring the magnetic properties by careful choice of the substrate material will be discussed.

MA 40.33 Thu 14:00 P2/EG

Angle dependent FMR studies on YIG films — •TIM VOGEL[1], DAVID BREITBACH[1], CARSTEN DUBS[2], BURKARD HILLEBRANDS[1], and PHILIPP PIRRO[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, Germany — [2]INNOVENT e.V. Technologieentwicklung, Jena, Germany

Yttrium iron garnet (YIG) is a commonly used material in magnonics due to its low spin-wave damping. Previous ferromagnetic resonance spectroscopy (FMR) studies on (111) grown YIG thin films suggested a deviation from the expected sixfold symmetry of the magnetocrystalline anisotropy for large external fields. For more in-depth investigations, we developed a fully autimized setup for angle dependent vector-network-analyzer-FMR studies of in-plane magnetized YIG films. We apply this setup to investigate a (111) grown, d=55nm thick LPE YIG film. Our results confirm the expected sixfold symmetry even for high external field values. Further, we apply the setup to quantify the effect of the present anisotropy field. This study contributes to the understanding of YIG thin films and the impact of magnetocrystalline anisotropy for magnonic applications.

This research is funded by the DFG - Project No. 271741898 and TRR 173-268565370 (B01) and the ERC Grant No. 101042439 'CoSpiN'.

MA 40.34 Thu 14:00 P2/EG

Quantification of anisotropic and magneto-elastic contributions to the SSW excitation in Bi:YIG films via UXRD — •STEFFEN PEER ZEUSCHNER[1], XI-GUANG WANG[3,4], MARWAN DEB[1], ELENA POPOVA[5], GREGORY MALINOWSKI[6], MICHEL HEHN[6], ALEXANDER VON REPPERT[1], NILS KELLER[5], JAMAL BERAKDAR[4], and MATIAS BARGHEER[1,2] — [1]Universität Potsdam, 14476 Potsdam, Germany — [2]Helmholtz-Zentrum Berlin, 12489 Berlin, Germany — [3]Central South University, Changsha 410083, China — [4]Martin-Luther-Universität, 06099 Halle/Saale, Germany — [5]Institut de Physique de Rennes (IPR, CNRS) UMR6251 Université Rennes, 35000 Rennes, France — [6]Institut Jean Lamour (IJL, CNRS) UMR 7198, Université de Lorraine, 54506 Vandaeuvre-lès-Nancy, France

The photoexcited standing spin waves (SSWs) in the ferromagnetic insulator Bi:YIG are generated by the ultrafast change of the magnetocrystalline anisotropy and the picosecond strain dynamics via magneto-elasticity. Ultrafast X-ray diffraction (UXRD) quantifies the strain and temperature spatio-temporally which is used as in input to a numerical micromagnetic model to fit the ultrafast time-resolved magneto-optical Kerr-effect (tr-MOKE) data of the thin film which exhibits SSWs. With this, we prove that both mechanisms drive the fundamental mode with opposite phase. Both mechanisms are also substantially active as the relative amplitude of the higher order modes indicates. This is a prime example for the exceptional assistance UXRD offers in the understanding and modelling of ultrafast magnetic phenomena.

MA 40.35 Thu 14:00 P2/EG

Generating small magnetic fields inside an open-end magnetic shielding with a superconducting solenoid magnet — •LUKAS VOGL[1,2], ANA STRINC[1,2,3], FRANZ HASLBECK[1], RUDOLF GROSS[1,2,3], and NADEZHDA KUKHARCHYK[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]Physik-Department, Technische Universität München, Garching, Germany — [3]Munich Center for Quantum Science and Technologies, München, Germany

Quantum memory is an essential part for the development of quantum computers. One of the most promising realisation of quantum memories has been realised for storage of optical photons in rare-earth-doped crystals, reaching a storage time of 6 hours. The long storage time has been achieved due to working

at the zero first-order Zeeman shift point (ZEFOZ). At this point, the phase-sensitivity of a spin system to the magnetic field fluctuations is strongly reduced, and thus longer coherence times can be achieved. Such ZEFOZ transitions are present in the hyperfine states of rare earth ions close to zero magnetic fields, which enables the design of quantum memories compatible with the zero-field environments required for superconducting quantum computing curcuits. Here, we present a setup for a highly controllable homogeneous magnetic environment with additional shielding from external background magnetic fields. This environment will allow for precise control of the magnetic field at the sample position, fine tuning to the ZEFOZ transitions, and additional protection of the superconducting quantum circuits from the fields applied to the rare earth spins.

MA 40.36 Thu 14:00 P2/EG

Design and set-up of an optomechanical readout apparatus to characterize magnetic field sensors encompassing high-Q resonators down to 4 K — TORBEN HÄNKE, •DHAVALKUMAR MUNGPARA, and ALEXANDER SCHWARZ — Institute of Nanostructure and Solid State Physics, University of Hamburg, Jungiusstr. 11, 20355 Hamburg

This work has been conducted as part of the OXiNEMS project that aims to realize an miniaturized all-oxide hybrid sensor able to detect magnetic fields in the fT-regime. Our envisaged design encompasses a superconducting pick-up loop with a constriction and a magnetically sensitive high-Q resonator placed directly above it.

Here, we present a set-up to characterize the mechanical properties of potential resonators alone or already integrated into the hybrid sensor. To do so, the resonator motion is detected using an all-fiber interferometer inside a dip stick, which can be pumped to pressures below 10^{-6} mbar and cooled down to 4 K. Alignment between fiber and resonator in x-, y- and z-directions is done with remotely operated precision piezomotors. The resonator can be excited using an integrated shaker piezo to record amplitude and phase response curves. Without external excitation the power spectral density can be recorded and to test the performance of the complete hybrid sensor in operation, the frequency change of the resonator can be monitored.

The OXiNEMS project (www.oxinems.eu) has received funding from the European Union's Horizon 2020 research and innovation program under Grant Agreement No. 828784.

MA 40.37 Thu 14:00 P2/EG

Micro-Hall magnetometry for multiscale magnetic measurements — •BEREKET GHEBRETINSAE[1], CHARU GARG[1], MARTIN LONSKY[1], MOHANAD AL MAMOORI[1], MICHAEL HUTH[1], CHRISTIAN SCHRÖDER[2], PRISCILA ROSA[3], and JENS MÜLLER[1] — [1]Institute of Physics, Goethe University, 60438 Frankfurt (M), Germany — [2]Institute for Applied Materials Research, University of Applied Sciences Bielefeld, Bielefeld 33619, Germany — [3]Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA

Micro-Hall magnetometry is a technique that allows for ultra-sensitive magnetic stray field measurements on macro- to micro- to nanoscaled samples. The magnetometer is a Hall sensor that utilizes the very high electron mobility of a two-dimensional electron gas inside a GaAs/AlGaAs heterostructure to resolve even smallest changes in the sample's stray field almost instantaneously. The technique is unique especially in its versatility. Firstly, the Hall sensor itself can serve as a substrate for the growth of nanoscaled magnetic samples with complex geometries. Secondly, microscopic and even macroscopic samples can be placed directly ontop of the sensor surface such that the stray field emanating from the surface of the sample is captured by the Hall sensor. Here we demonstrate the utility of this technique using (i) 3D ferromagnetic FeCo nanostructures and (ii) single crystalline micro-sized $Eu_5In_2Sb_6$ with two antiferromagnetic transitions. We present magnetic field- and temperature dependent micro-Hall measurements to explain the details of the technique and prove its usefulness as a tool for the study of multiscale magnetic phenomena.

MA 40.38 Thu 14:00 P2/EG

PUMA: Thermal neutron three axes spectrometer — •ALSU GAZIZULINA[1], AVISHEK MAITY[2], JITAE PARK[2], and FRANK WEBER[1] — [1]Institute of Quantum Materials and Technologies, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany — [2]Heinz Maier-Leibnitz Zentrum, Technical University of Munich, Garching, Germany

Thermal neutron three axes spectrometer PUMA is characterized by a very high neutron flux as a result of the efficient use of focusing techniques. An innovative option of the spectrometer is the multianalyzer/detector system, which allows a unique and flexible type of multiplexing. Using this option, a scattering angle range of 16° can be measured simultaneously and flexible $Q - \omega$ paths can be realized without repositioning the instrument. The typical scientific applications of PUMA are studies of phonons and magnons. Furthermore, a unique feature of the instrument is the possibility to perform stroboscopic, time resolved measurements of both elastic and inelastic signals on time scales down to the microsecond regime. Using this technique, the sample is periodically perturbed by an external variable such as temperature, electric field, etc. The signal is then recorded not only as a function of momentum and energy transfer, but also given

a time stamp, relative to the periodic perturbation. Since 2021, the Neutron Scattering Group of the Institute of Quantum Materials and Technologies (IQMT) of the Karlsruhe Institute of Technology (KIT) has been jointly operating the PUMA three-axes spectrometer at MLZ within the framework of a collaboration contract.

MA 40.39   Thu 14:00   P2/EG

Pulse-triggered detection of resonant magnetic small-angle scattering at a laser-driven X-ray source — •Leonid Lunin[1], Martin Borchert[1], Daniel Schick[1], Bastian Pfau[1], and Stefan Eisebitt[1,2] — [1]Max-Born-Institut, Berlin, Germany — [2]Technische Universität, Berlin, Germany

Resonant soft-x-ray scattering methods provide unique possibilities to study nanometer-scale magnetization dynamics on ultrashort timescales. Typically, these experiments are performed at synchrotron-radiation (SR) sources or x-ray free-electron lasers (XFELs) due to the required tunability and intensity of the radiation. While XFELs still offer only limited access, the available time resolution at SR sources on the order of 100 ps is insufficient for many phenomena in ultrafast magnetism. We developed an instrument based on a laser-driven plasma x-ray source to perform resonant x-ray scattering in the wavelength regime between 50 eV and 1500 eV with pulses of 10 ps duration. Specifically, we here present the first resonant small-angle x-ray scattering experiment on a laboratory scale with photon energies in the range of the transition-metal L edges and the rare-earth-metal M edges. In our pilot experiment, we detect scattering from domains forming in a ferrimagnetic Fe/Gd multilayer using an electronically triggered hybrid detector with single-photon sensitivity. Such laboratory-based measurements will allow studying magnetization dynamics with high spatio-temporal resolution in a much more efficient and flexible way than possible today.

MA 40.40   Thu 14:00   P2/EG

Quantitative high sensitivity Magnetic Force Microscopy in vacuum — •Christopher Habenschaden[1], Sibylle Sievers[1], and Andrea Cerreta[2] — [1]Physikalisch-Technische Bundesanstalt, Braunschweig, Germany — [2]Park Systems Europe GmbH, Mannheim, Germany

Magnetic Force Microscopy (MFM) allows the imaging of magnetic samples with spatial resolution of tens of nm and stray field resolution down to the mT range. However, it lacks comparability between measurements, which can be overcome by calibrating the tip, using a magnetic reference sample. This enables the calculation of sample stray fields in A/m, allowing quantitative MFM measurements.

Spatial resolution and field sensitivity can be pushed to several nm and the hundred uT range by measuring in vacuum conditions. This is due to the higher cantilever quality factors Q, that can be achieved in vacuum, directly leading to an increase in measurement signal. However, with increasing signal amplitude, non-linear behavior must be considered. Additionally, advanced feedback techniques are required for stable operation in vacuum.

Here we present an implementation by using phase-locked loops into a commercial Atomic Force Microscope (Park NX Hivac AFM), overcoming non-linearities in measurement signal. This allows stable, transfer function based, quantitative MFM also in vacuum. Advances in resolution and sensitivity are discussed and measurements on samples like skyrmion hosting multilayer stacks are shown and analyzed to demonstrate the feasibility of our measurement approach.

MA 40.41   Thu 14:00   P2/EG

Development of an AC susceptometer for magnetic thin film systems — •Matthias Zetzl, Grace Causer, and Christian Pfleiderer — Physik-Department, Technical University of Munich, D-85748 Garching, Germany

An ongoing challenge in thin film magnetism concerns the need for easy-to-use characterization tools exploiting the response to alternating magnetic fields. We report the development of a bespoke ac-susceptometer comprising a primary and a balanced pair of secondaries specifically tailored for thin film systems. To gauge the performance of the susceptometer we have revisited the properties of epitaxial layers of MnSi in the thick film limit, in which high-resolution measurements of the temperature and field history of the magnetization, complemented by neutron scattering and neutron reflectometry, have recently identified the formation of a cascade of solitonic layers.

MA 40.42   Thu 14:00   P2/EG

Comparison of continuous and pulsed neutron sources for MIEZE witz McStas. — •Korbinian Fellner[1], Johanna K. Jochum[1], Lukas Vogl[1], Lukas Beddrich[1], Jonathan Leiner[1], Christian Franz[2], and Christian Pfleiderer[3] — [1]Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, Garching, Germany — [2]Jülich Centre for Neutron Science JCNS-MLZ, Germany — [3]Physik-Department, Technische Universität München, Germany

The MIEZE method is a type of the neutron spin-echo technique that uses oscillating neutron intensities to record changes to the energy of a scattered neutron. This allows MIEZE, which is implemented at the spectrometer RESEDA

to study magnetic dynamics, quantum phenomena, and molecular diffusion in soft matter, to achieve an energy resolution of neV, taking advantage of a broad wavelength band of $\Delta\lambda/\lambda$=11.6 %. Nonetheless, a significant portion of the neutron beam is discarded by the velocity selector, making MIEZE at pulsed neutron sources increasingly attractive. We have implemented the polarization shaping components of RESEDA in the McStas framework to investigate the feasibility and data reduction of a MIEZE spectrometer at a pulsed neutron source (PNS). The large wavelength spread of a PNS allows for the measurement of the intermediate scattering function over many points in Fourier time, similar to a multi-detector option at a triple-axis spectrometer. Simulations of a quasielastic sample enable a comparison of the performance between a reactor source and a PNS. Additionally, tests of crucial data reduction algorithms that have not been addressed in previous instrument proposals, are discussed.

MA 40.43   Thu 14:00   P2/EG

Characterizing the defocusing behaviour of magnetic microparticles for the application in three-dimensional trajectory tracking — •Nikolai Weidt, Rico Huhnstock, Yahya Shubbak, and Arno Ehresmann — Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Str. 40, D-34132 Kassel

For the implementation in Lab-on-a-chip systems, superparamagnetic particles can be surface-functionalized to bind to specific analytes [1]. Making use of the transport of particles above magnetically stripe-patterned exchange bias layer systems is a promising approach to achieve a remote-controlled and directed transport of these particles [2]. The trajectories of particles during transport can be evaluated for detection of analyte binding events. To get access to the third dimension in optical microscopy, the image characteristics of particles moving out of the focal plane during transport steps are analyzed [3]. In this work quantization of defocusing is achieved by determining the Tenenbaum gradient of single particle images. Correlation between Tenenbaum gradient and the particle's vertical position is established by moving the particles in z-direction through the focal plane of the microscope defined steps. Here we show Tenenbaum gradient curves for differently composed particles and changing illumination conditions. [1] Rampini et al. (2016) Lab on a Chip, 16(19), pp. 3645-3663. [2] Holzinger et al. (2015) ACS Nano, 9(7), pp. 7323-7331. [3] Tasadduq et al. (2015) Flow Measurement and Instrumentation, 45, pp. 218-224.

Simulation of Interaction and Self-assembly of Magnetically Decorated Particles — Sibylle Gemming, •Maximilian Neumann, and Aaron Steinhäusser — TU Chemnitz, Chemnitz, Germany

Magnetic particles with the ability to self-assemble allow for the creation of complex structures from simple parts while retaining malleability, enabling easy manipulation through external influences (e.g. magnetic fields). By arranging permanent magnets along the edges of particles in specific patterns we can assign (multiple) unique patterns to different species of particles without introducing additional geometric limitations. This kind of magnetic assembly schemes improves the selectivity between different types of particles and promotes fixed orientations between those on assembly. Our work shows different simulations of assembly schemes with a focus on finding optimal parameters to maximize interaction and selectivity.

MA 40.45   Thu 14:00   P2/EG

Giant Magnetic Resistance sensor array directly on board — •Laila Bondzio, Torben Tappe, and Andreas Hütten — Bielefeld University, Germany

GMR multilayer systems of Py/Cu-bilayers exhibit nearly triangular shaped GMR curves with a high sensitivity, which is desirable for sensor applications. With a grid of multiple sensor elements a two dimensional magnetic landscapes can be mapped as changes in a magnetic field. To organize and contact a large number of sensor elements on a wide spread area of few centimeters it might be useful to sputter the structure directly onto contacts on a circuit board. Although the circuit board is not an ideal substrate, it has been shown that such application is feasible.

MA 40.46   Thu 14:00   P2/EG

Multifunctional Magneto-Optical Sensing of Temperature and Magnetic Field — •Michael P. Path, Finn Klingbeil, and Jeffrey McCord — Institute of Materials Science, Kiel University, Germany

Measurements of temperature and magnetic field are vital in laboratory and industry settings. We demonstrate multi-functional magneto-optical measurement schemes to relate magnetic and micromagnetic features to temperature and magnetic field using magneto-optical active iron garnet films. The focus lies upon a dual quadrature polarimetric measurement scheme. A calibration free temperature measurement using the relation of the first and third harmonic of the obtained signal during a magnetic sinusoidal excitation of the garnets is presented. Using the domain wall susceptibility a limit of detection of the magnetic field below 14 nT/$\sqrt{\text{Hz}}$ is reached. Indirect measurements of current in integrated circuits is demonstrated using spatially resolved magnetic field sensitivity utilizing a direct magneto-optical imaging setup. A connection of field

and temperature measurements in magneto-optical imaging is discussed. We acknowledge the DFG for funding through grant MC 9/20-2.

MA 40.48   Thu 14:00   P2/EG

Single magnetic domain magnetoelectric composites for picotesla field sensing — •Dennis Seidler, Patrick Hayes, Lars Thormählen, Dirk Meyners, Eckhard Quandt, and Jeffrey McCord — Kiel University, Institute for Materials Science, Kaiserstraße 2, 24143 Kiel, Germany

The contactless measurement of biomagnetic signals i.e., magnetocardiography or magnetoencephalography at ambient conditions has gained high interest for medical applications. Magnetoelectric (ME) cantilever-based field sensors have shown promising results in that regard [1]. To achieve the necessary limit of detection (LOD) a minimization of all noise sources has to be performed. Magnetic noise mainly results from magnetic domain wall activity during sensor operation. We demonstrate a single-domain thick magnetic multilayer stack, to minimize the magnetic noise in the ME sensors. The multilayer is prepared via sputter deposition in an applied magnetic field. We utilize a scalable approach based on magneto-statically coupled $(Fe_{90}Co_{10})_{78}Si_{12}B_{10}$ layers, with the magnetic sensitive layer showing single domain behavior while still achieving high field sensitivity. Integrated in converse ME composite sensors, we obtain a LOD of 40 pT·Hz$^{-0.5}$ at 10 Hz.

This work was funded by the German Research Foundation (DFG) through the Collaborative Research Centre CRC 1261.

MA 40.49   Thu 14:00   P2/EG

Spin-transfer torque ferromagnetic resonance in vortex magnetic tunnel junctions — •Johannes Demir, Karsten Rott, and Günter Reiss — Bielefeld University, Germany

We investigate the gyrotropic mode resonance frequency of the vortex as the free layer of a magnetic tunnel junction (MTJ) by means of spin-transfer torque ferromagnetic resonance (STT-FMR) using a two-port vector network analyzer (VNA). In order to obtain a proper resistance-area (RA) product the capping layer of a commercial wafer was mostly etched down to sputter 8.5 nm permalloy as the vortex layer on top of it afterwards. Subsequently, nanopillars of 300 and 600 nm diameter were fabricated using electron-beam lithography. Using a coplanar-waveguide to feed the GHz-range current through the nanopillar the transmission scattering-parameter S_{21} was determined. Resonance frequencies of around 240 and 150 MHz for the 300 and 600 nm diameter samples, respectively, were measured in accordance with literature [1]. We recognize a shift of the frequency with increasing the bias voltage indicating a DC-STT contribution.

MA 40.50   Thu 14:00   P2/EG

Growth and magnetic properties of Fe/Pt heterostructures with L10-FePt alloyed interface — Laura Scheuer[1] and •Evangelos Th. Papaioannou[2] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Technische Universität Kaiserslautern, Erwin-Schrödinger-Str. 56, 67663, Kaiserslautern, Germany — [2]Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, Von-Danckelmann-Platz 3, 06120 Halle, Germany

The growth of Fe/L10FePt/Pt trilayers was achieved by means of electron beam evaporation technique and appropriate annealing. We show the formation of the L10 alloy for the case of Fe(12nm)/Pt (6nm) [1] and we investigate the formation of L10 phase for Fe,Pt thicknesses smaller than 3 nm. Magneto-optical and Squid magnetometry reveal the strong change in the magnetization reversal when the L10 phase appears. Furthermore, ferromagnetic resonance studies show a large enhancement of the gilbert damping parameter for the alloyed interface. Mumax simulations are implemented in order to understand the role of the L10 in the magnetic properties of the heterostructures.

MA 40.51   Thu 14:00   P2/EG

Light-poling of antiferromagnetic domains in a magnetoelectric LiCoPO$_4$ — •Jakub Vit[1,2], Oleksiy Pashkin[3], Vilmos Kocsis[4], Yasujiro Taguchi[5], Istvan Kezsmarki[6], and Sandor Bordacs[1] — [1]Budapest University of Technology and Economics, Hungary — [2]Institute of Physics, Czech Academy of Sciences, Czechia — [3]Helmholtz-Zentrum Dresden-Rossendorf, Germany — [4]Institut für Festkörperforschung, Leibniz IFW-Dresden, Germany — [5]RIKEN Center for Emergent Matter Science (CEMS), Japan — [6]University of Augsburg, Germany

We selected antiferromagnetic domains in a magnetoelectric LiCoPO$_4$ single crystal by illuminating the sample by light while cooling through the Néel temperature. The experimental results and symmetry analysis indicate that the thermal gradient and resulting heat flow are responsible for such a novel effect: Propagation of thermally-activated quasi-particles is nonequivalent in different antiferromagnetic domains. The microscopic mechanism behind the observed effect is not clear at the moment, calling for future theoretical modeling.

MA 40.52   Thu 14:00   P2/EG

Spontaneous nanoscale square vs. hexagonal skyrmion lattices in Fe/Ir(111) — •Mara Gutzeit, Soumyajyoti Haldar, Tim Drevelow, Moritz A. Goerzen, and Stefan Heinze — Institute of Theoretical Physics and Astrophysics, University of Kiel, Leibnizstraße 15, 24098 Kiel, Germany

We investigate the occurrence of spontaneous skyrmion lattices in an Fe monolayer in both fcc and hcp stacking on the Ir(111) surface employing first-principles calculations based on density functional theory (DFT). For fcc-Fe the well-known non-collinear square nanoskyrmion lattice is confirmed as the magnetic ground state [1]. Surprisingly, for hcp-Fe a nearly collinear hexagonal multi-Q state turns out energetically more favourable than the hexagonal skyrmion lattice proposed based on spin-polarized scanning tunneling microscopy experiments [2]. By mapping total DFT energies of a variety of complex magnetic structures to an atomistic spin model we reveal the interplay of pairwise Heisenberg exchange, Dzyaloshinskii-Moriya interaction and higher-order exchange interactions to be responsible for the symmetry and the degree of collinearity of the respective spin lattice.

MA 40.53   Thu 14:00   P2/EG

Temperature dependent μ-ARPES of the exfoliated zigzag-type intralayer antiferromagnet FePS3 — •B. Pestka[1], J. Strasdas[1], A. K. Budniak[2], D. Baranowski[3], N. Leuth[1], H. Boban[3], M. Liebmann[1], V. Feyer[3], L. Pulcinski[3], E. Lifshitz[2], and M. Morgenstern[1] — [1]II Institute of Physics B and JARA-FIT, RWTH Aachen University, Germany — [2]Schulich Faculty of Chemistry, Solid State Institute of Thechnology, Haifa 3200003, Israel — [3]Forschungszentrum Jülich, Peter Grünberg Institute (PGI-6), Germany

The exfoliable intralayer antiferromagnets MPX3 (M: transition metal, P: phosphorus, X: chalcogenide) provide a multitude of spin arrangements such as Néel-, stripe- and zigzag-type. However, the electronic band structure of these semiconductors has barely been probed. Here, we provide micro-scale angle-resolved photoelectron spectroscopy (μ-ARPES) of the exfoliated intralayer antiferromagnet FePS3 above and below the Néel temperature TN. The material exhibits the zig-zag-type spin arrangement consisting of ferromagnetic zig-zag lines that are mutually coupled antiferromagnetically. We find changes of some of the probed bands across TN. Additionally, the changing bands differ in the different Gamma-K directions, if probed below TN, which is likely related to the selected orientation of the ferromagnetic zig-zag stripes. First low-temperature scanning tunneling spectroscopy results obtained with a Cr tip are also presented. The novel access to the electronic band structure will contribute to a detailed understanding of 2D antiferromagnets.

MA 40.54   Thu 14:00   P2/EG

Optimised mechanical exfoliation of antiferromagnetic MnPS$_3$ — •Niklas Leuth — II. Institute of Physics B, RWTH Aachen University, Aachen, Germany

An optimized mechanical exfoliation technique was developed to exfoliate large-area few-layer flakes of the antiferromagnetic van-der-Waals material MnPS$_3$. This was achieved by utilizing the process of oxygen plasma ashing on gold surfaces and making use of the good bonding strength between the gold surface and the sulfur atoms which terminate the individual layers of MnPS$_3$. Furthermore, there is evidence that the gold surface of the substrate gets oxidised by the oxygen plasma. With the optimised technique, it was possible to exfoliate ~ 100 μm^2-large mono- and bilayer flakes. Furthermore, a method was developed which characterises the layer thickness of the exfoliated flakes quantitatively based on the optical Michelson contrast.

MA 40.55   Thu 14:00   P2/EG

Dual-pulse-excitation all-optical switching of a Gd$_{26}$Fe$_{74}$ ferrimagnet — •Rahil Hosseinifar[1], Ivar Kumberg[1], Sangeeta Thakur[1], Sebastien Hadjadj[1], Jendrik Gordes[1], Chowdhury Awsaf[1], Mrio Fix[3], Florian Kronast[2], Manfred Albrecht[3], and Wolfgang Kuch[1] — [1]Institut für Ex-

perimentalphysik, Freie Universität Berlin, Berlin, Germany — [2]Helmholtz-Zentrum Berlin, Albert-Einstein-Straße 15, 12489 Berlin, Germany — [3]Institut für Physik, Universität Augsburg, Universitätsstraße 1, Augsburg, Germany

Individual linearly p-polarized laser pulses of 800 nm wavelength above a specific threshold fluence can reverse the magnetization of ferrimagnetic samples. We study this all-optical toggle switching in $Gd_{26}Fe_{74}$ ferrimagnetic alloys with out-of-plane easy axis of magnetization after dual-pulse excitation by x-ray magnetic circular dichroism photoelectron emission microscopy. The time between the two spatially overlapped pulses is varied. The experiment is done at room temperature and at 70 K, above and below the magnetic compensation temperature of the sample. In both cases, when the time delay is less than 1 ps, the threshold for toggle switching decreases. At T = 70 K, all the region in the footprint of the laser pulse above a certain fluence switches deterministically. However, at room temperature, in addition to a region of deterministic switching, another region appears at higher fluences where multi-domain nucleation is observed.

MA 40.56   Thu 14:00   P2/EG

Magnetoelastic coupling and magnetic anisotropy in LiMnPO$_4$ — •Timo Kleinbek[1], Sven Spachmann[1], Martin Jonak[1], Mahmoud Abdel-Hafiez[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Department of Physics and Astronomy, Uppsala University, Sweden

We report high-resolution capacitance dilatometry, magnetisation, and high-frequency electron-spin-resonance studies on LiMnPO$_4$ single crystals. Our findings imply sizeable magnetoelastic coupling as demonstrated by large anomalies in the thermal expansion coefficients associated with the evolution of long-range magnetic order at T_N = 33 K. We extract the uniaxial pressure dependencies. Existence of short-range magnetic order above T_N is indicated by magnetic entropy changes up to around 70 K. A spin flip for $B||b$-axis is indicative of a Dzyaloshinskii-Moriya-interaction-caused spin-canting in the ground state. The magnetic phase diagrams are constructed for the three crystallographic directions. The field dependence of the magnon branches implies a two-sublattice model of antiferromagnetic resonance with orthorhombic anisotropy. An anomalous magnon branch detected above the spin-flop field is shown to be accountable-for by a rotation of the easy anisotropy axis at the spin-flop field by 6.5° away from the a-axis towards the hard b-axis. With increasing temperature, the two zero-field excitation gaps remain distinct, implying the preservation of the orthorhombic anisotropy.

MA 40.57   Thu 14:00   P2/EG

Magnetoelastic coupling and uniaxial pressure dependencies of AFM ordering in 2D vdW M$_2$P$_2$S$_6$(M=Ni & Fe) — •Kranthi Kumar Bestha[1,2], Laura Teresa Corredor Bohorquez[1], Vilmos Kocsis[1], Sebastian Selter[1], Saicharan Aswartham[1], Bernd Buechner[1,2], and Anja U. B. Wolter[1] — [1]Institute for Solid State Research, Leibniz IFW Dresden, 01069, Dresden, Germany — [2]Institute of Solid State and Materials Physics and Wuerzburg-Dresden Cluster of Excellence ct.qmat, Technical University Dresden, 01062 Dresden, Germany

Two-dimensional van der Waals(vdW) magnets research has been intensified recently due to their myriad of applications. For these applications, an understanding of coupling of the mechanical degrees of freedom to electronic and magnetic order is crucial. In this work, we employed thermodynamic methods to study the magnetoelastic coupling in 2D vdW Fe$_2$P$_2$S$_6$ and Ni$_2$P$_2$S$_6$. These materials belong to the class of transition metal chalcogenophosphates(M$_2$P$_2$S$_6$), with XXZ- and Ising type antiferromagnetic order respectively. $M(T)$ and $C_p(T)$ on single crystals confirm AFM ordering in both Fe$_2$P$_2$S$_6$(T_N=118 K) and Ni$_2$P$_2$S$_6$(T_N=158 K). Our thermal expansion studies demonstrate positive thermal expansion coefficient along the crystallographic stacking axis, with signatures of magnetoelastic coupling by the onset of magnetic order for both Fe$_2$P$_2$S$_6$ and Ni$_2$P$_2$S$_6$ single crystals. We estimated the uniaxial pressure dependence of antiferromagnetic ordering temperature from heat capacity and thermal expansion.

MA 40.58   Thu 14:00   P2/EG

Unconventional Spin State Driven Spontaneous Magnetization in RE$_3$Fe$_3$Sb$_7$ — •S. Palazzese[1,2], F. Pabst[3], S. Chattopadhay[1], Sh. Yamamoto[1], T. Herrmannsdoerfer[1], D. Gorbunov[1], E. Weschke[4], O. Prokhnenko[4], H. Nojiri[5], T. Doert[3], B. Lake[4,6], J. Wosnitza[1,2], and M. Ruck[3] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — [2]Institut für Festkörperund Materialphysik, Technische Universität Dresden (TUD), Germany — [3]Fakultät für Chemie und Lebensmittelchemie, TUD, Germany — [4]Helmholtz-Zentrum Berlin für Materialien und Energie (HZB), Berlin, Germany — [5]Institute for Materials Research, Tohoku University, Sendai, Japan — [6]Institut für Festkörperphysik, Technische Universität Berlin, Germany

Consolidating a microscopic understanding of magnetic properties is crucial for a rational design of magnetic materials with tailored characteristics. The interplay of $3d$ and $4f$ magnetism in rare-earth transition metal antimonides is an ideal platform to search for such complex behavior. Here we present a detailed magnetization and electrical-transport study of novel RE$_3$Fe$_3$Sb$_7$ compounds. RE$_3$Fe$_3$Sb$_7$ shows a an emergent spontanoeus magnetization in zero applied

field and a kink in the temperature-dependent resistivity, indicating a symmetry breaking at the spin-reorientation transition (SRT). Our XMCD and additional neutron scattering results reveal an unusual antiparallel alignment of Pr and Fe magnetic moments.

MA 40.59   Thu 14:00   P2/EG

2D van-der Waals Heterostructures — •Burak Özer[1], Arthur Veyrat[1], Sebastian Selter[1], Saicharan Aswartham[1], Rudolf Schäfer[2], Ivan Soldatov[2], Bernd Büchner[1,3], and Burak Ozer[1] — [1]Leibniz IFW Dresden, Institute for Solid State Research, 01069 Dresden, Germany — [2]Helmholtzstr 20 — [3]Technische Universität Dresden, Faculty of Physics, 01062 Dresden, Germany

2D materials and their properties are being investigated since 2004 when researchers obtained the monolayer graphene and investigated its excellent electrical properties. To produce down-to-monolayer materials the mechanical exfoliation technique has been used since the very beginning. In 2013, researchers found a technique that allows to build a 3D structure from exfoliated 2D materials like LEGO blocks and control their physical properties, called van-der-Waals (vdW) stacking. Combining 2D materials for the discovery and characterization of new topological phases could pave the way for many opportunities for new and interesting fundamental aspects of physics, also for potential applications. This work shows how to exfoliate and encapsulate different materials, including graphene, hBN and Cr_2 Ge_2 Te_6 (T_c ~62 K) crystal, which is a paramagnetic at bulk; but recently researchers have found out at down-to-monolayer thicknesses, it showed ferromagnetic behavior. The magnetism of Cr_2 Ge_2 Te_6 has investigated at several thicknesses to observe their hysteresis curves by MOKE; to compare the difference between encapsulated with hBN and freestanding CGT behavior, we conducted the magnetic measurement for two different flakes.

MA 40.60   Thu 14:00   P2/EG

Strain control on band topology and surface states in antiferromagnetic EuCd2As2 — •Nayra Alvarez[1], Venkata Bharadwaj[1], Bennet Karetta[1], Rodrigo Jaeschke[1], Adrian Valadkhani[2], Libor Smejkal[1], and Jairo Sinova[1] — [1]Institut fur Physik, Johannes Gutenberg Universitat, Mainz, Germany — [2]Institut für Theoretische Physik, Goethe-Universität, Frankfurt am Main, Germany

We study the effect of strain on EuCd2As2 and the effect on its topological features in different interlayer antiferromagnetic configurations [1]. Magnetic Anisotropy calculations indicate that the modulation of the lattice structure with strain can lead to a change in the direction of the magnetic moment changing the topology of the system [2,3]. We performed band structure calculations for the different strained configurations, applying three different kinds of stress along the x-y plane: volumetric, longitudinal, and shear. In addition, we analyse the surface states at different cleavage surfaces.

MA 40.62   Thu 14:00   P2/EG

Influence of disorder and multi-magnon processes on the magnonic properties of ultrathin metallic ferromagnets — •Sebastian Paischer[1], Arthur Ernst[1], Igor Maznichenko[2], David Eilmsteiner[1], Khalil Zakeri[3], and Pawel Buczek[4] — [1]Johannes Kepler University, Linz, Austria — [2]Martin-Luther-Universität Halle-Wittenberg, Halle, Germany — [3]Karlsruhe Intitute of

Technology, Karlsruhe, Germany — [4]Hamburg University of Applied Sciences, Hamburg, Germany

Understanding the processes behind the excitation and relaxation of spin excitations in low-dimensional magnetic structures is one of the most intriguing research directions in solid-state physics. A detailed knowledge of the fundamental mechanisms involved in such processes is the key to understanding many different phenomena like ultrafast magnetization reversal. In this poster session we compare different magnon damping mechanisms in ultrathin metallic films. While the Landau-damping is the most dominant channel, we show that a significant contribution of the damping originates from substitutional disorder. Also the influence of multi-magnon processes on the magnonic properties of these materials will be discussed.

MA 40.63   Thu 14:00   P2/EG
Transverse magnetotransport in unconventional antiferromagnet Mn_5Si_3 — •Sebastian Beckert[1], Antonin Baďura[2], Miina Leiviskä[3], Eva Schmoranzerová[4], Ismaila Kounta[5], Dominik Kriegner[2], Andy Thomas[1,6], Libor Šmejkal[7], Jairo Sinova[7], Tomáš Jungwirth[2], Lisa Michez[5], Sebastian T. B. Goennenwein[8], Vincent Baltz[3], and Helena Reichlová[1,2] — [1]TU Dresden — [2]IoP ASCR Prague — [3]Spintec Grenoble — [4]Charles University Prague — [5]CINaM Marseille — [6]IFW Dresden — [7]JGU Mainz — [8]University of Konstanz

Traditional collinear antiferromagnets do not exhibit a spin polarization in the band structure. Therefore, the anomalous Hall and Nernst effect are forbidden in this materials. Recent theory developments predict a new class of magnetically ordered compensated materials with particular crystal and spin symmetries that break the time inversion symmetry in the reciprocal space [1,2]. One experimental demonstration are epitaxially grown Mn_5Si_3 films. In these samples with a (0001) film normal, we observe a robust anomalous Hall effect despite vanishing magnetization [3]. On this poster, we will discuss the magneto-thermal transport properties of this compound in more detail and the symmetry of measured signals.

MA 40.65   Thu 14:00   P2/EG
Tuning of magnetoelastic coupling with acoustic impedance matching techniques — •Johannes Weber[1,2], Manuel Müller[1,2], Stephan Geprägs[1], Rudolf Gross[1,2,3], Hans Huebl[1,2,3], and Matthias Althammer[1,2] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]TUM School of Natural Sciences, Technische Universität München, Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

Magnetoelastic coupling and the coherent emission of phonon modes generated by magnon Kittel modes have regained interest because of their potential applications in quantum devices [1]. So far primarily the ferrimagnetic insulator yttrium iron garnet (YIG) grown on single crystal substrates of the paramagnetic insulator gadolinium gallium garnet (GGG) has been used in experiments. However, as YIG requires epitaxial growth, the choice of material combinations is limited. Therefore we studied magnon-phonon coupling in acoustic resonators consisting of polycrystalline magnetic thin-films grown on silicon substrates, as this material platform would allow for the implementation of magnetoelastic coupling effects in existing CMOS-technology. In particular, we investigate whether a tuning of the magnetoelastic coupling between magnetic metal thin films and silicon substrate can be achieved by inserting an intermediated metallic layer, allowing for better acoustic impedance matching [2].

MA 40.66   Thu 14:00   P2/EG
Towards shaping picosecond strain pulses via magnetostrictive transducers — Maximilian Mattern[1], Jan-Etienne Pudell[1,2,3], Karine Dumesnil[4], •Alexander von Reppert[1], and Matias Bargheer[1,2] — [1]Institut für Physik und Astronomie, Universität 14476 Potsdam, Potsdam, Germany — [2]Helmholtz-Zentrum Berlin, 12489 Berlin, Germany — [3]European XFEL, 22869 Schenefeld, Germany — [4]Institut Jean Lamour (UMR CNRS 7198), Université Lorraine, 54000 Nancy, France

Using time-resolved x-ray diffraction, we demonstrate the manipulation of the picosecond strain response of a metallic heterostructure consisting of a dysprosium (Dy) transducer and a niobium (Nb) detection layer by an external magnetic field. We utilize the first-order ferromagnetic-antiferromagnetic phase transition of the Dy layer, which provides an additional large contractive stress upon laser excitation compared to its zero-field response. This enhances the laser-induced contraction of the transducer and changes the shape of the picosecond strain pulses driven in Dy and detected within the buried Nb layer. Based on our experiment with rare-earth metals we discuss required properties for functional transducers, which may allow for novel field-control of the emitted picosecond strain pulses.

MA 41: Focus Session: Altermagnetism: Transport, Optics, Excitations

While antiferromagnetic spintronics is an established research field, key spintronic functionalities such as giant/tunneling magnetoresistance (GMR/TMR), have remained elusive in compensated magnetic systems. This paradigm could change in the light of the recent theoretical discovery of a new class of magnetic materials so called altermagnets which feature alternating spin polarizations in both crystal-structure real space and electronic-structure momentum space. Despite the vanishing net magnetization and antiparallel spin arrangement, altermagnets were predicted to exhibit a robust anomalous Hall effect and GMR and spin transfer torque phenomena. The predictions have been already supported by initial experiments. The goal of this focus session is to introduce the concept of altermagnetism to the broad research community, to present the first experimental works and stimulate future research directions. Here, altermagnets are predicted to have a broad impact beyond spin-electronics in fields ranging from magneto-transport, ultra-fast photo-magnetism to superconductivity and magnetic topological matter. The Focus Session is organized by Dr. Matthias Althammer (Walther-Meißner-Institut, Garching), Prof. Sebastian Goennenwein (Uni Konstanz) and Dr. Andy Thomas (IFW Dresden).

Altermagnetism and spin symmetries — •Libor Šmejkal — Johannes Gutenberg Universitat Mainz, Germany — Institute of Physics, Czech Academy of Sciences, Prague, Czech Republic

Different phases of matter can be distinguished by symmetries and order parameters. In this talk, we will discuss the classification of magnetically ordered crystals according to recently studied spin symmetries [1]. Spin symmetries consider pairs of operations in spin and crystal space and remarkably reveal an un-

conventional magnetic class. This unconventional class, called altermagnetism, is sharply distinct from ferromagnets and antiferromagnets. It is characterized by an unconventional alternating spin order in electronic momentum space that breaks time-reversal symmetry and is spin compensated and anisotropic [1,2]. We show that these properties can arise from ordered and anisotropic spin densities and crystal fields, as described for a typical Ruthenium Dioxide altermagnet [1-4]. Finally, we show that altermagnetism provides a unifying explanation for the recently predicted and experimentally observed unconventional anomalous Hall effects in collinear systems without magnetisation [2,3,5 and references therein].

Invited Talk   MA 41.2   Thu 15:30   HSZ 02

Spontaneous Hall effect in Mn5Si3 altermagnet — •H. Reichlova[1,2], R. Lopes Seeger[3], R. González-Hernández[4], I. Kouta[6], R. Schlitz[1], D. Kriegner[2], P. Ritzinger[2], M. Lammel[9], M. Leiviska[3], V. Petricek[2], E. Schmoranzerova[7], A. Badura[2], A. Thomas[1,8], V. Baltz[3], L. Michez[6], J. Sinova[5,2], S.T.B. Goennenwein[9], T. Jungwirth[2,10], and L. Šmejkal[5,2] — [1]IFMP, Technische Universität Dresden — [2]Institute of Physics CAS, Czech Republic — [3]CNRS, CEA, Grenoble, France — [4]Universidad del Norte, Barranquilla, Colombia — [5]Johannes Gutenberg Universität Mainz — [6]CINaM, Marseille, France — [7]MFF Charles University, Praha, Czech Republic — [8]IFW Dresden — [9]Universität Konstanz — [10]University of Nottingham, United Kingdom

The family of materials that can exhibit spontaneous Hall effect has been significantly expanded by discovery of altermagnets with opposite spin sublattices coupled by crystallographic rotations [1]

I present our observations of the spontaneous Hall effect in an altermagnetic candidate - Mn5Si3 epilayers [2]. Epitaxial constraints stabilize a hexagonal unit cell in the magnetic state distinct from previously described phases in bulk crystals and we observe a sizable spontaneous Hall conductivity. The signal can be explained by an unprecedented altermagnetic band structure with time-reversal symmetry breaking spin-polarized valleys.

MA 41.3   Thu 16:00   HSZ 02

Spin-split collinear antiferromagnets: a large-scale ab-initio study — •Yaqian Guo[1], Hui Liu[1,2], Oleg Janson[1], Ion Cosma Fulga[1,2], Jeroen van den Brink[1,2], and Jorge I. Facio[1,3,4] — [1]Leibniz Institute for Solid State and Materials Research, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, Germany — [3]Centro Atómico Bariloche and Instituto Balseiro, Argentina — [4]Instituto de Nanociencia y Nanotecnología CNEA-CONICET, Argentina

It was recently discovered that, depending on their symmetries, collinear antiferromagnets can break the spin degeneracy in momentum space, even in the absence of spin-orbit coupling. Such systems are signalled by the emergence of a spin-momentum texture set mainly by the crystal and magnetic structure, relativistic effects playing a secondary role. Here we consider all collinear $q=0$ antiferromagnetic compounds in the MAGNDATA database allowing for spin-split bands. Based on density-functional calculations for the experimentally reported crystal and magnetic structures, we study more than sixty compounds and introduce numerical measures for the average momentum-space spin splitting. We highlight some compounds that are of particular interest, either due to a relatively large spin splitting, such as CoF_2 and $FeSO_4F$, or because of their low-energy electronic structure. The latter include $LiFe_2F_6$, which hosts nearly flat spin-split bands next to the Fermi energy, as well as RuO_2, $CrNb_4S_8$, and CrSb, which are metals.

MA 41.4   Thu 16:15   HSZ 02

Giant magnetoresistance effects in altermagnets — •Anna Birk Hellenes[1], Rafael González-Hernández[2], Jairo Sinova[1,3], Tomas Jungwirth[3,4], and Libor Šmejkal[1,3] — [1]Johannes Gutenberg Universität Mainz, Germany — [2]Universidad del Norte, Barranquilla, Colombia — [3]Czech Academy of Sciences, Prague, Czech Republic — [4]University of Nottingham, United Kingdom

Commercial spintronics devices using magnetoresistance effects rely on spin currents in ferromagnets, generated by a time-reversal symmetry broken band structure. To realise a counterpart effect with all-antiferromagnetic electrodes has remained experimentally elusive, as the combined time-reversal symmetry with translation or inversion in antiferromagnets prohibits nonrelativistic spin polarisation. Recently, a third fundamental magnetic order was discovered,

which exhibits exclusively different spin symmetries from ferromagnets and antiferromagnets[1]. In these altermagnets, the spin polarisation forms d,g, or i-wave compensated spin order in momentum space which breaks time-reversal symmetry. Hence, altermagnetism provides a unifying explanation for our recently predicted giant TMR and GMR effects[2,3]. In the present contribution, we describe the symmetry requirements that lead to distinct spin polarisations such as the d-wave type, and illustrate the GMR and TMR mechanism with tight-binding models and in the candidate materials RuO_2 and Mn_5Si_3. [1] L. Šmejkal et al., Phys. Rev. X 12, 031042, 2022. [2] L. Šmejkal, A. B. Hellenes et al., Phys. Rev. X 12, 011028, 2022. [3] H. Reichlova et al., arXiv:2012.15651v2.

Invited Talk   MA 41.5   Thu 16:30   HSZ 02

Generation of tilted spin-current by the collinear antiferromagnet RuO2 — •Arnab Bose — Johannes Gutenberg Universität, Mainz, Germany

Recently a new type of magnetic material is theoretically proposed, referred to as *altermagnet* which is a collinear antiferromagnet in real space although hosting the spin-split bands in the momentum space that allows it to exhibit the properties of ferromagnet depending upon the direction of the current flow with respect to the crystal axis [1,2]. We report the first experimental evidence of strongly crystal axis-dependent unconventional transverse spin-current generation by the altermagnet RuO_2 [3] arising from the novel spin-split bands as theoretically predicted [1]. This unconventional tilted spin-current is the key to the implementation of high-density nonvolatile magnetic memories.

Invited Talk   MA 41.6   Thu 17:00   HSZ 02

First-principles studies on the anomalous transport properties of ferromagnets, antiferromagnets, and altermagnets — •Wanxiang Feng — School of Physics, Beijing Institute of Technology, Beijing 100081, China

Magnetic topological semimetals bring new vitality to the ideas evolving around the next generation of dissipationless spintronic devices benefiting from their exotic anomalous and spin transport properties. I shall first show that ferromagnetic MF_3 (M = Pd, Mn) are high-quality nodal chain spin-gapless topological semimetals with 100% spin-polarized transport properties. The dominant intrinsic origin is found to originate entirely from the gapped nodal chains without the entanglement of any other trivial bands. The side-jump mechanism is predicted to be negligibly small, but the skew scattering enhances the intrinsic Hall and Nernst signals significantly. Second, I shall present the spin-chirality-dependent anomalous Hall and Nernst effects in coplanar noncollinear antiferromagnets Mn_3XN (X = Ga, Zn, Ag, and Ni) as well as the topological magneto-optical effects and their quantization in noncoplanar antiferromagnets γ-Fe_xMn_{1-x} and $K_{0.5}RhO_2$. Beyond ferromagnetism and antiferromagnetism, altermagnetism is recently discovered to be the third essential magnetic phase. Room-temperature metallic RuO_2 is a typical altermagnet, in which the rearrangement of nonmagnetic atoms induces crystal chirality playing a critical role in anomalous transport properties. Finally, I will discuss the crystal-chirality-dependent anomalous Nernst, anomalous thermal Hall, and magneto-optical effects in RuO_2.

Invited Talk   MA 41.7   Thu 17:30   HSZ 02

Insight into chemical and magnetotransport properties of epitaxial α-Fe2O3/Pt bilayers — •Anna Kozioł-Rachwał[1], Natalia Kwiatek[1], Witold Skowroński[3], Krzysztof Grochot[3], Jarosław Kanak[3], Ewa Madej[2], Kinga Freindl[2], Józef Korecki[2], and Nika Spiridis[2] — [1]Faculty of Physics and Applied Computer Science, AGH University of Science and Technology, Mickiewicza 30, 30-059 Kraków, Poland — [2]Jerzy Haber Institute of Catalysis and Surface Chemistry, Polish Academy of Sciences, 30-239 Kraków, Poland — [3]Institute of Electronics, AGH University of Science and Technology, Mickiewicza 30, 30-059 Kraków, Poland

Recently a spin Hall magnetoresistance (SMR) was presented for Pt/α-Fe2O3(hematite) bilayer.[1],[2] In our studies we investigated the chemical structure and SMR in epitaxial α-Fe2O3(0001)/Pt(111) bilayers with hematite layers grown by molecular beam epitaxy on a MgO(111) substrate.[3] We observed a sign change of the SMR from positive to negative when the thickness of the hematite increased from 6 to 15 nm. For α-Fe2O3(15 nm)/Pt, we demonstrated room-temperature switching of the Néel order with rectangular, nondecaying switching characteristics. Such structures open the way to extending magnetotransport studies to more complex systems with double asymmetric metal/hematite/Pt interfaces. [1] J. Fischer et al. Phys. Rev. Applied 13, 014019 (2020). [2] Y. Cheng et al. Phys. Rev. Lett. 124, 027202 (2020). [3] A. Kozioł-Rachwał et al., Phys. Rev. B 106, 104419 (2022).

MA 42: Caloric Effects in Ferromagnetic Materials

Time: Thursday 15:00–17:45								Location: HSZ 04

MA 42.1   Thu 15:00   HSZ 04

Exploring rare earth Laves phases for magnetocaloric hydrogen liquefaction — •BRUNO WEISE[1], MARVIN HOFMANN[1,2], LUKAS BEYER[1,3], and TINO GOTTSCHALL[4] — [1]Leibniz IFW, Dresden, Germany — [2]TU Dresden, Dresden, Germany — [3]TU Bergakademie Freiberg, Freiberg, Germany — [4]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

The replacement of fossil fuels with renewable energies is an integral part of fighting the global climate crisis. Green hydrogen, produced with renewable energies, is one of the most promising energy sources. The unsurpassed high storage density of liquid hydrogen offers great advantages, especially on long transport routes. By magnetocaloric cooling the efficiency of the energy-intensive liquefaction of hydrogen will be increased. RE-X_2 Laves phases, are ideal for low temperature hydrogen liquefaction in the temperature range between 77 and 20 K.

By substitution of individual elements in the RE-X_2 Laves phases the transition temperature can be manipulated, while maintaining the magnetocaloric performance. A substitution series of $DyNi_{2-x}Al_x$ was prepared by arc melting and studied by structural, magnetic and thermodynamic characterization methods. The investigated alloy series $DyNi_{2-x}Al_x$ shows a nonlinear substitution dependency of the Curie Temperature and adiabatic temperature change. In pulsed field measurements a temperature of up to 17 K for 10 T magnetic field pulse was measured. In the present contribution we will evaluate the suitability of the $DyNi_{2-x}Al_x$ rare earth Laves phases for magnetocaloric hydrogen liquefaction.

MA 42.2   Thu 15:15   HSZ 04

Lattice contribution to entropy change at first-order phase transition in Laves phase $DyCo_2$ — •JOHANNA LILL[1], BENEDIKT EGGERT[1], JIYONG ZHAO[2], BENEDIKT BECKMANN[3], BARBARA LAVINA[2], MICHAEL HU[2], KONSTANTIN SKOKOV[3], TOM TOELLNER[2], ESEN E. ALP[2], KATHARINA OLLEFS[1], OLIVER GUTFLEISCH[3], and HEIKO WENDE[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, Duisburg, Germany — [2]APS, Lemont, Illinois - US — [3]TU Darmstadt, Darmstadt, Germany

Laves phases are promising candidates for facilitating liquefaction, applying the magnetocaloric effect. The Laves phase of $DyCo_2$ undergoes a first-order phase transition around 140 K from a ferromagnetic (at low temperatures) to a disordered magnetic phase (at higher temperatures). The magnetic phase transition accompanies a structural change from cubic to tetragonal symmetry also resulting in a volume discontinuity. The magnetocaloric effect is a change in entropy along a phase transition, which in an adiabatically performed cooling cycle can lead to the desired cooling effect. This effect can be characterized by the amount of entropy change at the first-order phase transition. For magnetocaloric applications and improvement of reversible magnetocaloric effect it is therefore essential to understand the contributions of different subsystems to the overall entropy change. In this presentation, we show experimental data that resolves the Dy-partial lattice entropy of the $DyCo_2$ Laves phase along the first-order phase transition utilizing nuclear resonant inelastic x-ray scattering. We acknowledge financial support from DFG through TRR270 HoMMage.

MA 42.3   Thu 15:30   HSZ 04

Designing a light rare-earth-based material system for magnetocaloric hydrogen liquefaction — •WEI LIU[1], FRANZISKA SCHEIBEL[1], TINO GOTTSCHALL[2], EDUARD BYKOV[2], KONSTANTIN SKOKOV[1], and OLIVER GUTFLEISCH[1] — [1]TU Darmstadt — [2]Hochfeld- Magnetlabor Dresden, Helmholtz-Zentrum Dresden-Rossendorf, Germany

Hydrogen will play a key role in building a climate-neutral society, where renewables are the major energy sources [1]. Liquid hydrogen is essential for efficient storage and transport of hydrogen, but expensive due to the low efficiency of traditional gas-compression refrigeration [2]. As an emerging and energy-saving technology, magnetocaloric gas liquefaction can be a "game-changer". However, the high criticalities of the heavy rare-earth elements put a question on the usage of the heavy rare-earth-based magnetocaloric materials in industrial scales, although they show large magnetic entropy and adiabatic temperature changes.[3] On the other hand, the relatively high abundances of light rare-earth elements make their alloys appealing for industrial-scale applications. In this work, based on the analysis of mean-field theory, we propose a method of designing a light rare-earth-based magnetocaloric material system with Ce, Pr, and Nd for hydrogen liquefaction.

MA 42.4   Thu 15:45   HSZ 04

Multicaloric effect and exploited hysteresis in the Heusler alloy Ni-Mn-Sn-Fe-Co — •T. NIEHOFF[1,2], T. GOTTSCHALL[1], C. SALAZAR MEJIA[1], and J. WOSNITZA[1,2] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — [2]Institut für Festkörper- und Materialphysik TUD, Dresden, Germany

Today's research on commercial magnetocaloric cooling focuses on reducing the hysteresis of materials with first-order phase transitions. In contrast, this work exploits the width of hystereses to achieve more effective cooling performance with a combination of multiple caloric effects and investigates the coupling between the magnetocaloric and elastocaloric effects. The hysteresis is finetuned by substituting the proper amount of Fe and Co in the Heusler alloy Ni-Sn. To study the material, simultaneous magnetization, strain, and adiabatic temperature changes are compared at a range of different initial temperatures and various uniaxial loads in pulsed magnetic fields up to 50 T.

MA 42.5   Thu 16:00   HSZ 04

Effect of Pt substitution on the reversibility of the magnetocaloric effect in Ni-Pt-Mn-In Heusler alloys — •PARUL DEVI[1], C. SALAZAR-MEJIA[1], S. SINGH[2], and J. WOSNITZA[1,3] — [1]High Magnetic Field Laboratory (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, Germany — [2]School of Materials Science and Technology, Indian Institute of Technology (BHU), Varanasi, India — [3]Institut für Festkörper –und Materialphysik, TU Dresden, Germany

Among different magnetic shape memory Heusler alloys, $Ni_2Mn_{1.4}In_{0.6}$ is one of the most studied system for multiple caloric effects. However, obstacles such as the low-temperature martensitic transition and large thermal hysteresis hinder its technological applications motivating the search for novel materials showing better mechanical properties as well as higher martensitic transition temperature [1 and references within]. Here, we will present the experimental results such as the crystal structure determined by x-ray diffraction, magnetization in static magnetic fields, and the adiabatic temperature change in pulsed magnetic field of quaternary $Ni_{2-x}Pt_xMn_{1.4}In_{0.6}$ $(0 \leq x \leq 0.2)$ shape memory alloys. The substitution of Pt affects the geometric compatibility condition without changing the space group symmetry of the austenite and the martensite phase. Around the martensitic transition temperature, a large value of ΔT_{ad} was found in pulsed magnetic fields due to the compatibility of austenite and martensite phase.

MA 42.6   Thu 16:30   HSZ 04

Simultaneous measurements of adiabatic temperature change and magnetization in Fe-Ni-Rh. — •CATALINA SALAZAR-MEJIA[1], ALISA M. CHIRKOVA[2], SHINGO YAMAMOTO[1], JOCHEN WOSNITZA[1,3], and TINO GOTTSCHALL[1] — [1]High Magnetic Field Laboratory (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, Germany — [2]FH Bielefeld, University of Applied Sciences, Germany — [3]Institut für Festkörper- und Materialphysik, TU Dresden, Germany

We have performed simultaneous measurements of the magnetization and the adiabatic temperature change in an $Fe_{49}Ni_1Rh_{50}$ alloy. The material exhibits an antiferromagnetic (AFM) to ferromagnetic (FM) transition at $T_{tr} \approx 326$ K. Specifically, we have studied the field-induced metamagnetic AFM-FM transition at temperatures well below T_{tr} in high pulsed magnetic fields. Due to the large magnetocaloric effect (MCE) of the material, magnetization measurements in pulsed magnetic fields are not isothermal. Recording the temperature of the sample during the measurement allows not only to characterized the MCE of the material, but to precisely determine the magnetic phase diagram.

MA 42.7   Thu 16:45   HSZ 04

The local magnetic and geometric structure in Mn-doped $La(Fe,Si)_{13}$ — •BENEDIKT EGGERT[1], JOHANNA LILL[1], KONSTANTIN SKOKOV[2], CYNTHIA PILLICH[1], ALEXANDRA TERWEY[1], FABRICE WILHELM[3], MAURO ROVEZZI[3], ANDREI ROGALEV[3], KATHARINA OLLEFS[1], MARKUS E. GRUNER[1], OLIVER GUTFLEISCH[2], and HEIKO WENDE[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen — [2]Functional Materials, TU Darmstadt — [3]European Synchrotron Radiation Facility

Magnetic cooling has the potential to replace conventional gas compression refrigeration. Materials such as $La(Fe,Si)_{13}$ exhibit a sizeable first-order magnetocaloric effect. For Mn-H doped $La(Fe,Si)_{13}$, it is possible to tailor the phase transition towards room temperature while maintaining first-order character. In this contribution, we discuss the effects of Mn-doping in $La(Fe,Si)_{13}$ on the magnetic moments and the local environment by means of X-ray magnetic circular dichroism and extended X-ray absorption spectroscopy in the hard X-ray regime. Spectroscopic results indicate a reduction of the Fe magnetic moment and an increased structural disorder around the La site, which is not identified for the Fe sites. Furthermore, first-principles calculations reveal energetically unfavourable Mn-Si bonds that lead to a broad distribution of La-Si bond lengths that explain the experimentally observed structural disorder. We acknowledge the financial support through the Deutsche Forschungsgemeinschaft within the framework of the CRC/TRR 270 HoMMage and thank the ESRF for allocating beamtimes at ID12 and BM30.

MA 42.8   Thu 17:00   HSZ 04

Magnetocaloric effect in (La,Ce)(Fe,Si,Mn)$_{13}$ with tunable, low transition temperature — •M. STRASSHEIM[1,2], C. SALAZAR MEJIA[1], J. WOSNITZA[1,2], and T. GOTTSCHALL[1] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — [2]Institut für Festkörper- und Materialphysik Technische Universität Dresden, Dresden, Germany

The La(Fe,Si)$_{13}$ family is a very promising group of magnetocaloric materials due to their overall good cost-benefit ratio in comparison to alloys based on scarce rare earths such as Gd or Ho. By partly substituting La with Ce and Fe with Mn, the metamagnetic transition can be tuned down to at least 40 K, while maintaining a rather sharp transition to enable a notable magnetocaloric effect. Tuning the magnetocaloric effect down to these temperatures opens up large-scale applications such as the magnetic liquefaction of hydrogen. In this work, we synthesized $(La_{1-z}Ce_z)(Fe_{0.88-y}Mn_ySi_{0.12})_{13}$ with $z = 0 \ldots 0.4$, $y = 0 \ldots 0.04$ and determined the adiabatic temperature change in pulsed magnetic fields. For selected samples, we calculated the magnetic entropy change using isothermal magnetization measurements.

MA 42.9   Thu 17:15   HSZ 04

Rapid bulk sintering and magnetocaloric performance of polycrystalline Fe$_2$Al$_{1.15-x}$B$_2$Ge$_x$Ga$_x$ (x=0, 0.05) MAB phases — •BENEDIKT BECKMANN[1], TAREK EL-MELEGY[2], DAVID KOCH[1], ULF WIEDWALD[3], MICHAEL FARLE[3], FERNANDO MACCARI[1], JOSHUA SNYDER[2], KONSTANTIN SKOKOV[1], MICHEL BARSOUM[2], and OLIVER GUTFLEISCH[1] — [1]TU Darmstadt, Institute of Materials Science, Darmstadt, Germany — [2]Drexel University, Department of Materials Science & Engineering, Philadelphia, PA, USA — [3]University of Duisburg Essen, CENIDE, Duisburg, Germany

Reactive single-step hot-pressing at 1473 K and 36 MPa for 4 h produces dense, bulk, near single-phase, low-cost and low-criticality Fe$_2$Al$_{1.15}$B$_2$ and Fe$_2$Al$_{1.1}$B$_2$Ge$_{0.05}$Ga$_{0.05}$ MAB samples, showing a second-order magnetic phase transition with favorable magnetocaloric properties at room temperature. The maximum isothermal entropy change Δs_T of hot-pressed Fe$_2$Al$_{1.15}$B$_2$ in magnetic field changes of 2 and 5 T amounts to 2.5 and 5 J(kgK)$^{-1}$ at 287.5 K and increases by Ge and Ga addition to 3.1 and 6.2 J(kgK)$^{-1}$ at 306.5 K, respectively. The directly measured maximum adiabatic temperature change ΔT_{ad} in magnetic field changes of 1.93 T is improved by the alloy design from 0.9 to 1.1 K. Our criticality assessment shows that hot-pressed Fe-based MAB phases provide a promising compromise between material and processing cost, criticality and magnetocaloric performance around room temperature.

We acknowledge financial support from DFG (CRC/TRR 270, Project-ID 405553726).

MA 42.10   Thu 17:30   HSZ 04

MA 43.1   Thu 15:00   HSZ 401

Three-dimensional tomographic imaging of the magneti- zation vector field using Fourier transform holography — •MARISEL DI PIETRO MARTÍNEZ[1,2], ALEXIS WARTELLE[1,3], CARLOS HERRERO MARTÍNEZ[1], FARID FETTAR[4], JEAN-FRANÇOIS MOTTE[4], CLAIRE DONNELLY[2], LUKE TURNBULL[5], FEODOR OGRIN[5], GERRIT VAN DER LAAN[6], HORIA POPESCU[7], NICOLAS JAOUEN[7], FLORA YAKHOU-HARRIS[3], and GUILLAUME BEUTIER[1] — [1]UGA, CNRS, G-INP, SIMaP, Grenoble, France — [2]MPI-CPfS, Dresden, German — [3]ESRF, Grenoble, France — [4]UGA, CNRS, G-INP, Institut Néel, Grenoble, France — [5]School of Phys. and Engineering, University of Exeter, Exeter, UK — [6]Diamond Light Source, Didcot OX11 0DE, UK — [7]Synchrotron SOLEIL, Gif-sur-Yvette, France

Three-dimensional magnetic textures have recently attracted increasing interest both from a fundamental and a technological point of view. This emergent field of research comes with the need of new characterization techniques, specifically tomographic imaging. Here, we present a new tomographic technique based on Fourier transform holography, a lensless imaging technique that uses a known reference in the sample to retrieve the object of interest from its diffraction pattern in one single step of calculation. We obtain a 3D vectorial image of a 850nm-thick extended Fe/Gd multilayer in a 5000nm-diameter field of view with a resolution of 100nm, that reveals worm-like domains with magnetization pointing mostly out of plane near the surface of the sample but that falls in-plane near the substrate. As an outlook, this technique will enable a 3D study on the response to an external magnetic field.

MA 43.2   Thu 15:15   HSZ 401

Soft X-ray ptychography of micrometer thick samples — •JEFFREY N. NEETHIRAJAN[1], BENEDIKT DAURER[2], ALES HRABEC[3,4], MAJID KAZEMIAN[2], MARISEL DI PIETRO MARTÍNEZ[1], BURKHARD KAULICH[2], and CLAIRE DONNELLY[1] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]Diamond Light Source, Harwell Science and Innovation Campus, Didcot, United Kingdom — [3]Laboratory for Mesoscopic Systems, Department of Materials, ETH Zurich, Zurich, Switzerland — [4]Laboratory for Multiscale Materials Experiments, Paul Scherrer Institute, Switzerland

Magnetism at the nanoscale offers a playground to study topology in real space. Although topological spin textures have so far been mainly studied in 2D, there is a growing interest in 3D topological (Feal spin textures. Recently, 3D imaging of extended systems with hard X-rays has revealed topological singularities called Bloch points and spin structures called vortex rings with nanoscale spatial resolution. However, the imaging of extended systems with hard X-rays is limited by the weak XMCD signals observed in this regime and restricted currently to a few rare-earths. In contrast, soft X-rays offer a stronger XMCD signal but limited to imaging samples that are 200-300 nm thick. Here we demonstrate the imaging of micrometer thick samples using soft X-ray ptychography - accessing a thickness regime previously impractical with conventional soft X-ray imaging techniques. This result is a step forward in realizing 3D imaging of extended systems with soft X-rays which offers a strong XMCD signal and the possibility to image exotic systems hosting topological textures.

Soft X-ray Ptychography of Bismuth Ferrite Nanoplates — •TIM A. BUTCHER[1], MANUEL LANGER[1], SIMONE FINIZIO[1], LARS HELLER[1], MIRKO HOLLER[1], MICHAL JAMBOR[2], ELISABETH MÜLLER[3], ASHNA BAJPAI[4,5], CARLOS A. F. VAZ[1], ARMIN KLEIBERT[1], and JÖRG RAABE[1] — [1]Swiss Light Source, Paul Scherrer Institut, 5232 Villigen PSI, Switzerland — [2]Institute of Physics of Materials, Czech Academy of Sciences, Žižkova 22, 61600 Brno, Czech Republic — [3]Electron Microscopy Facility, Paul Scherrer Institut, 5232 Villigen PSI, Switzerland — [4]Department of Physics, Indian Institute of Science Education and Research, Pune 411008, India — [5]Centre for Energy Science, Indian Institute of Science Education and Research, Pune 411008, India

Soft x-ray ptychography is a scanning coherent diffractive imaging technique with spatial resolutions in the order of 10 nm, which relies on collecting diffraction patterns from overlapping illumination spots of the sample. The magnetic and ferroelectric structure of multiferroic bismuth ferrite nanoplates was studied with a new soft x-ray ptychography endstation at the Swiss Light Source. In particular, we demonstrate that the technique is able to resolve the antiferromagnetic spin cycloid and can yield the chirality in bismuth ferrite.

MA 43.4   Thu 15:45   HSZ 401

Direct imaging of nanoscale field-driven domain wall oscillations in Landau structures — •BALRAM SINGH[1], RACHAPPA RAVISHANKAR[1], JORGE A. OTÁLORA[2], IVAN SOLDATOV[1], RUDOLF SCHÄFER[1], DANIIL KARNAUSHENKO[3], VOLKER NEU[1], and OLIVER G. SCHMIDT[3] — [1]Institute for Integrative Nanosciences, Leibniz IFW Dresden, 01069 Dresden, Germany — [2]Departamento de Física, Universidad Católica del Norte, Avenida Angamos 0610, Casilla 1280, Antofagasta, Chile — [3]Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, 09126 Chemnitz, Germany.

Linear oscillatory motion of domain walls (DWs) in the kHz and MHz regime is crucial when realizing precise magnetic field sensors such as giant magnetoimpedance devices. Here, we report an imaging approach to investigate such

DW dynamics with nanoscale spatial resolution employing conventional table-top microscopy techniques. Time-averaged magnetic force microscopy and Kerr imaging methods are applied to quantify the DW oscillations in Permalloy rectangular structures with Landau domain configuration and are complemented by numeric micromagnetic simulations. We study the oscillation amplitude as a function of external magnetic field strength, frequency, magnetic structure size, thickness, and anisotropy and understand the excited DW behavior as a forced damped harmonic oscillator with restoring force being influenced by the geometry, thickness, and anisotropy of the Permalloy structure.

MA 43.5   Thu 16:00   HSZ 401

Tailoring magnetic switching via topology in nanoimprinted networks of Pt/Co/Pt caps on flexible membranes — •Jose A. Fernandez-Roldan[1], Rui Xu[1], Oleksii Volkov[1], Oleksandr Pylypovskyi[1], Ivan Soldatov[2], Andreas Worbs[1], Rene Hübner[1], Rudolf Schäfer[2], Jürgen Fassbender[1], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Leibniz IFW, Dresden, Germany

Perpendicular magnetic bit media consist of regular rigid nanostructured networks where data is stored in decoupled nanostructures. Flexible magnetic nanoelectronic devices rely on curvature-induced effects that introduce topological patterning [1]. We prepared arrays of magnetic bits with a size of 400 nm arranged in close-packed square and hexagonal arrays of Pt/Co/Pt cap-like structures on PDMS elastic membranes by means of nanoprinting and Al anodization. The magnetization reversal process indicates a magnetically decoupled switching process in the individual caps of the square array in contrast to the hexagonal array. Here we propose a method to evaluate this coupling by means of analysis of a series of field-dependent MOKE images. The results indicate that the magnetic coupling between the caps can be quantitatively characterized in terms of a fractal dimension. Overall, these results suggest that the magnetization switching in densely-packed networks can be tailored via topology.

Coherent Correlation Imaging for resolving fluctuating states of matter — •Christopher Klose[1], Felix Buettner[2,3,4], Wen Hu[3], Claudio Mazzoli[3], Kai Litzius[2], Riccardo Battistelli[4], Ivan Lemesh[2], Jason M. Bartell[2], Mantao Huang[2], Christian M. Guenther[5], Michael Schneider[1], Andi Barbour[3], Stuart B. Wilkins[3], Geoffrey S.D. Beach[2], Stefan Eisebitt[1,5],

and Bastian Pfau[1] — [1]Max Born Institute, Berlin — [2]Massachusetts Institute of Technology, Cambridge, MA, USA — [3]National Synchrotron Light Source II, Upton, NY, USA — [4]Helmholtz-Zentrum Berlin — [5]Technische Universitaet Berlin

Fluctuations and stochastic transitions are ubiquitous in nanometer-scale systems, especially in the presence of disorder. However, their direct observation has so far been impeded by a seemingly fundamental, signal-limited compromise between spatial and temporal resolution.

Here, we develop coherent correlation imaging (CCI) — a high-resolution, full-field imaging technique that realizes multi-shot, time-resolved imaging of stochastic processes. The key of CCI is the classification of camera frames that correspond to the same physical state by combining a correlation-based similarity metric with powerful classification algorithm developed for genome research.

We apply CCI to study previously inaccessible magnetic fluctuations in a highly degenerate magnetic stripe domain state with nanometer-scale resolution. The spatiotemporal imaging reveals the transition network between the states and details of the magnetic pinning landscape which have been inaccessible so far.

MA 43.7   Thu 16:30   HSZ 401

Origin of helicity-dependent photoconductivity in magnetic and nonmagnetic wires — •Atul Pandey[1,2], Rouven Dreyer[1], Palvan Seyidov[1], Chris Koerner[1], Saban Tirpanci[1], Binoy K. Hazra[2], Stuart Parkin[2], and Georg Woltersdorf[1,2] — [1]Institute of Physics, Martin Luther University Halle-Wittenberg, Von-Danckelmann-Platz 3, 06120 Halle, Germany — [2]Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle, Germany

We study the opto-electric response in metallic wire structures. The aim is to understand the origin of helicity-dependent photoconductivity. For nonmagnetic metals this effect is generally believed to probe spin polarization. Using magnetic wires we show that this method enables background free imaging of spin textures. Analyzing the physical origin we find that the circular dichroism slightly modulates the absorption. The corresponding thermal modulation explains the measured electrical signals. We apply this result to examine the spin Hall effect induced spin accumulation in heavy metals. Here, we show that previously reported results in nonmagnetic wires are well reproducible, but not related to the spin polarization.

Magnetic Force Microscopy Investigations of the Kagome Spin Ice Host HoAgGe — •Tsuei-Shin Wu[1], Subhajit Roychowdhury[2], Samuel D. Seddon[1], Peter Milde[1], Claudia Felser[2], and Lukas M. Eng[1,3] — [1]Institute of Applied Physics, Technische Universität Dresden, Dresden, Germany — [2]Max-Planck-Institute for Chemical Physics of Solids, Dresden, Germany — [3]Dresden-Würzburg Cluster of Excellence * Complexity and Topology in Quantum Matter (ct.qmat), TU Dresden, 01062 Dresden, Germany

The recent discovery of the quasi-2D spin ice on a Kagome lattice in HoAgGe [1] has highlighted this material system as the perfect environment in order to explore emerging questions and to clarify ongoing discussions regarding 2D spin ices within the scientific community. The presence of several high-order magnetization plateaus implies the possible existence of quantum magnetic states and/or non-collinear spin textures that may originate from quantum or thermal fluctuations [2]. Peaks in the topological Hall effect, which correlate with these magnetization plateaus, also potentially imply the presence of exotic spin textures - or at the very least non-collinear spin textures, which low-temperature (LT) Magnetic Force Microscopy (MFM) is perfectly placed to uncover. Here we present LT-MFM results when investigating the magnetic textures and their behaviors in HoAgGe samples under magnetic fields applied along the relevant crystallographic Kagome lattice directions.

MA 44.2   Thu 15:15   HSZ 403

Coexistence of antiferromagnetism and ferrimagnetism in adjacent honeycomb layers — •Dávid Szaller[1], Lilian Prodan[2,3], Korbinian Geirhos[2], Viorel Felea[2,3,4], Yurii Skourski[4], Denis Gorbunov[4], Tobias Förster[4], Toni Helm[4], Toshihiro Nomura[4,5], Atsuhiko Miyata[4], Sergei Zherlitsyn[4], Jochen Wosnitza[4,6], Alexander A. Tsirlin[2], Vladimir Tsurkan[2,3], and Istvan Kezsmarki[1] — [1]Tu Wien — [2]University of Augsburg — [3]Institute of Applied Physics, R. Moldova — [4]Hochfeld-Magnetlabor Dresden — [5]University of Tokyo, Kashiwa — [6]TU Dresden

Ferro/ferri- and antiferromagnetic orders are typically exclusive in nature, thus, their co-existence in atomic-scale proximity is expected only in heterostructures. Breaking this paradigm we report the observation of a new, atomic-scale hybrid spin state. This ordering is stabilized in three-dimensional crystals of the polar antiferromagnet $Co_2Mo_3O_8$ by magnetic fields applied perpendicular to the *Co* honeycomb layers and possesses a spontaneous in-plane ferromagnetic moment. Our microscopic spin model, capturing the observed field dependence of the longitudinal and transverse magnetization as well as the magnetoelectric/elastic properties, reveals that this novel spin state is composed of an alternating stacking of antiferromagnetic and ferrimagnetic honeycomb layers. We show that the proper balance of magnetic interactions can extend the stability range of this hybrid phase down to zero magnetic field. The layer-by-layer stacking of distinct spin orders via suitable combinations of microscopic interactions opens a new dimension toward the nanoscale engineering of magnetic states.

Coupled frustrated ferromagnetic and antiferromagnetic quantum spin chains in the quasi-one-dimensional mineral antlerite, $Cu_3SO_4(OH)_4$ — A.A. Kulbakov[1], D.Y. Kononenko[2], S. Nishimoto[2,3], Q. Stahl[1], A. Mannathanath Chakkingal[1], M. Feig[4], R. Gumeniuk[4], Y. Skourski[5], L. Bhaskaran[5], S.A. Zvyagin[5], J.P. Embs[6], I. Puente-Orench[7,8], A. Wildes[8], J. Geck[1,9], O. Janson[2], D.S. Inosov[1,9], and •D.C. Peets[1] — [1]IFMP, TU Dresden — [2]Leibniz IFW-Dresden — [3]ITP, TU Dresden — [4]IEP, TU Bergakademie Freiberg — [5]HLD-EMFL, HZRD Dresden — [6]PSI, Villigen, Schweiz — [7]INMA, CSIC-U. Zaragoza, Spain — [8]ILL, Grenoble, France — [9]ct.qmat

Magnetic frustration, the competition among exchange interactions, often leads to novel magnetic ground states with unique physical properties which can hinge on details of interactions that are otherwise difficult to observe. Such states are particularly interesting when it is possible to tune the balance among the interactions to access multiple types of magnetic order. We present antlerite, $Cu_3SO_4(OH)_4$, as a potential platform for tuning frustration. Contrary to previous reports, the low-temperature magnetic state of its three-leg zigzag ladders is a quasi-one-dimensional analogue of the magnetic state recently proposed to

exhibit spinon-magnon mixing in botallackite. Density-functional-theory calculations indicate that antlerite's magnetic ground state is exquisitely sensitive to fine details of the atomic positions, with each chain independently on the cusp of a phase transition, indicating an excellent potential for tunability.

MA 44.4   Thu 15:45   HSZ 403
High-Frequency Electron Spin Resonance Studies on the Quasi One-Dimensional Spin-1/2 Quantum Magnet $PbCuSeO_4(OH)_2$ — •RAHEL OHLENDORF, DANIEL KNAUER, CHANGHYUN KOO, and RÜDIGER KLINGELER — Kirchhoff Institute for Physics, Heidelberg, Germany

We report high-frequency ESR studies on a polycrystalline sample of the frustrated quasi-1D spin-1/2 quantum material $PbCuSeO_4(OH)_2$, isostructural to the well-studied natural mineral linarite ($PbCuSO_4(OH)_2$). Magnetisation data show the evolution of a magnetically ordered phase below $T_N = 4.8$ K and a spin-flop transition at $B_{SF} = 2.8$ T. A complex magnetic phase diagram is constructed from the data. ESR measurements on a loose powder evidence a gapless linear excitation mode within the ground state, which can be traced across the spin-flop transition, as well as two linear excitation modes within the in-field phase with a zero field gap of -31 ± 9 GHz and 32.9 ± 1.4 GHz, respectively. Measurements on fixed powder reveal a gapped magnon mode in the ground state with a zero field splitting of 70 ± 20 GHz. This mode might be accounted for by assuming an excitation of a spiral spin order in the ground state. Tracing the resonance positions with temperature suggests an easy-axis-type anisotropy with the paramagnetic g-factors 2.3 and 2.07. Changes in resonance position evidence the onset of short range fluctuations at around 70 K corresponding to $14 \times T_N$.

MA 44.5   Thu 16:15   HSZ 403
K_2ReCl_6: an unconventional Jahn-Teller system? — •ALEXANDRE BERTIN[1], TUSHARKANTI DEY[1], DANIEL BRÜNING[1], DMITRY GORKOV[1,2], KEVIN JENNI[1], ASTIN KRAUSE[1], PETRA BECKER[3], LADISLAV BOHATÝ[3], DANIEL KHOMSKII[1], THOMAS LORENZ[1], and MARKUS BRADEN[1] — [1]II. Physikalisches Institut, Universität zu Köln — [2]Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München — [3]Abteilung Kristallographie, Institut für Geologie und Mineralogie, Universität zu Köln

Antifluorite compounds of chemical formula K_2MX_6 (where M is a transition metal and X=Cl,Br) can exhibit various crystallographic phase transitions, often understood by the softening of rotary phonon modes of the ligand octahedra surrounding the central transition metal. Among this family, K_2ReCl_6 exhibits on cooling four distinct structural phases and may constitute a playground to investigate the interplay between spin-orbit coupling (SOC) and Jahn-Teller (JT) effect. The question whether one of the crystallographic phase transitions is JT driven will be tackled by presenting a detailed temperature dependent structural study of K_2ReCl_6 and of its non magnetic counterpart K_2SnCl_6 by means of powder and single crystal XRD. With neutron diffraction experiments and by taking the low temperature monoclinic symmetry into account, the magnetic structure was solved. Frustration is only partially lifted by the structural distortions and the magnetic order causes further symmetry reduction. Finally, the strong magneto-elastic effect seen in thermal expansion measurements will be discussed in terms of domain re-orientation and weak ferromagnetism.

MA 44.6   Thu 16:30   HSZ 403
Non-collinear magnetism and Fe-R interaction in $R_3Fe_3Sb_7$ — •FELIX SEEWALD[1], FALK PABST[2,5], SABRINA PALAZZESE[1,3,5], VADIM GRINENKOV[1,6], HUBERTUS LUETKENS[7], THOMAS HERRMANNSDÖRFER[3], SHINGO YAMAMOTO[3,5], DENIS GORBUNOV[3,5], SUMANTA CHATTOPADHYAY[3,5], CLEMENS RITTER[4], KATI FINZEL[2], THOMAS DOERT[2,5], MICHAEL RUCK[2,5], JOCHEN WOSNITZA[1,3,5], and HANS-HENNING KLAUSS[1] — [1]IFMP, TU Dresden, Germany — [2]Fakultät für Chemie und Lebensmittelchemie, TU Dresden, Germany — [3]HLD-EMFL, Helmholtz-Zentrum Dresden-Rossendorf, Germany — [4]Institute Laue-Langevin Grenoble, France — [5]Würzburg-Dresden Cluster of Excellence ct.qmat — [6]Tsung-Dao Lee Institute, Shanghai, China — [7]PSI, Villingen, Switzerland

In $R_3Fe_3Sb_7$ (R = Pr, Nd) Fe and R atoms form columns of stacked triangles separated by Sb. Fe exhibits non-collinear ferromagnetic order below $T_c \approx$ 380 K. On cooling at the onset of R order a spin reorientation ($T_{SRT,Pr} \approx 40$ K, $T_{SRT,Nd} \approx 50$ K) and magnetization reversal is observed [1].

Mössbauer spectra show two distinct magnetic Fe sites between T_c and T_{SRT}, both collapsing into one new site below T_{SRT}, reaching a static magnetic hyperfine-field of $B_{Hyp} = 20.59(21)$ T at 4.2 K. The data is the same for Nd and Pr except for the value of T_{SRT}. The local field obtained from μSR investigations is consistent with Mössbauer hyperfine-field at high temperatures. We will discuss the implications of our findings on the magnetic structure of the system.

MA 44.7   Thu 16:45   HSZ 403
Reentrant topological magnetic order and a spin-cholesteric phase in the $Sr_3Fe_2O_7$ perovskite — •NIKITA ANDRIUSHIN[1], NIKOLAI PAVLOVSKII[1], YULIIA TYMOSHENKO[1], DARREN C. PEETS[1], ALEXANDRE IVANOV[2], JACQUES OLLIVIER[2], BERNHARD KEIMER[3], OKSANA ZAHARKO[4], and DMYTRO INOSOV[1] — [1]TU Dresden, Germany — [2]ILL, Grenoble, France — [3]MPI for Solid State Research, Stuttgart, Germany — [4]PSI, Villigen, Switzerland

Topologically nontrivial magnetic structures, e.g., skyrmion lattices and magnetic vortex crystals, are well known in noncentrosymmetric materials, so that antisymmetric exchange interactions are allowed. Only recently, topological multi-q magnetic textures that spontaneously break the chiral symmetry, for example three-dimensional hedgehog lattices, were discovered in centrosymmetric compounds, where they are instead driven by frustrated interactions. Here we show that the bilayer perovskite $Sr_3Fe_2O_7$, previously believed to adopt a simple single-q spin-spiral order, hosts two distinct types of multi-q topological spin textures. Its ground state represents an unusual multi-q spin texture with unequally intense helical spin modulations at the two ordering vectors. It is followed in temperature by a new "spin cholesteric" phase, in which the chiral symmetry is spontaneously broken along one of the crystal directions, but the weaker modulation along the orthogonal direction melts, giving rise to intense short-range dynamical fluctuations. Shortly before the transition to the paramagnetic state, a more conventional skyrmion-lattice order spanned by two equivalent q vectors emerges.

MA 44.8   Thu 17:00   HSZ 403
Incommensurate and multiple-q magnetic misfit order in $Cu_3SO_4(OH)_4$ — •ANTON KULBAKOV[1], ELAHEH SADROLLAHI[1], FLORIAN RASCH[1], MAXIM AVDEEV[2,3], SEBASTIAN GASS[4], LAURA BOHORQUEZ[4], ANJA WOLTER[4,5], MANUEL FEIG[6], ROMAN GUMENIUK[6], HAGEN PODDIG[7], MARKUS STÖTZER[8], JOCHEN LITTERST[9], INES PUENTE-ORENCH[10,11], ANDREW WILDES[11], EUGEN WESCHKE[12], JOCHEN GECK[1,5], DMYTRO INOSOV[1,5], and DARREN PEETS[1] — [1]IFMP, TU Dresden, Germany — [2]ANSTO, Australia — [3]USYD, Australia — [4]IFW Dresden, Germany — [5]ct.qmat, TU Dresden, Germany — [6]TUBA Freiberg, Germany — [7]ACII, TU Dresden, Germany — [8]ACI, TU Dresden, Germany — [9]IPKM, TU Braunschweig, Germany — [10]INMA, Spain — [11]ILL, Grenoble, France — [12]HZB, Berlin, Germany

In antlerite, $Cu_3SO_4(OH)_4$, Cu^{2+} ($S = \frac{1}{2}$) quantum spins populate three-leg zigzag ladders in a highly frustrated quasi-one-dimensional structural motif. We demonstrate that at zero applied field, in addition to its recently reported low-temperature phase of coupled ferromagnetic and antiferromagnetic spin chains, this mineral hosts an incommensurate helical+cycloidal state, an idle-spin state, and a multiple-q phase which is the magnetic analog of misfit crystal structures. The antiferromagnetic order on the central leg is reentrant. The high tunability of the magnetism in antlerite makes it a particularly promising platform for pursuing exotic magnetic order.

MA 44.9   Thu 17:15   HSZ 403
Spin-liquid and Spin-glass states in Frustrated Tetragonal Pyrochlore $Zn_{0.8}Cu_{0.2}FeMnO_4$ — •SUCHIT KUMAR JENA[1], MANFRED REEHUIS[2], and SUBHASH THOTA[1] — [1]Department of Physics, Indian Institute of Technology Guwahati, Assam-781039, India — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Hahn-Meitner-Platz 1, D-14109 Berlin, Germany

Spinel (AB_2O_4) Pyrochlore lattices are capable of generating high degree of magnetic frustration owing to tunable competing exchange interactions achieved via suitable magnetic elements on B site together with non-magnetic A site, which leads to quantum spin-liquid/Ice state [1]. One such compound is cubic $ZnFe_2O_4$, which manifests high magnetic frustration index ($f \approx 12$) with antiferromagnetic Néel temperature, $T_N \sim 10$K [2]. Our results based on the neutron powder diffraction analysis shows that polycrystalline tetragonal $Zn_{0.8}Cu_{0.2}FeMnO_4$ (ZCFMO) lacks presence of long-range magnetic ordering. The dynamic ac magnetic susceptibility (χ' and χ'') measurements show multiple anomalies across 9K, 47K and 79K. Frequency dispersion in the loss spectrum ($\chi''(f, T)$) analyzed by employing empirical scaling-laws such as Vogel-Fulcher law and Power Law: $\tau = \tau_0[(T - T_{SG})/T_{SG}]^{-zv}$, yields cluster spin-glass state in ZCFMO with the spin freezing temperature (T_{SG}) at 41.8K and critical exponent zv=8.9, below the ferrimagnetic Néel temperature $T_{FiM} \sim 79$K. These results are further supported by the heat capacity ($C_p(T)$) studies. Below 9K, $C_p \sim T^2$, indicates co-existence of spin-glass and spin-liquid states in ZCFMO. [1] *Phys. Rev. B* **28**, 1 (1983). [2] *Phys. Rev. B* **66**, 064401 (2002).

Spin noise in magnetically ordered models — •Julius Schlegel, Martin Evers, and Ulrich Nowak — Department of Physics, University of Konstanz

Spin noise spectroscopy has emerged in the last years as a new tool to investigate magnetic material properties [1].

On the basis of a classical Heisenberg model and the stochastic Landau-Lifshitz-Gilbert equation of motion we numerically compute the time evolution of magnetically ordered structures on a time scale of several hundreds of picoseconds. By analyzing the spectral noise power density and the autocovariance of the magnetization in both ferro- and antiferromagnetic models, we find that the magnetic noise in thermal equilibrium comprises several features of the system. Resonances in the noise spectra are observed, which can be assigned to the eigenmodes of the magnetic structure. Moreover, the noise can mark phase transitions like the transition to the paramagnetic state or a spin-flop transition.

We thus conclude that by means of investigating the noise of the magnetization, the magnetic order of a system can be extracted even in cases where the mean equilibrium magnetization does not reflect the transition at all.

Spin and momentum resolved ultrafast carrier dynamics in antiferromagnetic Dirac semimetal models — •Marius Weber[1], Kai Leckron[1], Baerbel Rethfeld[1], Libor Šmejkal[2], Jairo Sinova[2], and Hans Christian Schneider[1] — [1]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, Germany

Systems with antiferromagnetic ordering in real space often exhibit topological features in momentum space that only recently have been investigated in a comprehensive fashion [1]. For instance, depending on the magnetic ordering, they may have band structures with a pronounced anisotropy in band energies and in the spin structure of their single-particle states due to Dirac fermions. We present numerical calculations of the electron dynamics due to electron-phonon interactions [2,3] in model systems with two-dimensional k-space that capture key properties of antiferromagnetic Dirac materials in momentum space. After an instantaneous heating of the electronic system we obtain a transient carrier distributions, which reflect the momentum-space features. Surprisingly, completely anisotropic carrier distribution may evolve, even from excited carrier distributions that are isotropic in energy, i.e., $f(E(k)) = f(E)$.

Inertial spin dynamics in ferromagnets and antiferromagnets — Ritwik Mondal[1], Lucas Winter[2], Sebastian Grossenbach[2], Ulrich Nowak[2], and •Levente Rózsa[2,3] — [1]Indian Institute of Technology (ISM) Dhanbad, Dhanbad, India — [2]University of Konstanz, Konstanz, Germany — [3]Wigner Research Centre for Physics, Budapest, Hungary

Inertial spin dynamics emerges in magnetic materials at very short time scales where the directions of the atomic magnetic moment and angular momentum become separated, and nutation can be observed. The inertia gives rise to additional high-frequency or nutational excitations recently detected in ferromagnetic resonance experiments [1].

Here the signatures of inertial spin dynamics are discussed theoretically in ferromagnets (FMs) and antiferromagnets (AFMs). The nutational spin-wave bands are shifted by a constant frequency compared to the low-frequency bands in FMs, while in AFMs the nutational bands have a maximum in the center of the Brillouin zone [2]. It is demonstrated that a resonant excitation of the nutation may be utilised for switching the order parameter [3]. The switching is found to proceed faster in AFMs than in FMs, and in AFMs tuning the excitation frequency can be used to control the direction of the switching.

Magnetic field-dependent ultrafast control of an antiferromagnet — •Abeer Arora[1,6], Yoav Will Windsor[2], Sang-Eun Lee[1], Jit Sarkar[1], Kristin Kliemt[3], Ch. Schüssler- Langeheine[4], Niko Pontius[4], Cornelius Krellner[3], Denis V. Vyalikh[5], and Laurenz Rettig[1] — [1]FHI der MPG, Berlin — [2]IOAP, TU Berlin — [3]Phy. Inst., Goethe-Uni., Frankfurt am Main — [4]HZB für Materialien und Energie GmbH, Berlin — [5]DIPC, Basque, Spain — [6]Fachbereich Physik, FU Berlin

Antiferromagnetic (AF) materials offer faster manipulation of spins, while making control of magnetic order challenging. A promising approach is utilizing the magnetic anisotropy (MA) to manipulate the spin arrangement on femtosecond timescales [1]. In addition, external magnetic fields can induce a spin flop (SF), providing an additional control knob for AF order. Understanding the interplay of these effects is of strong interest. Here, we present time-resolved resonant soft X-ray diffraction (RSXRD) experiments on the prototypical A-type antiferromagnet $GdRh_2Si_2$. We observe a coherent rotation of the AF arrangement followed by oscillations of the AF order due to light-induced change in the MA potential. Remarkably, upon increasing magnetic field, the frequency of the oscillations increases while the amplitude of reorientation upon photoexcitation decreases. These observations demonstrate the interplay of the MA potential and the SF field, and offer new ways towards deterministic control of AF spin order. [1]Windsor et al. Commun Phys 3, 139 (2020)

MA 46.5   Fri 10:30   HSZ 02

Dynamics of the Morin transition in hematite — •Maik Kerstingskötter[1], Tobias Dannegger[1], András Deák[2], László Szunyogh[2,3], and Ulrich Nowak[1] — [1]Department of Physics, University of Konstanz — [2]Department of Theoretical Physics, Budapest University of Technology and Economics — [3]ELKH-BME Condensed Matter Research Group, Budapest University of Technology and Economics

Below a critical temperature T_M of about 264 K, hematite is a perfect antiferromagnet with zero net magnetization due to the fact that the spins of the four sublattices are antiparallel and aligned with the c-axis. If the temperature exceeds this critical point, the spins reorient into the basal plane and assume a small canting angle that results in a finite net magnetization. This first-order phase transition from the antiferromagnet to the weak ferromagnetic phase is the Morin transition. While the equilibrium properties are well known, we want to investigate the nonequilibrium dynamics of the transition. Here we use atomistic spin dynamics simulations on the basis of an ab initio model to study the system's response to an instantaneous temperature increase from $T < T_M$ to $T > T_M$. In the model used, we indeed observe this Morin transition, which takes place in the range of five to a few hundred picoseconds, depending on the size of the Gilbert damping used.

MA 46.6   Fri 10:45   HSZ 02

Non-collinear spin reorientation in FeRh from first principles: Ultrafast laser quenching vs. coherent rotation of Fe moments — •Mike Jos Bruckhoff, Markus Ernst Gruner, and Rossitza Pentcheva — Faculty of Physics and Center for Nanointegration (CENIDE), University of Duisburg - Essen

The binary alloy FeRh exhibits a metamagnetic first-order phase transition from antiferromagnetic (AFM) to ferromagnetic (FM) order, which can be driven by an external magnetic field or laser excitation. Here, we present a comprehensive non-collinear density functional theory study, where we investigate the multidimensional energy landscape $E(M, V)$, by constraining the total spin moment in order to compare different kinds of spin reorientation pathways. The absence of significant energy barriers suggests that the coherent in-plane rotation of the Fe moments is a likely scenario for the magnetic phase transition in an external magnetic field. In contrast to this, FeRh exhibits an laser-induced ultrafast demagnetization, which is initiated by optical inter-site spin transfer (OISTR) and a net Rh-to-Fe charge transfer at early times after excitation. We study extensively the response of FeRh to laser pulses with different laser parameters in both magnetic phases, simulated by means of real-time time-dependent DFT (RT-TDDFT). We find that the magnitude of the response strongly depends on the incident laser pulse, as well as the magnetic state of FeRh. We conclude that laser excitations and applied magnetic fields initiate distinct transition pathways, which may be exploited to control the phase transition by the external stimuli.

MA 46.7   Fri 11:00   HSZ 02

Signature of spatial gradients in ultrafast demagnetization observed with angle-resolved complex magneto-optical Kerr-effect (CMOKE) — •Sanjay Ashok[1], Jonas Hoefer[1], Martin Stiehl[1], Martin Aeschlimann[1], Hans Christian Schneider[1], Bärbel Rethfeld[1], and Benjamin Stadtmüller[1,2] — [1]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau, Germany — [2]Institute of Physics, Johannes Gutenberg-University Mainz, Germany

Understanding the laser-induced ultrafast magnetization dynamics of thick metallic films is even in simple materials still challenging due to different transport mechanisms contributing to the magnetization dynamics. While heat- and particle diffusion are slow processes, ballistic and superdiffusive transport lead to an ultrafast equilibration of spatial inhomogeneities. However, quantifying experimentally their impact on ultrafast demagnetization of bulk material is difficult, since surface-sensitive experimental techniques integrate the response of the material over a certain depth.

Our theoretical calculations reveal that the Kerr-rotation dynamics is nearly insensitive to gradients in magnetization. In contrast, we find a strong influence for the angle-resolved ellipticity dynamics. These findings are confirmed by CMOKE experiments on Nickel films of varying thicknesses. The probe-angle resolved CMOKE technique thus provides a method to study the presence of transient gradients in magnetization at ultrafast timescales.

MA 46.8 Fri 11:15 HSZ 02

Dynamic versus Static Spectral Weight Transfer in LPCMO Thin Films — •KAREN P. STROH, TIM TITZE, PIA HENNING, DANIEL STEIL, STEFAN MATHIAS, and VASILY MOSHNYAGA — I. Physikalisches Institut, Georg-August-Universität Göttingen, DE

$(La_{1-y}Pr_y)_{1-x}Ca_xMnO_3$ (LPCMO) is a prototypical bandwidth-controlled manganite with strong electron-phonon coupling and colossal magnetoresistance (CMR), originating from a nm-scale phase separation with ferromagnetic nanodomains antiferromagnetically coupled by correlated Jahn-Teller polarons (CPs).

The present study made use of strain-engineered LPCMO thin films prepared by a metalorganic aerosol deposition technique on LAO-buffered STO(100) substrates. Temperature-dependent static reflectivity spectra, showing the phase-transition-mediated spectral weight transfer (SWT), served as reference for identifying thermally driven behaviour. Further, pump-probe reflectivity (PPR) and time-resolved magneto-optical-Kerr effect (MOKE) data at different temperatures and probe wavelengths provided insights into the role of CPs in ultrafast electron and magnetization dynamics on femto- to nanosecond timescales.

As a main result, we observed a long-lived non-thermal state with increased optical conductivity in the polaron hopping regime at a probe energy of 0.7eV, indicating the destruction of polarons or a loss of their correlation upon laser excitation.

MA 46.9 Fri 11:30 HSZ 02

Experimental exploration of criticality in dynamic magnetic phase transitions — •MIKEL QUINTANA and ANDREAS BERGER — CIC nanoGUNE BRTA, E-20018 Donostia-San Sebastián, Spain.

The dynamic phase transition (DPT) of ferromagnets is a well-known phenomenon describing an abrupt change in the time-evolution behavior of magnetization in the presence of a time-dependent magnetic field. Its similarities with the conventional thermodynamic phase transition (TPT), particularly in terms of scaling behavior close to their respective critical points, are of utmost importance to understand collective behaviors in systems out-of-equilibrium [1]. However, a lack of experimental verification of these theoretical predictions has impeded further progress in the field up to now. Here, we experimentally explore for the first time the scaling behavior and critical exponents of the DPT in ultrathin Co films by means of real-time magneto-optical Kerr effect measurements in the relevant dynamic phase space. Surprisingly, we observe that the DPT and TPT critical exponents correspond to different dimensionalities for the same film. Our results seem to indicate different dimensional crossover length-scales for the TPT and DPT, a fact that has not been explored to date. [1] P. Riego et. al., Physica B 549, 13-23 (2018).

MA 46.10 Fri 11:45 HSZ 02

Slow dynamics from ultrafast phononic driving in $CuGeO_3$ — •LEONIE SPITZ[1], EUGENIO PARIS[1], FLAVIO GIORGIANNI[1], BRUCE NORMAND[1], THORSTEN SCHMITT[1], and CHRISTIAN RÜEGG[1,2,3,4] — [1]Paul Scherrer Institute, CH-5232 Villigen-PSI, Switzerland — [2]Department of Quantum Matter Physics, University of Geneva, CH-1211 Geneva, Switzerland — [3]Institute of Physics, Ecole Polytechnique Fédérale de Lausanne (EPFL), CH-1015 Lausanne, Switzerland — [4]Institute of Quantum Electronics, ETH Zürich, CH-8093 Hönggerberg, Switzerland

The coherent manipulation of magnetism by optically driven phonons is a rapidly growing field [1-4]. However, experimental studies of quantum spin systems by ultrafast pump-probe schemes remain rare, because the most common optical techniques to probe magnetic phenomena fail in the absence of magnetic

order. We present a multi-method study of the spin-chain material $CuGeO_3$, in which the magnetic correlations are associated with a lattice instability, also called the spin-Peierls (SP) transition, that drives the system into a collective singlet ground state of spin dimers [5]. By the coherent driving of phonons we observe low-frequency dynamics of the optical response which may offer new insight into the mechanism driving the SP transition in $CuGeO_3$, a problem that has remained unsolved for almost 3 decades.

MA 46.11 Fri 12:00 HSZ 02

Spin-lattice coupling in a Van der Waals ferromagnet on ultrafast time scales — •HYEIN JUNG[1,2], VICTORIA C. A. TAYLOR[2], YOAV WILLIAM WINDSOR[1,2], and RALPH ERNSTORFER[1,2] — [1]Technische Universität Berlin, Berlin, Germany — [2]Fritz Haber Institute der MPG, Berlin, Germany

Two-dimensional (2D) van der Waals (vdW) magnetic materials hold great potential for spintronic applications. Cr2Ge2Te6 (CGT) is one such material which exhibits ferromagnetism even at the monolayer limit. With functionality in mind, investigation of dynamic processes on their fundamental time scales is of great importance, in particular energy flow and coupling between subsystems (carriers, spins, lattice). Furthermore, we have recently shown that understanding lattice dynamics in ferromagnets is essential for a complete understanding ultrafast spin dynamics. Here we use femtosecond electron diffraction (FED) to study lattice dynamics in CGT and other 2D magnets. We discuss the interaction between magnetic order and the lattice, and the influence of studying such effects at the monolayer limit.

MA 46.12 Fri 12:15 HSZ 02

Modelling spin-lattice coupling in computer simulation — •MICHAEL SAUR[1], MARKUS WEISSENHOFER[1], HANNAH LANGE[2], AKASHDEEP KAMRA[3], SERGIY MANKOVSKY[2], SVITLANA POLESYA[2], HUBERT HUBERT[2], and ULRICH NOWAK[1] — [1]University of Konstanz, Germany — [2]LMU Munich, Germany — [3]Universidad Autónoma de Madrid, Spain

We develop a multiscale framework for the description of spin-lattice coupling in computer simulations [1]. The derived Hamiltonian describes a closed system of spin and lattice degrees of freedom and explicitly conserves the total momentum, angular momentum and energy. Using a new numerical implementation that corrects earlier Suzuki-Trotter decompositions we perform simulations on the basis of the resulting equations of motion to investigate the combined magnetic and mechanical motion of a ferromagnetic nanoparticle. The framework developed herein will enable the use of multi-scale modeling for investigating and understanding a broad range of spin-phonon-mediated phenomena from slow to ultrafast time scales.

MA 46.13 Fri 12:30 HSZ 02

Ultrafast energy flow in the van der Waals ferromagnet Fe3GeTe2 (FGT) — •YOAV WILLIAM WINDSOR[1,2], DANIELA ZAHN[2], VICTORIA C. A. TAYLOR[2], THEODOR GRIEPE[4], TOMMASO PINCELLI[2], HYEIN JUNG[2], SANG-EUN LEE[2], CHRISTIAN SCHÜSSLER-LANGEHEINE[3], NIKO PONTIUS[3], UNAI ATXITIA[4], RALPH ERNSTORFER[1,2], and LAURENZ RETTIG[2] — [1]TU Berlin — [2]Fritz Haber Inst. — [3]Helmholz Zentrum Berlin — [4]CSIC Madrid

Van der Waals bonded magnetic materials expand the technological promise of 2D materials (TMDCs, Graphene) into the field of spintronics. To this end, understanding their nonequilibrium behavior is essential. Here we experimentally probed the response of FGT to photoexcitation using three probes: time-resolved ARPES (probes the carriers), time-resolved XMCD (probes the spins), and femtosecond electron diffraction (FED; probes the lattice). We resolve sub-picosecond responses in all three sub-systems, and find that the conventional M3TM model must be modified to reliably reproduce the combined response of all three sub-systems together.

MA 47: Skyrmions IV

MA 47.1 Fri 9:30 HSZ 04

Systematic parameter study of magnetic skyrmions and antiskyrmions stabilised by exchange interactions — •STEPHAN VON MALOTTKI and GEOFFROY HAUTIER — Thayer School of Engineering at Dartmouth College, Hanover, NH, USA

It is a major ongoing task to optimize the thermal stability of magnetic skyrmions (Sk) and antiskyrmions (ASk), which is in particular limited for sub-10 nm

Sk and ASk in 2D magnetic materials. We focus on a stabilisation of Sk and ASk by exchange frustration [1] and higher order exchange interactions (HOI) [2]. We explore the large interaction parameter space of the atomistic Heisenberg model, consisting of exchange interaction beyond nearest neighbours, DMI, magnetocrystalline anisotropy and HOI by means of highly automatised energetic optimisation and geodesic nudged elastic band method (GNEB) simulations. Here we present the resulting sizes and energy barriers for SK and ASK

in ferromagnetic and antiferromagnetic lattices with hexagonal and square geometry. This enables us to identify systematically the areas of parameters space in which metastable Sk and ASk can exist and how much their energy barriers can be enhanced in the framework of the atomistic extended Heisenberg model beyond nearest neighbours.

MA 47.2   Fri 9:45   HSZ 04

Coarse-graining skyrmion ensemble analysis — •Thomas Brian Winkler[1], Jan Rothörl[1], Maarten A. Brems[1], Hans Fangohr[2,3], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Germany — [2]Faculty of Engineering and Physical Sciences, University of Southampton, United Kingdom — [3]Max Planck Institute for the Structure and Dynamics of Matter Hamburg, Hamburg

Magnetic skyrmion are heavily investigated due to their interesting physics and their potential for unconventional computing schemes [1,2]. In confined geometries the thermal diffusion of skyrmions depends heavily on the ability of the skyrmion ensemble to arrange with respect to the confinement in a commensurate manner [3,4]. If external forces like spin-orbit torques are applied to such systems, the steady states of the system might change. We use a coarse-graining to analyse the system with methods from statistical physics [5] to ascertain the relevant states that the collective system is entering. We find in a simulational case study of four skyrmions in a triangular geometry that the steady states of a system are changing when external forces are applied. Such analysis is useful to optimise geometries or read-out positions of magnetic tunnel junctions for skyrmion-based devices. [1] K. Dzyaloshinskii-Moriya interactions in skyrmionic lacunar spinel GaV$_4$S$_8$ — •Vladislav Borisov[1], Patrik Thunström[1], Anna Delin[2,3], and Olle Eriksson[1,4] — [1]Department of Physics and Astronomy, Uppsala University, Sweden — [2]Department of Applied Physics, School of Engineering Sciences, KTH Royal Institute of Technology, Stockholm, Sweden — [3]SeRC (Swedish e-Science Research Center), KTH Royal Institute of Technology, Stockholm, Sweden — [4]Örebro University, Örebro, Sweden

Using the first-principles full-potential linear muffin-tin orbital method and magnetic force theorem we study the Heisenberg and Dzyaloshinskii-Moriya interactions in the lacunar spinel GaV$_4$S$_8$. This material hosts magnetic Néel skyrmions, in contrast to most other bulk magnets. The symmetry of the calculated DM vectors agrees with the C_{3v} structural symmetry and supports the stability of Néel skyrmions. The sizes of the magnetic interactions show some variations as a function of electronic correlations. These changes are also reflected in the estimated wavelength of the helical magnetic state. Our theoretical results indicate that the electronic and magnetic properties depend strongly on the spin configuration of the V$_4$ clusters, on which there is no clear consensus in the literature, and we make a suggestion for the configuration that fits better to the known measurements.

MA 47.4   Fri 10:15   HSZ 04

On the correlation between spin, orbital and chiral magnetizations of skyrmions — Imara Lima Fernandes[1] and •Samir Lounis[1,2] — [1]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich & JARA, 52425 Jülich, Germany — [2]Faculty of Physics, University of Duisburg-Essen & CENIDE, 47053 Duisburg, Germany

Skyrmions are spin-swirling textures hosting wonderful properties with potential implications in information technology. The magnetization carried by such objects is prospected as a mean of encoding magnetic bits while their topological nature gives rise to a plethora of exquisite features such as topological protection, the skyrmion Hall effect, topological Hall effect and topological orbital moment [1]. Here, the emergent magnetic field, which is directly proportional to the three-spin scalar chirality χ, plays a key role. We explore from ab-initio the rich set of magnetizations carried by single small magnetic skyrmions generated in PdFe bilayer on Ir(111) surface and focus on the correlation between spin, orbital, chiral magnetizations and χ after being excited by single atomic defects [2]. We identify a universal pattern that can guide the design of storage devices by engineering the magnitude of the magnetization carried by skyrmions via controlled implantation of defects.

MA 47.5   Fri 10:30   HSZ 04

Nature of magnetic Exchange interactions in Centrosymmetric Hexagonal NiMnGa — •Sunil Wilfred DSouza[1], Sanjay Singh[2], and Jan Minár[1] — [1]New Technologies Research Centre, University of West Bohemia, Univerzitní 8, CZ-306 14 Pilsen, Czech Republic. — [2]School of Materials Science and Technology, Indian Institute of Technology (Banaras Hindu University) Varanasi-221005, India.

Hexagonal NiMnGa hosts Novel magnetic biskyrmion state in which vortex-like nanometric spin textures are stable over a wide temperature range extending upto the Curie temperature making it a contender for potential applications in future high-performance spintronic devices. We present, The Heisenberg exchange couplings determined from the paramagnetic phase using the disordered local moment theory which is found to give a significantly more realistic description in comparison with the treatment of the material as a ferromagnet. Frustration caused by competing ferromagnetic and antiferromagnetic exchange couplings at the nearest-neighbor Mn-Mn interactions has been noticed in NiMnGa which is known to lead to non-collinear magnetic ordering. Total energy calculations establishes a non-collinear spin-structure which is stable at a specific Mn spin canting angle in c-plane which is resulting from the magnetocrystalline anisotropy. The Mean-Field Curie temperature determined from the exchange interactions is in good agreement with experiment.

MA 47.6   Fri 10:45   HSZ 04

Skyrmions in $4d$- and $5d$-doped B20 compounds — •Vladislav Borisov[1], Qichen Xu[2,3], Nikolaos Ntallis[1], Rebecca Clulow[4], Vitalii Shtender[4], Johan Cedervall[5], Martin Sahlberg[4], Kjartan Thor Wikfeldt[6], Danny Thonig[7,1], Manuel Pereiro[1], Anders Bergman[1], Anna Delin[2,3], and Olle Eriksson[1,7] — [1]Department of Physics and Astronomy, Uppsala University, Sweden — [2]Department of Applied Physics, School of Engineering Sciences, KTH Royal Institute of Technology, Stockholm, Sweden — [3]SeRC (Swedish e-Science Research Center), KTH Royal Institute of Technology, Stockholm, Sweden — [4]Department of Chemistry, Uppsala University, Sweden — [5]Department of Materials and Environmental Chemistry, Stockholm University, Sweden — [6]PDC Center for High Performance Computing, KTH Royal Institute of Technology, Stockholm, Sweden — [7]Örebro University, Örebro, Sweden

Based on theoretical calculations, we predict that $4d$- and $5d$-doped FeSi and CoSi compounds host skyrmions with a size between 50 nm for (Co,Os)Si and 148 nm for (Fe,Co)Si. Calculations are done using the full-potential linear muffin-tin orbital method and magnetic force theorem which allow to address the Heisenberg and Dzyaloshinskii-Moriya (DM) interactions, and the skyrmionic properties were determined using micromagnetic simulations. We find that the $5d$ doping (by Ir or Os) is particularly efficient in terms of enhancing the DM interaction. Convex-hull analysis suggests that the doped compounds are structurally stable, and we have managed to synthesize and characterize $Co_{1-x}Ru_xSi$ systems both in powder and single-crystal forms.

Bloch points in the ground state of chiral magnet nanocylinder — •Andrii Savchenko[1], Fengshan Zheng[2,3], Nikolai Kiselev[1], Luyan Yang[1,2], Qianqian Lan[1,2], Filipp Rybakov[4], Stefan Blügel[1], and Rafal Dunin-Borkowski[1,2] — [1]Peter Grünberg Institute, Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons, Forschungszentrum Jülich, 52425 Jülich, Germany — [3]Spin-X Institute, South China University of Technology, Guangzhou 511442, China — [4]Department of Physics and Astronomy, Uppsala University, SE-75120 Uppsala, Sweden

Experimental observation of Bloch points (BPs) is challenging since these topological defects represent energetically unfavorable configurations and usually appear only as a metastable state. The present study aims to find the systems where due to the competition between short-range and long-range interactions the BPs can emerge in the ground state of the system. A nanocylinder of an isotropic chiral magnet might be a good candidate for such a system. We found that the dipole string - the configuration containing two coupled BPs of opposite topological charge, at some geometrical parameters corresponds to the lowest energy state in such nanocylinder. Our micromagnetic simulations with realistic parameters agree well with the results of the transmission electron microscopy experiment on the FeGe sample.

MA 47.8   Fri 11:30   HSZ 04

Quantum correlation functions of magnetic skyrmions in chiral magnets — •Sopheak Sorn[1] and Markus Garst[1,2] — [1]Institute of Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76021 Karlsruhe, Germany — [2]Institute of Theoretical Solid State Physics, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany

Recent research activities have turned to studying quantum effects in skyrmion-hosting ordered phases within the context of numerical diagonalization of quantum spin Hamiltonians as well as semiclassical magnonic theories. In the later,

one can expand various operators in magnon fields around a classical spin-texture background. In this talk, I will present results from such a semiclassical theory for chiral magnets, focusing on various correlation functions involving the topological charge and the energy-momentum tensor at zero and nonzero temperature. I will also discuss how these correlation functions are related to linear responses of skyrmions to external perturbation.

MA 47.9   Fri 11:45   HSZ 04
Modeling stray fields using Bi-axial anisotropy in in-inplane magnets — •Venkata Krishna Bharadwaj[1], Karin Everschor-Sitte[2], Jairo Sinova[1,3], and Ricardo Zarzuela[1] — [1]Johannes Gutenberg-University, Mainz — [2]Faculty of Physics, University of Duisburg-Essen, D-47057 Duisburg, Germany — [3]Institute of Physics Academy of Sciences of the Czech Republic, Cukrovar-nická 10, 162 00 Praha 6, Czech Republic
Recently [1,2], magnetic bimreons, skyrmion analogs in in-plane magnetized films have gained interest due to their stark difference in current-driven dynamics with respect to Neel skyrmions showing uni-directional motion with SOT-driven torques. The other technological advantage is that they can be densely stacked without worrying about stray fields between the layers. However, the stray fields need to be handled carefully as they are not trivial as in out-of-plane films. In this work, we study the bi-axial anisotropy to model the stray field in in-plane magnetized films. We provide the phase diagram and look at the deformations of spin spiral phases and the presence of titled fields. Finally, we study the shape deformation of skyrmions due to stary fields and the effects in current-driven dynamics. [1] R. Zarzuela et al., Physical Review B 101, 054405 (2020), [2] B. Göbel, et al., Phys. Rev. B 99, 060407(R) (2019).

Magnetoelectric Cavity Magnonics in Skyrmion Crystals — Tomoki Hirosawa[1,2], •Alexander Mook[1,3,4], Jelena Klinovaja[1], and Daniel Loss[1] — [1]University of Basel, Basel, Switzerland — [2]Aoyama Gakuin University, Sagamihara, Kanagawa, Japan — [3]Technical University of Munich, Garching, Germany — [4]Johannes Gutenberg University, Mainz, Germany
We present a theory of magnetoelectric magnon-photon coupling in cavities hosting noncentrosymmetric magnets. Analogously to nonreciprocal phenomena in multiferroics, the magnetoelectric coupling is time-reversal and inversion asymmetric. This asymmetry establishes a means for exceptional tunability of magnon-photon coupling, which can be switched on and off by reversing the magnetization direction. Taking the multiferroic skyrmion host Cu_2OSeO_3 with ultralow magnetic damping as an example, we reveal the electrical activity of skyrmion eigenmodes and propose it for magnon-photon splitting of "magnet-ically dark" elliptic modes. Furthermore, we predict a cavity-induced magnon-magnon coupling between magnetoelectrically active skyrmion excitations. We discuss applications in quantum information processing by proposing protocols for all-electrical magnon-mediated photon quantum gates, and a photon-mediated split operation of magnons. Our study highlights magnetoelectric cavity magnonics as a novel platform for realizing coherent transduction between photons and magnons.

MA 47.11   Fri 12:15   HSZ 04
Artificial surface conductivity on metallic metamaterials and its effect on localized plasmon skyrmions — •Amin Khavasi[1] and Karin Everschor-Sitte[1,2] — [1]Faculty of Physics, University of Duisburg-Essen, 47057 Duisburg, Germany — [2]Center for Nanointegration Duisburg-Essen (CENIDE), Duisburg, Germany
Metallic metamaterials have been widely investigated for realizing different peculiar effects such as spoof surface plasmons [1] and extraordinary transmission of light [2]. Recently, topologically robust localized plasmonic skyrmions have been realized by spiral metallic meta-structures [3, 4].

For metal films with a periodic arrangement of cut-through slits, Khavasi and others have shown that the structure can be modeled by an anisotropic medium with an artificial surface conductivity [5]. In the subwavelength regime, the surface conductivity is imaginary considering lossless systems representing non-specular higher diffracted orders. We investigate the consequences of such artificial surface conductivities for the skyrmionic modes of the spiral meta-structures to obtain more insight on the behavior of the localized plasmonic skyrmions.

Portable devices for adding Spatial-Intensity-Modulation-mode capabilities to polarized neutron beams — •Denis Mettus[1], Jonathan Leiner[1], Johanna Jochum[2], and Christian Pfleiderer[1] — [1]Physik-Department, Technische Universität München, D-85748 Garching, Germany — [2]Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, Garching, Germany
The MIEZE (Modulated IntEnsity with Zero Effort) resonant spin-echo technique at the RESEDA instrument at FRM II has its optimum resolution at small scattering angles, i.e. SANS type geometries. It is possible to extend the MIEZE application to wide angles by incorporating magnetic Wollaston prisms (MWPs) into the beamline. MWPs can produce controlled spatially intensity modulations in addition to the intensity modulations in time inherent to MIEZE. This would allow correcting to the neutron time of flight differences, extending the MIEZE resolution function to any desired scattering angle.

Additionally, MWPs will be useful in the context of intra-particle mode-entangled neutron beams for potential use in probing many-body quantum entanglement in materials. Finally, the compact and modular nature of the MWPs will allow them to be used to measure diffraction peaks with enhanced resolution at several polarized beam instruments such as KOMPASS, LaDiff, and in general at small angle neutron scattering instruments. We present the plans for the construction of these superconducting MWPs for use at FRM II, and describe the details of their operation and the various possibilities they offer.

A signal-integrating approach to second harmonic generation imaging and spectroscopy — Lea Forster[1], •Jan Gerrit Horstmann[1], Jannis Lehmann[1,2], Thomas Lottermoser[1], and Manfred Fiebig[1] — [1]Dept. of Materials, ETH Zurich, Switzerland — [2]RIKEN Center for Emergent Matter Science (CEMS), Japan
We investigate the impact of different data normalization procedures on the signal-to-noise ratio in second harmonic generation (SHG) imaging and spectroscopy. Using both nanosecond and femtosecond laser systems in combination with standard detection schemes for SHG, we find that uncorrelated noise in the detection electronics often dominates over the contributions of pulse-to-pulse fluctuations of the laser system, long-term power drifts, or time-dependent changes of the beam profile. Consequently, normalization of SHG signals averaged over thousands of pulses can yield similar signal-to-noise ratios comparable with pulse-to-pulse-normalized data. Based on these results, we demonstrate that state-of-the-art CCD or sCMOS cameras can, in many cases, replace photomultiplier tubes as detectors in pump-probe SHG measurements, enabling ultrafast high-resolution SHG imaging of nonequilibrium dynamics in solids.

MA 48.3   Fri 10:00   HSZ 401
New versatile instruments for magnetism research at ID12 of the ESRF — •A. Aubert[1], K. Skokov[1], G. Gomez[2,3], F. Wilhelm[3], A. Rogalev[3], H. Wende[2], O. Gutfleisch[1], and K. Ollefs[2] — [1]Functional Materials, TU Darmstadt (Germany) — [2]Fac. of Phys., Uni. Duisburg-Essen (Germany) — [3]ESRF, Grenoble (France)
I will introduce two new instruments which have been implemented at the beamline ID12 of the European Synchrotron Radiation Facility (ESRF), in the framework of the ULMAG project funded by BMBF (grant 05K2019). These instruments offer the ESRF users a unique possibility to measure under strictly the same experimental conditions the element-specific X-ray absorption spectroscopy (XAS)/X-ray magnetic circular dichroism (XMCD), XRD simultaneously with the measurement of various macroscopic properties (magnetization, magnetostriction, magnetocaloric, magnetoresistance), as a function of magnetic field (up to 17 T) and temperature (5-325 K) [1].

To demonstrate the potential and features of these scientific instruments, I will present two case studies: (1) FeRh, which has a first-order anti-ferromagnetic to ferromagnetic transition around room temperature (2) HoCo2, which exhibits a first-order ferrimagnetic to paramagnetic transition. These two cases demonstrate new horizons for studying the physics of magnetic materials, where the interplay between the magnetic, structural, and electronic subsystems of the solid is essential.

MA 48.4 Fri 10:15 HSZ 401

XMCD in fluorescence-yield mode can measure the spin-orbit torque switching of both rare-earth and transition-metal sublattices in mesoscale devices of GdFe$_3$ thin films — •James M Taylor[1,2], Chen Luo[1,2], Victor Ukleev[1], Christian H Back[2], and Florin Radu[1] — [1]Helmholtz-Zentrum Berlin for Materials and Energy, 12489 Berlin, Germany — [2]Department of Physics, Technical University of Munich, 85748 Garching, Germany

Ferrimagnets containing one rare-earth and one transition-metal sublattice are of interest both for future spintronic devices and as sandbox materials for exploring ultrafast magnetism. In regard to the latter, ferrimagnetic Gd+Fe has been widely studied, due to its demonstration of all-optical switching (AOS). On the other hand, more interesting for technological applications is current-induced magnetization reversal driven by spin-orbit torques (SOTs). To fully understand SOT switching in ferrimagnets, it is important, as with AOS, to look at the respective behaviour of both sublattices. In this work, we take a step towards making such measurements more readily available: by using conventional, static x-ray magnetic circular dichroism (XMCD) operated in fluorescence-yield mode to measure the relative responses of the Gd and Fe sublattices during an SOT switching process. This was performed using sub-ms current pulses in μm-sized devices fabricated from GdFe$_3$ heterostructures down to 10 nm thick, in-situ in the VEKMAG beamline at the BESSY II synchrotron. We compare this with electrical detection of the switching using simultaneous anomalous Hall effect measurements, which follow the Fe sublattice, as expected.

MA 48.5 Fri 10:45 HSZ 401

Periodogram-based detection of unknown frequencies in time-resolved scanning transmission X-ray microscopy — •Simone Finizio[1], Joe Bailey[1,2], Bart Olsthoorn[3], and Jörg Raabe[1] — [1]Paul Scherrer Institut, Villigen PSI, Switzerland — [2]EPFL, Lausanne, Switzerland — [3]Nordita, KTH Royal Institute of Technology and Stockholm University, Stockholm, Sweden

Pump-probe time-resolved imaging is a powerful technique that enables the investigation of dynamical processes. Signal-to-noise and sampling rate restrictions normally require that cycles of an excitation are repeated many times with the final signal reconstructed using a reference. However, this approach imposes restrictions on the types of dynamical processes that can be measured, namely that they are phase locked to a known external signal (e.g. a driven oscillation or impulse). This rules out many interesting processes such as auto-oscillations and spontaneously forming populations e.g. condensates. In this work we present a method for time-resolved imaging, based on the Schuster periodogram, that allows for the reconstruction of dynamical processes where the intrinsic frequency is not known. In our case we use time of arrival detection of x-ray photons to reconstruct magnetic dynamics without using *a-priori* information on the dynamical frequency. This proof of principle demonstration will allow for the extension of pump-probe time-resolved imaging to the important class of processes where the dynamics are not locked to a known external signal and in its presented formulation can be readily adopted for x-ray imaging and also adapted for wider use.

MA 48.6 Fri 11:00 HSZ 401

Towards switchable probes for advanced Magnetic Force Microscopy — •Aniruddha Sathyadharma Prasad, Rachappa Ravishankar, Rudolf Schäfer, Volker Neu, Bernd Büchner, and Thomas Mühl — IFW Dresden, Helmholtzstraße 20, 01069 Dresden

In magnetic force microscopy (MFM) on samples consisting of non-homogeneous materials and challenging topography, the "magnetic" contrast is often overwhelmed by additional non-magnetic forces arising from differing contact potentials and from changes in the capacitive coupling due to topographical features. The elimination of such interfering signals can be done by a differ-

ential imaging process with inverted tip magnetization. Earlier implementations either require precise repositioning of the probe after external switching of the magnetization or application of global magnetic fields which can cause changes in the sample. In our work, we overcome these difficulties by switching the magnetization externally, and using feature matching in the post processing step to eliminate the need for precise repositioning. We also showcase first steps towards an in-situ switching of MFM probes for developing a high-speed differential process within the MFM instrument. This involves the design and fabrication of planar micro-coils capable of providing sufficient magnetic field to switch high quality Iron filled Carbon Nanotube (FeCNT) MFM probes. The switching was verified by applying the inhomogeneous field distributions of planar micro-coils in micromagnetic simulation studies on a FeCNT. Preliminary MFM results from an FeCNT probe interacting with such a coil are also presented.

MA 48.7 Fri 11:15 HSZ 401

Measuring Antiferromagnets at Room Temperature in a Magnetically Shielded Environment — •Michael Paulsen[1], Silvia Knappe-Grüneberg[1], Jens Voigt[1], Allard Schnabel[1], Rainer Körber[1], Michael Fechner[2], and Dennis Meier[3] — [1]Physikalisch-Technische Bundesanstalt, Berlin, Germany — [2]Max Planck Institute for the Structure and Dynamics of Matter, CFEL, Hamburg, Germany — [3]NTNU Norwegian University of Science and Technology, Trondheim, Norway

Antiferromagnetic materials possess zero net dipole magnetization. However, higher-order magnetizations, such as quadrupolar magnetic field contributions, have been predicted for non-centrosymmetric antiferromagnets. Classical low-temperature measurements on Cr$_2$O$_3$ [1] indeed indicated an external quadrupole field at 4.2 K [2, 3], but the validity of the results was put into question due to the limited sensitivity of the applied experiment. Here, we present magnetization measurements gained at room temperature in an ultra-low magnetic field environment (< 1 nT). A multi-channel setup with Superconducting Quantum Interference Devices (SQUIDs) and Optically Pumped Magnetometers (OPMs) are used as magnetic field detectors. The results corroborate the emergence of a quadrupolar far-field in Cr2O3, providing new opportunities for the characterization of antiferromagnets and materials with ultra-small remanent magnetization in general.

Improving the magnetic adhesion of a metal-pipe crawling robot using elastomeric toes — •Muhammad Khan, Kilian Schäfer, and Oliver Gutfleisch — Functional Materials, Institute of Materials Science, Technical University Darmstadt, D-64287 Darmstadt, Germany

To assist human inspectors who examine thousands of kilometres spread oil and gas pipelines, robots are being utilized. A key challenge in robotic pipeline inspection is to ensure that a robot does not fall off a metal pipe. In this work, we show that a two-legged robot crawls on metal pipes using its electromagnetic feet. The robot slip was fixed by introducing an elastomeric toe, implanted under the robot feet. It was shown that the soft toe increased the magnetic adhesion of the feet by enabling the stable stance of the robot feet. The behaviour of the foot-toe was further characterized by conducting surface adaptability test (measurement of toe deformation), calculating its coefficient of friction on different metal pipes, and real-world robot pipe-crawling experiments. Furthermore, use of a magneto-active compound consisting of hard magnetic Nd2Fe14B particles in a thermoplastic polyurethane (TPU) matrix, fabricated to form the fin-ray structure will be also discussed as a potential replacement of the electromagnet. However, such a fin-ray structure would require a large and continuously available activation field which is obviously highly challenging. Here, a concept demonstration at the miniature level can be shown by modifying the robot's shape and size, matching the miniature setup.

Spin revolution breaks time reversal symmetry of rolling magnets — •Elena Vedmedenko and Roland Wiesendanger — University of Hamburg

The classical laws of physics are usually invariant under time reversal. Here, we reveal a novel class of magnetomechanical effects rigorously breaking time-reversal symmetry. These effects are based on the mechanical rotation of a hard magnet around its magnetization axis in the presence of friction and an external magnetic field, which we call spin revolution. The spin revolution leads to a variety of symmetry breaking phenomena including upward propulsion on vertical surfaces defying gravity as well as magnetic gyroscopic motion that is perpendicular to the applied force. The angular momentum of spin revolution differs

from those of the magnetic field, the magnetic torque, the rolling axis, and the net torque about the rolling axis. The spin revolution emerges spontaneously, without external rotations, and offers various applications in areas such as magnetism, robotics and energy harvesting.

E. Y. Vedmedenko and R. Wiesendanger, Spin revolution breaks time reversal symmetry of rolling magnets, Sci. Rep. 12, 13608 (2022).

Towards nanomechanical detection of fT magnetic fields — Dhavalkumar Mungpara, Torben Hänke, and •Alexander Schwarz — Institute of Nanostructure and Solid State Physics, University of Hamburg, Jungiusstr. 11, 20355 Hamburg

This work has been conducted in the framework of the OXiNEMS project that aims to establish etching protocols for oxides similar to those nowadays available for silicon and to develop a novel all-oxide nano-mechanical sensor to detect biomagnetic field in the fT-regime required for magnetoencephalography (MEG).

Our envisaged hybrid sensor consists of a superconducting loop with a constriction that functions as field-to-gradient converter and a magnetically sensitive mechanical resonator that detects the Oersted field above the constriction. To increase the signal above the thermal noise limit we present an optimized constriction-resonator arrangement that encompasses a spiral geometry instead of a single constriction. This optimized geometry, can be fabricated using up-to date technology and should be able reach a sensitivity of 10 fT/$\sqrt{Hz}$ at 77 K.

The OXiNEMS project (www.oxinems.eu) has received funding from the European Union's Horizon 2020 research and innovation program under Grant Agreement No. 828784. The author gratefully acknowledges the fruitful discussions with all members of the consortium, particularly Luca Pellegrino, Stefania Della Penna, Alexei Kalaboukhov, Federico Maspero, Nicola Manca, Simone Cuccurullo, Warner Venstra, Daniele Marré and Riccardo Bertacco.

Magnetic noise theory of magnetoelastic magnetic field sensors — •Elizaveta Spetzler[1], Benjamin Spetzler[2], and Jeffrey McCord[1] — [1]Institute for Materials Science, Kiel University, Kiel, Germany — [2]Department of electrical engineering and information technology, Technical University Ilmenau, Ilmenau, Germany

Intrinsic magnetic noise currently limits the performance of many magnetoelastic magnetic field sensors. Therefore, understanding and estimating the magnetic noise level is crucial for further sensor improvement. This work reviews the theory of thermal-magnetic noise in general and discusses additional magnetic noise sources relevant to magnetoelastic magnetic field sensors. We highlight the limitations and assumptions of previous approaches and develop important model extensions. We demonstrate and quantify the strong connection between magnetic sensitivity, loss, and noise by implementing the magnetic noise description in a multilevel model of a magnetoelastic magnetic field sensor based on the ΔE effect. The excellent match of simulations and measurements reveals a significant influence of the fundamental nonlinearity of the ΔE effect on the sensor performance. While the model is applied to ΔE effect sensors, many of the results are also valid for other magnetic field sensors and magnetoelastic modulated devices.

This work was funded by the German Research Foundation (DFG) through the Collaborative Research Centre CRC 1261 "Magnetoelectric Sensors - From Composite Materials to Biomagnetic Diagnostics" and the Carl-Zeiss Foundation via the Project MemWerk.

Transfer printing of GMR sensing elements for curved electronics — •Bezsmertna Olha[1], Rui Xu[1], Eduardo Sergio Oliveros-Mata[1], Clemens Voigt[2], Sindy Mosch[2], Jürgen Fassbender[1], Mykola Vinnichenko[2], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V., 01328 Dresden, Germany — [2]Fraunhofer Institute for Ceramic Technologies and Systems IKTS, 01277 Dresden, Germany

In the post-covid era, touchless interaction between human beings and environments is attracting more and more attentions. Sensors based on giant magnetoresistance (GMR) effect are widely considered as a workhorse to address this demand. However, the fabrication of GMR multi-layer elements face many limitations (e.g., inappropriate to substrates with curved and/or rough surfaces) due to the layer thickness dependence of performance. Here, we propose a transfer technique to overcome the aforementioned limitations. With the assistance of two sacrificial layers, a large scale and wrinkle-free coverage is realized on various substrates (of different materials, roughness, and curvatures) with little loss of GMR performance. Notably, such technique is easy processing, without the need of any substrate deformation, temporary carriers or high-temperature processing. The transferred sensors are integrated into skin-mountable electronics, successfully functioning as a human-machine interface.

MA 49.6　Fri 11:00　HSZ 403
Printed Giant Magnetoresistive Sensors — •Yevhen Zabila, Eduardo Sergio Oliveros Mata, Minjeong Ha, Gilbert Santiago Cañón Bermúdez, Rico Illing, Ingolf Mönch, Jürgen Fassbender, and Denys Makarov — Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

Printing is an affordable and high-throughput method to process electronics in soft substrates. Printable magnetoresistive pastes have been developed as an alternative single-step fabrication method to obtain magnetic field sensors. Until now, there were no examples of magnetic printed sensors that deliver steady sensing behavior upon mechanical stretching. Here, we will present low-noise printable magnetic field sensors sensitive down to sub-mT, which are mechanically stretchable after printing. The pastes are composites of poly(styrene-butadiene-styrene) copolymer (SBS) with embedded magnetoresistive microflakes. Our printed sensors were demonstrated to be used as electronic skin interfaces.[1]

MA 49.7　Fri 11:15　HSZ 403
Printed magnetic field sensors based on bismuth showing large non-saturating magnetoresistance — •Eduardo Sergio Oliveros-Mata[1], Clemens Voigt[2], Gilbert Santiago Cañón Bermúdez[1], Zevhen Zabila[1], Rico Illing[1], Marco Fritsch[2], Sindy Mosch[2], Mihails Kusnezoff[2], Jürgen Fassbender[1], Mykola Vinnichenko[2], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Fraunhofer-Institut für Keramische Technologien und Systeme, Dresden, Germany

The development of functional inks allows to create novel printed electronics with unconventional form factors. Here, we show the fabrication of printed magnetic field sensors based on bismuth microparticles. Sensors showed non-saturating large magnetoresistance (146%, 5T, at room temperature), and resilience to mechanical bending (2000 cycles). We demonstrated large area magnetically sensitive interfaces such as smart locks and interactive wallpapers.[1]

MA 49.8　Fri 11:30　HSZ 403
Self-healable printed magnetic field sensors using alternating magnetic fields — •Rui Xu[1], Gilbert Santiago Cañón Bermúdez[1], Oleksandr V. Pylypovskyi[1], Oleksii M. Volkov[1], Eduardo Sergio Oliveros Mata[1], Yevhen Zabila[1], Rico Illing[1], Pavlo Makushko[1], Pavel Milkin[2], Leonid Ionov[2], Jürgen Fassbender[1], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]University of Bayreuth, Ludwig Thoma Str 36a, 95447 Bayreuth, Germany

Percolation network of fillers plays a critical role in rendering printable electronics functionality and durability1. We employ alternating magnetic fields (AMF) to drive magnetic fillers actively and guide the formation and self-healing of percolation networks2. Relying on AMF, we fabricate printable magnetoresistive sensors revealing an enhancement in sensitivity and figure of merit of more than one and two orders of magnitude relative to previous reports. These sensors display low noise, high resolution, and are readily processable using various printing techniques that can be applied to different substrates. The AMF-mediated self-healing has six characteristics: 100% performance recovery; repeatable healing over multiple cycles; room-temperature operation; healing in seconds; no need for manual reassembly; humidity insensitivity. By virtue of these advantages, the AMF-mediated sensors are used in safety application, medical therapy, and human-machine interfaces for augmented reality. 1 Nat. Electron. 2, 144-150 (2019); 2 Nat. Commun. 13, 6587 (2022).

MA 50: Magnetic Domain Walls (non-skyrmionic)

Time: Friday 9:30–11:15　　　　　　　　　　　　　　　　　　　　　　　　　　Location: POT 6

MA 50.1　Fri 9:30　POT 6
Geometrically controlled domain wall dynamics in curved 3D nanostructures — •Sandra Ruiz-Gomez[1], Pamela Morales[1], Claudia Fernandez-Gonzalez[1], Aurelio Rodriguez-Hierro[2], Michael Foerster[3], Miguel Angel Nino[3], Ewa Madej[4], Dorota Wilgocka-Slezak[4], Anna Mandziak[4], Amalio Fernandez-Pacheco[5], and Claire Donnelly[1] — [1]MPI-CPfS, Dresden, Germany — [2]Nothnitzer strasse 40 — [3]Alba Synchrotron, Barcelona, Spain — [4]Solaris synchrotron, Krakow, Poland — [5]INMA, Zaragoza, Spain

Three dimensional nanomagnetic systems, with novel and unconventional spin textures, represent an exciting platform to explore new magnetic phenomena for the development of more efficient, capable and multifunctional technologies. In particular, the 3D geometry is predicted to have a significant influence on the dynamics of magnetic domain walls through the introduction of curvature and torsion, where new physics and functionalities can be realised.

Here, we experimentally explore the influence of 3D geometry on the energetics of domain walls by introducing curvature using focused electron beam induced deposition. We probe the behaviour of DWs within 3D curved systems with soft x-ray magnetic microscopy, that allows us to directly observe the magnetic state and the domain walls, and determine their response to the application of magnetic fields . This insight into the control that can obtained via complex geometries will help pave the way to the next generation of 3D spintronic devices.

MA 50.2   Fri 9:45   POT 6

Geometry-induced effects in domain wall dynamics in stripes with spatially varying cross section — •Kostiantyn V. Yershov[1,2] and Denis D. Sheka[3] — [1]Leibniz Institute for Solid State and Materials Research, Dresden, Germany — [2]Bogolyubov Institute for Theoretical Physics, Kyiv, Ukraine — [3]Taras Shevchenko National University of Kyiv, Ukraine

Here we study both analytically and numerically the influence of curvature and cross section deformation effects on the motion of a domain wall in curved stripes which corresponds to geometry of recent experiments [1]. We base our study on a phenomenological Landau–Lifshitz–Gilbert equations using collective variable approach based on a $q - \Phi$ model. We show that (i) curvature and nonzero gradient of cross-section deformation result in a modification of a ground state and can be interpreted as an effective magnetic field. (ii) The presence of a nonzero gradient of cross section deformation also results in a pinning potential for domain walls in addition to the curvature-induced potential [2]. In effective equations of motions the spatially varying cross section and curvature appear as a driving forces which can suppress or reinforce the action of each other. The eigenfrequency oscillations of domain wall in vicinity of the pinning potential is obtained as a function of curvature and cross section deformation and their gradients. All analytical predictions are well confirmed by full scale micromagnetic simulations. [1] L. Skoric et al, ACS Nano **16**, 8860 (2022); [2] K. V. Yershov et al, PRB **92**, 104412 (2015).

MA 50.3   Fri 10:00   POT 6

Domain wall tilt in thin CrOx/Co/Pt corrugated stripes — •Jose A. Fernandez-Roldan[1], Mikel Quintana[1,2], Shahrukh Shakeel[1], Oleksii Volkov[1], Oleksandr Pylypovskyi[1], Eduardo Sergio Oliveros-Mata[1], Florian Kronast[3], Mohamad-Assaad Mawass[3], Claas Abert[4], Dieter Suess[4], Denise Erb[1], Jürgen Fassbender[1], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]CIC nanoGUNE BRTA, Donostia-San Sebastian, Spain — [3]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany — [4]Physics of Functional Materials, University of Vienna, Vienna, Austria

Curvilinear magnetism is a flourishing field of interest for applications in flexible magnetoelectric devices, microrobots, sensors and nanoelectronics [1-2]. Curvilinear phenomena often result in magnetization patterning, symmetry breaks and Domain Wall (DW) pinning. However, these phenomena have remained so far unexplored in stripes. Here, spin-orbit torques allow the manipulation of DWs [3] with a low power consumption. A recent approach permits the estimation of Dzyaloshinskii-Moriya interaction from DW tilt in thin stripes [4]. Here we provide first results on 100 nm wide 2 nm thin corrugated CrOx/Co/Pt stripes with a mean curvature of $0.06\,\mathrm{nm}^{-1}$. Our results open a perspective for the design of curvature-induced effects with application prospects in current challenges of nanoelectronics. [1] D. Makarov et al., Adv.Mater. 34(3), 2101758 (2022); [2] D. Sheka et al., Small 18, 2105219 (2022); [3] O. Pylypovskyi et al. Sci.Rep. 6, 23316 (2016); [4] O. M. Volkov et al., Phys.Rev.Appl. 15, 034038 (2021).

MA 50.4   Fri 10:15   POT 6

Get in Shape - Closed Magnetoelastic Domain Wall Loops in Antiferromagnets — •Bennet Karetta and Olena Gomonay — Johannes-Gutenberg Universität Mainz

Antiferromagnets are new candidates to be used as active spintronics elements as they are faster and more stable than the ferromagnets in current devices. However, their lack of a net magnetization introduces the challenge to manipulate the magnetic state. Recent studies suggested that the magnetoelastic coupling can be used for this task. Thus, understanding the interaction between strain and Néel vector is of high priority. We study the orientation in different antiferromagnetic domain walls which is influenced by magnetostriction. We show how the energy of the domain wall depends on its orientation on the antiferromagnet. Further, we apply the results to a system of a closed domain wall loops. The anisotropy of the energy significantly changes the shape of the closed loop to an anisotropic

form. The exact shape is given by the type of domain wall and magnetoelastic coupling strength. For its determination we finally present a method to quantify the change of the domain wall shape from the zero magnetoelastic coupling case.

MA 50.5   Fri 10:30   POT 6

Magneto-Optic Effects and Domain Imaging in EuO film and EuO/Co Heterostructure — •Seema Seema[1], Henrik Jentgens[1], Paul Rosenberger[1,2], and Martina Müller[1] — [1]Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany — [2]Fakultät Physik, Technische Universität Dortmund, 44221 Dortmund, Germany

Ferromagnetic semiconductors and stable half-metallic ferromagnets with Curie temperatures (Tc) equal to or more than room temperature have been sought for their applications in novel spintronic devices. Europium oxide (EuO) is one of the potential candidates as it possesses strong ferromagnetism (FM) of 7 μB with a Tc of 69 K. The present work focuses on the magnetization reversal mechanisms and domain images in EuO probed using magneto-optic Kerr microscopy. We aimed to visualize magnetic proximity effect induced changes in the coercivity of hysteresis loops as well as magnetic domains in EuO film and in a EuO/3d-FM heterostructure. We synthesized EuO/Co heterostructure sample using molecular beam epitaxy on Nb:STO and observed the differences in the domain saturation behavior as well as the Kerr rotation below Tc. This had been performed by magnetic hysteresis measurement along with simultaneous domain imaging using a Kerr microscope. To explore the temperature-dependent magneto-optic effects in EuO in the proximity of Co, we measured hysteresis at various temperatures below and above Tc. This study of proximity effect-induced changes in magnetic domains in EuO due to Co can provide insights into achieving room-temperature FM in EuO.

MA 50.6   Fri 10:45   POT 6

Electric field induced magnetic swicthing in spin-spiral multiferroics — Francesco Foggetti[1,2] and •Sergey Artyukhin[1] — [1]Italian Institute of Technology, Genova, Italy — [2]Uppsala University, Sweden

Switching in magnetic materials gives rise to rich physical phenomena and lies at the heart of their technological applications. Although domain wall motion in ferro- and antiferromagnets has been studied, in spiral magnets it is still poorly understood despite 20 years of active research since the discovery of spiral multiferroics. The problem of the domain wall motion in a spiral magnet is a compelling one, the more so the magnetic domain walls in cycloidal spiral phase are also ferroelectric, thus enabling electric control of magnetism, i.e. domain wall motion under the action of an external electric field. Phase transition to a spiral phase leads to a formation of chiral domains with opposite spin rotation senses, that are separated by chiral domain walls. Spiral order breaks inversion symmetry and induces a ferroelectric polarization, whose sign is determined by the chirality of the domain. Thus the spiral order allows for the manipulation of spins via an external electric field. Here we study domain wall motion in magnets with spiral ground state, that are the most basic non-collinear magnets. We formulate a simplified variational model and derive the equation of motion for the domain wall driven by an external electric field. The results are corroborated with atomistic spin dynamics simulations. The results suggest a linear dependence of the wall speed on the external electric field, and a peculiar dependence on the system geometry and domain structure.

MA 50.7   Fri 11:00   POT 6

Visualisation of an 4f-antiferromagnetic domain pattern in multiferroic $Dy_{0.7}Tb_{0.3}FeO_3$ — •Yannik Zemp[1], Mads C. Weber[1,2], Ehsan Hassanpour[1,3], Thomas Lottermoser[1], Yusuke Tokunaga[4], Yasujiro Taguchi[5], Yoshinori Tokura[5,6], and Manfred Fiebig[1] — [1]Department of Materials, ETH Zurich — [2]IMMM, Le Mans Université — [3]UDEM Inselspital, University of Bern — [4]Department of Advanced Materials Science, University of Tokyo — [5]RIKEN CEMS, Japan — [6]Department of Applied Physics, University of Tokyo

We visualize the antiferromagnetic (AFM) domain pattern of the 4f-rare-earth subsystem in $Dy_{0.7}Tb_{0.3}FeO_3$. To do so, we exploit the unique order-parameter interaction in the multiferroic phase of this material, where the magnetic rare-earth- and iron subsystems induce ferroelectricity. By magnetic-field cooling into the multiferroic phase, we force the 4f-rare-earth- and ferroelectric domain pattern to be identical. We can then access the former by imaging the latter using optical second harmonic generation, which is very sensitive to a breaking of inversion symmetry. The 4f-AFM domains form stripes with a thickness of several 10 μm along the antiferromagnetic easy axis. As a consequence, the ferroelectric domains are forced to form energetically unfavourable head-to-head and tail-to-tail domain walls. Also, the domain pattern is very dissimilar to the weakly ferromagnetic bubble-domain structure of the iron sublattice that is present at higher temperatures. These observations show that the rare-earth system orders independently from the other magnetic- and electric influences.

Sessions
– Invited Talks, Topical Talks, Tutorials, Contributed Talks, and Posters –

MM 1: Hands-on Tutorial on Workflows for Materials Science Simulation (joint session MM/TUT)

Time: Sunday 16:00–18:00   Location: HSZ 03

Tutorial   MM 1.1   Sun 16:00   HSZ 03
Hands-on tutorial on workflows for materials science simulations — •Jörg Neugebauer[1], Tilmann Hickel[1], and Ralf Drautz[2] — [1]Max-Planck-Institut für Eisenforschung, Düsseldorf — [2]ICAMS, Ruhr-Universität Bochum
Advanced computational simulations in materials science have reached a maturity that allows one to accurately describe and predict materials properties and processes. The underlying simulation tasks often involve several different models and software that requires expert knowledge to set up a project and to vary input parameters. The accompanying increasing complexity of simulation protocols means that the workflow along the simulation chain becomes an integral part

of research. Effective workflow management therefore is important for efficient research and transparent and reproducible results.

In this hands-on tutorial we will provide an interactive hands-on introduction into managing workflows with pyiron (www.pyiron.org). Pyiron is an integrated development environment for materials science built on python and Jupyter notebooks that may be used for a wide variety of simulation tasks, from rapid prototyping to high performance computing. The tutorial will first give a general introduction to using pyiron, with a focus on atomistic simulation tasks. In the second part of the tutorial, the training and validation of ace-machine learning potentials from reference density functional calculations will provide a real-life application example.

MM 2: Invited Talk: Lilleodden

Time: Monday 9:30–10:00   Location: SCH A 251

Invited Talk   MM 2.1   Mon 9:30   SCH A 251
Function follows form: on tailoring functional materials via microstructural design — •Erica Lilleodden — Fraunhofer-IMWS
While the Bauhaus adage say that form follows function, materials scientists understand that function follows form; we aim to exploit structuring of materials to achieve targeted function; the inherent interplay between processing, structure and properties is indeed the cornerstone of materials science. In this talk, I will

present two examples in which various structural elements can be used to tune the functional response of materials in ways that may be unexpected: exploiting structural geometry to tailor strength to stiffness ratios; and how alloying and thermal treatments can lead to a simultaneous increase in both strength and hardening. These examples will be placed in the context of how we view classical laws governing structure-property relations, with an outlook on new approaches to materials design going forward.

MM 3: Development of Computational Methods: Evaporation, Growth and Oxidation – Density Functional, Tight Binding

Time: Monday 10:15–13:00   Location: SCH A 251

MM 3.1   Mon 10:15   SCH A 251
Towards machine learning potentials for field evaporation — •Shyam Katnagallu, Joerg Neugebauer, and Christoph Freysoldt — Department of computational materials design, Max Planck Institut für Eisenforschung GmBH, Düsseldorf, Germany.
Field evaporation, an electrostatic field-induced ionization and subsequent evaporation of surface atoms, is the underlying principle of atom probe tomography. Ab initio simulations including 1-10 V/Å fields on metallic slabs have recently shed light [1] on the intricacies of the field evaporation process. These simulations underscore the importance of knowing the path of the evaporating atom prior to complete ionization to improve the spatial resolution of the technique. However, to properly sample the extremely shallow potential energy surface due to the electrostatic field extensive simulations with computationally expensive ab initio accuracy are needed. We, therefore, combine machine learning interatomic potentials with a charge equilibration scheme. To demonstrate the performance and accuracy of our scheme, we validate the Rappe et al charge equilibration model [2] using Hirshfeld decomposed DFT reference charges acquired from (13,5,7) Pt slab under electric fields ranging from (1-4.5 V/Å) and develop potentials for field evaporation in Al. [1]*M. Ashton, A. Mishra, J. Neugebauer, and C. Freysoldt, Ab Initio Description of Bond Breaking in Large Electric Fields, Phys. Rev. Lett. 124, (2020). [2]*A. K. Rappe and W. A. G. Iii, Charge Equilibration for Molecular Dynamics Simulations, J. Phys. Chem 95, 3358 (1991).

High temperature chlorine corrosion in waste-to-energy-plants: sulphation of chloride particles as source of released chlorine — •Sebastian Pentz, Matthias Kroh, and Ferdinand Haider — University of Augsburg, Chair for Experimental Physics I, Universitätsstr. 1, 86159 Augsburg
Chlorine induced high temperature corrosion leads to massive problems especially in waste-to-energy-plants. During the combustion process chloride containing particles are released and deposited on heat exchanger surfaces. There chlorides get converted into sulphates with a release of chlorine species which then lead to severe corrosion. For chloride particle sampling from a plant a tempered probe was developed, allowing time series of deposit built-up at defined

temperatures. From this online particle sampling during plant operation we collect information about sticking probability, size distribution of deposited particles and the chemical composition of the deposit built up. Especially the relation between detected chlorine to sulphur is of high interest, leading to the degree of conversion of deposited chlorides, which equals the amount of released chlorine. In further laboratory experiments the sulphation process of synthetic chloride particles can be systematically studied. From this we get the sulphation kinetics under various conditions like temperature, particle size or gas composition, which lead to an estimation of the time required for full chloride conversion. By combining the results gained from laboratory experiments, online particle sampling and offline deposit analysis, we try to model the ongoing sulphation process.

How to teach my deep generative model to create new RuO_2 surface structures? — •Patricia König, Hanna Türk, Yonghyuk Lee, Chiara Panosetti, Christoph Scheurer, and Karsten Reuter — Fritz-Haber Institute, Max-Planck-Society, Faradayweg 4-6, 14195 Berlin, Germany
Data-driven approaches to inversely design novel materials with desired properties constitute an emerging pillar in the exploration of energy conversion materials. In recent works, artificial neural networks were successfully used to create crystalline porous materials. Here, we present a related approach to tackle the problem of structure generation for nano-porous to partially amorphous surfaces. As a model system, we use the well-studied RuO_2 catalyst for oxidative conversion of CO to CO_2. To explore the chemical space of RuO_2 surface structures, we trained a Generative Adversarial Network (GAN) that is capable of cheaply generating diverse structural guesses for novel surface structures. For the training set, $28,903$ RuO_2 surface terminations were created with a grand-canonical basin hopping method using ML potential energetics. The atomic positions of these structures were mapped to Gaussian densities on a three-dimensional grid to generate the GAN input. We demonstrate how realistic three-dimensional surface models with inferred lattice lengths and energy conditioning can be created and how these generated densities can be mapped back to atomistic structures as a basis for property calculations.

MM 3.4   Mon 11:00   SCH A 251

Liquid-Diffusion-Limited Growth of Vanadium Dioxide Single-Crystals — •Nico Sprinkart, Daniel Kazenwadel, Roman Hartmann, and Peter Baum — Department of Physics, University of Konstanz

Vanadium dioxide (VO_2) is a strongly correlated material with an ultrafast first-order phase transition between rutile/insulator and monoclinic/metallic close to room temperature. The unusual and complex properties of this transition make VO_2 one of the most heavily investigated materials in modern condensed matter physics. Consequently, high-quality single-crystals are in large demand.

Here we present a method for the growth of mm-sized stoichiometric VO_2 crystals by thermal decomposition of liquid V_2O_5. Time-resolved measurements of the oxygen release reveal that the crystal growth rate is limited by liquid-phase diffusion; the properties of the gaseous environment, which were previously assumed to be decisive, are almost insignificant.

Our results signify the role of gas-liquid diffusion in crystal growth and will simplify future research on VO_2 and its subsequent application in ultrafast electronics and thermal energy management.

MM 3.5   Mon 11:15   SCH A 251

Dynamic restructuring of oxidation states in magnetite — •emre gürsoy[1], gregor b. vonbun-feldbauer[2], and robert h. meissner[1,3] — [1]Institute of Polymer and Composites, Hamburg University of Technology, Hamburg, Germany — [2]Institute of Advanced Ceramics, Hamburg University of Technology, Hamburg, Germany — [3]Institute of Surface Science, Helmholtz-Zentrum Hereon, Geesthacht, Germany

Magnetite is a mineral that undergoes a metal-insulator transition called the Verwey transition at 125 K (T_V). Its conducting behaviour above T_V is linked to electron hops between Fe^{2+} and Fe^{3+} on octahedral sites and complex oxidation state patterns emerge as a direct consequence. Oxidation states are frequently assessed using quantum mechanical methods, but these computationally expensive methods are not scalable to relevant systems with several thousand atoms. Therefore, a computationally inexpensive method that provides a detailed atomistic description of magnetite would be beneficial. We present a hybrid Monte Carlo/Molecular Dynamics (MC/MD) approach for atomistic modeling of magnetite, magnetite surfaces, and nanoparticles that can capture many aspects of this oxidation state patterning. It is based on swapping the oxidation states of Fe ions using MC either in simulated annealing, or in a hybrid combination with MD. We confirmed the accuracy of our model by comparison with oxidation states determined from density functional theory. This simple yet efficient approach paves the way to elucidate aspects of oxidation state ordering and electron hopping in inverse spinel structures in general.

Role of an adsorbed gas layer in field ion microscopy contrast — •Shalini Bhatt, Felipe F.Morgado, Shyam Katnagallu, Christoph Freysoldt, and Jörg Neugebauer — Max Planck Institut für Eisenforschung GmbH Düsseldorf Germany

The imaging contrast in field ion microscopy (FIM) is associated with the ionization probability of gas atoms near a surface under 10-100 V/nm electric fields. To better understand contrast variations among atoms observed in FIM, we employ density functional theory (DFT) in combination with the Tersoff-Hamann approximation that links electron tunneling from the gas atom to the surface with the surface's local density of states at the position of the gas atom 3-6 Å away from the surface. Based on our new EXTRA approach (extrapolated tail via reverse algorithm) that eliminates numerical noise in the tails of the wavefunctions, we demonstrate a chemical brightness contrast for Ta in Ni (012) surface. However, we find that the simulated imaging contrast for Ni alone is much lower than in experiment. We therefore explore the role of an adsorbed gas layer as an essential ingredient to explain FIM's unexpectedly large spatial resolution.

MM 3.7   Mon 12:00   SCH A 251

A Workflow for Obtaining Robust Density Functional Tight Binding Parameters Across the Periodic Table — •Mengnan Cui, Johannes T. Margraf, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin, Germany

The Density Functional Tight Binding (DFTB) approach allows electronic structure based simulations at length and time scales far beyond what is possible with first-principles methods. This is achieved by using minimal basis-sets and empirical approximations. Unfortunately, the sparse availability of parameters across the periodic table is a significant barrier to the use of DFTB in many cases.

In this contribution, we therefore propose a workflow which allows the robust

and consistent parameterization of DFTB across the periodic table. Importantly, the approach requires no element-pairwise parameters and can thus easily be extended to new elements. Specifically, the parameters defining the band energy and repulsive potential are obtained via Bayesian Optimization on a set of elemental solids. In this way, robust baseline parameters can be obtained for arbitrary element combinations. The transferability of the parameters and applications in hybrid DFTB/Machine Learning models will be discussed.

MM 3.8   Mon 12:15   SCH A 251

Coupling Many Body Perturbation Theory (MBPT) with Polarizable Continuum Models (PCM) — •Pino D'Amico[1], Dario A. Leon Valido[2], Margherita Marsili[3], Daniele Varsano[1], Stefano Corni[4], and Andrea Ferretti[1] — [1]S3 Center, Istituto Nanoscienze CNR, Modena, Italy — [2]Dpt. REALTEK, Norw. Univ of Life Sci., Ås, Norway — [3]Dpt. di Fisica e Astronomia, Univ. di Bologna, Italy — [4]Dpt. di Scienze Chimiche, Univ. di Padova, Italy

The theoretical description of quantum systems embedded in external environments represents a challenge for the application of MBPT approaches to the study of the electronic excitations. Different level of accuracy can be used to treat the actual system, for which a quantum mechanical description is employed, and its sorrounding environment, that can be approximated through a simplified quantum model, a molecular mechanical approach, or a continuum model. We will present a theoretical framework in which a MBPT treatment of the quantum system (eg at the level of GW and BSE) is coupled to a PCM description of its sorrounding environment. The formalism has been implemented within the YAMBO code[1], based on plane-waves and pseudopotentials, by exploiting the ENVIRON package[2] coupled to the Quantum ESPRESSO suite[3]. Preliminary results of the newly developed methodology will be presented, focusing on selected molecules and two-dimensional materials in water. [1] D. Sangalli et al., J.of Phys.:Cond.Mat. 31, 325902 (19).[2] O. Andreussi et al., J.Chem.Phys. 136, 064102 (12).[3] P. Giannozzi et al., J.Phys.:Cond.Mat. 29, 465901 (17).

MM 3.9   Mon 12:30   SCH A 251

A DFTB-based approach to calculating electron-phonon couplings — •Alexander Croy[1], Elif Unsal[2], Gianaurelio Cuniberti[2], and Alessandro Pecchia[3] — [1]Institute of Physical Chemistry, FSU Jena, Germany — [2]Institute of Materials Science, TU Dresden, Germany — [3]Institute of Nanostructured Materials, CNR, Italy

The calculation of electron-phonon couplings from first principles is computationally very challenging and remains mostly out of reach for systems with a large number of atoms. Resorting to semi-empirical methods, like density-functional based tight-binding (DFTB), has been shown to be a viable approach for obtaining quantitative results at moderate computational costs. In this contribution, we present a method for calculating the electron-phonon coupling matrix within the DFTB approach and demonstrate its implementation which is based on dftb+ and phonopy. It further allows the calculation of relaxation times and interfaces with BoltzTrap2 to compute transport properties. Exemplarily, we show results for γ-graphyne which was recently synthesized. Consistent with earlier predictions we obtain mobilities on the order of $10^4 cm^2 V^{-1} s^{-1}$ at room temperature.

MM 3.10   Mon 12:45   SCH A 251

Toward Coarse-Grained Elasticity of Single-Layer Covalent Organic Frameworks — •David Bodesheim[1], Antonios Raptakis[1], Arezoo Dianat[1], Alexander Croy[2], and Gianaurelio Cuniberti[1] — [1]TU Dresden, Dresden, Germany — [2]FSU Jena, Jena, Germany

Covalent Organic Frameworks (COFs) are crystalline porous materials that are based on organic monomeric units, so called building blocks. As a multitude of different building blocks can be combined in reticular chemistry, manifold different porous structures with tailored properties have been synthesized in recent years. Through current experimental progress, monolayer COF materials have been synthesized, providing a new class of 2D materials.[1,2] However, these materials have defects and grain boundaries which make it challenging to describe properties of realistic materials computationally. To approach this issue, we show in this work how to use a surrogate model to calculate elastic properties of 2D COFs based on density functional based tight binding (DFTB) calculations.[3] This allows us to model defective systems at low computational cost and paves the way for multiscale modeling. Furthermore, this approach enables us to predict elastic properties from the properties of the monomeric building blocks.

MM 4: Topical Session: Fundamentals of Fracture − Micromechanical Fracture Experiments

Time: Monday 10:15–13:00   Location: SCH A 216

Topical Talk   MM 4.1   Mon 10:15   SCH A 216
Crack and dislocations interactions: coupling DDD and XFEM — Elena
Jover-Carrasco[1], Erik Bitzek[2], and •Marc Fivel[1] — [1]CNRS/SiMaP, Univ.
Grenoble Alpes, Grenoble, France — [2]MPIE, Computational Materials Design,
Dusseldorf, Germany

The objective of this study is to build a numerical tool which could handle both
cracks and dislocations in a dynamic manner. To do so, a 3D Discrete Dislo-
cation Dynamics (DDD) code has been combined to the Extended Finite Ele-
ment Method (X-FEM) via a strong coupling with the Finite Element software
CAST3M. In the original FEM code, the crack advance is computed from the
G-θ method which gives access to the stress intensity factors K. In this formal-
ism, θ is the kinematically admissible virtual displacement of the crack and G
is the energy release rate at the crack tip. When dislocations are present in the
simulated box, they modify the evaluations of the energy and consequently the
values of the derived stress intensity factors. These modifications are computed
locally all along the crack front which is defined using level set functions. The
crack front may locally change its direction of motion depending on the relative
values of the stress intensity factors, especially KII. This will then lead to blunting
effect of the crack tip.

In this presentation, full details of the coupling will be given. Test cases will
then be presented where the behavior of a single dislocation in vicinity of a crack
will be compared to atomistic simulations. Finally, large scale simulations of a
mode I opening crack will be performed.

Topical Talk   MM 4.2   Mon 10:45   SCH A 216
multiscale studies on the fracture behaviors of body centered cubic metal —
•Yinan Cui, Zhijie Li, and Zhangtao Li — Applied Mechanics Lab., School of
Aerospace Engineering, Tsinghua University, Beijing 100084, PR China

How the plasticity features influence the fracture behaviors of material is a crit-
ical question but remains far from well understood. To disclose this mystery, a
multiscale plasticity-fracture coupled model is developed, which considers the
atomistic-scale dislocation motion mechanism, the mesoscopic scales of discrete
crack-dislocation interactions, and the continuum scale of crystalline plastic-
fracture response. Body center cubic (bcc) material is chosen as an example to
demonstrate the effectiveness of the developed model due to their wide appli-
cations and their speical plasticity feactures, such as strong temperature depen-
dence and non-Schmid effect. Several new insights about the fracture behavior
of bcc material are gained.

                                MM 4.3   Mon 11:15   SCH A 216
**Micro-cantilever experiments to study the influence of pre-deformation and
He irradiation on the fracture toughness of W single crystals** — Stefan
Gabel[1], Manuel Köbrich[1], Jan Vollhüter[1], Benedikt Eggle-Sievers[1],
Benoit Merle[2], Erik Bitzek[3], and •Mathias Göken[1] — [1]Friedrich-
Alexander-University Erlangen-Nürnberg (FAU) — [2]University Kassel — [3]Max-
Planck-Institut für Eisenforschung, Düsseldorf

Micro-cantilever fracture testing has been proven to be a very reliable method
to determine the fracture toughness at the very small scale. In the work by Ast
et al.[1] the influence of the specimen size on the fracture behavior of single
and polycrystalline tungsten has been investigated in detail from which it can be
concluded that the fracture toughness as analysed with the J-integral approach
slightly increases with the specimen size. Here we focus on the brittle-to-ductile
transition and the influence of pre-deformation and He irradiation on w single
crystals. The fracture toughness is analysed in a temperature regime from 233 K
up to 353 K with a FemtoTools in-situ nanoindentation system. Pre-deformation
by compression in the <110>direction led to a population of specific glide sys-
tems. The results show depending on the sample orientation an increase of the
hardness and a slightly higher fracture toughness at low temperatures. Irradi-
ation by He+ ions clearly lead to a decrease of the fracture toughness although
the hardness increases. The experimental results will be discussed in compari-
son with modelling results. [1] *J. Ast, M. Göken, K. Durst, Acta Materialia 138
(2017) 198-211

Topical Talk   MM 4.4   Mon 11:45   SCH A 216
**Capturing Micromechanical Crack Tip Stress States and Toughening Plas-
ticity in 2D and 3D** — •Thomas E. J. Edwards[1], Johannes Ast[1,2], Szilvia
Kalácska[1,3], Xavier Maeder[1], Jon Wright[4], and Johann Michler[1] —
[1]Empa, Feuerwerkerstrasse 39, 3602 Thun, Switzerland — [2]CEA, 17 rue des
Martyrs, 38054 Grenoble, France — [3]Mines Saint-Etienne, Univ Lyon, CNRS,
UMR 5307 LGF, France — [4]ESRF, 38000, Grenoble, France

Crack tip toughening mechanisms in metals require plasticity, i.e. slip; the
present study sheds predictive light on what local stress states lead to an increased
dissipation of mechanical energy through plasticity. It also confirms the notion

that the plastic performance of a material cannot be solely interpreted from elas-
tic strain measurements, even if undertaken in-situ, or from post-mortem TEM
imaging of dislocation structures. Pre-notched single crystal W microcantilevers
were deformed in situ, whilst elastic and total strains at the notch tip were cap-
tured correlatively by DIC and HR-EBSD with sub-100 nm resolution. From
the basic elastic and total strains and rotations hence measured, as well as post-
mortem TEM, the following could be extracted: maps of shear stresses resolved
onto individual slip systems, pure plastic strain resolved onto slip axes and GND
density - all throughout loading, as well as the total dislocation density of the
near-surface layer post-mortem. Further, we demonstrate a novel method to ex-
tract the full stress tensor, point-wise in 3D, again with ~100 nm resolution, on
micromechanical testpieces under load: nano-beam 3D-XRD computed tomog-
raphy at ESRF ID11.

                                MM 4.5   Mon 12:15   SCH A 216
**Size effect in fracture mechanics: a detailed investigation regarding crack
initiation and growth on the micro- and mesoscale** — •Jutta Luksch[1],
Aloshious Lambai[2], Gaurav Mohanty[2], Florian Schaefer[1], and Chris-
tian Motz[1] — [1]Materials Science and Methods, Saarland University, 66123
Saarbruecken, Germany — [2]Materials Science and Environmental Engineering,
Tampere University, 33014 Tampere, Finland

Fracture mechanics are strictly regulated by standards. This includes limitations
of specimen size as a function of the plastic zone size that mainly depends on
the material itself. Hence, established test procedures are not easily downscals-
ble to nanomechanic testing. With progress in specimen preparation by FIB and
test design e.g. in-situ testing in SEM, there are now ways to investigate a size
effect systematically according crack initiation and growth. In the present study
nanocrystalline nickel with a grain size of 40-50 nm is used as material to en-
sure a polycrystalline, quasi-homogeneous microstructure even for small sam-
ples. Micro bending beams of different dimensions are made using a FIB in order
to study the fatigue size effect. Special attention was layed to introduce a fatigue
pre-crack into the sample by cyclic loading with R<0 in a SEM with a nanoin-
denter. A study of crack initiation stress and number of needed cycles was made.
The focus was given on microstructural changes. This pre-crack is then subjected
to fatigue (R>0) and crack growth is quantified by the compliance method. In
addition, the stress intensity factor is evaluated and related to the crack growth.

                                MM 4.6   Mon 12:30   SCH A 216
**Quantitative measurement of fracture toughness from the bridge notch
failure in microcantilever** — •Yinxia Zhang[1], Matthias Bartosik[2],
Steffen Brinckmann[3], Subin Lee[1], and Christoph Kirchlechner[1] —
[1]Institute for Applied Materials, Karlsruhe Institute of Technology, Eggenstein-
Leopoldshafen, 76344, Germany — [2]Department of Materials Science, Monta-
nuniversität Leoben, Leoben, 8700, Austria — [3]Microstructure and Properties
of Materials (IEK-2), Forschungszentrum Jülich, 52425, Jülich, Germany

Focused ion beam (FIB) milling has been widely used to prepare micron-sized
specimens for micromechanical testing, but there are different types of artefacts
originated from FIB. One is the imperfections in through-thickness notch ge-
ometries of microcantilevers. Bridge notches can overcome some of the prob-
lems by, upon loading, thin bridges fail first, creating atomically sharp natu-
ral cracks. Even though this bridge failure is widely assumed and predicted by
FEM simulations, it has never been observed and quantified experimentally. This
study presents the first experimental observation of cracking at the bridge notch
and crack arrest before the entire through-thickness notch fails. This is possi-
ble by designing very thin bridges and using a very stiff loading rig with su-
perior load resolution. Consequently, we obtained multiple fracture toughness
values from one test. Using reported geometry correction factors calculated by
FEM simulations, the fracture toughness estimated from the bridge failure was
corrected and compared with the one from the failure of the through-thickness
notch. The two approaches show consistent results.

                                MM 4.7   Mon 12:45   SCH A 216
Stable fracture of ceramics in the TEM — Oriol Gavalda-Diaz[1,2], Shelly
Conroy[1], Eduardo Saiz[1], and •Finn Giuliani[1] — [1]Department of Materials,
Imperial College London, UK — [2]Department of Mechanical, Manufacturing
and Materials Engineering, University of Nottingham, UK

Small scale fracture tests have allowed many elements of a microstructure to be
tested in isolation such as phase or grain boundaries. In our previous work we
have shown that stable fracture tests in the SEM can accurately measure surface
energies and the energy of individual grain boundaries. Furthermore, these tests
allow the crack path and the effect of crack-defect interactions to be to be stud-
ied. However, tests in the SEM struggle to give in-depth information around the
crack tip. Therefore, in this work we will demonstrate how it is possible to carry
out stable fracture experiments in the TEM via a double cantilever geometry.
This will be demonstrated on both silicon carbide and zirconia samples where

the different mechanisms of energy dissipation will be discussed. Furthermore, a stable geometry allows additional analysis to carried out during the test, here

we will discuss the possibility of using to 4D STEM to map the strain field around the crack tip.

MM 5: Materials in Energy Conversion: Mechanical Properties and Solid State Batteries

MM 5.1   Mon 10:15   SCH A 215

Interplay between mechanics and electrochemistry in Li-Si anodes by atomistic simulation — •Daniel Mutter[1], Manisha Poudel[1,2], Daniel Pfalzgraf[1], and Leonhard Mayrhofer[1] — [1]Fraunhofer IWM, 79108 Freiburg — [2]Institute of Physics, University of Freiburg, 79104 Freiburg

Silicon is a promising anode material for Li-ion batteries due to its high capacity, which considerably exceeds that of commonly used graphite. Its direct applicability however is hampered by the huge volume change the material undergoes during loading and unloading with Li, concomitant with mechanical stresses arising in the microstructure. In this work, we provide a deeper understanding on the interplay of mechanics and electrochemistry by analyzing the effect of deformation on the electrochemical potential. Using atomistic first principles calculations, we studied crystalline as well as amorphous Li-Si phases with different Li concentrations. We present results of elastic moduli, and the change of voltage during charging and discharging cycles under various characteristic mechanical loading scenarios. The results are essential input for continuum models acting on the nanoparticle scale to correctly describe the microstructural evolution.

MM 5.2   Mon 10:30   SCH A 215

Design of zero strain cathode materials based on colquiriite-type $Li_xCa(M,M')F_6$ — •Aljoscha Felix Baumann[1,2], Daniel Mutter[2], Daniel Urban[1,2], and Christian Elsässer[1,2] — [1]Freiburger Materialforschungszentrum, Stefan-Meier-Straße 21, 79104 Freiburg im Breisgau — [2]Fraunhofer-Institut für Werkstoffmechanik IWM, Wöhlerstr. 11, 79108 Freiburg

The long-term stability of Li ion batteries can be negatively affected by mechanical stresses in the microstructure of the cathode material during charge/discharge cycles. Therefore, materials are of great interest which show a zero-strain (ZS) behavior, i.e. a negligible volume change during insertion or extraction of Li ions. For specific compounds of the material class of colquiriites, $Li_xA^{II}M^{III}F_6$, ZS behavior was predicted theoretically and measured experimentally for different Li concentration ranges. In this work we investigate the effect of the electrochemically active cation M^{III} (M = Ti, V, Cr, Mn, Fe, Co, Ni) on the volume change during (de-)lithiation. Using density-functional theory we calculated the equilibrium volumes at different Li concentrations. The analysis of the electronic and magnetic structures and the calculation of local structural parameters indicate that the total volume change depends mainly on the counteracting effects of expanding fluorine octahedra around the M ions due to the changing oxidation state, and a decrease of repulsion between fluorine anions due to the inserted Li ions. The trends in the properties along the period of the $3d$ transition metals provide a guideline for a design of new ZS cathode materials in solid solutions of type $Li_xCa(M,M')F_6$.

MM 5.3   Mon 10:45   SCH A 215

Planar gliding and vacancy condensation: The role of dislocations in the chemomechanical degradation of layered transition metal oxides — •Marcel Sadowski[1], Karsten Albe[1], and Sabrina Sicolo[2] — [1]Technical University of Darmstadt, Darmstadt, Germany — [2]BASF SE, Ludwigshafen, Germany

Stacking faults driven by dislocations have been observed in layered transition metal oxides cathodes both in cycled and uncycled materials. The reversibility of stacking-sequence changes directly impacts the material performance. Irreversible glide due to lattice invariance or local compositional changes can initiate a catastrophic sequence of degradation mechanisms. In this study we compare the chemomechanical properties of $LiCoO_2$ and $LiNiO_2$ by combining density functional theory (DFT) and anisotropic linear elasticity theory. We calculate stacking fault energies as a function of Li content and quantify the "pillar effect" of excess Ni in hindering stacking-sequence changes. We then characterize screw dislocations, which mediate stacking-sequence changes, and find a peculiarly compliant behavior of $LiNiO_2$ due to the interaction of Jahn-Teller distortions with the dislocation strain field. Finally, we analyze the tendency of vacancies to segregate along dislocation lines. This study represents the first instance of explicit ab-initio atomistic dislocation models in layered oxides and paves the way for the understanding and optimization of the chemomechanical behavior of cathode active materials during battery operation.

MM 5.4   Mon 11:00   SCH A 215

Modification of iron-based oxide anodes for potassium ion storage — •Zidong Wang, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Due to the abundance of potassium and its easy accessibility, potassium-based electrochemical energy storage technology has attracted extensive research in-

terests and significant progress of it has been made in recent years. Among different anode materials for anodes of potassium-ion storage devices, transition metal oxides especially of iron-based oxides have high potential due to their high capacity and low cost. However, their poor electrical conductivity and weak structure impede their development. In this work, adjustment of the anionic and cationic composition of iron oxides is achieved. This adjustment can effectively result in a high-performance anode for potassium ion storage. In brief, the synergistic effect of multivalent metal cations will result in excellent potassium storage properties. And the conductivity can be further improved by the replacement of anions. Our results indicate that the adjusted iron-based compound can be used as a promising high-performance anode material for potassium ion storage devices.

MM 5.5   Mon 11:15   SCH A 215

Construction of V5S8/Sb2S3@C Heterostructures as High-Performance Anode Materials for Potassium -ion Batteries — •Vincent Hartmann, Yulian Dong, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau

Transition metal sulfides (TMSs) have been studied widely and deeply as anode materials for potassium ion batteries (PIBs) owing to their relatively high theoretical capacities. However, poor electrical conductivity, large volume expansion, and slow diffusion kinetics hinder their further applications. Herein, a unique hierarchical structure of V5S8/Sb2S3@C is fabricated by a concise solvothermal method and subsequently annealing. Such a well-designed architecture affords fast K+ diffusion kinetics and improved charge transfer at the heterointerfaces due to the metallicity of the internal V5S8. In addition, the synergistic coupling interaction among the interior V5S8, interlayer Sb2S3, and external C layer generates a stable nanostructure, which extremely accelerates the electronic/ion transport and effectively alleviates the volume expansion upon long cyclic performance. As a result, it exhibits a high initial capacity of 525.19 mAh/g at 100 mA/g and excellent cyclic stability with 95% capacity retention after 500 cycles at 1 A/g. Our results reveal that the combination of heterostructures construction and interfacial interaction enables optimizing electronic structures and macroscopic mechanical properties of TMSs, thus achieving high-performance anodes for PIBs with high energy density.

MM 5.6   Mon 11:45   SCH A 215

Influence of interstitial Li on the electronic properties of Li_xCsPbI_3 for photovoltaic and battery applications — •Wei Wei[1,2], Julian Gebhardt[1,2], Daniel Urban[2,3], and Christian Elsässer[1,2,3] — [1]Cluster of Excellence livMatS, University of Freiburg, Germany — [2]Fraunhofer Institute for Mechanics of Materials IWM, Freiburg, Germany — [3]Freiburg Materials Research Center (FMF), University of Freiburg, Germany

The stability of crystalline $CsPbI_3$ with interstitial Li ions is investigated together with the effect that Li has on the electronic structure of the resulting compound Li_xCsPbI_3. We analyze this by two structural models for $CsPbI_3$ at room temperature, the cubic α phase and a distorted structure analogous to the γ phase (γ' structure). The hypothetical α phase does thermodynamically not allow Li uptake and is likely to be structurally unstable for x>1/4, while adding Li up to x=1 in the γ' structure is possible. In all cases, Li promotes structural distortions, namely tilting of bond angles $\Delta_{Pb-I-Pb}$ and Cs off-center displacements Δr_{Cs}, which are increasing with the Li concentration.

Interstitial Li has the following effects on the electronic structure of $CsPbI_3$: i) the induced structural distortion leads to a significant increase of the band gap; ii) the screening of additional electrons in the conduction band leads to a small increase of the band gap; iii) the effect of Li 2s states on the band edges and band gap is negligible. Altogether, the change of the band gap is dominated by the tilting of $\Delta_{Pb-I-Pb}$ angles: stronger distortion caused by increasing Li content is accompanied by an increased band gap.

Design for Dual-Functional Electrode Promoting Dendrite-free and CO2 Utilization Enabled High-Reversible Symmetrical Na-CO2 batteries — •Changfan Xu, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

A one stone two-birds strategy is presented by using carbon paper embedded with Ru nanoparticles (RuCP) as dual-functional electrodes for both the Na anode and CO2 cathode. As an anode host, the RuCP with remarkable sodiophilic-

ity can dominate Na nucleation behavior and achieve a uniform Na ion flux for the inhibition of dendrite formation, meanwhile, the RuCP affords high catalytic activity for catalyzing the formation/decomposition of Na2CO3 in CO2 cathode. As a result, the Na was homogeneously deposited on the RuCP anode without Na dendrite formation, showing a high Coulombic efficiency of over 99% and a long cycle lifetime, and the RuCP cathode demonstrates low overpotentials and excellent cycling stability (>300 cycles). Implementation of the RuCP@Na anode and RuCP cathode allows for the construction of a symmetrical Na-CO2 battery with long-duration cyclability because of the dendrite-free sodium morphology and numerous Ru catalytic sites. Such electrodes and battery designs offer an effective method for the tailoring and optimization of sodium metal batteries with high energy density.

Dynamic stability and *ab initio* free energy calculations of argyrodite Li$_6$PS$_5$Cl solid electrolyte — •Yongliang Ou, Yuji Ikeda, Prashanth Srinivasan, and Blazej Grabowski — Institute for Materials Science, University of Stuttgart, 70569 Stuttgart, Germany

High ionic conductivity of argyrodite Li$_6$PS$_5$Cl, which was shown in both experiments and simulations, renders it a promising candidate for the solid electrolyte in all-solid-state lithium-ion batteries. Although the diffusion mechanism has been intensively investigated in previous studies, the dynamic and thermodynamic stability of Li$_6$PS$_5$Cl have not yet been fully understood. To address this issue, systematic investigations are carried out under the *ab initio* framework in this study. At 0 K, the dynamic instability of the ideal structure is revealed by the calculated imaginary phonon modes. Molecular dynamics simulations accelerated by machine-learning interatomic potentials show dynamic stabilization via vibrational entropy at finite temperatures. Further, *ab initio* free energy calculations are performed in wide temperature and pressure ranges utilizing a multistage thermodynamic integration technique. The calculated free energies provide important information for subsequent studies focusing on the energetic aspects, e.g., defect or grain boundary formation energy, of Li$_6$PS$_5$Cl. It can be expected that the present results benefit the research and application of all-solid-state lithium-ion batteries.

MM 5.9   Mon 12:30   SCH A 215

Exploration of cathode-stable layered solid-state electrolytes — •Sina Ziegler, Christoph Scheurer, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin, Germany

Promising higher safety and capacity, all-solid-state lithium batteries are envisioned to replace standard lithium-ion batteries in the future. Lithium thio-

phosphates achieve the highest Li ion conductivities of all solid-state electrolytes (SSE) known to date but their instability towards high-performance electrodes remains a critical challenge. To address this issue, we investigate the concept of rare earth lithium halides as a material-efficient, nanometer thick cathode coating in contact with thiophosphate electrolytes. Halides provide wide electrochemical stability windows as well as good chemical and thermodynamic stability [1,2].

To determine a suitable halide/thiophosphate combination, an energetically feasible reaction pathway in the multidimensional phase diagram between the two materials needs to be identified. Consequently, the thermodynamic stabilities of the emerging SSE / halide interfaces are examined by ab initio thermodynamics to screen reaction free enthalpies of possible interface reactions. Next, an end member analysis is performed to analyze possible compositions of interface products and possible secondary phases.

Active Site Deactivation of the Air Electrode in High-Temperature Solid Oxide Cells — •Hanna Türk, Thomas Götsch, Franz-Philipp Schmidt, Axel Knop-Gericke, Robert Schlögl, Thomas Lunkenbein, Karsten Reuter, and Christoph Scheurer — Fritz-Haber-Institut der MPG, Berlin, Germany

Degradation of the air electrode in electrolysis mode severely limits the commercial adoption of solid oxide cells (SOCs). This degradation goes hand in hand with the oxygen evolution reaction (OER) taking place at the triple-phase boundary (TPB) between the anode, the solid electrolyte, and the gas phase. Up to now, the atomistic structure of this active catalyst region is essentially unknown, though, which prevents a detailed analysis of the actual degradation mechanisms.

Recently, we took the first step in elucidating the TPB structure by revealing a complexion at the underlying solid/solid interface of the sintered anode[1], featuring partial amorphization and varying elemental distributions deviating from the confining bulk phases. Based on this finding, we now expand our force field based Monte-Carlo simulations to the OER active site. Our experimentally validated results show unexpected compositional changes with respect to the thermodynamic equilibrium, that combined with a spatially resolved diffusion study indicate a hitherto unknown mechanism underlying the deactivation of the anode[2].

Large-scale Atomistic and Quantum Mechanical Study of the Na$^+$ Transport Mechanism in Sodium-ion Battery Electrolytes — •Amal Kanta Giri[1] and Harald Oberhofer[1,2] — [1]University of Bayreuth — [2]TU Munich

A steady increase of the greener and safer energy sources have led to a rise in the need for energy storage technologies. In the last three decades, the lithium ion batteries (LIBs) dominated the global market from small to large scale storage of the energy. Yet, the shortage of the lithium and its localized geographical distribution raises concerns. New charge carriers for batteries beyond the lithium such as Na, is viable alternative for safe and large-scale energy storage, mainly due to its large abundance and high electrochemical potential.

Here, to improve our understanding of the Na+ transport mechanism, aggregation, and electrolyte performance in sodium ion batteries, we perform a theoretical investigation using a combination of all-atoms molecular dynamics (MD) simulations based on the OPLS forcefield and density functional theory calculations (DFT). In this regard, we simulate NaPF6 salt in various organic electrolytes including ethylene carbonate (EC), propylene carbonate (PC), dimethoxyethane (DME), and dimethyl carbonate (DMC), and their binary mixtures at 320 K. Specifically, we focus on the conductivity, diffusivity and solvation of Na+ in the liquid electrolyte mediums. Furthermore, the solvation structure and the binding energy of ions in the electrolytes are thoroughly analyzed. We find the diffusivity of Na+ ions in the order DMC>DME>EC>PC, which follow the viscosity of the electrolytes.

Fast ion conduction in glassy and crystalline phases of Na_3PS_4: Insight from a machine-learning potential molecular dynamics study — •YuTao Li, Tabea Huss, Carsten Staacke, Karsten Reuter, and Christoph Scheurer — Fritz-Haber-Institute of the Max-Planck-Society

Its earth-abundance and chemical similarity makes sodium a promising substitute for lithium in future, sustainable solid-state batteries. In that respect the

sodium thiophosphate (NaPS) material class has proven to provide electrolytes with high ionic conductivities [1]. Similar to the lithium thiophosphate (LiPS) material class, the NaPS class is characterized by a high degree of structural variety. It limits the transferability of *ab initio* studies, which are restricted to small model systems or short time scales for more complex models. Machine learning force-fields (ML-FF) provide a computationally cheaper yet sufficiently accurate alternative.

We have previously reported on a universal ML-FF for the whole LiPS material class [2]. In this work, we now develop a related ML-FF for glassy and crystalline phases of Na_3PS_4. Using the obtained ML-FF, we probe sodium ion conductivity in the glassy and crystalline phases. We systematically compare ion conductivity in LiPS vs. NaPS, and disentangle cation and anion dynamics in both material classes. Our aim is to understand the influence of stoichiometry and thiophosphate microchemistry on phase stability and ion conductivity.

Accelerating structure prediction of solid-solid interfaces in solid electrolytes using Machine Learning Potentials — •Tabea Huss, Carsten Staacke, Karsten Reuter, and Christoph Scheurer — Fritz-Haber-Institut der MPG

The lithium thiophosphate (LPS) material class provides promising candidates for solid-state electrolytes (SSE) in lithium ion batteries due to high lithium ion conductivities, non-critical elements, and low material cost. LPS materials are characterized by structural disorder and occur in a multitude of glassy and crystalline phases, depending on their stochiometry. The most performant glass-ceramic SSEs from the LPS class are characterized by omnipresent two-dimensional interfaces between crystalline and glassy domains, which can dominate the materials performance and cycle stability. To address this complexity we present a protocol for the construction of polycrystalline solid-solid interfaces in the LPS system. Within our protocol, expensive ab-initio random structure

search (AIRSS) calculations are replaced by a Machine Learning surrogate accelerated approach. We present a pathway towards a full assessment of partially amorphous interfaces in the LPS material class.

MM 6.4   Mon 11:00   SCH A 118

Understanding Oxide Ion Transport In Yttria Stabilized Zirconia: Fresh Insights from Molecular Dynamics Simulations — •Sudeshna Madhual, Krishnanjan Pramanik, and Padma Kumar Padmanabhan — Indian Institute of Technology Guwahati, Guwahati, Assam, India, 781039

A comprehensive molecular dynamics investigation of yttria stabilized zirconia, $Y_x Zr_{1x} O_{2x/2}$, is carried out for a wide range of compositions, x = 4 to 40 mol%, and over temperatures spanning 800 - 2200 K. The lattice parameter of the fluorite cell shows a monotonic increase with concentration, while the self-diffusivity of oxide ion as well as the resulting ionic conductivity, shows an optimum value around x = 10 mol%. These gross structural and transport properties of the system from the present study is in good agreement with previous experimental and theoretical investigations. It is noted that the oxygen migration occurs along straight channels parallel to the crystallographic axes, connecting the tetrahedral holes of the fluorite lattice occupied by them. A microscopic investigation of distinct oxygen environments, variably coordinated to Y 3+ and Zr 4+ cations, and of the channels connecting them is carried out. Analysis of these local channels for their energetics and their contribution to overall oxygen transport, resolved in terms of the cationic edges connecting them, provides fresh insights on the oxygen migration mechanism in the system.

MM 6.5   Mon 11:15   SCH A 118

Modelling accelerated ion transport in porous metal organic frameworks — •Thomas Bergler[1,2] and Harald Oberhofer[1,2] — [1]University of Bayreuth — [2]Bavarian Center for Battery Technologies

To date, metal organic frameworks (MOFs) have found a number of successful applications, for example in gas storage or as a filter for gas mixtures. So far, these mostly incorporated them as passive materials, but recent research points the way towards a more active role, possibly through the external manipulation of the materials's internal properties. One recent example for such a property is the susceptibility of the lattice parameters of multiple specific MOFs towards electric fields, which have been shown to distort on application of the fields. The aim of this project is to further investigate this behaviour from a theoretical point of view and gain insight into it through the use of molecular dynamics (MD) and meta-dynamics (MTD) simulations. These simulations are based on density functional theory (DFT) with the Perdew-Burke-Ernzerhof (PBE) functional but also on extended tight-binding (xTB) models and MOF-specialized force-fields. After confirmation that xTB-DFT and force-field MDs yield similar results to PBE-DFT MDs, MTDs have been performed with xTB-DFT to gain information on the energy-barriers for linker rotations inside some MOFs. Afterwards, MDs of multiple ps-length and an applied external E-field were performed with these force-fields to find the minimum strength of the E-field required to have an influence on the linker's rotation statistics.

MM 6.6   Mon 11:45   SCH A 118

Opposite in-plane anisotropy in thermal diffusivity and resistivity — •Fei Sun[1], Simli Mishra[1], Philippa McGuinness[1], Zuzanna Filipiak[1], Igor Markovic[1], Dmitry Sokolov[1], Sean Hartnoll[2], Andrew Mackenzie[1,3], and Veronika Sunko[4] — [1]MPI, CPfS, Dresden, Germany — [2]Univ. of Cambridge, Cambridge, UK — [3]Univ. of St Andrews, St Andrews, UK — [4]UC Berkeley, California, USA

We report the temperature dependence of the anisotropic thermal and electrical transport in the orthorhombic bilayer ruthenate Ca3Ru2O7. Measurements are performed using two bespoke experimental techniques: optical measurement of thermal diffusivity, and resistivity measurements on devices micro-structured using Focused Ion Beam (FIB) sculpting. Intriguingly, we find that the electrical conductivity is higher along the direction where thermal conductivity is lower at all temperatures. The mechanism underlying this unusual behavior will be discussed in this talk.

MM 6.7   Mon 12:00   SCH A 118

Non-local microwave electrodynamics in ultra-pure PdCoO$_2$ — •Graham Baker[1], Timothy W Branch[1], Jake Bobowski[1], James Day[1], Davide Valentinis[2], Mohamed Oudah[1], Philippa McGuinness[3], Seunghyun Khim[3], Piotr Surówka[4], Yoshiteru Maeno[5], Roderich Moessner[6], Jörg Schmalian[2], Andrew Mackenzie[3], and Doug Bonn[1] — [1]University of British Columbia — [2]Karlsruhe Institute of Technology — [3]Max Planck Institute for Chemical Physics of Solids — [4]Wrocław University of Science and Technology — [5]Kyoto University — [6]Max Planck Institute for the Physics of Complex Systems

There has been significant recent interest in unconventional electronic transport regimes in which a local, Ohmic relationship between electric current and field breaks down. To date, the vast majority of experimental work has been done in the DC limit. Here we introduce a novel approach via AC measurements with a bespoke microwave spectrometer, using the skin effect rather than sample dimensions to induce non-local transport. Through measurements on Sr_2RuO_4 and Sn, we verify the predictions for the magnitude and frequency dependence of the surface resistance for the classical and anomalous skin effects. Data from $PdCoO_2$, in contrast, deviate from any previous prediction of frequency-dependent surface resistance. Analysis of such data required the construction of a more complete electrodynamic theory of metals than previously existed, and allows us to conclude that the $PdCoO_2$ data are due to the combination of a highly anisotropic Fermi surface and a contribution from momentum-conserving scattering.

MM 6.8   Mon 12:15   SCH A 118

Spin Hall effect in tungsten and tantalum via first-principles calculations — •Reena Gupta, Stefano Sanvito, and Andrea Droghetti — School of Physics and CRANN, Trinity College, 2, Dublin, Ireland

We study theoretically the spin Hall effect (SHE), a phenomenon where a longitudinal charge current in a material sample gets converted into a transverse spin current and leads to spin accumulation on the sample boundaries. The common theoretical methods to calculate the intrinsic SHE conversion efficiency (i.e., the "spin Hall angle") are semi-classical or rely on the relaxation time approximation. To go beyond these limitations, we combine the non-equilibrium Green's function approach with Density Functional Theory. We study the SHE in bulk as well as slab geometries for different phases of tungsten and tantalum. We find values for the spin Hall angles, which are comparable to the most recent experimental results. Furthermore, in the slab geometries, we find that the spin Hall effect is accompanied by current-induced spin polarization (CISP). We then discuss the relative magnitude of the SHE and of CISP suggesting how the two effects can be distinguished in experiments.

MM 6.9   Mon 12:30   SCH A 118

Transport properties of Dirac materials: the role of plasmons — •Kitinan Pongsangangan — TU Dresden, Dresden, Germany

We study the thermoelectric transport of Coulomb interacting Dirac electrons with Keldysh quantum field theory. We study it from a weak-coupling and a strong-coupling perspective. We demonstrate that long-range Coulomb interactions play two independent roles: (i) they provide the inelastic and momentum-conserving scattering mechanism that leads to fast local equilibration; (ii) they facilitate the emergence of collective excitations, for instance plasmons, that contribute to transport properties on equal footing with electrons. Our approach is based on an effective field theory of the collective field coupled to electrons. Within a conserving approximation for the coupled system we derive a set of coupled quantum-kinetic equations. This builds the foundation of the derivation of the Boltzmann equations for the interacting system of electrons and plasmons. From this, we explicitly derive all the conservation laws and identify the extra contributions of energy density and pressure from the plasmons. We demonstrate that plasmons show up in thermo-electric transport properties as well as in quantities that enter the energy-momentum tensor, such as the viscosity.

Dragging effect of the Berry curvature in ferromagnetic Weyl semimetals NiMnSb and PtMnSb — Sukriti Singh[1], •Ana García-Page[1], Jonathan Noky[1], Subhajit Roychowdhury[1], Maia G. Vergniory[1,2], Horst Borrmann[1], Hans-Henning Klauss[3], Claudia Felser[1], and Chandra Shekhar[1] — [1]Max-Planck-Institute for Chemical Physics of Solids, Dresden 01187, Germany — [2]Donostia International Physics Center, Donostia-San Sebastián 20018, Spain — [3]Institute for Solid State and Materials Physics, Technische Universität Dresden, Dresden 01069, Germany

The Anomalous Hall effect is a transport phenomenon in ferromagnets, which exhibit currents even in the absence of a magnetic field. Their inner magnetization breaks Time Reversal Symmetry, allowing the Berry Curvature (BC) to be finite. As a result, topological features close to the Fermi energy have a deep impact in the transport properties, leading to huge Anomalous Hall Conductivities (AHC). This has been a well-established paradigm for the last years for the linear AHC.

However, recent experimental results in the Weyl semimetals NiMnSb and PtMnSb might be pointing to something beyond it. By combining ab-initio calculations with a toy-model, we show that the steep slope-bands both compounds exhibit are capable of dragging the BC originated in Weyl nodes far away from the Fermi level, leading to a huge AHC in these compounds. We propose that this dragging effect of the BC can be generalized to the other materials exhibiting this band structure behaviour, which enrichens the paradigm described above. Further research in this direction is currently being done.

Molecular dynamics simulations of shock waves in alloys: Interplay of defects and phase transition — •NINA MERKERT — TU Clausthal, Germany

The study of materials under high-pressure conditions is essential not only for industrial activities but also for geological and astronomical applications. We consider iron and iron-carbon alloys showing a pressure induced phase transformation from the bcc to the hexagonal close-packed phase at around 13 GPa depending on the carbon content. We study compression waves in polycrystalline Fe and Fe-C using interatomic potentials that faithfully incorporate this phase transition at the desired equilibrium pressure.

Our simulations show that the phase transformation is preceded by plastic activity, leading to the so-called 3-wave structure: An elastic compression wave is followed by a plastic wave, which then leads to a phase-transformation front. We investigate the interplay of defects in bcc with the transformation process. These defects also influence the fracture (spallation) of the shocked iron samples.

Recently, we extended our results to high-entropy alloys (HEAs) that consist of equiatomic mixtures of five or more elements and are attracting increasing interest due to their promising material properties. We studied shock-induced spallation in HEAs and found exceptionally high spall strengths that are beneficial for high strain-rate applications.

Adaptively Compressed Exchange in LAPW — •DAVIS ZAVICKIS, KRISTIANS KACARS, JANIS CIMURS, and ANDRIS GULANS — Electronic Structure Group, University of Latvia, Jelgavas st. 3, LV-1004, Riga, Latvia

We address precision and reproducibility issues in DFT calculations with hybrid functionals. Linearized augmented plane waves (LAPW) method currently serves as the de facto reference tool within the electronic structure community. In the current implementation of the Fock exchange in LAPW, the total and band energies depend on the number of orbitals used. We overcome these issues by implementing the adaptively compressed exchange (ACE) method [Lin Lin, J. Chem. Comput., 2016, 12, 5] in `exciting` code that introduces a low rank approximation and apply it to light atoms, molecules and solids [D. Zavickis et al., Phys. Rev. B., 2022, 106, 165101]. In case of atoms and molecules, we show that ACE leads to highly precise total energies which are within a few microhartrees off the results obtained by multi-resolution analysis method. In solids we calculate band structures that are compared with other all-electron hybrid implementations. Lastly, we apply optimizations and fine tuning to ACE, analyze its complexity and computational performance by comparing it to the previous Fock-exchange implementation in the `exciting` code.

How much laser power can two-photon 3D printed microoptics withstand? — •SEBASTIAN KLEIN, PAVEL RUCHKA, TOBIAS STEINLE, and HARALD GIESSEN — 4th Physics Institute and Research Center SCoPE, University of Stuttgart, Germany

In recent years, the manufacturing of small 3D printed microoptics has seen a rise in importance. 3D printed lenses are used for applications where space is of big concern. Tailored free form optics are ideally suited to improve the performance for specific use cases. New applications also include printing these optics onto optical fibers, for example for endoscopes in the biomedical field or for focusing a laser beam inside a compact fiber laser. In the latter case, the sustainability of high intensities of the pump laser is important. This is directly dependent on the maximum power the material of the lens can withstand.

In this work, we obtain a first insight into laser damage thresholds of the 2PP photoresist IP-S in the near-IR spectral range. We determine damage thresholds with femtosecond laser pulses for wavelengths in the range of 1550-2000 nm. We conduct these experiments on cube samples printed from IP-S and evaluate the damage of the exposed samples visually under a microscope, employing also differential interference contrast. The observed damage is mostly of thermal nature. Knowledge of damage thresholds of 3D printed micro-optics further pushes the applications to these limits, enabling high-power applications at safe operating intensities.

Molecular Dynamics Simulation of Selective Laser Melting — FABIO OELSCHLÄGER[1], AZAD GORGIS[1], DOMINC KLEIN[1], SARAH MÜLLER[2], and •JOHANNES ROTH[1] — [1]FMQ, Universität Stuttgart, Germany — [2]GSaME, Universität Stuttgart, Germany

Traditionally, manufacturing has been subtractive which means removing material from a workpiece. Additive manufacturing on the other hand is defined by successive addition of material and fusion with the help of heat for example. Here we report atomistic simulations of selective laser melting (SLM) used to produce additive manufactured objects. After a short introduction into the subject we present challenges to SLM. Next, modifications to basic molecular dynamics simulation are described which are required to simulate the annealing process. Although the sample sizes studied are already impressively large, scaling of system parameters are required to relate simulation and experiment. First

results from the study of single and rows of spheres will be reported and further developments and improvements will be addressed.

                    MM 8.4   Mon 16:30   SCH A 251
Exploring Enhanced Sampling Concepts based on Boltzmann Generators — •DAVID GRETEN, KARSTEN REUTER, and JOHANNES T. MARGRAF — FHI Theory Department, Berlin, DE

Computational surface science and catalysis research is still mainly conducted with static density functional theory (DFT) calculations. This approach is computationally convenient, but misses important aspects of surface chemistry, such as anharmonic free energy contributions. In principle, DFT-based molecular dynamics (MD) simulations (ideally combined with enhanced sampling algorithms) would allow a much more accurate description of these processes. Unfortunately, these are far too expensive to be routinely applied to complex surface/adsorbate systems. This is due to the fact that configurations in MD are generated sequentially. As a consequence, MD configurations are not statistically independent so that a very large number of samples is required to obtain converged ensemble properties. To overcome this limitation, Noé and co-workers recently proposed a generative machine learning model called the Boltzmann Generator, which was used to generate independent configurations of biomolecules. In this contribution, we explore how we can expand ML based sampling concepts utilizing Boltzmann Generators. In particular, training protocols and validation metrics will be discussed.

When does the Tamura model of phonon-isotope scattering break down? — •NAKIB PROTIK and CLAUDIA DRAXL — Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany

A standard approach to the phonon-isotope scattering problem is the Tamura model [1]. This non-self-consistent 1st Born approximation of the scattering T-matrix expansion is exact for the low energy phonons, and higher order perturbative corrections for the higher energy, dispersive acoustic phonons have been argued to be small [1]. To our knowledge, the validity of this approach for the optic phonons has not yet been demonstrated. In this talk, we compare the Tamura model to the ab initio computed non-perturbative phonon-isotope scattering T-matrix for a set of well-studied materials. We show under what conditions the Tamura model breaks down.

[1] Tamura, S. I. (1983). Isotope scattering of dispersive phonons in Ge. Physical Review B, 27(2), 858.

Physics-inspired Machine Learning for Predicting Ionization Energies of Electronically Localized Systems — •KE CHEN[1,2,3], CHRISTIAN KUNKEL[1], BINGQING CHENG[3], KARSTEN REUTER[1], and JOHANNES T. MARGRAF[1] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]Technische Universität München, Garching, Germany — [3]Institute of Science and Technology, Klosterneuburg, Austria

Machine learning (ML) has been successfully applied to predict many chemical properties, most prominently energies and forces in molecules and materials. The strong interest in predicting energies in particular has lead to a 'local energy'-based paradigm for modern chemical ML models, which ensures size extensivity and linear scaling of computational cost. However, some electronic properties (such as excitation energies or ionization potentials) are not size-extensive and may even be spatially localized. Using extensive models in these cases can lead to large errors. In this work, we explore different strategies for predicting intensive and localized properties, using ionization energies

in organic molecules as a test case. In particular, we compare size-intensive aggregation functions and effective, machine-learned Hamiltonians. The physical interpretability and cost/benefit ratios of the approaches will be discussed.

MM 8.7   Mon 17:30   SCH A 251

Kernel Charge Equilibration: Machine Learned Interatomic Potentials With Full Long-Range Electrostatics — •Martin Vondrak, Johannes T. Margraf, and Karsten Reuter — Fritz Haber Institute of the Max Planck Society, Berlin, Germany

Machine learning (ML) techniques have recently been shown to bridge the gap between accurate first-principles methods and computationally cheap empirical potentials. This is achieved by learning a mapping between a systems structure its physical properties. State-of-the-art models typically represent chemical structures in terms of local atomic environments to this end. This inevitably leads to the neglect of long-range interactions (most prominently electrostatics) and non-local phenomena (e.g. charge transfer), resulting in significant errors in the description of polar molecules and materials (particularly in non-isotropic environments). To overcome these issues, we recently proposed a ML framework for predicting charge distributions in molecules termed Kernel Charge Equilibration (kQEq). Here, atomic charges are derived from a physical model using environment-dependent atomic electronegativities. In this contributions, strategies for creating kQEq interatomic potentials are discussed, including the combination of short-ranged Gaussian Approximation Potentials with kQEq.

MM 9: Topical Session: Fundamentals of Fracture – Interface Fracture

Modeling of grain boundary embrittlement phenomena in metallic materials — •Lorenz Romaner[1], Alexander Reichmann[1], Christoph Dösinger[1], Tobias Spitaler[1], Daniel Scheiber[2], Oleg Peil[2], Markus Alfreider[1], Michael Wurmshuber[1], and Daniel Kiener[1] — [1]Department of Materials Science, Montanuniversität Leoben, 8700 Leoben, Austria. — [2]Materials Center Leoben Forschung GmbH, 8700 Leoben Austria.

Intergranular embrittlement phenomena are of strong relevance for many technological materials including steels, nickel-based alloys, coinage metals or refractory metals. The decisive process is grain boundary segregation where solutes diffuse and enrich at grain boundaries thereby modifying their cohesive properties which can favor or impede crack propagation. We present a multiscale simulation framework for grain boundary segregation employing atomistic, thermokinetic and data-driven computational methods and show how chemistry and propensity against crack propagation can be modeled from basic knowledge of composition and processing parameters. Validation examples with several experimental methods including atom probe tomography, high resolution transmission electron microscopy and micromechanical testing are presented. Furthermore, we discuss the potential of statistical learning methods to replace density functional theory simulations in future, in particular to address advanced phenomena such as concentration dependence and co-segregation.

MM 9.2   Mon 16:15   SCH A 216

Atomistic study of impurity-induced intergranular embrittlement in tungsten — •Pär A. T. Olsson[1,2], Praveenkumar Hiremath[2], and Solveig Melin[2] — [1]Materials Science and Applied Mathematics, Malmö University, SE-205 06 Malmö, Sweden — [2]Division of Mechanics, Materials & Components, Lund University, Box 118, SE-221 00 Lund, Sweden

In the present work we study the impact of phosphorus (P) impurities on the grain boundary strength of tungsten (W) by means of classical atomistic modelling to explore the role of impurities on the grain boundary (GB) embrittlement of W. To this end, we have fitted a new binary 2NN-MEAM potential for the W-P system that is designed to capture the embrittleing potency of P in W GBs as predicted by means of density functional theory (DFT) modelling. Analysis of the GB work of separation and generalized stacking fault energy data derived from DFT and the 2NN-MEAM potential show that substitutional P-impurities reduce the resistance to both cleavage and slip. Mode I tensile and crack simulations reveal that the most dominant mode of GB failure is cleavage and that pristine GBs, which are initially ductile, on most accounts change to brittle upon introduction of impurities. Such tendencies are in line with experimentally observed correlations between P-impurity content and reduced ductility.

Characterization of the stability of metal/metal interfaces by atomistic simulations — •Daniel F. Urban, Reyhaneh Ghassemizadeh, and Christian Elsässer — Fraunhofer Institute for Mechanics of Materials IWM, Freiburg, Germany

The reliable prediction of the adhesion and mechanical stability of interfaces between two metal phases from density functional theory (DFT) calculations remains a challenge. One possible approach to systematically address this issue is an idealized cleavage simulation analysed in terms of the Rose-Ferrante-Smith universal binding energy relationship (UBER) which results in a measure for the ideal work of separation and the maximum tolerable normal strain. Another approach is the study of the gamma surface, i.e. the generalized stacking fault energy, as function of lateral displacement, which yields information on the critical resolved shear stress of dislocation motion. Here we systematically study coherent [111]-oriented interfaces between fcc metals in terms of the above mentioned methods. We analyze the interface energy in terms of coupled tensile and shear displacements which include the effect of the tension softening of the interface. Furthermore, the influence of an additional lateral mechanical strain on the two phases, as often present in experimentally grown thin layers, is examined.

The heterogeneous nature of grain boundary segregation and embrittlement — •Remi Dingreville — Sandia National Laboratories, Albuquerque NM, USA

Nanostructured materials are inherently unstable due to the high density of non-equilibrium defects that provide a substantial driving force for exaggerated or unexpected evolution. Departing from most mesoscale models for grain boundaries (GB), there is a clear recognition that GB properties, especially GB embrittlement and GB fracture, are not single-valued for a given material, but widely disparate depending on the configuration of the particular boundary and its neighboring grain. Taking this one step further, both GB character and GB defects control the GB embrittlement and fracture in response to mechanical, thermal, and irradiation stimuli. Each different type of stimuli perturb the GB character in distinctly different processes: e.g. stress causes elastic mismatch that tilts the energy barrier whereas strain drives specific dislocation content into the GB; non-implanting irradiation on the other hand creates local thermal spikes and atomic shuffling. In this presentation, I will discuss these effects on GB segregation and GB fracture properties from both a theoretical and atomistic perspectives.

Sandia National Laboratories is a multi-mission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC., a wholly owned subsidiary of Honeywell International, Inc., for the U.S. Department of Energy National Nuclear Security Administration under contract DE-NA0003525.

Modelling the grain boundary segregation of phosphorus in iron using thermodynamical approaches and Bayesian inference — •Alexander Reichmann[1], Christoph Dösinger[1], Daniel Scheiber[2], Oleg Peil[2], Vsevolod Razumovskiy[2], and Lorenz Romaner[1] — [1]Department of Materials Science, Montanuniversität Leoben, Austria — [2]Materials Center Leoben Forschung GmbH, Leoben, Austria

The chemistry and structure of grain boundaries (GBs) play a key role for understanding fracture in metallic alloys. Atomistic simulations provide a direct access to one of the key fundamental GB characteristics, the GB solute segregation energy. Experimentally, the solute segregation can be evaluated by measuring the GB solute concentration using a variety of techniques, one of which is the Auger electron spectroscopy. However, a direct comparison of experimentally measured GB solute excess and calculated GB segregation energy requires an additional step of conversion, which is a non-trivial task in many cases. As a result, calculated and measured data are not always found in good agreement with each other and often require an in-depth investigation. In this talk, we will present an approach for getting a consistent comparison between the calculated and experimentally measured data based on the Bayesian inference framework, which we use in combination with Markov chain Monte Carlo simulations for uncertainty quantification and model evaluation. We apply this framework to analyze phosphorus segregation in iron and evaluate theoretical and experimental data on GB excess.

MM 9.6   Mon 17:30   SCH A 216

Characterizing interface toughness in functional materials — •Eloho Okotete[1], Subin Lee[1], Steffen Brinckmann[2], and Christoph Kirchlechner[1] — [1]Institute for Applied Materials, Karlsruhe Institute of Technology, 76344 Eggenstein-Leopoldshafen, Germany — [2]Structure and Function of Materials (IEK-2), Forschungszentrum Jülich, 52425 Jülich, Germany

Interfaces are the backbones of functionality in emerging material systems for this new age. However, mechanical failure usually occurs in these interfaces leading to degradation of functional properties. Experimental methods to investigate the interface strength and its failure mechanisms include peel test, super layer test, or indentation test. These methods output qualitative data with

huge experimental scatter and a lack of in-depth understanding of underlying mechanisms of failure. Small-scale mechanical testing using single and double cantilever beams makes it possible to extract quantitative data for interface properties of micro/ nanometer-sized films. However, these methods are prone to unstable crack growth, finite notch root radius, and other problems arising from testing geometries. In this talk, we propose a new micro cantilever design that provides reliable quantitative interface toughness. Our initial finite element calculations showed the optimized geometry could propagate a pre-notch in a stable manner, which is essential to generate a natural crack front without FIB-induced damage/artifacts. This observation is validated with in situ experiments on the interface between a hard coating and silicon substrate.

Abnormal internal oxidation of grain boundary and its cracking behavior under mechanical stress in an FeCr alloy — •Kuan Ding[1], Xiao Shen[2], Siyuan Zhang[3], Jiejie Li[4], Enrico Bruder[1], Jianjun Li[4], Wenwen Song[2], Karsten Durst[1], James P. Best[3], and Xufei Fang[1] — [1]Department of Materials and Earth Sciences, TU Darmstadt, 64287 Darmstadt, Germany — [2]Steel Institute

(IEHK), RWTH Aachen University, 52072 Aachen, Germany — [3]Max-Planck-Institut für Eisenforschung GmbH, 40237 Düsseldorf, Germany — [4]School of Mechanical and Electrical Engineering, Central South University, 410083 Changsha, China

FeCr-based Ferritic stainless steels display great potential for applications as interconnects of solid oxide fuel cells at temperatures below 800 ˚C. Cr provides good oxidation resistance by forming a protective oxide layer to prevent the substrate from exposing to corrosive environment. However, grain boundaries (GBs) act as fast diffusion paths, and internal oxidation along the GB can form brittle oxide, which is prone to cracking under mechanical stresses. In this work, we investigated the abnormal growth of GB oxide at 600 ˚C in air and its impact on GB cracking in Fe-15wt.%Cr alloy. The microstructure and chemical characterization of the abnormal GB oxide revealed a layer of chromium oxide forming with a large penetration depth. To study the mechanical response, we conducted both ex-situ and in-situ micromechanical tests and simulation and observed the cracking behavior of the abnormal GB oxide. Our finding provides insights into improving the oxidation and fracture resistance through material design.

MM 10: Materials for Storage and Conversion of Energy: New Storage Materials

Improving the cleanliness of TEM investigation of catalyst samples — •Julia Menten[1], Robert Schlögl[1,2], and Walid Hetaba[1] — [1]Max Planck Institute for Chemical Energy Conversion, Mülheim an der Ruhr, Germany — [2]Fritz Haber Institute of the Max Planck Society, Berlin, Germany

Transmission electron microscopy (TEM) offers a powerful tool for the analysis of specimens down to an atomic scale. In order to achieve high quality data, sample preparation is a crucial step. Many samples contain a high carbon content, e.g. as organic ligands or solvents. Electron beam exposure can lead to the deposition of carbon on the specimen surface and limit the image resolution and quality of obtained spectroscopic data. Different mitigation strategies can be applied in order to reduce contamination, though these methods can easily harm the specimens or lead to accumulation of carbonaceous molecules in the microscope environment [1].

In our work we focus on the removal of undesirable carbon species before the sample is inserted into the microscope. Our sample cleaning setup allows to investigate the influence of different preparation parameters, e.g. drying time or temperature, on how long solvents remain in the vacuum system and therefore can have an impact on the TEM analysis. Evaluation of the decrease in pressure while pumping our setup with a TEM sample gives insight in necessary drying times. The impact of our sample treatment can be investigated in the TEM by evaluating contrast and thickness measurements.

Ultrafast Electron Transfer in Photoexcited Fullerene-Derivatives — •Mohamed E. Madjet, Adrian Dominguez-Castro, Fulu Zheng, and Thomas Frauenheim — Bremen Center for Computational Materials Science, University of Bremen, Bremen, Germany

Fullerene derivatives continue to attract a lot of interest both experimentally and theoretically. They have been known to be excellent electron acceptors due to their interesting ground and excited state properties. The chemical functionalization of fullerenes made possible to synthesize and develop new compounds. These derivatives are used as building blocks for molecular complexes and devices with potential applications in solar cells, sensing and in biomedical applications. Using non-adiabatic molecular dynamics simulations combined with time-dependent density functional theory [1-3], we study the photoinduced electron dynamics and charge transfer processes in some fullerene derivatives upon a selective and localized excitation on the donor molecule. Results on hot electron dynamics, charge transfer and nonradiative recombination processes will be presented, discussed, and compared to the experimental results in [4].

Carrier Multiplication in Transition Metal Dichalcogenides Beyond Threshold Limit — •Yuxiang Liu[1], Thomas Frauenheim[1], and ChiYung Yam[2] — [1]Bremen Center for Computational Materials Science, University of Bremen, Am Fallturm 1, 28359 Bremen, Germany — [2]Shenzhen Institute for Advanced Study, University of Electronic Science and Technology of China, Shenzhen, 518000, China

Carrier multiplication (CM), multiexciton generation by absorbing a single photon. Beard et al. predicted that CM could overcome the Schokley-Queisser limit and raise solar cell efficiency to ~46%[1]. The current state-of-the-art nanomaterials including quantum dots and carbon nanotubes have demonstrated CM phenomenon, but not satisfactory owing to high threshold energy and inherent difficulties with carrier extraction. We found a below threshold limit CM in monolayer transition metal dichalcogenides (TMDCs) MX2 (M = Mo, W; X= S, Se, Te). Surprisingly, the threshold energy of CM in monolayer TMDCs can be substantially reduced due to lattice vibrations. Electron-phonon couplings (EPC) could cause significant changes in electronic structures, even trigger semiconductor-metal transition, and eventually decrease the threshold energy of CM to less than twice bandgap[2]. Our results identify TMDCs as attractive candidate materials for efficient optoelectronic devices with the advantages of high photoconductivity and phonon-assisted tunable CM characteristics.

Stability and electronic structure of NV centers at dislocation cores in diamond — •Reyhaneh Ghassemizadeh, Wolfgang Körner, Daniel F. Urban, and Christian Elsässer — Fraunhofer Institute for Mechanics of Materials IWM, Freiburg, Germany

Due to its outstanding coherence properties, the negatively charged nitrogen-vacancy defect (NV center) in diamond is a promising system for quantum magnetometry and solid-state based quantum computing. However, its performance can be limited by the presence of crystal defects. We study the influence of dislocations on the stability and physical properties of the NV center within a density

functional theory analysis [1]. We model the most common dislocations in diamond, namely the 30° and 90° partial glide, and calculate the defect formation energy, structural geometry, electronic defect levels and zero-field splitting (ZFS) parameters. Our simulations reveal that dislocations potentially trap NV defects with an energy release of up to 3 eV. In general, the properties of NV centers at dislocations show strong deviations with respect to their bulk values. However, the lowest energy configuration of a NV center at the core of a 30° dislocation shows very bulk-like properties. Its electronic level spectrum is only slightly modified and ZFS values deviate less than 5% from their bulk values. These results open the perspective to align multiple NV centers along this dislocation type with a linear-chain arrangement whose collective behavior may become advantageous for quantum technology applications. First-principles calculation of electroacoustic properties of wurtzite (Al,Sc)N — •Daniel F. Urban[1], Oliver Ambacher[2], and Christian Elsässer[1] — [1]Fraunhofer Institute for Mechanics of Materials IWM, Freiburg, Germany — [2]INATECH–Department of Sustainable Systems Engineering, University Freiburg, Germany

We study the electroacoustic properties of aluminum scandium nitride crystals $Al_{1-x}Sc_xN$ with the metastable wurtzite structure by means of first-principles calculations based on density functional theory [1]. We extract the material property data relevant for electroacoustic device design, namely the full tensors of elastic and piezoelectric constants. Atomistic models were constructed and analyzed for a variety of Sc concentrations $0 \leq x \leq 50\%$. The functional dependence of the material properties on the scandium concentration was extracted by fitting the data obtained from an averaging procedure for different disordered atomic configurations. We give an explanation of the observed elastic softening and the extraordinary increase in piezoelectric response as a function of Sc content in terms of an element specific analysis of bond lengths and bond angles.

Template-mediated well-defined nanostructure arrays for optical, electrical, and magnetic applications — •Rui Xu[1], Denys Makarov[1], and Yong Lei[2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Ilmenau University of Technology, Ilmenau, Germany.

Advanced devices play a critical role for sustaining the ever-growing demands of our society for energy, information, health care, etc. To achieve high performance, devices with nanoscaled features are attracting more and more attentions by virtue of their unique and promising effects emerging at nanoscale. Structural design and engineering of materials provides a versatile platform to optimize the device performance and improve the commercial competitivity. Regarding the structural engineering, controlling the geometrical parameters (i.e., size, shape, hetero-architecture, and spatial arrangement) of nanostructures have been the central aspects of investigations and practical applications. By using anodic aluminum oxide template, we realized well-defined controlling of nanostructures over the size, in-plane/out-of-plane shape, hetero-architecture, and spatial ar-

rangement. With such well-defined nanostructures, the optical, electrical, and magnetic performance of nanodevices can be obviously enhanced.

MM 11.4 Mon 17:45 SCH A 215

Advantages of oxygen-free wire-arc sprayed titanium coatings — •Maik Szafarska[1], Manuel Rodriguez Diaz[2], Cornelius Boekhoff[1], René Gustus[1], Kai Möhwald[2], Hans Jürgen Maier[2], and Wolfgang Maus-Friedrichs[1] — [1]TU Clausthal, Clausthal Centre of Material Technology — [2]Leibniz Universität Hannover, Institut für Werkstoffkunde

Typically, thermal spraying is carried out in air, with compressed air acting as the cooling agent. However, the application of oxygen-affinitive materials like titanium is heavily influenced by the oxygen content in the atmosphere. Besides the impact on chemical composition, it can negatively influence the wetting behavior of the surface, the residual stress inside the coating and the formation of cracks and defects. Alternatives like cold gas spraying and vacuum plasma spraying grant only slight improvements coupled with an increased difficulty or cost for industrial use. Using silane-doped argon, it is possible to reduce the oxygen partial pressure to extremely low levels well below 10E-23 mbar. This makes application of wire-arc spraying possible for oxygen-affinitive materials like titanium. The titanium coatings feature a significantly reduced porosity caused by improved wetting behavior of titanium particles during the spraying process. Additionally, the coatings show extremely high adhesive tensile strengths compared to coatings formed in air. Discussed topics include particle formation, surface morphology and chemical composition, splat profiles, coating cross sections and interfacial diffusion between titanium coatings with iron-substrates.

Simulative study on crocheted fabrics via finite element method — •Jan Lukas Storck[1], Dennis Gerber[1], Liska Steenbock[1], and Yordan Kyosev[2] — [1]Bielefeld University of Applied Sciences, Bielefeld, Germany — [2]Technische Universität Dresden, Dresden, Germany

Crochet is a rarely studied but very versatile textile technology. Industrial production of crochet does not yet exist but approaches to automation have recently emerged. In order to research the properties of crocheted fabrics by simulation, the finite element method (FEM) is well suited as a numerical approach due to the high complexity of the crochet structure. To the best of our knowledge, the FEM study presented here is the first one on the basic mechanical properties of crocheted fabrics [1]. A topology based key point model of an exemplary crocheted fabric at the meso scale was developed and studied with LS-DYNA (Livermore Software Technology Corporation). Displacements in the two textile directions (course and wale) revealed an even distribution of stresses in the fabric, whereby the stresses in course direction propagated faster. This and the differing stitch deformations show anisotropic properties. Such fast-calculating FEM simulations in combination with the developed flexible modelling can also be used in the future for engineering crocheted textiles for technical applications.

Time-of-Flight X-ray Photoelectron Microscopy (ToF-X-PEEM) — •G. Schönhense[1], O. Tkach[1,2], O. Fedchenko[1], Y. Lytvynenko[1], D. Vasilyev[1], Q.L. Nguyen[3], T.R.F. Peixoto[4], A. Gloskovskii[4], S. Chernov[4], M. Hoesch[4], N. Wind[4,5], M. Heber[4], C. Schlueter[4], C. Sharma[5], K. Rossnagel[4,5], M. Scholz[4], and H.-J. Elmers[1] — [1]Mainz Univ. — [2]Sumy State Univ. — [3]SLAC Nat. Accel. Lab., USA — [4]DESY Hamburg — [5]Kiel Univ.

The classical solution for photoelectron imaging in the X-ray range (X-PEEM) employs a hemispherical analyzer, as first described by Tonner1. X-PEEM shows reduced spatial and energy resolution and notoriously low transmission, a consequence of the slits and small angular acceptance of the hemisphere. ToF-X-PEEM combines time-of-flight energy recording with a new lens optics minimizing spherical aberration. Systematic ray tracings predict a resolution in the (sub-) micron range, when a k-confining aperture array is placed in the second reciprocal plane, where the k-magnification can be zoomed in a large range. The new optics has been recently commissioned at PETRA-III (soft X-rays), studying ultrathin flakes and Moiré sandwich patterns of various transition-metal dichalcogenides. We demonstrate the high quality of deposited flakes by systematic ToF-X-PEEM characterization. Imaging large field of view >3mm with widened X-ray beam profile enables rapid chemical mapping with frame rates up to 1/s for strong core levels. Contracting the beam spot to <20mu and placing it on the desired flake allows small-area SX-ARPES employing the momentum-microscopy mode. [1] B.Tonner, NIMS A291, 60(1990)

Chlorine Corrosion of Superheater Steels — •Matthias Kroh, Sebastian Pentz, Ferdinand Haider, and Georg Krupkov — Univ. Augsburg, Inst. f. Physik, 86159 Augsburg

During combustion in waste-incineration-plants a variety of chemical substances are released into the gas stream. Especially under the environment present in an incineration plant the active Chlorine-catalysed high temperature corrosion caused by released Cl2 and HCl proves detrimental to the lifetime of heat exchanger tubes, which are essential for the power production. According to literature, Cl2 is far more corrosive than HCl, but these studies were rather qualitative and do not reflect conditions like e.g. in a real power plant To simulate this process in a laboratory environment with realistic Cl-concentrations, a Chlorine generator was designed, which produces Cl2 from a reaction of liquid NaOCl and H2SO4. The formed Chlorine concentrations were quantified via GCMS and UV VIS spectrometry to produce Cl2 concentrations akin to those in real plants. In these experiments the corrosional attack of Cl2 and of HCl on samples of a typical superheater steel was determined for various temperatures and defined gas atmospheres. Especially the influence of water and sulfur dioxide in the gas atmosphere were studied. The experimental setup is based on a horizontal furnace, containing the samples in a quartz tube, exposed to a flow of the desired gas atmosphere, and a subsequent gas analysis. Weight loss of the samples after removing reaction products as well as the morphology of the reaction zone are determined after various exposure times.

MM 12.3   Mon 18:15   P2/OG1+2

Nanoscale heat transport in heterostructures measured with UXRD at European XFEL — •Jan-Etienne Pudell[1,2,3], Marc Herzog[2], Max Mattern[2], Jasmin Jarecki[2], Alexander von Reppert[2], Ulrike Boesenberg[1], Angel Rodriguez-Fernandez[1], Wonhiuk Jo[1], Roman Shayduk[1], Wei Lu[1], Gregory Malinowski[4], Michel Hehn[4], Matias Bargheer[2,3], and Anders Madsen[1] — [1]European XFEL, Germany — [2]Institut für Physik und Astronomie, Universität Potsdam, Germany — [3]Helmholtz-Zentrum Berlin, Germany — [4]Institut Jean Lamour, Université Lorraine, France

The transport of heat (or energy in general) in nanoscopic heterostructures is of great interest on a fundamental as well as a technological level, e.g. in the context of thermal management in devices or heat-assisted magnetic recording. In metal heterostructures, heat can be conducted by electrons that are in or out of equilibrium with lattice vibrations. Using ultrafast x-ray diffraction (UXRD), we investigate the influence of thin layers with high electron-phonon coupling on the thermal transport through a 100 nm Cu/Au layer sandwiched by thin Pt and Ni films on picosecond time scales after femtosecond laser excitation. The MID end-station at Europen XFEL is able to perform these time-resolved laser-pump x-ray-probe measurements to track the time dependence of the heat transport.

A time-dependent diffusive two temperature transport model reproduces our experimental data and thus verifies the efficient transport channel from the laser excited Pt-layer to the Ni-layer via hot electrons.

MM 12.4   Mon 18:15   P2/OG1+2

Structural evolution and atomic transport in severely deformed bi-metallic samples — •Shraddha V. Sevlikar, Gerhard Wilde, and Sergiy V. Divinskiy — Westfälische Wilhelms-Universität Münster, Institut für Materialphysik, Münster, Germany

Mechanical mixing, deformation-induced transport, and chemically-driven diffusion in layered bi-metallic Ni/Cr, Ni/Cu, Cu/Ag, and Cu/Au systems are investigated using scanning- and transmission electron microscopy, electron probe microanalysis and secondary ion mass spectroscopy. Alternatively, stacked Ni/Cr, Ni/Cu, Cu/Ag, and Cu/Au layers were subjected to room temperature high pressure torsion (HPT) using 10 and more revolutions. Atomic mixing is observed and discussed in terms of a high dislocation density, high concentration of non-equilibrium vacancies, and an impact of grain boundaries. The role of creep deformation is addressed by performing shear compression tests at selected temperatures on specially designed Ni or Cu samples with layers of Cr/Cu or Ag/Au deposited on the gauge sections. Mechanical mixing-induced recrystallization in the Cu-Au and Cu-Ag systems is observed and is discussed.

MM 12.5   Mon 18:15   P2/OG1+2

Study of Electron Transport in a DNA model — •Jorge Cardenas-Gamboa[1], José García[2], and Solmar Varela[1,3] — [1]Yachay Tech University, School of Chemical Sciences & Engineering, 100119-Urcuquí, Ecuador — [2]Institu Català de Nanociència I Nanotecnología(ICN2) ,08193-Barcelona, España — [3]Institute for Materials Science and Nanotechnology, Technische Universität Dresden. Dresden 01062, Germany

In this work, we use the Landauer-Buttiker formula as implemented in the package KWANT (Python library) for studying quantum transport in a DNA molecule based in an analytical tight-binding Hamiltonian recently developed. In our simulation, we used a Hamiltonian considering a kinetic term, a term for intrinsic Spin-Orbit (SO) interaction related to the atomic SO coupling, and a Rashba interaction due to the electric dipoles associated with hydrogen bonds between the bases of the double strand of DNA and we tested the effect of magnetic and no-magnetic leads in the spin-selectivity of the molecule. We obtained that in our model, the spin-orbit coupling associated with the molecule can not be enough to explain the spin selectivity, however, in a system with presence of ferromagnetic leads, enhance the spin selectivity when it is included, which could explain the selectivity observed in similar experiments.

MM 12.6   Mon 18:15   P2/OG1+2

Investigations on thermal contact conductance between filled polymer composites and solids using micro thermography — •Oliver Roser[1,2], Andreas Griesinger[3], and Othmar Marti[2] — [1]Center for Heat Management (ZFW), Stuttgart — [2]Institute of Experimental Physics, Ulm University — [3]Baden-Wuerttemberg Cooperative State University (DHBW) Stuttgart

When optimizing cooling paths in electronic devices, thermal interface materials (TIMs) are used to optimize the thermal transfer between two solid surfaces. TIMs are thermally conductive filled polymer composites with a complex microstructure. We investigated the intrinsic thermal conductivity of TIMs and the thermal contact conductance between TIMs and solid substrate surfaces using micro thermography. The physical principles of thermal transport when considering this kind of contact have not yet been investigated in detail and just a few experimental results are available. Most common measurement techniques determine a macroscopic conductance. Random surface and filler structures however, cause several variations and some specific effects on contact conductance, which need to be investigated on a microscale. With the utilized IR camera system, we can take pictures with a resolution of down to 14 microns per pixel. The

new method allows us to analyze the microscopic heat paths on the particle scale and to understand the physical principles of heat transport in contact zones of TIMs. The main parameters which affect the contact conductance were identified and will be presented in addition to comparisons to other measurement methods, and a microscale simulation approach.

MM 12.7   Mon 18:15   P2/OG1+2

Hydrogen Diffusion in High-Pressure Torsion (HPT) deformed Magnesium and Magnesium-alloys — •Giorgia Guardi[1], Sabine Schlabach[1,2,3], Julia Ivanisenko[2,3], Stefan Wagner[1], and Astrid Pundt[1] — [1]Karlsruhe Institute of Technology, Institute for Applied Materials, Karlsruhe, Germany — [2]Karlsruhe Institute of Technology, Institute of Nanotechnology, Karlsruhe, Germany — [3]Karlsruhe Institute of Technology, Karlsruhe Nano Micro Facility, Karlsruhe, Germany

Magnesium is considered a promising material for solid-state Hydrogen storage due to the high achievable gravimetric density of 7.6 wt.% upon Magnesium Hydride (MgH_2) formation. There are however limitations to its practical application, mainly due to the low diffusion rate of Hydrogen in the Magnesium hydride phase, which leads to slow absorption kinetics. A possible way to improve hydrogen kinetics in Magnesium hydride is by increasing the volume fraction of grain boundaries, which can act as fast-diffusion pathways; this can be achieved in bulk samples by severe plastic deformation. In this work we use High-Pressure Torsion (HPT) to increase the grain boundaries concentration in bulk Mg and Mg-Zn-Zr alloys (ZK30 and ZK60) and we investigate how this affects hydrogen diffusion. The diffusivity of hydrogen in Magnesium is evaluated by gas volumetry at room temperature.

MM 12.8   Mon 18:15   P2/OG1+2

A systematic investigation of metastable phases in Niobium using density-functional theory — •Susanne Kunzmann[1], Gabi Schierning[1], and Anna Grünebohm[2] — [1]Universität Bielefeld, Germany — [2]Ruhr-Universität Bochum

Although Niobium is a well studied transition metal, it exhibits anomalies such as type II superconductivity, unusual instabilities under pressure. Furthermore a martensitic phase transition has been reported, which is still under debate and raises questions concerning the source.

The present work attempts to approach these previously unexplained observations in a multifaceted manner. Using density functional theory we investigate low energy metastable phases, their instability against deformation and potential transition paths to bcc ground state for selected phases and the influence of Tantalum contamination. We find both A15 and Pnma phases to be potential candidates for distorted Niobium, as they are low in energy and we discuss a simple transition path with a low energy barrier for the latter.

Computational local point-based boundary conditions method for eigenfrequencies in microwave eccentric spherical cavities — •Zoya Eremenko[1], Igor Volovichev[1], Oleksiy Breslavets[1], and Grigorios Zouros[2] — [1]O. Ya. Usikov Inst. for Rad. & Electr. Nat. Acad. of Sci. of Ukraine Kharkiv, Ukraine — [2]School of Electrical & Comp. Eng. Nat. Tech. Univ. of Athens, Athens, Greece

We have elaborated a new method for solving the electrodynamic problem for a resonant structure like a spherical cavity with a spherical dielectric inhomogeneity is randomly located without any limitations. The main feature of the method is the ability to satisfy the boundary conditions at the interface between two dielectric media at individual points located on these boundaries. There is no need to integrate and formulate boundary conditions for each basic mode, as it is usually done by classical methods for solving electrodynamic problems in the frequency domain. We carry out a numerical study to compute the eigenfrequencies in such eccentric configurations. We validate the results and compare the computational efficiency of our method with HFSS commercial software.

MM 12.10   Mon 18:15   P2/OG1+2

Machine learning force fields in VASP — •Ferenc Karsai[1], Andreas Singraber[1], Jonathan Lahnsteiner[1], Ryosuke Jinnouchi[2], and Georg Kresse[2] — [1]VASP Software GmbH, Sensengasse 8, Vienna, Austria — [2]University of Vienna, Department of Physics, Kolingasse 14-16, Vienna, Austria

An efficient and robust method for on-the-fly machine learning force fields implemented into the Vienna Ab-initio Simulation Package (VASP) is presented. This method realizes the automatic generation of machine learning force fields on the basis of Bayesian inference during molecular-dynamics simulations, where the first-principles calculations are only executed when new configurations out of already sampled data sets appear. The power of the method is demonstrated in several applications such as e.g. melting points of ionic and covalent compounds, thermal transport in Zirconia, delta-learning of Carbon monoxide adsorbed on transition-metal surfaces and solid-solid phase transitions in perovskites. The applications show that during learning 99% of the ab-initio calculations are skipped. The implementation of our on-the-fly learning scheme is fully automatized and is mainly controlled by a few parameters. Hence one can optimally sample through a large phase space and the amount of human intervention for the usually laborious task of training is drastically reduced. Finally,

the calculations are accelerated by more than 4 orders of magnitude compared to ab initio, while the accuracy remains the same.

MM 12.11 Mon 18:15 P2/OG1+2

Structure prediction of iron hydrides at high pressures by machine-learned interatomic potentials — •Hossein Tahmasbi[1], Kushal Ramakrishna[1], Mani Lokamani[1], Mandy Bethkenhagen[2], and Attila Cangi[1] — [1]Center for Advanced Systems Understanding (CASUS), HZDR, Görlitz, Germany — [2]CNRS, ENS de Lyon, Laboratoire de Géologie, Lyon, France

The structure and properties of iron hydrides under pressure have been of interest to geoscientists. At ambient conditions, there are no stable solid iron hydrides. Previous theoretical and experimental studies suggest that the double hcp phase of FeH is stable at low pressures with phase transitions to the hcp and fcc phases up to 80 and 140 GPa, respectively. Here, we present a theoretical investigation of the potential energy surfaces of FeH at high pressure. We construct a highly transferable machine-learned interatomic potential with a hierarchical approach using the PyFLAME code. Then, using this fast and accurate neural network potential, we systematically explore the potential energy surfaces of bulk structures of FeH by global sampling using the minima hopping method, to predict stable and metastable iron hydrides up to 200 GPa. We have carried out density functional theory calculations to refine the predicted structures and to evaluate the dynamical stability of selected structures as well. In an automated and systematic approach, we are going to show how a transferable machine-learned interatomic potential can be trained and validated using global optimization and analyze the phase diagram of the stoichiometric Fe-H system under pressure.

MM 12.12 Mon 18:15 P2/OG1+2

Machine Learning Interatomic Potentials for amorphous mesoporous metallosilicates — •Julian Greif, Konstantin Gubaev, and Blazej Grabowski — Universität Stuttgart, D-70049, Stuttgart, Germany

Improving the efficiency of catalysis continues to be an important topic in modern chemistry. A promising approach currently under investigation is to utilize molecular catalysts in confined geometries. In the present project, we aim to model porous amorphous silica containing metal atoms on the pore surfaces that can act as co-catalysts. We conduct atomistic simulations using ab initio-trained machine learning potentials to obtain insights into the location of the metal atoms and the chemical configuration of hydrogen saturated surfaces in the silica structure. To that end, a potential capable of simulating the remelting of SiO_2 + Al was trained and checked on the bulk amorphous SiO_2-system against experimental data in terms of realistic densities, bond lengths and bond angles. Using this potential, new structures are then created by melting and quenching and a new potential is trained for simulations of mesoscale cells.

MM 12.13 Mon 18:15 P2/OG1+2

Deep learning for generation of optimal reaction environments — •Rhyan Barrett[1] and Julia Westermayr[2] — [1]Leipzig University — [2]Leipzig University

The design of reaction environments to reduce activation energies holds enormous potential for advancing many areas of chemical engineering but remains a difficult task due to the high combinatorial complexity of different conditions that influence a reaction. Herein, we use a cutting-edge deep learning model to enable the optimization of reactions. Initially we use a model to generate an abstract electrostatic field that reduces the activation barrier of a given reaction. We then look to optimize the ratio of continuum solvents to match the influence of the optimal electrostatic field generated by the model. The advantage of our method is that it is not limited to the initial solvent selection since any designed mixture will be compared with the global optimum electrostatic field produced by our model. The potential of the method will be demonstrated by optimization of the Claisen rearrangement reaction of allyl-p-tolyl ether and construction of an optimal environment but is generally applicable to any organic reaction.

MM 12.14 Mon 18:15 P2/OG1+2

Efficient graph neural networks for accurate interatomic potentials between surfaces and adsorbed atoms — •Nian Wu[1], Fabio Priante[1], Eric Kramer Rosado[1], and Adam S Foster[1,2] — [1]Department of Applied Physics, Aalto University, 00076, Espoo, Finland — [2]WPI Nano Life Science Institute (WPI-NanoLSI), Kanazawa University, Kakuma-machi, Kanazawa 920-1192, Japan

Various advanced microscopy techniques have been developed to resolve molecular systems on surfaces with increasing resolution. However, 2D images representing 3D structures generally lead to missing information, making the interpretation of images challenging. Density functional theory (DFT) with explicit 3D structures offer a route to understanding through analyzing multiple molecular conformations, but the DFT is extremely computationally demanding. To address this issue, in this work we train a neural network potential to predict the interatomic interactions between adsorbates and surfaces as an efficient substitute for DFT calculations with decent accuracy. Firstly, we established a dataset of 2000 organic molecules adsorbed on the Cu(111) surface either in equilibrium or distorted, which includes total energy, atomic force, electrostatic potential,

and charge obtained by DFT calculations. And then, based on the small training dataset, we further developed a model on a basis of the NequIP framework, to predict forces. With the auxiliary information from charge and electrostatic potential, our modified model could reach state-of-the-art performance with forces mean absolute errors of ~1.0 meV/atom, comparable to DFT accuracy.

MM 12.15 Mon 18:15 P2/OG1+2

Investigation of bonding mechanism between early transition metals and antimony — •Carolin Petersen, Christian Stenz, and Matthias Wuttig — I. Institute of Physics (IA), RWTH Aachen University

Using density functional theory (DFT) one can calculate the number of electron transferred (ET) and electron shared (ES) for crystalline materials. By plotting ET and ES for different materials on the x- and y- axes, the so-called bonding map is created. It can categorize the different bonding mechanisms, like covalent, ionic, metallic or metavalent and can predict properties such as the band gap, effective coordination number, electrical conductivity, or Born effective charge.

This algorithm works especially for crystalline s- and p-bonded materials. Due to the complexity of d-orbitals in early transition metals, it is unclear how to reasonably normalize ET in that case. The question is where such systems with bonding between d- and p-electrons are located in the bonding map. By examining the properties of such a material, the region in the bonding map can be identified reversely.

Therefore, TiSb is produced by co-sputter deposition and the amorphous phase is investigated by means of electrical transport, e.g. by Hall- and magneto-resistance measurements down to 2K. It is assumed that TiSb is an exotic metal and shows unconventional transport properties.

MM 12.16 Mon 18:15 P2/OG1+2

DFT structural characterization of β- and δ- intermetallic Al-Fe-Si phases — •Nebahat Bulut[1], Hanka Becker[2], Andreas Leineweber[2], and Jens Kortus[1] — [1]TU Bergakademie Freiberg, Institute of Theoretical Physics, Germany — [2]TU Bergakademie Freiberg, Institute of Materials Science, Germany

The β-$Al_{4.5}FeSi$ and δ-Al_3FeSi_2 phases are known stable phases of Fe-containing hypoeutectuc Al-Si alloys. Despite the known stoichiometry of the β- and δ-phase the positions of the Al and Si atoms in these Al-Fe-Si intermetallic phases could not be uniquely determined experimentally. Therefore possible positions of Si atoms in these intermetallic phases were investigated using the density functional theory (DFT) code Quantum Espresso, which is based on plane waves and pseudopotentials [2]. For both β- and δ- phase different arrangements of Si atoms in the Al-Fe-Si intermetallics were considered. We compare the energies of these arrangements (1) relaxing the atomic positions keeping the unit cell volume constant and (2) fully relaxing atomic positions and unit cell shape and volume. As result we find that arrangements where the Si atoms are not nearest neighbours are energetically favored [2]. Further, we analyze the electronic structure and investigate the bonding.

MM 12.17 Mon 18:15 P2/OG1+2

A method for charge-sloshing free precise linear-scaling density-functional calculations — •Rudolf Zeller — Forschungszentrum Jülich and JARA, D-52425 Jülich, Germany

A fundamental problem for large-scale density-functional calculations is charge sloshing caused by the long-ranged Coulomb potential which necessitates that the number of self-consistency steps increases proportionally to the square of system length. To overcome this problem, Manninen et al. (1975) used a screened Coulomb potential to devise a real-space potential-mixing scheme which in reciprocal space is well-known as Kerker mixing.

It will be described how (1) this scheme works in the linear-scaling real-space code KKRnano which is part of the JuKKR code family developed at the reasearch center Jülich, how (2) it can be turned into a real-space preconditioning method for potential mixing and how (3) it can be refined for excellent numerical performance.

Benchmark calculations will be presented for spin-orbit induced noncollinear magnetism in B20 MnGe and for a vacancy in Cu. It will be shown that the computing effort is drastically reduced, that the number of self-consistency steps does not increase with system size and that precise total-energy differences can be obtained even for supercells with more than 100000 atoms.

It should be noted that the method presented does not rely on using linear response or properties of the static dielectric matrix.

MM 12.18 Mon 18:15 P2/OG1+2

How to Train a Neural Network Potential — •Alea Miako Tokita[1,2] and Jörg Behler[1,2] — [1]Lehrstuhl für Theoretische Chemie II, Ruhr-Universität Bochum, 44780 Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, 44780 Bochum, Germany

High-Dimensional Neural Network Potentials (HDNNPs) provide potential energy surfaces (PESs) with the accuracy of electronic structure calculations at strongly reduced computational costs, which enables extended molecular dy-

namics simulations of large systems. They are trained on reference energy and force data to learn an approximate but accurate functional relation between the atomic structure and the PES. However, due to the non-physical functional form, which is shared with many other types of machine learning potentials, this training and the validation of the potential have to be done with great care. In this contribution the construction of HDNNPs will be explained step by step including a discussion of possible pitfalls and tricks of the trade.

MM 12.19 Mon 18:15 P2/OG1+2
PyRamanGUI: An open-source multi-purpose tool to analyze Raman spectra — •Simon Brehm, Cameliu Himcinschi, Jakob Kraus, and Jens Kortus — TU Bergakademie Freiberg, Germany

PyRamanGUI is a software tool which was developed to process and analyze Raman spectra. Available functionalities include smoothing, baseline correction, cosmic spikes removal, peak fitting, and multivariate statistical methods. Furthermore, it is possible to create workflows, which can be personalized and adapted. The application is designed as a graphical user interface (GUI), so no prior knowledge in programming is needed. The program is completely written in python and thus usable across different platforms. The source code is is freely available on GitLab (https://gitlab.com/brehmsi/PyRamanGUI).

MM 12.20 Mon 18:15 P2/OG1+2
Non-contact friction on various material systems — •Kim Lambert[1], Niklas Weber[1], Matthias Krüger[2], and Cynthia Vokert[1] — [1]Institut für Materialphysik, Friedrich-Hund-Platz 1, 37077 Göttingen — [2]Institut für Theoretische Physik, Friedrich-Hund-Platz 1, 37077 Göttingen

To gain a deeper understanding of the origins of frictional losses and of how these connect to internal damping in the material, we investigate non-contact friction in various material systems, including graphene flakes and spinodal decomposed systems using AFM-based methods. A main goal of this work is to understand the degrees of freedom that contribute to energy dissipation and to identify the mechanisms contributing to non-contact friction.

For this purpose, we perform friction measurements on these systems under UHV and ambient conditions as well as with different dynamic AFM-based methods. Furthermore, we conduct experiments in contact mode to understand how the damping measured in non-contact is correlated with the energy dissipation measured in contact mode. These insights will be compared to the results of previous studies on [LaMnO3]m/[SrMnO3]n superlattices [1] as well as to theoretical studies on frictional damping via a theory of viscoelasticity [2].

Thermodynamical Stability Analysis of a Model Quasicrystal — •Moritz Holzwarth, Johannes Roth, and Hans-Rainer Trebin — FMQ, Uni Stuttgart, Germany

The random tiling hypothesis, first proposed by Henley in 1991, states that quasicrystals are entropy-stabilized and, hence, are high temperature phases. We confirm the hypothesis for a two-dimensional Tübingen triangle tiling which arises in molecular dynamics simulations with a Lennard-Jones-Gauß potential, by investigating the temperature dependence of its two phason elastic constants λ_6 and λ_8. These are the second derivatives of the free energy $F(\chi_6, \chi_8, T)$ with respect to the symmetrized phason strain modes χ_6 and χ_8. At $T = 0$, F has a saddle point by descending along the χ_8 direction. Therefore, $\lambda_8 < 0$ characterizes the quasicrystal's initial instability. The configurational entropy due to phason flips turns F upwards at higher temperatures, reverses the sign of λ_8 and leads to a stable quasicrystal. We obtain this result by applying exclusively geometric methods in the form of the polar calculus, where the atomic domain (AD) is divided into sections for each vertex environment. We extend the calculus to a dynamic one by separating the AD into areas that characterize the different kinds of phason flips. By phasonic deformation of the AD, we can determine the types of flips and their frequency in dependence of phason strain, can perform energy relaxations by flips and compute the configurational entropy. We find that an important mechanism supporting the quasicrystal stability is the symmetric nearest neighbour coupling of phasonic flips.

MM 12.22 Mon 18:15 P2/OG1+2
Excitation-induced non-thermal effects in silicon — •Simon Kümmel, Dominic Klein, and Johannes Roth — FMQ University of Stuttgart, Germany

Ultra-fast laser excitation of silicon leads to highly non-linear, non-equilibrium effects in covalent materials. Especially the non-thermal melting in covalent materials like silicon has been observed in experiments. A rigorous explanation in the context of the induced macroscopic material dynamics during laser ablation is still missing. Here, we present novel results from laser ablation simulations taking this effect into account via an electron temperature-dependent interaction potential. We report non-thermal surface evaporation and pre-shockwave melting comparable to experimental investigations. Furthermore, we give more insight into non-thermal melting from electron temperature-dependent phase diagrams obtained from thermodynamic integration of the same electron temperature-dependent interaction potential.

MM 12.23 Mon 18:15 P2/OG1+2
Towards understanding the chemical bonding of unconventional metals — •Christian Stenz, Johannes Holters, and Matthias Wuttig — Institute of Physics IA, RWTH Aachen University, 52074 Aachen, Germany.

Solids can be distinguished based on their properties such as the band gap, effective coordination number, electrical conductivity, Born effective charge and so on. Based on these properties a classification into metallic, covalent, ionic and metavalent bonding seems appropriate. Metavalent bonding is a distinct bonding mechanism characterized by a competition between electron localization and electron delocalization. Chalcogenides like GeTe and Sb_2Te_3 and pnictides like Sb employ this bonding mechanism and can be characterized as 'incipient metals'. This raises the question if there are related metals, which are characterized by the same competition between electron localization and electron delocalization. We thus have been looking for such unconventional metals and focus on compounds of Te with transition metals. The overlap between Te p- and transition metal d- orbitals gives rise to a configuration which resembles the p-p σ-bond in incipient metals. Hence we are looking for related fingerprints such as soft, anharmonic bonds, an unconventional bond rupture and other characteristics which are found for incipient metals.

MM 12.24 Mon 18:15 P2/OG1+2
An efficiently automated method to sample the energies of grain boundaries — •Timo Schmalofski[1], Martin Kroll[2,3], Rebecca Janisch[1], and Holger Dette[3] — [1]ICAMS, Ruhr-University Bochum — [2]Department of Mathematics, Physics, and Computer Science, University of Bayreuth — [3]Department of Mathematics, Ruhr-University Bochum

Grain growth and microstructure evolution depend on the anisotropy of the energy of grain boundaries, which is a function of the five geometric degrees of freedom (DOF) of the grain boundaries. To access this parameter space in an efficient way and discover energy cusps in unexplored regions, a method was established, which combines atomistic simulations with statistical methods [1]. It has been successfully applied to sample the 2D subspace of GB plain inclinations for fixed misorientations. The poster explains the main features of the algorithm: Initial design, sequential design, the stopping criterion and the final interpolation of the energy. The algorithm draws its strengths from two aspects, the choice of the next point, which balances a homogeneous distribution of points with a precise sampling of the cusps, and the stopping criterion, which monitors the error of the prediction as well as the number of cusps which have been found. With these features, the method is able to outperform a regular high-throughput sampling.

MM 12.25 Mon 18:15 P2/OG1+2
Cubic scaling GW in the exciting code — •Manoar Hossain[1], Alexander Buccheri[1], Andris Gulans[2], and Claudia Draxl[1] — [1]Physics Department and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin Germany — [2]Department of Physics, University of Latvia, Riga, Latvia

The GW approximation is the state-of-the-art method to incorporate many-body effects through the self-energy correction to the Kohn-Sham single-particle states. A serious drawback is that it becomes often computationally prohibitive due to its typical quartic dependence on system size. This restricts its use to systems with a few tens of atoms, highlighting the need to develop computationally efficient algorithms to extend the computation of the quasi-particle electronic structure to materials consisting of hundreds of atoms. In this work, we present a cubic-scaling algorithm implementation of the GW approximation in the exciting[1] code which is based on the linearized augmented planewave method. Our implementation employs the real-space imaginary-time formalism[2, 3] and relies heavily on Fast Fourier Transforms and efficient linear-algebra operations. To this extent we develop and make use of high-performance libraries, within the NOMAD CoE[4] with the aim to bring GW to exascale performance.

Physics Informed Neural Networks based Solvers for the Time-Dependent Schrödinger Equation — •Karan Shah and Attila Cangi — Center for Advanced Systems Understanding, Helmholtz-Zentrum Dresden-Rossendorf, Görlitz, Germany

We demonstrate the utility of Physics Informed Neural Network based solvers for the solution of the Time-Dependent Schrödinger Equation. We study the performance and generalisability of PINN solvers on a simple quantum system. The method developed here can be potentially extended as a surrogate model for Time-Dependent Density Functional Theory, enabling the simulation of large-scale calculations of electron dynamics in matter exposed to strong electromagnetic fields, high temperatures, and pressures.

MM 12.27 Mon 18:15 P2/OG1+2

High-throughput calculations for property maps of solids — •Daniela Ivanova[1], Daniel Wortmann[1], Stefan Blügel[1], Matthias Wuttig[2], and Carl-Friedrich Schön[2] — [1]Peter Grünberg Institute and Institute for Advanced Simulation, Forschungszentrum Jülich, Germany — [2]Department of Physics, RWTH Aachen University, Aachen, Germany

Over the last two decades, high-throughput computations have become a vital pillar of the scientific research and development process in the field of computational science. In order to forecast material properties for larger sets of atomic configurations, Density Functional Theory (DFT) has been employed as an automated, robust, and highly-predictive first-principles approach. In this work, the DFT code Quantum ESPRESSO is deployed through the open source Automated Inter-active Infrastructure and Database for Computational Science AiiDA framework. Aside from the existence of (1) covalent, (2) metallic, and (3) ionic bonding, as well as the two weaker forms of (4) hydrogen and (5) van der Waals bonding, compelling evidence has recently been found for another bonding mechanism in solids such as crystalline chalcogenides, termed as (6) 'metavalent bonding'. Effective mass calculations promise essential data for mapping distinctions between the bonding mechanisms along the materials data set chosen for high-throughput computing.

MM 12.28 Mon 18:15 P2/OG1+2

A high-level workflow-based approach towards the exploration of magnetocaloric Heusler alloys by automated high-throughput simulations — •Simon Bekemeier[1], Alisa Chirkova[1], and Christian Schröder[1,2] — [1]Bielefeld Institute for Applied Materials Research, FH Bielefeld — [2]Faculty of Physics, Bielefeld University

Digitalization poses a huge chance to accelerate knowledge generation and materials discovery. Due to increasing computational capacities ever more materials data and simulations can be processed. Still the underlying processing and simulations often must be run by scienctists manually, slowing down the digital process and hindering the useage of its full potential. One major issue is the translation between tools, to concatenate the tools required to transform given input data via several steps into the wanted output. We present one 'workflow' to calculate entropy change induced by the magnetocaloric effect starting from a description of the material under consideration. It consists of several simulation steps using different methods: from DFT, via spin dynamics simulation, to calculating the entropy change. It allows our group to perform high-throughput simulations but also enables exchange of simulational tools with other scientists, who otherwise need to develop and handle those tools themselves. Especially, experimentalists are enabled to use simulations to further enhance their knowledge generation process by extending their work with theoretical simulations on their own. Furthermore such a workflow opens doors to use AI methods to reveal relations, that were unknown before.

MM 12.29 Mon 18:15 P2/OG1+2

Ontology-Template-Based Description of Anisotropic Conductivity Measurements — •Lennart Schwan[1,2], Michael Feige[2], Moritz Bluhm[3], Basil Ell[3], Andreas Hütten[2], and Sonja Schöning[1] — [1]Bielefeld Institute for Applied Materials Research (BIfAM), Bielefeld University of Applied Sciences, Department of Engineering Sciences — [2]Thin Films & Physics of Nanostructures, Bielefeld University, Department of Physics — [3]Semantic Computing Group, Bielefeld University, Faculty of Technology

Digitalization in materials science is an emerging field of research that opens up many new opportunities, e.g. in materials engineering. In particular, if large data sets of many experiments can be evaluated with the help of artificial intelligence. The more information about production, characterization, etc. can be recorded and processed in a machine-readable form, the greater the additional benefit.

A particular challenge is to transfer information that would be recorded in the classic lab book with a simple sketch into a machine-readable form, like the exact position of a measurement. However, this data is important for the evaluation of the experiment.

The application considered is the 3D printing of conductive nanosilver and the determination of the anisotropic electrical conductivity. We semantically describe printing process, environment parameters and characterization in an ontology to investigate dependencies of the conductivity. Therefore, we developed a template-based ontology engineering approach with OTTR templates, to add an abstraction layer to the common but very technical ontology engineering processes.

MM 12.30 Mon 18:15 P2/OG1+2

An Ontology of Magnetocaloric Materials Research — Simon Bekemeier[1], Moritz Blum[2], Luana Caron[3], Philipp Cimiano[2], Basil Ell[2], Inga Ennen[3], Michael Feige[1], Thomas Hilbig[1], Andreas Hütten[3], Günter Reiss[3], Tapas Samanta[3], Sonja Schöning[1], Christian Schröder[1,3], Lennart Schwan[1,3], and •Martin Wortmann[3] — [1]Bielefeld Institute for Applied Materials Research, University of Applied Sciences Bielefeld, Interaktion 1, Bielefeld, Germany — [2]Faculty of Technology and CITEC, Inspiration 1, Bielefeld, Germany — [3]Faculty of Physics, Bielefeld University, Germany

Magnetic refrigeration based on the magnetocaloric effect is an energy-saving and environmentally friendly alternative to compression based cooling. The cooling effect is based on the heat release or uptake during a magnetic phase-transitions of a magnetocaloric material that can be controlled by a magnetic field. The decades-long search for an alloy suitable for mass application could be made much more efficient by digitizing the scientific process chain. The research project DiProMag thus seeks to digitize the entire research procedure from the production and characterization of magnetocaloric materials to their theoretical description and prototypical application. For this purpose, an ontology - that is a structured representation of knowledge - was developed using a hierarchical template-based approach for the acquisition, semantic representation and abstraction of raw ontological data. The focus of the project is on the advancement of Heusler alloys, with Co2CrAl serving as the first promising model system.

MM 12.31 Mon 18:15 P2/OG1+2

Laser processing of metal materials created by additive technologies. Optimization of structure and mechanical properties — •Iryna Galstian[1], Evgen Len[1], Tobias Gustmann[2], and Nicole Geissler[2] — [1]G. V. Kurdyumov Institute for Metal Physics of the N.A.S.U. Kyiv, Ukraine — [2]IFW Institute for Complex Materials. Dresden, Germany

In this work, the authors investigated the physical regularities of the structural-phase and chemical state formation in the volume of 3D printed titanium products consisting of several layers (surface layers of 3D printed alloys in the original and modified state and transition zones surface layers of 3D printed alloys in the original and modified state and transition zones) depending on the applied methods and regimes of obtaining and high-energy processing. The authors of the method provided a physical justification of the effectiveness of the combination of electron beam 3D printing with surface treatment by means of precision gas dynamic 3D printing and laser treatment. It has been established that this approach makes it possible to eliminate the main disadvantages of 3D-printed alloys, which are their structural imperfection, which causes low plasticity, fatigue strength and corrosion resistance. From a fundamental point of view, it allows to give a complete physical picture of the process of forming the structure and physical and mechanical properties of metal materials during 3D printing and to find ways of managing this process.

MM 12.32 Mon 18:15 P2/OG1+2

MD Simulation of 3D Laser Printing — •Jonas Schmid, Kevin Vietz, Dominic Klein, and Johannes Roth — FMQ University of Stuttgart, Stuttgart, Germany

While most people associate the manufacturing of metal parts with a CNC milling machine, the Fraunhofer Society developed an additive manufacturing process in 1995 which is based on laser melting of a metal powder. In this process, metal components are printed layer by layer, while the metal powder is fused onto the previous layer.

Our research focuses on developing molecular dynamics (MD) simulations of 3D laser printing in order to study defects such as gas pockets, cracks or structural irregularities caused by the manufacturing process. In contrast to finite element method calculations, MD simulations describe the highly non-equilibrium dynamics on an atomistic scale. This allows for a more physical interpretation while making less assumptions on the system.

In particular, our simulated system contains a three-dimensional multi-layer powder structure on a fixed ground surrounded by a protective gas. The simulation features laser absorption depending on atom density and atom type, as well as active cooling by using a different thermostat integrator for the ground layer. The overall goal of our research is to optimize the laser and powder properties to reduce defects and increase the stress resistance of the sample.

MM 12.33 Mon 18:15 P2/OG1+2

Molecular dynamics simulation of additive manufacturing: A highly non-equilibrated business — •Kevin Vietz, Azad Gorgis, Dominic Klein, and Johannes Roth — FMQ University of Stuttgart, Germany

Powder-bed additive manufacturing is a process that melts the powder with a laser beam, layer upon layer. By performing this melting-solidification process several times, one can build three-dimensional samples. This process is known as 3D printing. Up to now, most simulation studies on additive manufacturing rely on pure metals in vacuum. To fill this gap, we investigate the influence of argon gas on pure metals and explore the suitability of binary alloys for various initial cluster structures, such as core-shell-clusters. We perform large-scale molecular dynamics simulations to depict the highly non-equilibrium material dynamics and evaluate our results by analyzing defects and properties on microscopic and macroscopic scales. Results show that the argon gas stabilizes the system and new material compositions could enhance the variety of applicable materials for additive manufacturing.

MM 12.34 Mon 18:15 P2/OG1+2

Atomistic simulations of crack-tip interface interactions in lamellar TiAl microstructures — •Onur Can Sen and Rebecca Janisch — ICAMS, Ruhr-University Bochum, Germany

Molecular dynamics simulations are an excellent tool for understanding crack-tip interactions in interface-dominated microstructures, but the simulation setup can affect the predicted behavior as there are many degrees of freedom. To shed light on this and at the same time to understand the impact of the specific interface structure, a systematic study of crack-tip interface interactions in nano-lamellar two-phase TiAl was carried out. To separate microstructure and crack geometry influences, the type of interface, crack configuration, and loading direction were varied in these simulations. Results show that the semi-coherent γ-pseudo twin interface is the strongest barrier for the crack propagation while the coherent true twin interface is the weakest. The analysis of the contributing factors shows, that the crack orientation has more influence on the crack evolution than the crack aspect ratio. The effect of the individual interfaces can be quantified by calculating their shielding effects, but as it turns out this effect is strongly dependent on the crack configuration. However, regardless of the crack configurations, the coherent γ-true twin interface appears to be the most effective interface in terms of shielding.

MM 12.35   Mon 18:15   P2/OG1+2

Overview of Crack-Heterogeneity Interactions at the Atomic Scale — •Leon Pyka[1], Tarakeshwar Lakshmipathy[2], and Erik Bitzek[2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Department Computational Materials Design, Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf, Germany

The study of nano- and microstructure is crucially important for creating materials with more favorable mechanical properties. Specifically in the design of fracture resistant materials, the interaction of cracks with other heterogeneities plays a vital role. In this regard classical atomistic simulations are beneficial. They allow us to gain information on crack-heterogeneity interactions, some of which require sample sizes too large for more accurate electronic structure methods. This information can then be used to improve meso- and continuum-scale models.

We provide an overview of a variety of crack-heterogeneity interactions studied at the atomic scale and their relation to established models. Some simulations of cracks interacting with heterogeneities are also performed using a nearest neighbour "snapping-spring" harmonic potential. In addition to providing material-generic insights, due to the linear interatomic force interactions such potentials allow for direct comparisons with continuum models based on linear elasticity.

Fracture surface energy of glasses obtained from crystalline structure and bond energy data — •Marco Holzer[1], Tina Waurischk[1], Janine George[1,2], Robert Maass[1,3], and Ralf Müller[1] — [1]Bundesanstalt für Materialforschung und -prüfung (BAM), Berlin, Germany — [2]Institute of Condensed Matter Theory and Solid-State Optics at Friedrich Schiller University, Jena, Germany — [3]Department of Materials Science and Engineering at University of Illinois, Urbana-Champaign, USA

Extending our earlier work on nucleation and surface energies [1], we present a simple approach for predicting the fracture surface energy (g) of oxide glasses using readily available crystallographic structure data and diatomic bond energies. The proposed method assumes that (g) of a glass equals the surface fracture energy of the weakest fracture (cleavage) plane of the isochemical crystal. For non-isochemically crystallizing glasses, an average (g) is calculated from the weighed fracture energy data of the constitutional crystal phases according to Conrad [2]. Our predictions yield good agreement with the glass density- and chemical bond energy-based prediction model of Rouxel [3] and with experimentally obtained (g) values known at present. [1] C. An in situ crack detection approach in additive manufacturing based on acoustic emission and machine learning — •Viktoriia Nikonova[1], Denys Kononenko[1], Dmitry Chernyavsky[1], Mikhail Seleznev[2], and Jeroen van den Brink[1,3] — [1]Institute for Theoretical Solid State Physics, IFW Dresden, 01069 Dresden, Germany — [2]Institute of Materials Engineering, Technische Universitaet Bergakademie Freiberg, Gustav-Zeuner-Straße 5, D-09599, Freiberg, Germany — [3]Institute for Theoretical Physics, TU Dresden, 01069 Dresden, Germany

Laser Powder Bed Fusion (LPBF) is a state-of-the-art solution for producing metal elements with complex shapes in various industries, from automotive to aerospace. One of the crucial practical drawbacks of LPBF is the presence of structural defects in the printed part, especially cracks. Here we propose an in situ monitoring system of cracks formation during the LPBF process utilizing acoustic emission and machine learning. We demonstrate that the representation of acoustic emission events in the space of principal components (PC) of the spectra yields a robust differentiation of crack events from the noise bursts. The ML classification algorithms achieve high accuracy of ~99 % for the PC-based descriptors. The presented approach advances the method of in situ quality control systems and brings it closer to practical implementations.

Exploring the Slow Dynamics of Interfaces and Glasses via Markov State Models — Siavash Soltani[1], Joerg Rottler[2,3], and •Chad Sinclair[1] — [1]Department of Materials Engineering, The University of British Columbia, Vancouver, BC, Canada V6T 1Z4 — [2]Department of Physics and Astronomy, The University of British Columbia, Vancouver, BC, Canada V6T 1Z1 — [3]Stewart Blusson Quantum Matter Institute, The University of British Columbia, Vancouver, BC, Canada V6T 1Z4

A persistent challenge for molecular simulations is to assess slow processes efficiently from short trajectories. Important examples of slow phenomena in materials are the motion of interfaces in alloy crystals or the structural relaxation

in glass forming liquids. Markov State Models (MSM) are an attractive tool to unveil the slowest processes of a complex atomistic system in a low dimensional space of feature variables. This talk describes the predictions and insights gained from such MSMs constructed using machine learning techniques. For grain boundaries, the model learns a hierarchy of timescales associated with transformations between geometrically distinct motifs. When applied to a binary glass former, our model finds a transition timescale between states that is larger than the conventional structural alpha-relaxation time. In both systems, the MSMs are able to access kinetics at temperatures where brute force calculations become computationally expensive or impossible.

Performance of pseudopotentials in chemically diverse materials — •Andris Gulans[1] and Stefan Goedecker[2] — [1]University of Latvia, Riga, Latvia — [2]University of Basel, Switzerland

We present a novel framework for assessing quality of pseudopotentials. It comprises a database of atomization energies and new highly precise norm-conserving pseudopotentials. The database covers more than 700 molecules with 65 elements from six rows of the periodic table. It accounts for chemical diversity by considering every atom in a variety of oxidation states. For each molecule, we provide highly precise scalar-relativistic atomization energies obtained with lin-

earized augmented plane waves obtained using PBE exchange-correlation functionals. The new pseudopotentials reproduce the reference data within the chemical accuracy limit of 1 kcal/mol. They are crucial for assessing other pseudopotentials, as we use them for decomposing the total error in atomization energies into individual atomic contributions. Our calculations reveal that even state-of-the-art pseudopotential families are still not fully compliant with chemical accuracy, and the largest errors arise in molecules with atoms in high oxidation states.

Pushing to the limits of machine-learning potentials for high-entropy alloys — •Konstantin Gubaev, Victor Zaverkin, Prashanth Srinivasan, and Blazej Grabowski — University Stuttgart

Chemically complex multicomponent alloys have garnered widespread interest owing to their exceptional properties coming from a sheer inexhaustible compositional space. The complexity poses severe challenges for atomistic modelling and interatomic potential development. Here, we explore the limits of two complementary state-of-the-art machine-learned potentials—the moment tensor potential (MTP) and the Gaussian moment neural network (GM-NN)—in simultaneously describing both the configurational *and* vibrational degrees of freedom in the prototype Ta-V-Cr-W alloy family. Both models are equally accurate with exceptional performance in comparison to classical potentials. A single potential is able to achieve root-mean-square-errors of 1.37-4.35 meV/atom and 0.023-0.057 eV/Å in 0 K energies and forces, respectively, across all subsystems of the alloy family, and 0.156-0.179 eV/Å in high-temperature molecular dynamics forces for the disordered quaternary. MTPs achieve faster convergence with the training size than the GM-NNs, whereas GM-NNs are faster in execution. Active learning is partially beneficial and has to be complemented with a conventional human-based training set generation.

Extracting free energies from local composition fluctuations in solids: Theoretical background and atomistic simulations — Daniel Bitter[1], Marvin Poul[2], Guido Schmitz[1], and •Sebastian Eich[1] — [1]Institute of Materials Science, University of Stuttgart, Heisenbergstraße 3, D–70569 Stuttgart, Germany — [2]Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Straße 1, D–40237 Düsseldorf, Germany

While thermodynamic fluctuation theory has been applied to liquids for decades in order to obtain direct thermodynamic information, i.e. Gibbs free energies, from local composition fluctuations, the present work offers an extension for the application in solids. It is demonstrated that composition fluctuations are affected by an additional elastic work term which arises only in solids, thus covering liquids as a special case. The extended fluctuation model is verified through atomistic simulations in an exemplary Cu–Ni embedded-atom system for which Monte Carlo simulations have been carried out in the semi-grandcanonical ensemble at fixed temperature over the entire composition range. Composition fluctuations were monitored in a subvolume over time and statistically evaluated in terms of the variance, demonstrating perfect agreement with the prediction from the extended model. This method has been developed primarily for the application to experimental atom probe data, where three-dimensional chemical information is available with sub-nanometer accuracy, allowing a direct measurement of local composition fluctuations to extract thermodynamic information.

MM 14.4   Tue 11:00   SCH A 251

Extracting free energies from local composition fluctuations in solids: Application on the atom probe data obtained from TAPSim simulations — •Jianshu Zheng[1], Marvin Poul[2], and Sebastian Eich[1] — [1]Institute of Materials Science, University of Stuttgart, Heisenbergstr. 3, D-70569 Stuttgart, Germany — [2]Max-Planck-Institute für Eisenforschung GmbH, Max-Planck-Straße 1, D-40237 Düsseldorf, Germany

This work proposes a novel methodology to extract direct thermodynamic information, i.e. Gibbs free energies, from local composition fluctuations found in atom probe data based on statistical mechanics. The proof-of-concept is demonstrated with an exemplary simulated Cu–Ni alloy, which has first been equilibrated using Monto Carlo techniques with an embedded-atom potential and subsequently field evaporated by TAPSim[1]. It is shown that the variance of the local composition on the reconstructed data reveals a significant dependence on the size of the chosen (sub-) volume used for the evaluation, but nevertheless the extrapolation to an infinitely large volume unveils a remarkable link to the curvature of the Gibbs free energy. Given the composition range is explored at several points, the Gibbs excess free energy of mixing could be recovered in a CALPHAD-style parametrization. This methodology promises to improve the accuracy of thermodynamic information from direct atom probe measurements. [1] C. Oberdorfer, S.M. Eich, G. Schmitz. Ultramicroscopy 128, (2013), 55.

A general-purpose framework for kinetic Monte-Carlo simulations — •Roya Ebrahimi Viand and Sebastian Matera — Fritz Haber Institute of the Max Planck Society, Berlin, Germany

The kinetic Monte Carlo (kMC) method has gained popularity in the last years for the simulation of problems whose dynamics are controlled by rare events. Applications range from atomic-scale models for heterogeneous catalysis or charge transport to disease modeling, and a number of specialized codes have been developed for different classes of models. However, specialization is often the bottleneck when trying to extend the codes to a more general setting or to implement new algorithms. We present our first steps towards a flexible general-purpose framework for implementing kMC models to overcome these limita-

tions. This assumes nothing more than that the model can be regarded as a continuous time, discrete state Markov process, which is common among all kMC models. The specific physical model must be provided by the user in terms of update functions for the transition rates of the different possible elementary processes. Besides illustrating the usage on simple and well investigated models, we demonstrate how the tool can be used to implement models with long range interactions, e.g., for the simulation of charge transport in solid materials.
